NEPA Effects: Under Existing Conditions, striped bass are observed in salvage operations of the south Delta facilities throughout the year, with the majority of juvenile striped bass entrainment occurring during the summer (May through July). As described in Chapter 11, Section 11.3.5, in Appendix A, operation of the north Delta intakes under Alternative 4A would be expected to reduce overall entrainment of screenable life stages (i.e., early juveniles and older, around 20 mm long) because of the reduction in use of the south Delta facilities, which do not have the state of the art fish screens proposed for the north Delta intakes. Differences in potential entrainment as a function of exports that were provided for juvenile Sacramento splittail under Impact AQUA-111 are representative of the late spring/early summer reductions in entrainment that could occur for juvenile striped bass. As described in Chapter 11, Section 11.3.5, in Appendix A, eggs and larval striped bass are susceptible to entrainment at the proposed north Delta intakes. Particle tracking modeling results for ten monthly periods during March-June suggested that overall entrainment of eggs and larvae of striped bass originating in the Sacramento River upstream of the Delta and moving downstream into the Delta would increase relative to NAA_ELT (see Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). For Alternative 4A, scenario H3_ELT, the mean entrainment was increased from 6.5% of particles to 21% of particles, a 220% increase. Note that entrainment of the early life stages of striped bass at the north Delta intakes may be moderated by real-time operational adjustments being made under Alternative 4A during the spring to benefit covered fishes such as spring-run Chinook salmon, and that the results presented in Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS for Alternative 4A reflect the H3_ELT scenario, whereas spring entrainment under the H4_ELT scenario would be somewhat less. Note also that although the north Delta intake screens are estimated to include larvae or juvenile fish of around 20-22 mm and larger, they may also exclude smaller fish to some extent, based on observations from other fish screens in the Delta (Nobriga et al. 2004). As described in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, density-dependence during the juvenile stages of the striped bass life cycle means that losses of early life stages do not necessarily translate into proportional reductions in abundance of older individuals, and entrainment has not recently been identified as a significant driver of juvenile abundance (Mac Nally et al. 2010; Thomson et al. 2010). Therefore it is concluded with some uncertainty that there would be an adverse effect on striped bass.

CEQA Conclusion: The impact of water operations on entrainment of striped bass would be similar to the effects described immediately above. Relative to Existing Conditions, particle tracking modeling for Alternative 4A scenario H3_ELT showed mean entrainment was increased by around 160% (from 8% to 21%; Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). As described in the NEPA Effects section above, increased losses of striped bass eggs and larvae need not necessarily translate into reductions in abundance of later life stages. Nevertheless, there is no feasible mitigation that would reduce this potential impact. Thus, this impact is significant and unavoidable.

American Shad

As described for Alternative 4, American shad eggs and larvae would be vulnerable to entrainment at the proposed north SWP/CVP Delta intakes as these life stages are passively transported downstream to the north Delta. Most American shad spawning though takes place well upstream of the Delta and juveniles may rear to sufficiently large size to avoid entrainment as state-of-the-art fish screens on the proposed north Delta intakes would exclude juvenile and adult American shad.

NEPA Effects: Differences in potential entrainment as a function of exports that were provided for juvenile Sacramento splittail under Impact AQUA-111 are representative of the late spring/early summer reductions in entrainment that could occur for juvenile American shad. As described in Chapter 11, Section 11.3.5, in Appendix A, eggs and larval American shad are susceptible to entrainment at the proposed north Delta intakes. Particle tracking modeling results for ten monthly periods during March-June suggested that overall entrainment of eggs and larvae of American shad originating in the Sacramento River upstream of the Delta and moving downstream into the Delta would increase relative to NAA_ELT (see Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). For Alternative 4A, scenario H3_ELT, and as discussed above for striped bass, the mean entrainment was increased from 6.5% of particles to 21% of particles, a 220% increase. As noted for striped bass, entrainment of the early life stages of American shad at the north Delta intakes may be moderated by real-time operational adjustments being made under Alternative 4A during the spring to benefit covered fishes such as spring-run Chinook salmon; in addition, the results presented in Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS for Alternative 4A reflect the H3_ELT scenario, whereas spring entrainment under the H4_ELT scenario would be somewhat less. Note also that although the north Delta intake screens are estimated to include larvae or juvenile fish of around 20-22 mm and larger, they may also exclude smaller fish to some extent, based on observations from other fish screens in the Delta (Nobriga et al. 2004). As described in Chapter 11, Section 11.3.5, in Appendix A, although American shad early life stages may rear to sufficiently large size above the Delta to avoid entrainment, they could also be entrained in appreciably greater magnitude than currently occurs and therefore it is also concluded that the effects of entrainment on American shad would be adverse.

CEQA Conclusion: The impact of water operations on entrainment of American shad would be similar to the effects described immediately above. Relative to Existing Conditions and as described above for striped bass, particle tracking modeling for Alternative 4A scenario H3_ELT showed mean entrainment was increased by around 160% (from 8% to 21%; Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). As described in the NEPA Effects section above, American shad early life stages may rear to sufficiently large size above the Delta to avoid entrainment. Nevertheless, there is no feasible mitigation that would reduce this potential impact. Thus, this impact is significant and unavoidable to American shad.

Threadfin Shad

NEPA Effects: The impact and conclusion would be the same as discussed for Alternative 1A (Impact AQUA-201 for Threadfin Shad). Entrainment at the south delta would be reduced due to overall decreased exports from the SWP/CVP south Delta facilities. Entrainment losses would be further reduced under Scenario H4 compared to the other flow scenarios for Alternative 4A. There would be potential entrainment of threadfin shad eggs and larvae to the north Delta intakes, although this risk is minimal because threadfin shad are most abundant in the south Delta (Baxter et al. 2010; see also discussion in Chapter 11, Section 11.3.5, in Appendix A). Overall, threadfin shad entrainment would be reduced because they are most abundant in the southern Delta and would particularly benefit from reduced south Delta exports. The effect would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of threadfin shad would be similar to the effects described immediately above in the NEPA Effects section. The impact would be less than significant and no mitigation would be required.

Largemouth Bass

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The impact would be less than significant and no mitigation would be required.

Sacramento Tule Perch

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The impact would be less than significant and no mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The impact would be less than significant and no mitigation would be required.

Hardhead

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The impact would be less than significant and no mitigation would be required.

California Bay Shrimp

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A. The impact would be less than significant and no mitigation would be required.

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

See Alternative 1A, Impact AQUA-202 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

In general, the effects of Alternative 4A on the quality and quantity of spawning, egg incubation, and initial rearing habitat conditions for striped bass would not be adverse relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or slightly greater than flows under NAA_ELT during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to flows under NAA_ELT during April through June, except in above normal years during April (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT during April through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be moderately to substantially greater than flows under NAA_ELT during April through June, except in critical years during May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT during April through June, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would be similar to those under NAA_ELT during April through June, regardless of water year type.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside the range would be similar to or lower than the percentage under NAA_ELT in all water year types (Table 11-4A-138).

Table 11-4A-138. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay are outside the 59°F to 68°F Water Temperature Range for Striped Bass Spawning, Embryo Incubation, and Initial Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0 (0%)	-5 (-10%)
Above Normal	-3 (-7%)	-13 (-24%)
Below Normal	-14 (-33%)	-16 (-36%)
Dry	0 (0%)	-10 (-18%)
Critical	8 (21%)	-3 (-6%)
All	-2 (-5%)	-9 (-18%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through June striped bass spawning, embryo incubation, and initial rearing period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be similar to or up to 548% greater than flows under NAA_ELT during April through June, except in June of wet and critical water years, when the flow would be 12% and 10% lower, respectively, than flow under NAA_ELT.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT during April through June, except for 10% higher flow during April of critical water years, 14% lower flow for May of critical years, and 10% lower flow for June of dry years.

Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT during April through June, except for 17% lower flow during April of above normal water years.

Flows under H4_ELT in the San Joaquin and Stanislaus Rivers and in Clear Creek would be similar to flows under NAA_ELT throughout the period.

The percentage of months under H4_ELT with mean water temperatures outside the 59°F to 68°F suitable water temperature range in the Feather River below Thermalito Afterbay would be 10% higher than the percentage under NAA_ELT in wet years, 11% and 7% lower than the percentage under NAA_ELT in below normal and dry water years, respectively, and would be the same as the percentage under NAA_ELT in above normal and critical water years (Table 11-4A-139). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. Water temperature modeling was not conducted in Clear Creek or the San Joaquin River.

Table 11-4A-139. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months during April–June in which Water Temperatures in the Feather River below Thermalito Afterbay are Outside the 59°F to 68°F Water Temperature Range for Striped Bass Spawning, Embryo Incubation, and Initial Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	10 (23%)	5 (10%)
Above Normal	10 (22%)	0 (0%)
Below Normal	-3 (-7%)	-5 (-11%)
Dry	6 (13%)	-4 (-7%)
Critical	11 (28%)	0 (0%)
All	7 (16%)	0 (0%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in striped bass spawning, incubation, or initial rearing habitat. Flows in all rivers examined during the April through June spawning, incubation, and initial rearing period under Alternative 4A would generally be similar to or greater than flows under the NAA_ELT. There would be no substantial temperature effects under Alternative 4A in any river examined. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under NAA_ELT.

CEQA Conclusion: In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for striped bass relative to Existing Conditions.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during April through June, except in below normal years in April (6% lower) and wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to flows under Existing Conditions during April and June, but lower during May (16% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April through June, with few exceptions.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be up to 14% lower than to those under Existing Conditions during April through June, except during wet years, in which flow would range from 0.3% lower in April to 11% greater in June.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers.

Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June would be the same as or lower than the percentage under Existing Conditions in all water years except critical years (21% higher on a relative scale; 8% higher on an absolute scale) (Table 11-4A-138). This is a relatively small effect that would not have biologically meaningful negative effects on the striped bass population because it only occurs in one water year type.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through June striped bass spawning, embryo incubation, and initial rearing period would generally be similar to flows under Existing Conditions, except during May of wet years when flows would be 11% lower under H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 509% greater than flows under Existing Conditions during April through June, except during June of wet and critical water years, when flow under H4_ELT would be 37% lower and 6% lower, respectively.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under Existing Conditions during April, and generally up to 27% lower than flows under Existing Conditions during May and June.

Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during April through June, except for June of wet and dry water years, when flows under H3_ELT would be 16% and 12% lower, respectively.

Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be up to 14% lower than to those under Existing Conditions during April through June, except during wet years, in which flow would range from 0.3% lower in April to 11% greater in June.

Flows under H4_ELT in the Trinity River and Clear Creek would be similar to flows under Existing Conditions throughout the period, with minor exceptions.

The percentage of months under H4_ELT with mean water temperatures outside the 59°F to 68°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar or up to 28% higher than the percentage under Existing Conditions depending on water year type (Table 11-4A-139). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact would not be significant because Alternative 4A would not cause a substantial reduction in spawning, incubation, and initial rearing habitat of striped bass relative to Existing Conditions. Therefore, no mitigation is necessary. Flows in all rivers except the San Joaquin and Stanislaus Rivers during the April through June spawning, incubation, or initial rearing period under Alternative 4A would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types in the San Joaquin and Stanislaus Rivers that would not have biologically meaningful negative effects to striped bass. There would be no substantial temperature effects under Alternative 4A on striped bass. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under Existing Conditions.

American Shad

In general, the effects of Alternative 4A on the quality and quantity of spawning and egg incubation habitat conditions for American shad would not be adverse relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to flows under NAA_ELT during April through June, except in above normal years during April (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT during April through June, regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be moderately to substantially greater than flows under NAA during April through June, except in critical years during May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT during April through June, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under H3_ELT would be similar to those under NAA_ELT during April through June, regardless of water year type.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside the 60°F to 70°F water temperature range would be lower than the percentage under NAA_ELT regardless of water year type (Table 11-4A-140).

Table 11-4A-140. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 60°F to 70°F Water Temperature Range for American Shad Adult Migration and Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-6 (-13%)	-2 (-5%)
Above Normal	-3 (-8%)	-15 (-31%)
Below Normal	-2 (-6%)	-7 (-19%)
Dry	-2 (-5%)	-4 (-10%)
Critical	-3 (-8%)	-6 (-15%)
All	-4 (-10%)	-6 (-15%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through June American Shad migration and spawning period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be similar to or up to 548% greater than flows under NAA_ELT during April through June, except in June of wet and critical water years, when the flow would be 12% and 10% lower, respectively, than flows under NAA_ELT.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT during April through June, except for 10% higher flow during April of critical water years, 14% lower flow for May of critical years, and 10% lower flows for June of dry years.

Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT during April through June, except for 17% lower flow during April of above normal water years.

Flows under H4_ELT in the San Joaquin and Stanislaus Rivers and in Clear Creek would be similar to flows under NAA_ELT throughout the period.

The percentage of months under H4_ELT with mean water temperatures outside the 60°F to 70°F suitable water temperature range in the Feather River below Thermalito Afterbay would be up to 10% higher and up to 8% lower on a relative scale than the percentage under NAA_ELT, in depending on water year type (Table 11-4A-141). On an absolute scale, these differences would be very small (≤4%) and, therefore, would not be biologically meaningful to American shad.

Table 11-4A-141. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 60°F to 70°F Water Temperature Range for American Shad Adult Migration and Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	0 (0%)	4 (10%)
Above Normal	16 (44%)	4 (8%)
Below Normal	2 (6%)	-3 (-8%)
Dry	2 (5%)	0 (0%)
Critical	0 (0%)	-3 (-8%)
All	3 (8%)	1 (2%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in American shad spawning or adult migration. Flows in all rivers examined during the April through June adult migration and spawning period under Alternative 4A would generally be similar to or greater than flows under the NAA_ELT. There would be no substantial temperature effects under Alternative 4A in any river examined. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under NAA_ELT.

CEQA Conclusion: In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for American shad relative to Existing Conditions.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during April through June, except in below normal years in April (6% lower) and wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to flows under Existing Conditions during April and June, but lower during May (16% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April through June.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be up to 14% lower than to those under Existing Conditions during April through June, except during wet years, in which flow would range from 0.3% lower in April to 11% greater in June.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside of the 60°F to

70°F water temperature range would be lower than the percentage under Existing Conditions in all water year types (Table 11-4A-140).

H4_ELT /HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through June American Shad migration and spawning period would generally be similar to flows under Existing Conditions, except during May of wet years when flows would be 11% lower under H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 509% greater than flows under Existing Conditions during April through June, except during June of wet and critical water years, when flow under H4_ELT would be 37% lower and 6% lower, respectively.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under Existing Conditions during April, and up to 27% lower than flows under Existing Conditions during May and June.

Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during April through June, except for June of wet and dry water years, when flows under H4_ELT would be 16% and 12% lower, respectively.

Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be up to 14% lower than to those under Existing Conditions during April through June, except during wet years, in which flow would range from 0.3% lower in April to 11% greater in June.

Flows under H4_ELT in the Trinity River and Clear Creek would be similar to flows under Existing Conditions throughout the period, with minor exceptions. The percentage of months under H4_ELT with mean water temperatures outside the 60°F to 70°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under Existing Conditions in all water types except above normal water years, for which the percentage under H4_ELT would be 44% higher (Table 11-4A-141). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact would not be significant because Alternative 4A would not cause a substantial reduction in American shad adult migration and spawning habitat relative to Existing Conditions, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus Rivers during the April through June adult migration and spawning period under Alternative 4A would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types in the San Joaquin and Stanislaus Rivers that would not have biologically meaningful negative effects. There would be no temperature related effects of Alternative 4A on American shad. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under Existing conditions.

Threadfin Shad

In general, the effects of Alternative 4A on the quality and quantity of spawning habitat conditions for threadfin shad would not be adverse relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during April through August threadfin shad spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during April through August, except in dry years during August (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to flows under NAA_ELT during April through August, except in above normal years during April (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT during April through August, except in critical years during July (14% lower) and in critical years during August (11% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be moderately to substantially greater than flows under NAA_ELT during April through June (to 106% greater), except during critical years in May (10% lower) and June (8% lower), and moderately to substantially lower than flows under NAA_ELT during July and August (to 48% lower), except during critical years in August (23% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Based on occurrence late in the spawning period, these flow reductions are not expected to have biologically meaningful effects.

In the American River below Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during April through July and lower than flows under NAA_ELT during August (to 21% lower) regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These flow reductions are small to moderate in magnitude and limited to late in the spawning period and, therefore, would not have biologically meaningful negative effects.

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT during April through August, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would be similar to those under NAA_ELT during April through August, regardless of water year type.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT below 68°F would be greater than those under NAA_ELT (4% to 25% greater) in all but dry and critical years (Table 11-4A-142). On an absolute scale, these are small increases (≤4%) that would not have biologically meaningful effects, except in below normal water years (14% increase).

Table 11-4A-142. Difference and Percent Difference in the Percentage of Months during April–August in Which Water Temperatures in the Feather River below Thermalito Afterbay fall below the 68°F Water Temperature Threshold for Threadfin Shad Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	1 (1%)	2 (4%)
Above Normal	-9 (-12%)	4 (6%)
Below Normal	1 (2%)	14 (25%)
Dry	-26 (-34%)	-2 (-4%)
Critical	-22 (-33%)	-2 (-4%)
All	-10 (-14%)	3 (5%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through August threadfin shad spawning period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT during April through August, except for 17% lower flow during April of above normal water years.

Flows under H4_ELT in Clear Creek below Whiskeytown would generally be similar to flows under NAA_ELT during April through August, except for 14% lower flow during July of critical water years and 11% higher flow in August of critical years.

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 548% greater than flows under NAA_ELT during April through June, except for 10% lower and 12% lower flows during June of critical and wet years, respectively, and would be up to 46% lower than flows under NAA_ELT during July and August, except for 48% higher flows in August of critical water years. Based on occurrence late in the spawning period, these flow reductions are not expected to have biologically meaningful effects.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT during April through August, except for 14% lower flow in May of critical water years, 28% lower flow in August of critical years, and 18% greater flow in August of below normal water years.

Flows under H4_ELT in the San Joaquin and Stanislaus Rivers would be similar to flows under NAA_ELT throughout the period.

The percentage of months under H4_ELT with mean water temperatures below the 68°F temperature threshold in the Feather River below Thermalito Afterbay would be similar to or lower than the percentage under NAA_ELT in all water years (Table 11-4A-143). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. Water temperature modeling was not conducted in Clear Creek or the San Joaquin River.

Table 11-4A-143. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay fall below the 68°F Water Temperature Threshold for Threadfin Shad Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	-7 (-11%)	-5 (-9%)
Above Normal	-27 (-36%)	-15 (-23%)
Below Normal	-13 (-18%)	0 (0%)
Dry	-29 (-39%)	-6 (-11%)
Critical	-22 (-33%)	-2 (-4%)
All	-18 (-26%)	-5 (-9%)

[a] A negative value indicates a reduction in percentage of months outside suitable range H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in threadfin shad spawning habitat. Flows in all rivers examined during the April through August spawning period under Alternative 4A would generally be similar to or greater than flows under the NAA_ELT. Some flow reductions would occur late in the spawning season in the Feather River and would be too small in magnitude or frequency to have a biologically meaningful effect on threadfin shad. The percentage of years below the spawning temperature threshold would be similar or lower under Alternative 4A relative to the NAA_ELT, except in below normal years, but this increase is not expected to have a biologically meaningful effect on the threadfin shad population because it occurs in only one water year type and is isolated to the Feather River. Flow conditions in the Feather River under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under NAA_ELT.

CEQA Conclusion: In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to Existing Conditions.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during April through August spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through August, except in wet years during May (10% lower) and in dry and critical years during August (11% and 13% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These are relatively small-magnitude and infrequent flow reductions and would not have biologically meaningful effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through August, except in critical years during May and August (6% and 8% lower, respectively) and in wet years during July (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions during April through August (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during April through June, except in below normal years during April (6% lower) and in wet years during May (15% lower), and would be lower than flows under Existing Conditions in dry and critical years during July (22% and 52% lower, respectively) and in below normal and dry years during August (7% and 45% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to flows under Existing Conditions during April and lower than flows under Existing Conditions during May through August (up to 46% lower)respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April and May, and would be up to 23% lower than flows under Existing Conditions during June through August.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would be similar to or up to 14% lower than to those under Existing Conditions during April through August, except for 11% greater flow during June of wet years.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months below the 68°F water temperature threshold for threadfin shad spawning under H3_ELT would be similar to or 12% to 34% lower than the percentage under Existing Conditions, depending on water year type (Table 11-4A-142).

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through August threadfin shad spawning period would generally be similar to flows under Existing Conditions except during May of wet years, when flow would be 11% lower(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 509% greater than flows under Existing Conditions during April through June, except for 38% and 6% lower flows during June of wet and critical water years, respectively, and would generally be up to 54% lower than flows under Existing Conditions during July and August, except for 26% higher flows in August of critical water years.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under Existing Conditions during April, and similar to or up to 37% lower than flows under Existing Conditions during May through August, except during August of below normal years (9% greater flow)

Flows in the Trinity River below Lewiston Reservoir and in Clear Creek at Whiskeytown Dam H4_ELT would generally be similar to flows under Existing Conditions during April through August, with minor exceptions.

Flows in the San Joaquin River at Vernalis under H4_ELT would generally be similar to or slightly lower than those under Existing Conditions during April and May, and would be up to 23% lower than flows under Existing Conditions during June through August.

Flows in the Stanislaus River at the confluence with the San Joaquin River under H4_ELT would generally be similar to or up to 14% lower than to those under Existing Conditions during April through August, except for 11% greater flow during June of wet years.

The percentage of months under H4_ELT with mean water temperatures below the 68°F temperature threshold in the Feather River below Thermalito Afterbay would be lower than the percentage under Existing Conditions in all water years (Table 11-4A-143). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. Collectively, flows would be lower under Alternative 4A during the threadfin shad spawning period relative to Existing Conditions. Flows would be moderately to substantially lower in the Feather, American, Stanislaus, and San Joaquin rivers during substantial portions of the spawning period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable spawning habitat as a result of flow reductions.

Summary of CEQA Conclusion

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 4A. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Largemouth Bass

In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for largemouth bass relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during March through June, except in above normal years during April (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be moderately to substantially greater than flows under NAA_ELT during March through June, except in below normal years during March (13% lower) and in critical years during May and June (10% and 8% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT during March through June, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would be similar to those under NAA_ELT during March through June, regardless of water year type.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside the 59°F to 75°F water temperature range would be similar to or lower than the percentage under NAA_ELT in all water year types (Table 11-4A-144).

Table 11-4A-144. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Be outside the 59°F to 75°F Water Temperature Range for Largemouth Bass Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-2 (-4%)	0 (0%)
Above Normal	-2 (-4%)	0 (0%)
Below Normal	0 (0%)	0 (0%)
Dry	-5 (-11%)	0 (0%)
Critical	-9 (-20%)	-3 (-8%)
All	-3 (-6%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the March through June largemouth bass spawning period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be similar to or up to 548% greater than flows under NAA_ELT during March through June, except in June of wet and critical water years, when the flow would be 12% and 10% lower, respectively, than flow under NAA_ELT.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT during March through June, except for 10% higher flow during April of critical water years, 14% lower flow for May of critical years, and 10% lower flows for June of dry years.

Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT during March through June, except for 17% lower flow during April of above normal water years.

Flows under H4_ELT in Clear Creek at Whiskeytown Dam would generally be similar to flows under NAA_ELT during March through June, except for 12% greater flow during March of below normal water years.

Flows under H4_ELT in the San Joaquin and Stanislaus Rivers would be similar to flows under NAA_ELT throughout the period.

The percentage of months under H4_ELT with mean water temperatures outside the 59°F to 75°F water temperature range in the Feather River below Thermalito Afterbay would be similar to or greater than the percentage under NAA_ELT in all water year types although these small increases on an absolute scale (≤5%) would not have biologically meaningful effects on largemouth bass spawning habitat conditions (Table 11-4A-145). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. Water temperature modeling was not conducted in Clear Creek or the San Joaquin River.

Table 11-4A-145. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Be outside the 59°F to 75°F Water Temperature Range for Largemouth Bass Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	3 (5%)	5 (9%)
Above Normal	0 (0%)	2 (4%)
Below Normal	1 (2%)	1 (2%)
Dry	-5 (-11%)	0 (0%)
Critical	-6 (-14%)	0 (0%)
All	-1 (-2%)	2 (4%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in largemouth bass spawning habitat. Flows in all rivers examined during the March through June spawning period under Alternative 4A would generally be similar to or greater than flows under the NAA_ELT. There would be no substantial temperature effects under Alternative 4A in any river examined. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under NAA_ELT.

CEQA Conclusion: In general, Alternative 4A would not reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to Existing Conditions.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (8% lower) and in wet years during May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (6% lower) and in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during March through June, except in below normal and dry years during March (39% and 17% lower, respectively), in below normal years during April (6% lower), and in wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during March, April and June, except in critical years during March (8% lower), above normal years during April (5% lower), and in wet and critical years during June (21% and 29% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be lower than flows under Existing Conditions during May (to 16% lower) except in critical years (13% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water year types, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude throughout the spawning period and would not have biologically meaningful negative effects.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during March through June.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be up to 23% lower than to those under Existing Conditions during March through June, except during these four months in wet years, in which flows under H3_ELT would range from 0.3% lower to 11% greater.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside of the 59°F to 75°F water temperature range for largemouth bass spawning would be the same or lower than the percentage under Existing Conditions in all water year types (Table 11-4A-144).

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the March through June largemouth bass spawning period would generally be similar to or slightly lower than flows under Existing Conditions, except during May of wet years when flows would be 11% lower under H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be similar or up to 509% greater than flows under Existing Conditions during March through June, except during March of below normal and dry water years, when flows under H4_ELT would be 22% and 11% lower, respectively, and during June of wet and critical water years, when flow under H4_ELT would be 37% lower and 6% lower, respectively.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under Existing Conditions during March and April, and generally up to 27% lower than flows under Existing Conditions during May and June.

Flows under H4_ELT in the Trinity River at Lewiston would generally be similar to those under Existing Conditions during March through June, except during March of wet years, in which flow under H4_ELT would be 14% greater than flow under Existing Conditions.

Flows under H4_ELT in Clear Creek at Whiskeytown Dam would generally be similar to those under Existing Conditions during March through June, except during March of below normal and critical water years, in which flow under H4_ELT would be 13% and 10% greater, respectively, than flow under Existing Conditions.

Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during March through June, except during March of below normal and dry water years, when flow under H4_ELT would be 11% and 12% lower, respectively, and during June of wet and dry water years, when flows would be 16% and 12% lower, respectively.

Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be up to 23% lower than to those under Existing Conditions during March through June, except during wet years, in which flow under H4_ELT would range from 0.3% lower to 11% greater than flow under Existing Conditions.

The percentage of months under H4_ELT with mean water temperatures below outside the 59°F to 75°F water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under Existing Conditions in wet, above normal, and below normal water year types and would be lower than the percentage under Existing Conditions in dry and critical water year types (Table 11-4A-143). The reductions would not be large enough to have biologically meaningful effects on largemouth bass spawning habitat conditions. Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact would not be significant because Alternative 4A would not cause a substantial reduction in largemouth bass spawning habitat relative to Existing Conditions, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus Rivers during the March through June spawning period under Alternative 4A would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types in the San Joaquin and Stanislaus Rivers that would not have biologically meaningful negative effects to largemouth bass. There would be no substantial temperature effects under Alternative 4A on largemouth bass. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under Existing Conditions.

Sacramento Tule Perch

NEPA Effects: The effects of water operations on spawning habitat for Sacramento tule perch under Alternative 4A would be similar to that described for Alternative 1A due to similarities in hydrology. For a detailed discussion, please see Alternative 1A, Impact AQUA-202. The effects would not be adverse.

CEQA Conclusion: As described under Alternative 1A, Impact AQUA-202 the impacts on Sacramento tule perch spawning would be not be significant and no mitigation is required.

Sacramento-San Joaquin Roach – California species of special concern

In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during March through June, except in above normal years during April (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be moderately to substantially greater than flows under NAA_ELT during March through June, except in below normal years during March (13% lower) and in critical years during May and June (10% and 8% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT during March through June, regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Stanislaus River at the confluence with the San Joaquin River flows under H3_ELT would be similar to those under NAA_ELT during March through June, regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months in which temperatures would be below the 60.8°F water temperature threshold for roach spawning initiation under H3_ELT would be similar to or lower than the percentage under NAA_ELT in all water year types (Table 11-4A-146).

Table 11-4A-146. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Fall below the 60.8°F Water Temperature Threshold for the Initiation of Sacramento-San Joaquin Roach Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-8 (-11%)	0 (0%)
Above Normal	-5 (-8%)	0 (0%)
Below Normal	-2 (-4%)	0 (0%)
Dry	-8 (-15%)	-3 (-6%)
Critical	-6 (-11%)	2 (4%)
All	-6 (-11%)	0 (-1%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT /HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the March through June Sacramento-San Joaquin roach spawning period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be similar to or up to 548% greater than flows under NAA_ELT during March through June, except in June of wet and critical water years, when the flow would be 12% and 10% lower, respectively, than flow under NAA_ELT.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT during March through June, except for 10% higher flow during April of critical water years, 14% lower flow for May of critical years, and 10% lower flows for June of dry years.

Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT during March through June, except for 17% lower flow during April of above normal water years.

Flows under H4_ELT in Clear Creek at Whiskeytown Dam would generally be similar to flows under NAA_ELT during March through June, except for 12% greater flow during March of below normal water years.

Flows under H4_ELT in the San Joaquin and Stanislaus Rivers would be similar to flows under NAA_ELT throughout the period. The percentage of months under H4_ELT with mean water temperatures below the 60.8°F water temperature range in the Feather River below Thermalito Afterbay would be similar to or up to 18% greater than the percentage under NAA_ELT, although these small increases on an absolute scale (≤9%) would not have biologically meaningful effects on roach spawning habitat conditions. (Table 11-4A-147). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. Water temperature modeling was not conducted in Clear Creek or the San Joaquin River.

Table 11-4A-147. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Fall below the 60.8°F Water Temperature Threshold for Sacramento-San Joaquin Roach Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	-4 (-6%)	4 (6%)
Above Normal	5 (8%)	9 (18%)
Below Normal	4 (7%)	5 (11%)
Dry	-4 (-8%)	1 (3%)
Critical	-11 (-19%)	-2 (-4%)
All	-3 (-4%)	3 (6%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in roach spawning habitat. Flows in all rivers examined during the March through June spawning period under Alternative 4A would generally be similar to or greater than flows under the NAA_ELT. The occurrence of flow reductions would not be of sufficient magnitude or frequency to have a biologically meaningful effect on roach. There would be no substantial temperature effects under Alternative 4A in any river examined. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under NAA_ELT.

CEQA Conclusion: In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to Existing Conditions.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (8% lower) and in wet years during May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (6% lower) and in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during March through June, except in below normal and dry years during March (39% and 17% lower, respectively), in below normal years during April (6% lower), and in wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during March, April and June, except in critical years during March (8% lower), above normal years during April (75% lower), and in wet and critical years during June (21% and 29% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be lower than flows under Existing Conditions during May (to 16% lower), except in critical years (13% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water year types, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude throughout the spawning period and would not have biologically meaningful negative effects.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during March through June, except during March of below normal and dry water years, when flow under H3_ELT would be 11% and 12% lower, respectively, and during June of wet and dry water years, when flows would be 16% and 11% lower, respectively.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during March through June.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be up to 23% lower than to those under Existing Conditions during March through June, except during these four months in wet years, in which flows under H3_ELT would range from 0.3% lower to 11% greater.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT in which temperatures would be below the 60.8°F water temperature threshold for roach spawning initiation would be lower than the percentage under Existing Conditions in all water year types (Table 11-4A-146).

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the March through June Sacramento-San Joaquin roach spawning period would generally be similar to or slightly lower than flows under Existing Conditions, except during May of wet years when flows would be 11% lower under H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be similar or up to 509% greater than flows under Existing Conditions during March through June, except during March of below normal and dry water years, when flows under H4_ELT would be 22% and 11% lower, respectively, and during June of wet and critical water years, when flow under H4_ELT would be 37% lower and 6% lower, respectively.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under Existing Conditions during March and April, and generally up to 27% lower than flows under Existing Conditions during May and June.

Flows under H4_ELT in the Trinity River at Lewiston would generally be similar to those under Existing Conditions during March through June, except during March of wet years, in which flow under H4_ELT would be 14% greater than flow under Existing Conditions.

Flows under H4_ELT in Clear Creek at Whiskeytown Dam would generally be similar to those under Existing Conditions during March through June, except during March of below normal and critical water years, in which flow under H4_ELT would be 13% and 10% greater, respectively, than flow under Existing Conditions.

Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during March through June, except during March of below normal and dry water years, when flow under H4_ELT would be 11% and 12% lower, respectively, and during June of wet and dry water years, when flows would be 16% and 12% lower, respectively.

Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be up to 23% lower than to those under Existing Conditions during March through June, except during wet years, in which flow under H4_ELT would range from 0.3% lower to 11% greater than flow under Existing Conditions.

The percentage of months under H4_ELT with mean water temperatures below the 60.8°F water temperature range in the Feather River below Thermalito Afterbay would be up to 7% and 8% higher than the percentage under Existing Conditions in above normal and below normal water years, respectively, and would be up to 19% lower than the percentage under Existing Conditions in the other three water year types (Table 11-4A-147). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact would not be significant because Alternative 4A would not cause a substantial reduction in Sacramento-San Joaquin roach spawning habitat relative to Existing Conditions, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus Rivers during the March through June spawning period under Alternative 4A would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types in the San Joaquin and Stanislaus Rivers that would not have biologically meaningful negative effects to Sacramento-San Joaquin roach. There would be no substantial temperature effects under Alternative 4A on Sacramento-San Joaquin roach. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under Existing Conditions.

Hardhead – California species of special concern

In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during April and May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to flows under NAA_ELT during April and May, except in above normal years during April (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT during April and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be similar to moderately greater than flows under NAA_ELT during April and May, except in critical years in May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during April and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT during April and May, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under H3_ELT would be similar to those under NAA_ELT during April and May, regardless of water year type.

Water Temperature

The percentage of years outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature-related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of years under H3_ELT outside the 59°F to 64°F suitable water temperature range would be similar to or lower than the percentage under NAA_ELT in all water year types (Table 11-4A-148).

Table 11-4A-148. Difference and Percent Difference in the Percentage of Months during April–May in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Be outside the 59°F to 64°F Water Temperature Range for Hardhead Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	1 (2%)	0 (0%)
Above Normal	4 (6%)	-5 (-7%)
Below Normal	18 (42%)	4 (7%)
Dry	5 (9%)	-6 (-9%)
Critical	-8 (-15%)	-8 (-15%)
All	4 (7%)	-3 (-5%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT /HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through May period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would be similar to or up to 548% greater than flows under NAA_ELT during April and May.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT during April and May, except for 10% higher flow during April of critical water years and 14% lower flow for May of critical years.

Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT during April and May, except for 17% lower flow during April of above normal water years.

Flows under H4_ELT in the San Joaquin and Stanislaus Rivers and in Clear Creek would be similar to flows under NAA_ELT in both April and May.

The percentage of months under H4_ELT with mean water temperatures outside the 59°F to 64°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to or up to 19% lower than the percentage under NAA_ELT in all water years, except wet years (10% greater) (Table 11-4A-149). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. Water temperature modeling was not conducted in Clear Creek or the San Joaquin River.

Table 11-4A-149. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months during April–May in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Fall outside the 59°F to 64°F Water Temperature Range for Hardhead Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	7 (11%)	6 (10%)
Above Normal	-5 (-8%)	-14 (-19%)
Below Normal	14 (33%)	0 (0%)
Dry	5 (9%)	-6 (-9%)
Critical	-4 (-7%)	-4 (-7%)
All	5 (9%)	-2 (-3%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in hardhead spawning habitat. Flows in all rivers examined during the April through May spawning period under Alternative 4A would generally be similar to or greater than flows under the NAA_ELT. There would be no substantial temperature effects under Alternative 4A in any river examined. Flow and water temperature conditions under H4_ELT would be less favorable than those under H3_ELT, but would be similar to those under NAA_ELT.

CEQA Conclusion: In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for hardhead relative to Existing Conditions.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to flows under Existing Conditions during April through May, except in wet years during May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through May, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under Existing Conditions during April through May, except in critical years during May (6% lower)(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during April through May, except in below normal years during April (6% lower) and in wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April, except in above normal years (5% lower), but generally lower than flows under Existing Conditions during May, except in critical years (13% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These few flow reductions are relatively small in magnitude and, therefore would not have biologically meaningful negative effects.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April and May.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be similar to or up to 12% lower than to those under Existing Conditions during April and May.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside of the 59°F to 64°F water temperature range for hardhead spawning would be greater than the percentage under Existing Conditions in all water years types, except critical years (15% lower) (Table 11-4A-148).

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through May period would generally be similar to or up to 11% lower (May of wet years) than flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 509% greater than flows under Existing Conditions during April and May.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under Existing Conditions during April, and up to 18% lower than flows under Existing Conditions during May.

Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during April and May.

Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be similar to or up to 13% lower than to those under Existing Conditions during April and May.

Flows under H4_ELT in the Trinity River and Clear Creek would be similar to flows under Existing Conditions in both months, except for 10% higher flows in Clear Creek during April of critical water years.

The percentage of months under H4_ELT with mean water temperatures outside the 59°F to 64°F suitable water temperature range in the Feather River below Thermalito Afterbay would be slightly lower than the percentage under Existing Conditions in above normal and critical water years and would be up to 33% higher than the percentage under Existing Conditions in wet, below normal and dry water years (Table 11-4A-149). Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H4_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the effect would be less than significant because Alternative 4A would not cause a substantial reduction in roach spawning habitat, and no mitigation is necessary. Flows in most rivers examined during the April through May spawning period under Alternative 4A would generally be similar to or greater than flows under Existing Conditions. Flows in the San Joaquin and Stanislaus Rivers would be lower under Alternative 4A, although these reductions would not have population-level effects on hardhead. There would be no substantial temperature effects under Alternative 4A on roach. Therefore, the impact would be less than significant and no mitigation is required.

California Bay Shrimp

NEPA Effects: The effect of water operations on spawning habitat of California bay shrimp under Alternative 4A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-202) due to similarities in hydrology. For a detailed discussion, please see Alternative 1A, Impact AQUA-202. The effects would not be adverse.

CEQA Conclusion: The impact of water operations on spawning habitat of California bay shrimp would be the same as described immediately above. The impact would be less than significant and no mitigation would be required.

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

See Alternative 1A, Impact AQUA-203 for additional background information relevant to non-covered species of primary management concern. The analysis for striped bass, American shad, and bay shrimp includes new analysis across all alternatives that is described in detail in Chapter 11, Section 11.3.5, in Appendix A. The analysis below for Alternative 4A draws on that analysis.

Striped Bass

NEPA Effects: The discussion under Alternative 4A, Impact AQUA-202 for striped bass also addressed the embryo incubation and initial rearing period. That analysis indicates that there is no adverse effect on striped bass rearing during that period. As discussed further in Chapter 11, Section 11.3.5, in Appendix A, water operations have the potential to affect striped bass juvenile abundance through changes in the extent of rearing habitat in the Plan Area as indexed by X2 (Kimmerer et al. 2009). Several X2-abundance index or X2-survival index relationships from Kimmerer et al. (2009) were applied to striped bass in order to assess the potential effects on abundance or survival through changes in rearing habitat. Application of these relationships suggested that, in relation to NAA_ELT, there generally would be only a small change in mean abundance index (<5%) as a result of change in rearing habitat under Alternative 4A scenarios H3_ELT and H4_ ELT (See Table 11-mult-6, Table 11-mult-7, Table 11-mult-8, Table 11-mult-9, and Table 11-mult-10 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). The exceptions were the mean bay midwater trawl abundance index (7% reduction; Table 11-mult-9) and the mean summer townet survival index (6% reduction; Table 11-mult-6). These results indicate that the operational effects would not be adverse, because they would not result in a substantial reduction in the rearing habitat for striped bass.

CEQA Conclusion: The analysis of potential water operations-related rearing habitat effects illustrated that in relation to Existing Conditions (see Table 11-mult-6, Table 11-mult-7, Table 11-mult-8, Table 11-mult-9, and Table 11-mult-10 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS), there could be significant impacts of the Alternative 4A on survival or abundance of striped bass, in contrast to the conclusion presented above in the NEPA Effects section. As described in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both Alternative 4A and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur in the ELT, including the projected effects of climate change (precipitation patterns), sea level rise and future water demands. Because Alternative 4A modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands. In the case of the X2-related analyses of rearing habitat for striped bass, the effect of sea level rise in particular confounds the interpretation of the effects of the alternatives. When compared to NAA_ELT and informed by the NEPA analysis above, the change in rearing habitat would be less than significant. No mitigation would be necessary.

American Shad

NEPA Effects: As discussed further in Chapter 11, Section 11.3.5, in Appendix A, water operations have the potential to affect American shad juvenile abundance through changes in the extent of rearing habitat in the Plan Area as indexed by X2 (Kimmerer et al. 2009). Two X2-abundance index relationships from Kimmerer et al. (2009) were applied to American shad in order to assess the potential effects on abundance through changes in rearing habitat. Application of these relationships suggested that, in relation to NAA_ELT, there would be only a small change in mean abundance index (<5%) as a result of change in rearing habitat under Alternative 4A scenarios H3_ELT and H4_ELT(See Table 11-mult-11, Table 11-mult-12 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). These modeling results indicate that the operational effects would not be adverse, because they would not result in a substantial reduction in the rearing habitat for American shad.

CEQA Conclusion: Similar to striped bass, the analysis of potential water operations-related rearing habitat effects illustrated that in relation to Existing Conditions, there could be a greater impact of Alternative 4A on abundance of American shad (Table 11-mult-11, Table 11-mult-12 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS), than found in the NEPA Effects section. As noted for striped bass, the comparison to the NAA_ELT is a better approach than comparison to Existing Conditions because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands. In the case of the X2-related analyses of rearing habitat for American shad, the effect of sea level rise in particular confounds the interpretation of the effects of the alternatives. Based on the discussion presented above for the NEPA Effects, the change in rearing habitat would be less than significant. No mitigation would necessary.

Threadfin Shad

NEPA Effects: The effects of water operations on rearing habitat for threadfin shad under Alternative 4A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203) due to similarities in hydrology. For a detailed discussion, please see Alternative 1A, Impact AQUA-203. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on threadfin shad rearing habitat would be less than significant and no mitigation would be required.

Largemouth Bass

H3_ELT/ESO_ELT

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during April through October with some exceptions (to 14% lower), and would be lower in all water year types during November (to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to flows under NAA_ELT with isolated exceptions, including flow reduction in above normal years during April (to 17% lower) and small flow reductions in above normal years during October (7% lower) and in wet years during November (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT during April through November, except in critical years during August (11% greater) and in critical years during July, September, and October (to 14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be moderately to substantially greater than flows under NAA during April through June (to 106% greater), except in critical years during May and June (to 10% lower); moderately to substantially lower than flows under NAA during July through September (to 48% lower), except in critical years during August and September (to 25% greater); and similar to or greater than flows under NAA_ELT during October and November (to 19% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions during July through September would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA during April through July and October, except in wet years during October (6% lower), and would be similar to or lower than flows under NAA_ELT during August, September, and November (to 22% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT during April through November, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under H3_ELT would be similar to those under NAA_ELT during April through November, regardless of water year type.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of H3_ELT in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 88°F under NAA_ELT or H3_ELT. As a result, there would be no difference between NAA_ELT and H3_ELT in the percentage of months in which the 88°F water temperature threshold is exceeded (Table 11-4A-150).

Table 11-4A-150. Difference and Percent Difference in the Percentage of Months during April–November in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 88°F Water Temperature Threshold for Juvenile Largemouth Bass Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during year-round adult largemouth bass residency period. Lower flows could reduce the quantity and quality of instream habitat available for adults.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT throughout the year with some exceptions (up to 14% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during the period, except in above normal years in April and October (17% and 8% lower, respectively), and in wet years during November (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT throughout the year, except in critical years during July (14% lower), August (11% greater), September (10% lower), and October (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be lower than flows under NAA_ELT during January and July through September, except in critical years in August and September (23% and 25% greater, respectively); would generally be similar to or greater than flows under NAA during February through June, except for below normal years during February and March (11% and 13% lower, respectively) and in critical years during May and June (10% and 8% lower, respectively); and would generally be similar to or greater than flows under NAA_ELT during November and December, except in wet years during December (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would be more persistently lower under H3_ELT relative to NAA_ELT (up to 48% lower) during July, August, and in all water year types except critical years during September. Flow reductions would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during January through July and December, except in below normal years during January (11% lower), and would be similar to or lower than flows under NAA_ELT (up to 22% lower) during August through November, except in below normal and critical years during October (16% and 22% greater, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under H3_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

The analysis for Alternative 1A indicates that there would be no differences in flows between H3 and NAA_ELT.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass residency period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of habitat and increased stress and mortality for adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of H3_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F under NAA_ELT and H3_ELT (Table 11-4A-151). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between NAA_ELT and H3_ELT.

Table 11-4A-151. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Adult Largemouth Bass Survival[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT /HOS_ELT

Juveniles

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through November juvenile largemouth bass rearing period would generally be similar to flows under NAA_ELT, except during November of all water year types, when flows would be up to 15% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 548% greater than flows under NAA_ELT during April through June, except for 12% and 10% lower flows during June of wet and critical water years, respectively, and would generally be similar to or up to 60% lower than flows under NAA_ELT during July through November, except in August through November of critical water years, when flows under NAA_ELT would range from 11% to 52% higher. Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT during April through November, except for 14% lower flow in May of critical water years, 28% lower flow in August of critical years, 20% lower flows in September of below normal years, 18% greater flow in August of below normal years, and 15% and 21% greater flows in October of below normal and critical water years, respectively. Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT, during April through November, except for 17% lower flow during April of above normal water years, 16% greater flow in September of critical years, and 11% greater flow during October of above normal water years. Flows under H4_ELT in Clear Creek below Whiskeytown would generally be similar to flows under NAA_ELT during April through November, except for 14% lower flow and 11% higher flow during July and August, respectively, of critical water years. Flows under H4_ELT in the San Joaquin and Stanislaus Rivers would be similar to flows under NAA_ELT throughout the period.

Water temperatures in the Feather River below Thermalito Afterbay during the April through November juvenile largemouth bass rearing period would not exceed the 88°F water temperature threshold in H4_ELT or NAA_ELT. As a result, there would be no difference between H4_ELT and NAA_ELT in the percentage of months in which the 88°F water temperature threshold is exceeded (Table 11-4A-152).

Table 11-4A-152. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months during April–November in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 88°F Water Temperature Threshold for Juvenile Largemouth Bass Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

Adults

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the year-round adult largemouth bass residency period would generally be similar to flows under NAA_ELT, except for 10% lower flow during September of below normal water years and except during November of all water year types, when flows would be up to 15% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 548% greater than flows under NAA_ELT during April through June, except for 12% and 10% lower flows during June of wet and critical water years, respectively. The Feather River flows under H4_ELT would generally be similar to or up to 60% lower than flows under NAA_ELT during July through November, except in August through November of critical water years, when flows under NAA_ELT would range from 11% to 52% higher, and the flows would generally be similar to or up to 40% higher under NAA_ELT during December through March. Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT throughout the year, except for 14% lower flow in May of critical water years, 28% lower flow in August of critical years, 20% lower flows in September of below normal years, 18% greater flow in August of below normal years, and 15% and 21% greater flows in October of below normal and critical water years, respectively. Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT throughout the year, except for 10% higher flow during February of wet years, 17% lower flow during April of above normal water years, 16% greater flow during September of critical years, and 11% greater flow during October of above normal water years. Flows under H4_ELT in Clear Creek below Whiskeytown would generally be similar to flows under NAA_ELT throughout the year, except for 12% higher flow in March of below normal water years, and 14% lower flow and 11% higher flow during July and August, respectively, of critical water years. Flows under H4_ELT in the San Joaquin and Stanislaus Rivers would be similar to flows under NAA_ELT throughout the year.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass residency period would not exceed the 86°F water temperature threshold in H4_ELT or NAA_ELT. As a result, there would be no difference between H4_ELT and NAA_ELT in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4A-153).

Table 11-4A-153. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Adult Largemouth Bass Survival[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in juvenile rearing and adult spawning habitat. Flows in all rivers examined during the year under Alternative 4A are generally similar to or greater than flows under the NAA_ELT in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the largemouth bass population. Flow-related habitat conditions for both juvenile and adult largemouth bass under H4_ELT would be less favorable than those under H3_ELT although not different from NAA_ELT. There are no temperature-related effects in any other rivers examined.

CEQA Conclusion: In general, Alternative 4 would not reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to Existing Conditions.

H3_ELT/ESO_ELT

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through July, except in wet years during

May (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during August through November (to 22% lower), except in above normal and below normal years during August (to 7% greater) and in wet and above normal years during September (to 32% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April through July, except in critical years during May (6% lower) and in wet years during July (10% lower), and similar to or lower than flows under Existing Conditions during August through November (to 17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions years during August through November would have a localized effect on rearing conditions.

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions during April through November, except in critical years during September (19% lower) and in below normal years during October (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively small, isolated effect limited to a single water year type and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during April through June, September, and October, with a few isolated exceptions (to 50% lower)(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be moderately to substantially lower than flows under Existing Conditions during July, August, and November (to 52% lower), except in wet and above normal years during July and August (to 50% greater) and in above normal years during November (5% greater).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during April, except in above normal years (5% lower), but generally lower, by up to 46%, during May through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be moderate flow reductions in drier water year types, when effects would be most critical for habitat conditions, for some months/water year types from May through November that would affect rearing conditions at this location.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April and May and September through November, and would be similar to or up to 23% lower than flows under Existing Conditions during June through August.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be similar to or up to 14% lower than to those under Existing Conditions during April through July, except for 11% greater flow during June of wet years, and would be similar to or slightly lower than flows under Existing Conditions during August through November.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under Existing Conditions. Therefore, there would be no temperature related effects of H3_ELT in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 88°F water temperature threshold for juvenile largemouth bass during the April through November rearing period under Existing Conditions or H3_ELT (Table 11-4A-150). As a result, there would be no difference in the percentage of months in which the 88°F water temperature threshold is exceeded between H3_ELT and Existing Conditions.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round adult largemouth bass residency period. Lower flows could reduce the quantity and quality of instream habitat available for adults.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during January through April and December, except in drier years during January (to 13% lower), in dry and critical years during February (8% and 6% lower, respectively), in critical years during March (8% lower), in above normal years in April (5% lower), and in dry and critical years during December (8% and 5% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during May through November (to 46% lower), except in critical years during May (13% greater), in below normal and dry years during June (8% and 25% greater, respectively), and in below normal and critical years during October (10% and 15% greater, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be primarily small flow reductions in some water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during January through June and December, except in below normal years during January (16% lower), in below normal years during March (6% lower), and in critical years during May (6% lower), but would generally be similar to or lower than flows under Existing Conditions during July through November, except in below normal years during July (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions in critical years would have a localized effect on conditions for adults in that water year type.

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during September and in below normal years during October (19% and 6% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively isolated effect limited to a single water year type in each month and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during February through June, September, and October, except in drier years during February (to 48% lower), in below normal and dry years during March (39% and 17% lower, respectively), in below normal years during April (6% lower), in wet years during May (15% lower), in below normal and critical years during September (26% and 50% lower, respectively), and in wet and critical years during October (6% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be moderately to substantially lower than flows under Existing Conditions in January, July, August, November, and December, except in wet and above normal years during July (15% and 9% greater, respectively), in below normal and dry years during August (7% and 45% greater, respectively), in above normal years during November (5% greater), and in above normal years during December (18% greater).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions in wetter years during January, in wet and below normal years during December, and in most water year types during February through April, except in dry and critical years during February (8% and 6% lower, respectively), in critical years during March (7% lower), and in above normal years during April (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be similar to or lower than flows under Existing Conditions during May through November, except in critical years during May (13% greater), in below normal and dry years during June (8% and 25% greater, respectively), and in below normal and critical years during October (10% and 15% greater, respectively). There would be persistent small to substantial flow reductions that would affect conditions for adults at this location.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April, May and September through November, would be similar to or up to 23% lower than flows under Existing Conditions during February, March, and June through August, and would be similar to or up to 11% greater than flows under Existing Conditions during December and January.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow in wet years during February and June, respectively, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass residency period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of habitat for adults and increased stress and mortality of adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under Existing Conditions. Therefore, there would be no temperature related effects of H3_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 86°F water temperature threshold for adult largemouth bass under Existing Conditions or H3_ELT (Table

11-4A-151). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between H3_ELT and Existing Conditions.

H4_ELT/HOS_ELT

Juveniles

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the April through July juvenile largemouth bass rearing period would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under in the Feather River at Thermalito Afterbay would be greater (up to 509%) than those under Existing Conditions June, with few exceptions. Flows under H4_ELT in the American River at Nimbus Dam would generally be similar to flows under Existing Conditions during April, but up to 27% lower than flows under Existing Conditions during May and June. Flows under H4_ELT in the Trinity River would generally be similar to flows under Existing Conditions with minor exceptions. Flows under H4_ELT in Clear Creek would be similar to flows under Existing Conditions. Flows under H4_ELT in the San Joaquin River at Vernalis would generally be lower (up to 16% lower) than those under Existing Conditions. Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be up to 14% lower than to those under Existing Conditions.

Based on these flow reductions, juvenile rearing habitat conditions would generally be less favorable under H4 relative to NAA_ELT in the Feather River.

Adults

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the year-round adult largemouth bass residency period would generally be similar to or up to 18% lower than flows under Existing Conditions throughout the year, except during September, when flows would be for 27% and 49% in wet and above normal, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Differences in flows between H4_ELT and Existing Conditions in the Feather River at Thermalito Afterbay would be highly variable, with flows under H4_ELT up to 509% greater than those under Existing Conditions during April through June and September, except for 37% and 6% lower flows during June of wet and critical water years, respectively, and 49% and 47% lower flows during September of below normal and dry years, respectively. The Feather River flows under H4_ELT would generally be similar to or up to 54% lower than flows under Existing Conditions during July, August, and October through March, except in August through November of critical water years, when flows under H4_ELT would range up to 55% higher. Flows under H4_ELT in the American River at Nimbus Dam would generally be similar to or up to 38% lower than flows under Existing Conditions throughout the year, except for 15% greater flow in January of wet years, 12% to 14% greater flow in February of wet, above normal and below normal water years, and 14% greater flow in October of critical water years. Flows under H4_ELT in the Trinity River would generally be similar to flows under Existing Conditions throughout the year, but would range from 10% to 29% higher during December through March of wet years, would be 22% higher in February of above normal years, would be 16% lower in January of below normal years, and would be 10% lower in July of wet years. Flows under H4_ELT in Clear Creek would generally be similar to flows under Existing Conditions throughout the year, but would be 40% and 13% greater in January and February, respectively, of wet years, would be 10% higher in December through April of critical water years, 11% higher in October of critical years, 13% higher in March of below normal years. Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during January, April, May and September through

November, would be similar to or up to 23% lower than flows under Existing Conditions during February, March, and June through August, and would be similar to or 12% higher (wet years) in December. Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow during February and June, respectively, of wet years, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water temperatures in the Feather River below Thermalito Afterbay would not exceed the 86°F water temperature threshold for adult largemouth bass under H4_ELT or Existing Conditions. As a result, there would be no difference between H4_ELT and Existing Conditions in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4A-153).

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 4A during the adult largemouth bass residency period relative to Existing Conditions. Flows would be persistently and moderately to substantially lower in several rivers during substantial portions of the period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce the quantity and quality of habitat for adults as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 4A. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Sacramento Tule Perch

In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during year-round juvenile and adult Sacramento tule perch occurrence period. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT throughout the year with some exceptions (up to 14% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during the period, except in above normal years in April and October (17% and 8% lower, respectively), and in wet years during November (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT throughout the year, except in critical years during July (14% lower), August (11% greater), September (10% lower), and October (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be lower than flows under NAA during January and July through September, except in critical years in August and September (23% and 25% greater, respectively); would generally be similar to or greater than flows under NAA_ELT during February through June, except for below normal years during February and March (11% and 13% lower, respectively) and in critical years during May and June (10% and 8% lower, respectively); and would generally be similar to or greater than flows under NAA_ELT during November and December, except in wet years during December (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would be more persistently lower under H3_ELT relative to NAA_ELT (up to 48% lower) during July, August, and in all water year types except critical years during September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions would be partially offset by increases in flow in the adjoining months. In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during January through July and December, except in below normal and critical years during October (11% lower), and would be similar to or lower than flows under NAA_ELT (up to 22% lower) during August through November, except in below normal and critical years during October (16% and 22% greater, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under H3_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

The analysis for Alternative 4A indicates that there would be no biologically meaningful differences in flows between H3 and NAA_ELT because flows would not be reduced enough or frequently enough to affect habitat conditions.

Water Temperature

The percentage of months exceeding water temperature thresholds of 72°F and 75°F for the year-round juvenile and adult Sacramento tule perch occurrence period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quantity and quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of H3_ELT in these rivers during any month. In the Feather River below Thermalito Afterbay, the percentage of years under H3_ELT exceeding the 72°F threshold would be higher than the percentage under NAA_ELT by up to 164% depending on water year type (Table 11-4A-154). Although relative differences are large due to small values in the divisor, the absolute differences in percent exceedance are negligible (≤2%) and, therefore, do not represent biologically meaningful effects to Sacramento tule perch.

The percentage of months under H3_ELT exceeding the 75°F threshold would be similar to or up to 29% lower than the percentage under NAA_ELT (Table 11-4A-154). As with the 72°F threshold, although relative differences are large due to small values in the divisor, the absolute differences in percent exceedance are negligible (≤1%) and, therefore, do not represent biologically meaningful effects to Sacramento tule perch.

Table 11-4A-154. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed 72°F and 75°F Water Temperature Thresholds for Sacramento Tule Perch Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA vs. H3_ELT
72°F Threshold		
Wet	1 (59%)	2 (84%)
Above Normal	0 (NA)	0 (NA)
Below Normal	2 (NA)	2 (NA)
Dry	4 (NA)	2 (164%)
Critical	5 (114%)	1 (18%)
All	2 (185%)	2 (76%)
75°F Threshold		
Wet	0 (NA)	0 (0%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	3 (400%)	-1 (-29%)
All	1 (500%)	0 (-25%)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the year-round juvenile and adult Sacramento tule perch occurrence period would generally be similar to flows under NAA_ELT, except for 10% lower flow during September of below normal water years and except during November of all water year types, when flows would be up to 15% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 548% greater than flows under NAA_ELT during April through June, except for 12% and 10% lower flows during June of wet and critical water years, respectively. The Feather River flows under H4_ELT would generally be similar to or up to 60% lower than flows under NAA_ELT during July through November, except in August through November of critical water years, when flows under NAA_ELT would range from 11% to 52% higher, and the flows would generally be similar to or up to 40% higher under NAA_ELT during December through March.

Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT throughout the year, except for 14% lower flow in May of critical water years, 28% lower flow in August of critical years, 20% lower flows in September of below normal years, 18% greater flow in August of below normal years, and 15% and 21% greater flows in October of below normal and critical water years, respectively.

Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT throughout the year, except for 10% higher flow during February of wet years, 17% lower flow during April of above normal water years, 16% greater flow during September of critical years, and 11% greater flow during October of above normal water years.

Flows under H4_ELT in Clear Creek below Whiskeytown would generally be similar to flows under NAA_ELT throughout the year, except for 12% higher flow in March of below normal water years, and 14% lower flow and 11% higher flow during July and August, respectively, of critical water years.

Flows under H4_ELT in the San Joaquin and Stanislaus Rivers would be similar to flows under NAA_ELT throughout the year.

The percentage of months under H4_ELT exceeding the 72°F and 75°F water temperature thresholds in the Feather River below Thermalito Afterbay during the year-round juvenile and adult Sacramento tule perch occurrence period would generally be higher than the percentage under NAA_ELT, but absolute differences would be small (≤4%) and, therefore, would not represent a biologically meaningful effect to Sacramento tule perch (Table 11-4A-155).

Table 11-4A-155. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed 72°F and 75°F Water Temperature Thresholds for Sacramento Tule Perch Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
72°F Threshold		
Wet	3 (145%)	4 (184%)
Above Normal	2 (NA)	2 (NA)
Below Normal	2 (NA)	2 (NA)
Dry	5 (NA)	3 (229%)
Critical	7 (164%)	4 (46%)
All	4 (292%)	3 (143%)
75°F Threshold		
Wet	1 (NA)	1 (233%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	1 (NA)	1 (NA)
Critical	2 (300%)	-2 (-43%)
All	1 (700%)	0 (0%)

NA = could not be calculated because the denominator was 0.
[a] A negative value indicates a reduction in percentage of months outside suitable range under H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in the quantity or quality of Sacramento tule perch habitat. Flows in all rivers examined during the year under Alternative 4A are generally similar to or greater than flows under the NAA_ELT in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the Sacramento tule perch population. There would be no substantial differences in water temperature between Alternative 4A and NAA_ELT in any river examined that would cause a biologically meaningful effect to Sacramento tule perch.

CEQA Conclusion: In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to Existing Conditions.

H3_ELT/ESO_ELT

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during year-round juvenile and adult Sacramento tule perch occurrence period. Lower flows could reduce the quantity and quality of instream habitat available for tule perch.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during January through April and December, except in drier years during January (to 13% lower), in dry and critical years during February (8% and 6% lower, respectively), in critical years during March (8% lower), in above normal years in April (5% lower), and in dry and critical years during December (8% and 5% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during May through November (to 46% lower), except in critical years during May (13% greater), in below normal and dry years during June (8% and 25% greater, respectively), and in below normal and critical years during October (10% and 15% greater, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be primarily small flow reductions in some water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during January through June and December, except in below normal years during January (16% lower), in below normal years during March (6% lower), and in critical years during May (6% lower), but would generally be similar to or lower than flows under Existing Conditions during July through November, except in below normal years during July (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions would have a localized effect on habitat conditions in that water year type.

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during September and in below normal years during October (19% and 6% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively isolated effect limited to a single water year type in each month and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during February through June, September, and October, except in drier years during February (to 48% lower), in below normal and dry years during March (39% and 17% lower, respectively), in below normal years during April (6% lower), in wet years during May (15% lower), in below normal and critical years during September (26% and 50% lower, respectively), and in wet and critical years during October (6% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be moderately to substantially lower than flows under Existing Conditions in January, July, August, November, and December, except in wet and above normal years during July (15% and 9% greater, respectively), in below normal and dry years during August (7% and 45% greater, respectively), in above normal years during November (5% greater), and in above normal years during December (18% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions in wetter years during January, in wet and below normal years during December, and in most water year types during February through April, except in dry and critical years during February (8% and 6% lower, respectively), in critical years during March (7% lower), and in above normal years during April (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be similar to or lower than flows under Existing Conditions during May through November, except in critical years during May (13% greater), in below normal and dry years during June (8% and 25% greater, respectively), and in below normal and critical years during October (10% and 15% greater, respectively). There would be persistent small to substantial flow reductions that would affect habitat conditions at this location.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April, May and September through November, would be similar to or up to 23% lower than flows under Existing Conditions during February, March, and June through August, and would be similar to or up to 11% greater than flows under Existing Conditions during December and January.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow in wet years during February and June, respectively, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water Temperature

The percentage of months exceeding water temperatures of 72°F and 75°F for the year-round juvenile and adult Sacramento tule perch occurrence period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures exceeding these thresholds could lead to reduced habitat quality and increased stress and mortality. Water temperatures were not modeled in Clear Creek or the San Joaquin River.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under Existing Conditions. Therefore, there would be no temperature related effects of H3_ELT in these rivers during any month. In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT exceeding 72°F relative to the percentage under Existing Conditions would be similar to or greater, by up to 114% (Table 11-4A-154). However, these relative increases correspond to small absolute increases (≤5%) that are not expected to have biologically meaningful effects.

The percentage of years under H3_ELT exceeding 75°F would be similar to the percentage under Existing Conditions in all water years except critical years (400% higher) (Table 11-4A-154). As with the 72°F threshold, this increase corresponds to a small absolute increase (3%) that is not expected to have biologically meaningful negative effects.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the year-round juvenile and adult Sacramento tule perch occurrence period would generally be similar to or up to 18% lower than flows under Existing Conditions throughout the year, except during September, when flows would be for 27% and 49% in wet and above normal, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Differences in flows between H4_ELT and Existing Conditions in the Feather River at Thermalito Afterbay would be highly variable, with flows under H4_ELT up to 509% greater than those under Existing Conditions during April through June and September, except for 37% and 6% lower flows during June of wet and critical water years, respectively, and 49% and 47% lower flows during September of below normal and dry years, respectively. The Feather River flows under H4_ELT would generally be similar to or up to 54% lower than flows under Existing Conditions during July, August, and October through March, except in August through November of critical water years, when flows under H4_ELT would range up to 55% higher. Flows under H4_ELT in the American River at Nimbus Dam would generally be similar to or up to 38% lower than flows under Existing Conditions throughout the year, except for 15% greater flow in January of wet years, 12% to 14% greater flow in February of wet, above normal and below normal water years, and 14% greater flow in October of critical water years. Flows under H4_ELT in the Trinity River would generally be similar to flows under Existing Conditions throughout the year, but would range from 10% to 29% higher during December through March of wet years, would be 22% higher in February of above normal years, would be 16% lower in January of below normal years, and would be 10% lower in July of wet years. Flows under H4_ELT in Clear Creek would generally be similar to flows under Existing Conditions throughout the year, but would be 40% and 13% greater in January and February, respectively, of wet years, would be 10% higher in December through April of critical water years, 11% higher in October of critical years, 13% higher in March of below normal years. Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during January, April, May and September through November, would be similar to or up to 23% lower than flows under Existing Conditions during February, March, and June through August, and would be similar to or 12% higher (wet years) in December. Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow during February and June, respectively, of wet years, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

The percentage of months under H4_ELT exceeding the 72°F and 75°F water temperature thresholds in the Feather River below Thermalito Afterbay during the year-round juvenile and adult Sacramento tule perch occurrence period would generally be similar to those under Existing Conditions, except in wet and critical years for the 72°F threshold and in critical years for the 75°F threshold. Although these relative differences would be large, the absolute differences would be small (≤7%) and, therefore, would not have a biologically meaningful effect on the quantity or quality of habitat for Sacramento tule perch (Table 11-4A-155).

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 4A during the juvenile and adult Sacramento tule perch occurrence period relative to Existing Conditions. Flows would be persistently and moderately to substantially lower in several rivers during substantial portions of the period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable rearing habitat as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the

alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 4A. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Sacramento-San Joaquin Roach

In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach occurrence period. Lower flows could reduce the quantity and quality of instream habitat for juvenile and adult Sacramento-San Joaquin roach.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT throughout the year with some exceptions (up to 14% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during the period, except in above normal years in April and October (17% and 8% lower, respectively), and in wet years during November (10% lower)(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT throughout the year, except in critical years during July (14% lower), August (11% greater), September (10% lower), and October (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be lower than flows under NAA_ELT during January and July through September, except in critical years in August and September (23% and 25% greater, respectively); would generally be similar to or greater than flows under NAA_ELT during February through June, except for below normal years during February and March (11% and 13% lower, respectively) and in critical years during May and June (10% and 8% lower, respectively); and would generally be similar to or greater than flows under NAA_ELT during November and December, except in wet years during December (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would be more persistently lower under H3_ELT relative to NAA_ELT (up to 48% lower) during July, August, and in all water year types except critical years during September. Flow reductions would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during January through July and December, except in below normal and critical years during October (11% lower), and would be similar to or lower than flows under NAA_ELT (up to 22% lower) during August through November, except in below normal and critical years during October (16% and 22% greater, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under H3_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach occurrence period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3 _ELT would generally be the same as those under NAA _ELT. Therefore, there would be no temperature related effects of H3 _ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F under NAA_ELT or H3_ELT (Table 11-4A-156). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between NAA_ELT and H3_ELT.

Table 11-4A-156. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Sacramento-San Joaquin Roach Survival[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the year-round Sacramento-San Joaquin roach occurrence period would generally be similar to flows under NAA_ELT, except for 10% lower flow during September of below normal water years and except during November of all water year types, when flows would be up to 15% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 548% greater than flows under NAA_ELT during April through June, except for 12% and 10% lower flows during June of wet and critical water years, respectively. The Feather River flows under H4_ELT would generally be similar to or up to 60% lower than flows under NAA_ELT during July through November, except in August through November of critical water years, when flows under NAA_ELT would range from 11% to 52% higher, and the flows would generally be similar to or up to 40% higher under NAA_ELT during December through March. Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT throughout the year, except for 14% lower flow in May of critical water years, 28% lower flow in August of critical years, 20% lower flows in September of below normal years, 18% greater flow in August of below normal years, and 15% and 21% greater flows in October of below normal and critical water years, respectively. Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT throughout the year, except for 10% higher flow during February of wet years, 17% lower flow during April of above normal water years, 16% greater flow during September of critical years, and 11% greater flow during October of above normal water years. Flows under H4_ELT in Clear Creek below Whiskeytown would generally be similar to flows under NAA_ELT throughout the year, except for 12% higher flow in March of below normal water years, and 14% lower flow and 11% higher flow during July and August, respectively, of critical water years. Flows under H4_ELT in the San Joaquin and Stanislaus Rivers would be similar to flows under NAA_ELT throughout the year.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round Sacramento-San Joaquin roach occurrence period would not exceed the 86°F water temperature threshold in H4_ELT or NAA_ELT. As a result, there would be no difference between H4_ELT and NAA_ELT in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4A-157).

Table 11-4A-157. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Sacramento-San Joaquin Roach Survival[a]

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in quantity and quality of habitat for juvenile and adult Sacramento-San Joaquin roach rearing habitat. Flows in all rivers examined during the year under Alternative 4A are generally similar to or greater than flows under the NAA_ELT in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the Sacramento-San Joaquin roach population. Flow-related habitat conditions for roach under H4_ELT would be less favorable than those under H3_ELT although not different from NAA_ELT. There are no temperature-related effects in any other rivers examined.

CEQA Conclusion: In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach occurrence period. Lower flows could reduce the quantity and quality of instream habitat for juvenile and adult Sacramento-San Joaquin roach.

In the Sacramento River upstream of Red Bluff, flows under H4_ELTwould generally be similar to or greater than flows under Existing Conditions during January through April and December, except in drier years during January (to 13% lower), in dry and critical years during February (8% and 6% lower, respectively), in critical years during March (8% lower), in above normal years in April (5% lower), and in dry and critical years during December (8% and 5% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during May through November (to 46% lower), except in critical years during May (13% greater), in below normal and dry years during June (8% and 25% greater, respectively), and in below normal and critical years during October (10% and 15% greater, respectively). There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during January through June and December, except in below normal years during January (16% lower), in below normal years during March (6% lower), and in critical years during May (6% lower), but would generally be similar to or lower than flows under Existing Conditions during July through November, except in below normal years during July (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions in critical years would have a localized effect on habitat conditions in that water year type.

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during September and in below normal years during October (19% and 6% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively isolated effect limited to a single water year type in each month and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during February through June, September, and October, except in drier years during February (to 48% lower), in below normal and dry years during March (39% and 17% lower, respectively), in below normal years during April (6% lower), in wet years during May (15% lower), in below normal and critical years during September (26% and 50% lower, respectively), and in wet and critical years during October (6% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be moderately to substantially lower than flows under Existing Conditions in January, July, August, November, and December, except in wet and above normal years during July (15% and 9% greater, respectively), in below normal and dry years during August (7% and 45% greater, respectively), in above normal years during November (5% greater), and in above normal years during December (18% greater).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions in wetter years during January, in wet and below normal years during December, and in most water year types during February through April, except in dry and critical years during February (8% and 6% lower, respectively), in critical years during March (7% lower), and in above normal years during April (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be similar to or lower than flows under Existing Conditions during May through November, except in critical years during May (13% greater), in below normal and dry years during June (8% and 25% greater, respectively), and in below normal and critical years during October (10% and 15% greater, respectively). There would be moderate flow reductions in drier water year types, when effects would be most critical for habitat conditions, for some months/water year types from May through November that would affect rearing conditions at this location. There would be persistent small to substantial flow reductions that would affect habitat conditions at this location.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April, May and September through November, would be similar to or up to 23% lower than flows under Existing Conditions during February, March, and June through August, and would be similar to or up to 11% greater than flows under Existing Conditions during December and January.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow in wet years during February and June, respectively, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach occurrence period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of habitat and increased stress and mortality for juvenile and adult Sacramento-San Joaquin roach. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of H3_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 86°F water temperature threshold for Sacramento-San Joaquin roach under Existing Conditions or H3_ELT (Table 11-4A-156). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between H3_ELT and Existing Conditions.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the year-round juvenile and adult Sacramento-San Joaquin roach occurrence period would generally be similar to or up to 18% lower than flows under Existing Conditions throughout the year, except during September, when flows would be for 27% and 49% in wet and above normal, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Differences in flows between H4_ELT and Existing Conditions in the Feather River at Thermalito Afterbay would be highly variable, with flows under H4_ELT up to 509% greater than those under Existing Conditions during April through June and September, except for 37% and 6% lower flows during June of wet and critical water years, respectively, and 49% and 47% lower flows during September of below normal and dry years, respectively. The Feather River flows under H4_ELT would generally be similar to or up to 54% lower than flows under Existing Conditions during July, August, and October through March, except in August through November of critical water years, when flows under H4_ELT would range up to 55% higher. Flows under H4_ELT in the American River at Nimbus Dam would generally be similar to or up to 38% lower than flows under Existing Conditions throughout the year, except for 15% greater flow in January of wet years, 12% to 14% greater flow in February of wet, above normal and below normal water years, and 14% greater flow in October of critical water years. Flows under H4_ELT in the Trinity River would generally be similar to flows under Existing Conditions throughout the year, but would range from 10% to 29% higher during December through March of wet years, would be 22% higher in February of above normal years, would be 16% lower in January of below normal years, and would be 10% lower in July of wet years. Flows under H4_ELT in Clear Creek would generally be similar to flows under Existing Conditions throughout the year, but would be 40% and 13% greater in January and February, respectively, of wet years, would be 10% higher in December through April of critical water years, 11% higher in October of critical years, 13% higher in March of below normal years. Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during January, April, May and September through November, would be similar to or up to 23% lower than flows under Existing Conditions during February, March, and June through August, and would be similar to or 12% higher (wet years) in December. Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow during February and June, respectively, of wet years, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round juvenile and adult Sacramento-San Joaquin roach occurrence period would not exceed the 86°F water temperature threshold in H4_ELT or Existing Conditions. As a result, there would be no difference between H4_ELT and Existing Conditions in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4A-157).

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 4A during the year-round juvenile and adult Sacramento-San Joaquin roach occurrence period relative to Existing Conditions. Flows would be persistently and moderately to substantially lower in several rivers during substantial portions of the rearing period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable rearing habitat as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 4A. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Hardhead

In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead occurrence period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult hardhead.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT throughout the year with some exceptions (up to 14% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT during the period, except in above normal years in April and October (17% and 8% lower, respectively), and in wet years during November (10% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to flows under NAA_ELT throughout the year except in critical years during July (14% lower), August (11% greater), September (10% lower), and October (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3_ELT would generally be lower than flows under NAA_ELT during January and July through September, except in critical years during August and September (23% and 25% greater, respectively); would generally be similar to or greater than flows under NAA_ELT during February through June, except for below normal years during February and March (11% and 13% lower, respectively) and in critical years during May and June (10% and 8% lower, respectively); and would generally be similar to or greater than flows under NAA_ELT during November and December, except in wet years during December (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would be more persistently lower under H3_ELT relative to NAA_ELT (up to 48% lower) during July, August, and in all water year types except critical years during September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under H3_ELT would be similar to or greater than flows under NAA_ELT during January through July and December, except in below normal years during January (to 11% lower), and would be similar to or lower than flows under NAA_ELT (up to 22% lower) during August through November, except in below normal and critical years during October (16% and 22% greater, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under H3_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under H3_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

Water Temperature

The percentage of months outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality for juvenile and adult hardhead. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of H3_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside the range would be similar to or lower than the percentage under NAA_ELT in all water year except below normal years (6% greater) (Table 11-4A-158).

Table 11-4A-158. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 65°F to 82.4°F Water Temperature Range for Juvenile and Adult Hardhead Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0 (0%)	1 (1%)
Above Normal	-3 (-4%)	-3 (-4%)
Below Normal	0 (0%)	4 (6%)
Dry	-1 (-1%)	0 (0%)
Critical	-4 (-6%)	-2 (-3%)
All	0 (0%)	1 (1%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the year-round juvenile and adult hardhead occurrence period would generally be similar to flows under NAA_ELT, except for 10% lower flow during September of below normal water years and except during November of all water year types, when flows would be up to 15% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT in the Feather River at Thermalito Afterbay would generally be up to 548% greater than flows under NAA_ELT during April through June, except for 12% and 10% lower flows during June of wet and critical water years, respectively. The Feather River flows under H4_ELT would generally be similar to or up to 60% lower than flows under NAA_ELT during July through November, except in August through November of critical water years, when flows under NAA_ELT would range from 11% to 52% higher, and the flows would generally be similar to or up to 40% higher under NAA_ELT during December through March. Flows under H4_ELT in the American River below Nimbus Dam would generally be similar to flows under NAA_ELT throughout the year, except for 14% lower flow in May of critical water years, 28% lower flow in August of critical years, 20% lower flows in September of below normal years, 18% greater flow in August of below normal years, and 15% and 21% greater flows in October of below normal and critical water years, respectively. Flows under H4_ELT in the Trinity River below Lewiston would generally be similar to flows under NAA_ELT throughout the year, except for 10% higher flow during February of wet years, 17% lower flow during April of above normal water years, 16% greater flow during September of critical years, and 11% greater flow during October of above normal water years. Flows under H4_ELT in Clear Creek below Whiskeytown would generally be similar to flows under NAA_ELT throughout the year, except for 12% higher flow in March of below normal water years, and 14% lower flow and 11% higher flow during July and August, respectively, of critical water years. Flows under H4_ELT in the San Joaquin and Stanislaus Rivers would be similar to flows under NAA_ELT throughout the year.

The percentage of months under H4_ELT outside the 65°F to 82.4°F water temperature range in the Feather River below Thermalito Afterbay during the year-round juvenile and adult hardhead occurrence period would be similar to or lower than the percentage under Existing Conditions in all water year types (Table 11-4A-159).

Table 11-4A-159. Difference and Percent Difference between the Baseline Scenarios and H4_ELT in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 65°F to 82.4°F Water Temperature Range for Juvenile and Adult Hardhead Occurrence[a]

Water Year Type	EXISTING CONDITIONS	NAA_ELT vs. H4_ELT
Wet	-2 (-3%)	-1 (-1%)
Above Normal	0 (0%)	0 (0%)
Below Normal	-4 (-6%)	0 (0%)
Dry	-1 (-1%)	0 (0%)
Critical	-4 (-6%)	-2 (-3%)
All	-2 (-3%)	-1 (-1%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 4A would not cause a substantial reduction in the quantity or quality of habitat for juvenile and adult hardhead. Flows in all rivers examined during the year under Alternative 4A are generally similar to or greater than flows under the NAA_ELT in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on hardhead. Flow-related habitat conditions for hardhead under H4_ELT would be less favorable than those under H3_ELT although not different from NAA_ELT. There are no temperature-related effects in any other rivers examined.

CEQA Conclusion: In general, Alternative 4A would not affect the quality and quantity of upstream habitat conditions for juvenile and adult hardhead relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead occurrence period. Lower flows could reduce the quantity and quality of instream habitat for juvenile and adult hardhead.

In the Sacramento River upstream of Red Bluff, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during January through April and December, except in drier years during January (to 13% lower), in dry and critical years during February (8% and 6% lower, respectively), in critical years during March (8% lower), in above normal years in April (5% lower), and in dry and critical years during December (8% and 5% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during May through November (to 46% lower), except in critical years during May (13% greater), in below normal and dry years during June (8% and 25% greater, respectively), and in below normal and critical years during October (10% and 15% greater, respectively)*.* There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions during January through June and December, except in below normal years during January (16% lower), in below normal years during March (6% lower), and in critical years during May (6% lower), but would generally be similar to or lower than flows under Existing Conditions during July through November, except in below normal years during July (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* The persistent, small to moderate flow reductions in critical years would have a localized effect on rearing conditions in that water year type. In Clear Creek at Whiskeytown Dam, flows under H3_ELT would be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during September and in below normal years during October (19% and 6% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* This flow reduction is a relatively isolated effect limited to a single water year type in each month and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3_ELT would be greater than flows under Existing Conditions during February through June, September, and October, except in drier years during February (to 48%), in below normal and dry years during March (39% and 17% lower, respectively), in below normal years during April (6% lower), in wet years during May (155 lower), in below normal and critical years during September (26% and 50% lower, respectively), and in wet and critical years during October (6% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* Flows under H3_ELT would generally be moderately to substantially lower than flows under Existing Conditions in January, July, August, November, and December, except in wet and above normal years during July (15% and 9% greater, respectively), in below normal and dry years during August (7% and 45% greater, respectively), in above normal years during November (5% greater), and in above normal years during December (18% greater).

In the American River at Nimbus Dam, flows under H3_ELT would generally be similar to or greater than flows under Existing Conditions in wetter years during January, in wet and below normal years during December, and in most water year types during February through April, except in dry and critical years during February (8% and 6% lower, respectively), in critical years during March (7% lower), and in above normal years during April (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* Flows under H3_ELT would generally be similar to or lower than flows under Existing Conditions during May through November, except in critical years during May (13% greater), in below normal and dry years during June (8% and 25% greater, respectively), and in below normal and critical years during October (10% and 15% greater, respectively). The persistent, small to moderate flow reductions in critical years would have a localized effect on habitat conditions in that water year type.

In the San Joaquin River at Vernalis, flows under H3_ELT would generally be similar to or slightly lower than those under Existing Conditions during April, May and September through November, would be similar to or up to 23% lower than flows under Existing Conditions during February, March, and June through August, and would be similar to or up to 11% greater than flows under Existing Conditions during December and January.

In the Stanislaus River at the confluence with the San Joaquin River, flows under H3_ELT would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow in wet years during February and June, respectively, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water Temperature

The percentage of months in which year-round in-stream temperatures would be outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality for juvenile and adult hardhead. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under H3_ELT would generally be the same as those under Existing Conditions. Therefore, there would be no temperature related effects of H3_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, the percentage of months under H3_ELT outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead would be similar to or lower than the percentage under Existing Conditions in all water years (Table 11-4A-158).

H4_ELT/HOS_ELT

Flows under H4_ELT in the Sacramento River upstream of Red Bluff during the year-round juvenile and adult hardhead occurrence period would generally be similar to or up to 18% lower than flows under Existing Conditions throughout the year, except during September, when flows would be for 27% and 49% in wet and above normal, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Differences in flows between H4_ELT and Existing Conditions in the Feather River at Thermalito Afterbay would be highly variable, with flows under H4_ELT up to 509% greater than those under Existing Conditions during April through June and September, except for 37% and 6% lower flows during June of wet and critical water years, respectively, and 49% and 47% lower flows during September of below normal and dry years, respectively. The Feather River flows under H4_ELT would generally be similar to or up to 54% lower than flows under Existing Conditions during July, August, and October through March, except in August through November of critical water years, when flows under H4_ELT would range up to 55% higher. Flows under H4_ELT in the American River at Nimbus Dam would generally be similar to or up to 38% lower than flows under Existing Conditions throughout the year, except for 15% greater flow in January of wet years, 12% to 14% greater flow in February of wet, above normal and below normal water years, and 14% greater flow in October of critical water years. Flows under H4_ELT in the Trinity River would generally be similar to flows under Existing Conditions throughout the year, but would range from 10% to 29% higher during December through March of wet years, would be 22% higher in February of above normal years, would be 16% lower in January of below normal years, and would be 10% lower in July of wet years. Flows under H4_ELT in Clear Creek would generally be similar to flows under Existing Conditions throughout the year, but would be 40% and 13% greater in January and February, respectively, of wet years, would be 10% higher in December through April of critical water years, 11% higher in October of critical years, 13% higher in March of below normal years. Flows under H4_ELT in the San Joaquin River at Vernalis would generally be similar to or slightly lower than those under Existing Conditions during January, April, May and September through

November, would be similar to or up to 23% lower than flows under Existing Conditions during February, March, and June through August, and would be similar to or 12% higher (wet years) in December. Flows under H4_ELT in the Stanislaus River at the confluence with the San Joaquin River would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow during February and June, respectively, of wet years, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

The percentage of months under H4_ELT outside the 65°F to 82.4°F water temperature range in the Feather River below Thermalito Afterbay during the year-round juvenile and adult hardhead occurrence period would be similar to or less than the percentage under Existing Conditions in all water year types (Table 11-4A-159).

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 4A during the juvenile and adult hardhead occurrence period relative to Existing Conditions. Flows would be persistently and moderately to substantially lower in several rivers during substantial portions of the rearing period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce habitat for juvenile and adult hardhead as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 4A. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

California Bay Shrimp

NEPA Effects: As discussed further in Chapter 11, Section 11.3.5, in Appendix A, water operations have the potential to affect California bay shrimp juvenile abundance through because of an increase in residual circulation in the estuary with increasing outflow (as indexed by X2) that could translate to more rapid or more complete entrainment into the estuary, or more rapid transport to rearing grounds, both of which presumably could increase survival from hatching to settlement (Kimmerer et al. 2009). An X2-abundance index relationship from Kimmerer et al. (2009) was applied to bay shrimp in order to assess the potential effects on abundance through changes in rearing habitat. Application of these relationships suggested that, in relation to NAA_ELT, there would be only a small change in mean abundance index (<5%) as a result of change in rearing habitat under Alternative 4A scenarios H3_ELT and H4_ELT(See Table 11-mult-13 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). These modeling results indicate that the operational effects would not be adverse, because they would not result in a substantial reduction in the rearing habitat for California bay shrimp.

CEQA Conclusion: Similar to striped bass and American shad, the analysis of potential water operations-related rearing habitat effects illustrated that in relation to Existing Conditions, there could be a greater impact of Alternative 4A on abundance of California bay shrimp (Table 11-mult-13 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS), than found in the NEPA Effects section. As noted for striped bass and American shad, the comparison to the NAA_ELT is a better approach than comparison to Existing Conditions because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands. In the case of the X2-related analyses of rearing habitat for California bay shrimp and as noted for striped bass and American shad, the effect of sea level rise in particular confounds the interpretation of the effects of the alternatives. Based on the discussion presented above for the NEPA Effects, the change in rearing habitat would be less than significant. No mitigation would necessary.

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

See Alternative 1A, Impact AQUA-204 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

NEPA Effects: Under Alternative 4A Scenario H3_ELT, average spring (March–May) monthly flows in the Sacramento River downstream of the north Delta intake would be reduced 18–22% during the adult striped bass migration compared to baseline (NAA_ELT). The reduction would be less (4–18%) for the H4_ELT scenario. Sacramento River flows are highly variable inter-annually, but striped bass are still able to migrate upstream the Sacramento River during years of lower flows. The effect of reduced Sacramento flows under Alternative 4A would not be adverse.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because the changes in spring flow under Scenarios H3_ELT (21–23% lower compared to Existing Conditions) and H4_ELT (10–18% lower compared to Existing Conditions) would not interfere substantially with movement of pre-spawning striped bass through the Delta. No mitigation would be required.

American Shad

NEPA Effects: Flows in the Sacramento River below the north Delta diversion facilities under Scenarios H3_ELT and H4_ELT would be reduced 18–22% and 4–18%, respectively, relative to the NEPA point of comparison (NAA_ELT) during March–May, as described above for striped bass. River flows are highly variable inter-annually, and American shad are still able to migrate upstream the Sacramento River during lower flow years. Overall, the impact to American shad migration habitat conditions would not be adverse under Alternative 4A.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because, as described above for striped bass, the changes in flow under Scenario H3_ELT (21–23% lower compared to Existing Conditions) and H4_ELT (10–18% lower compared to Existing Conditions) would not interfere substantially with movement of American shad from the Delta to upstream spawning habitat. No mitigation would be required.

Threadfin Shad

NEPA Effects: Threadfin shad are semi-anadromous, moving between freshwater and brackish water habitats. Threadfin shad found in the Delta do not actively migrate upstream to spawn. Therefore there is no effect on migration habitat conditions.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because flow changes in the Delta under Alternative 4 would not alter movement patterns for threadfin shad. No mitigation would be required.

Largemouth Bass

NEPA Effects: Largemouth bass are non-migratory fish within the Delta. Therefore they do not use the Delta as a migration habitat corridor. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes under Alternative 4 would not affect largemouth movements within the Delta. Therefore, the impact is less than significant. No mitigation would be required.

Sacramento Tule Perch

NEPA Effects: Similar with largemouth bass, Sacramento tule perch are a non-migratory species and do not use the Delta as a migration corridor as they are a resident Delta species. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes would not affect Sacramento tule perch movements within the Delta. Therefore, the impact is less than significant. No mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: For Sacramento-San Joaquin roach, the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 4, Impact AQUA-202 for spawning. As described there, the flows would slightly improve the upstream conditions relative to the NAA_ELT. These conditions would not be adverse.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-202, the impacts of water operations on migration conditions for Sacramento-San Joaquin roach would be less than significant and no mitigation would be required.

Hardhead

NEPA Effects: For hardhead the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 4, Impact AQUA-202 for spawning due to similar flows and temperatures. As described there, the flows would slightly improve the upstream conditions relative to the NAA_ELT. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for hardhead would be less than significant and no mitigation would be required.

California Bay Shrimp

NEPA Effects: The effect of water operations on migration conditions of California bay shrimp under Alternative 4A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-204) due to similar flows and temperatures. For a detailed discussion, please see Alternative 1A, Impact AQUA-204. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on California bay shrimp migration conditions would be less than significant and no mitigation would be required.

Restoration Measures (Environmental Commitment Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

As noted previously, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A, upon which the discussion of impacts for Alternative 4 is based. In particular, *Environmental Commitment 4 Tidal Natural Communities Restoration* is reduced from 65,000 acres to 59 acres, so that any impacts would be extremely small. The effects of restoration measures under Alternative 4A would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-7 under delta smelt for a discussion of the effects of construction of restoration measures on non-covered species of primary management concern because effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and implementing the commitments described in detail under Impact AQUA-1 and in Appendix 3B, *Environmental Commitments*. The potential effects of the construction of restoration measures under Alternative 4A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-7). For a detailed discussion, please see Alternative 1A, Impact AQUA-7. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of the construction of restoration measures would be less than significant and no mitigation would be required.

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-8 under delta smelt for a discussion of the effects of contaminants associated with restoration measures on non-covered species of primary management concern. The potential effects of contaminants associated with restoration measures under Alternative 4A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-8), although would be greatly reduced in extent. For a detailed discussion, please see Alternative 1A, Impact AQUA-8. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of the contaminants associated with restoration measures would be less than significant and no mitigation would be required.

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-9 under delta smelt for a general discussion of the effects of restored habitat conditions on non-covered species of primary management concern. Although there are minor differences, the effects are similar because restoration would provide new habitat areas for those species that occur in the areas that are restored. The effect of restoration activities under Alternative 4A relative to NAA_ELT would not be adverse.

CEQA Conclusion: The impacts of restored habitat conditions would range from slightly beneficial to beneficial, depending on where the restoration occurs and how it is designed. No mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

The effects of other Environmental Commitments under Alternative 4A would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (Environmental Commitment 12)

NEPA Effects: Refer to Impact AQUA-10 under delta smelt for a discussion of the effects of methylmercury management on non-covered species of primary management concern. The potential effects of methylmercury management under Alternative 4A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-10). For a detailed discussion, please see Alternative 1A, Impact AQUA-10. The effects would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As described immediately above, the impacts of methylmercury management would be less than significant and no mitigation would be required.

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (Environmental Commitment 15)

NEPA Effects: Refer to Alternative 1A, Impact AQUA-13 under delta smelt for a discussion of the effects of predatory fish (striped bass and largemouth bass) and predator management on non-predatory fish. The purpose of predatory fish management is to reduce predation pressure at predation hotspots and not to reduce the overall populations of these species. This management will have localized negative effects on predatory fish; under Alternative 4A, the efforts will be focused solely at the south Delta export facilities and the proposed north Delta intakes. Given that the numbers of predatory fish are high and the extent of the habitats in which they occur is extensive, the effects of Environmental Commitment 15 will not be adverse.

CEQA Conclusion: Refer to Alternative 1A, Impact AQUA-13 under delta smelt for a discussion of the effects of predatory fish and predator management on non-predatory fish. The purpose of predatory fish management is to reduce predation pressure at predation hotspots and not to reduce the overall populations of these species. This management will have localized negative effects on predatory fish; under Alternative 4A, the efforts will be focused solely at the south Delta export facilities and the proposed north Delta intakes. Given that the numbers of predatory fish are high and the extent of the habitats in which they occur is extensive, the effects of Environmental Commitment 15 will be less than significant. No mitigation is necessary.

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (Environmental Commitment 16)

NEPA Effects: As described for Alternative 1A, nonphysical barriers (NPBs) are designed to alter juvenile salmon migration routes using sound, light, and bubbles and are not intended for other species. Alternative 4A proposes only one location for a NPB, at the divergence of Georgiana Slough from the Sacramento River. The in-water structures associated with this barriers may attract fish predators (including the non-covered aquatic species striped bass and largemouth bass), increasing localized predation risk for smaller individuals of the noncovered aquatic species migrating past the barriers, but the extent of this effect is highly uncertain. The general potential effects of nonphysical fish barriers under Alternative 4A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-14). For a detailed discussion, please see Alternative 1A, Impact AQUA-14. Whereas striped bass, American shad, threadfin shad, and largemouth bass could encounter the proposed barrier, Sacramento-San Joaquin roach and hardhead are unlikely to be present in the vicinity of the nonphysical barrier, and California bay shrimp do not occur in these habitats so there would be no effect. The effects on non-covered aquatic species of primary management concern would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of a nonphysical fish barrier would be less than significant and no mitigation would be required.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: As discussed in Alternative 1A, Impact AQUA-217 and reported in Table 11-1A-102, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 4A would not be substantially reduced when compared to the No Action Alternative. Carryover storage thresholds for all CVP and SWP reservoirs would be similar between the No Action Alternative and Alternative 4A.

CEQA Conclusion: As discussed in Alternative 1A, Impact AQUA-217 and reported in Table 11-1A-102, Alternative 4A would reduce the quantity of coldwater fish habitat in the CVP and SWP relative to Existing Conditions. There would be There would be 5 and 7 fewer years (7% and 9% lower, respectively) that exceed the 250 TAF carryover storage threshold in Folsom Reservoir under H3_ELT and H4_ELT, respectively, relative to Existing Conditions, which could result in a significant impact.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of results between the alternative and NAA is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA and informed by the NEPA analysis above, there would be negligible effects on mean monthly reservoir storage. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in reservoir storage under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

4.3.8 Terrestrial Biological Resources

Section 4.1, *Description of Alternatives*, of the RDEIR/SDEIS provides details of Alternative 4A, and Figure 3-9 depicts the alternative.

Study Area

The study area for conducting the terrestrial biology analysis of Alternative 4A consists of all of the BDCP Plan Area and the areas of additional analysis identified for BDCP Alternative 4 (see Figure 12-1 in the Draft EIR/EIS).

Methods

The methods used to conduct the terrestrial biology analyses for Alternative 4A are generally the same as those used to analyze all BDCP alternatives (see Section 12.2.3.4 of the Draft EIR/EIS) except it is compared to the No Action Alternative at the early long-term. Also, the methods used for the analysis of effects on wetlands and waters of the United States (contained in Section 4.3.8.4, *General Terrestrial Biology*, of the RDEIR/SDEIS) for alternative 4A are different than the methods used for the BDCP alternatives. Modifications to this methodology are presented in a revised version of Section 12.3.2.4, *Methods Used to Assess Wetlands and Other Waters of the United States,* in Appendix D of this RDEIR/SDEIS.

Significance Criteria

The significance criteria used to determine the severity of potential Alternative 4A effects are the same as those used to analyze all BDCP alternatives. They are included in Section 12.3.1.2, *Significance Criteria for Terrestrial Biological Resources*, of the Draft EIR/EIS.

Organization

The impact analysis below includes separate sections for effects on natural communities, special-status wildlife species, special-status plant species and a number of other biological resources issues (wetlands and waters of the United States, waterfowl and shorebirds, wildlife corridors).

Natural Communities

Tidal Perennial Aquatic

Construction, operation, maintenance, and management associated with the implementation of Alternative 4A would have no long-term adverse effects on the habitats associated with the tidal perennial aquatic natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal or modification of this community (see Table 12-4A-1). A small amount of this community could also be lost to channel margin habitat enhancement (Environmental Commitment 6).

Table 12-4A-1. Changes in Tidal Perennial Aquatic Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	207	2,098[b]
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	207	2,098

[a] See discussion below for a description of applicable environmental commitments.
[b] The large acreage of tidal perennial aquatic habitat affected by Alternative 4A is related primarily to dredging of Clifton Court Forebay; the habitat would not be permanently removed, it would be expanded.

Impact BIO-1: Changes in Tidal Perennial Aquatic Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities for Alternative 4A would permanently affect an estimated 207 acres and temporarily remove 2,098 acres of tidal perennial aquatic natural community in the study area. The large temporary loss of this natural community would be primarily related to dredging of Clifton Court Forebay. These modifications represent less than 3% of the 86,263 acres of the community that is mapped in the study area. The permanent and temporary effects would occur during the construction period for Alternative 4A as water conveyance facilities are developed. An undetermined amount of this natural community could also be affected by channel margin habitat enhancement along the major Delta waterways. The 450-acre expansion of Clifton Court Forebay during the water conveyance facility construction would offset the permanent losses.

The effects of water conveyance facilities and Environmental Commitment 6 are addressed below. A summary statement of impacts and NEPA and CEQA conclusions follows the individual environmental commitment discussion.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would permanently remove 207 acres and temporarily remove 2,098 acres of tidal perennial aquatic community. Most of the permanent loss would occur where new facilities are constructed at Clifton Court Forebay and where Intakes 2, 3, and 5 encroach on the Sacramento River's east bank between Clarksburg and Courtland (see the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of proposed facilities overlain on natural community mapping). The footings and the screens at the intake sites would be placed into the river margin and would displace moderately deep to shallow, flowing open water with a mud substrate and very little aquatic vegetation. Permanent losses would also occur where new control structures would be built into the California Aqueduct and the Delta Mendota Canal adjacent to Clifton Court Forebay, where Clifton Court Forebay levees are modified, and where permanent new transmission lines would be constructed along Lambert Road just west of Interstate 5.
- The temporary effects on tidal perennial aquatic habitats would occur at numerous locations, with the largest effect occurring at Clifton Court Forebay, where the entire forebay would be dredged to provide additional storage capacity. Other temporary effects would occur in the

Sacramento River at Intakes 2, 3, and 5, and at temporary barge unloading facilities established at four locations along the tunnel route. The barge unloading construction would temporarily affect Potato Slough at the south end of Boldin Island, Venice Reach of the San Joaquin River at the south end of Venice Island, Connection Slough at the north end of Bacon Island, and Old River just south of its junction with North Victoria Canal. The details of these locations can be seen in the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS. These losses would take place during the 14-year construction time period.

- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of tidal perennial aquatic habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would be implemented on tidal perennial aquatic habitat margins, including levees and channel banks. The improvements could be implemented on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the effects discussed above and describe other project actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the first 14 years of Alternative 4A implementation, the project would affect the tidal perennial aquatic community through water conveyance facilities construction losses (207 acres permanent and 2,098 acres temporary). These losses would occur primarily at Clifton Court Forebay due to dredging, and along the Sacramento River at intake sites.

NEPA Conclusion: The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with Alternative 4A environmental commitments. Loss of tidal perennial aquatic natural community would be considered both a loss in acreage of a sensitive natural community and a loss of waters of the United States as defined by Section 404 of the CWA. The largest loss would occur at Clifton Court Forebay, and would be temporary. This tidal perennial habitat is of relatively low value to special-status terrestrial species in the study area. The permanent expansion of the Clifton Court Forebay aquatic habitat (approximately 450 acres) during the first 14 years of Alternative 4A implementation would offset the permanent loss; the restoration of Clifton Court Forebay aquatic habitat following construction-related dredging would offset the temporary project effects. These actions would avoid any adverse effect. Typical project-level mitigation ratios (1:1 for restoration) would indicate 2,305 acres of restoration would be needed to offset (i.e., mitigate) the 2,305 acres of effect (the total permanent and temporary near-term effects listed in Table 12-4A-1) associated with water conveyance facilities construction.

The alternative also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS. Therefore, changes in tidal perennial aquatic natural community as a result of implementing Alternative 4A would not be adverse.

CEQA Conclusion**:** Alternative 4A would result in the near-term loss or conversion of approximately 2,305 acres of tidal perennial aquatic natural community due to construction of the water conveyance facilities. The construction losses would occur primarily at Clifton Court Forebay, along the Sacramento River at intake sites, and along various Delta waterways at barge offloading sites. The losses and conversions would be spread across the 14-year water conveyance facilities construction period. These losses and conversions would be offset by planned restoration and expansion of Clifton Court Forebay (a combined acreage of approximately 2,595) following project-related dredging scheduled for the first 14 years of Alternative 4A implementation. AMM1, AMM2, AMM6, AMM7, and AMM10 would also be implemented to minimize impacts. Because of these offsetting near-term restoration activities and AMMs, there would be no permanent loss of this sensitive natural community and impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 2,305 acres of restoration would be needed to offset (i.e., mitigate) the 2,305 acres of loss or conversion. The restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species. Therefore, impacts associated with changes in tidal perennial aquatic natural community as a result of implementing Alternative 4A would be less than significant. No mitigation is required.

Impact BIO-2: Increased Frequency, Magnitude and Duration of Periodic Inundation of Tidal Perennial Aquatic Natural Community

Alternative 4A would not result in periodic effects on the tidal perennial aquatic natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-3: Modification of Tidal Perennial Aquatic Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the water conveyance facilities and conservation lands that could affect tidal perennial aquatic natural community in the study area. The ongoing actions include diverting Sacramento River flows in the north Delta, and reduced diversion from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities, levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with project mitigation requirements. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversion from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of a sensitive natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of tidal perennial aquatic community would be reduced on a permanent basis. Some increases and some decreases would be expected to occur during some seasons and in some water-year types, but there would be no permanent loss. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in tidal perennial aquatic community downstream of these diversions. Tidal influence on water levels in the Sacramento River and Delta waterways would continue to be dominant. Reduced diversions from the south Delta channels would not create a reduction in this natural community.

The periodic changes in flows in the Sacramento River, Feather River, and American River associated with Alternative 4A operations would affect salinity, water temperature, dissolved oxygen levels, turbidity, contaminant levels, and dilution capacity in these rivers and Delta waterways. These changes are discussed in detail in Section 4.3.4, *Water Quality*, of the RDEIR/SDEIS. Potentially substantial increases in electrical conductivity (salinity) are predicted for the Delta and Suisun Marsh as a result of increased export of Sacramento River water. These salinity changes are not expected to result in a permanent reduction in the acreage or value of tidal perennial aquatic natural community for terrestrial species in the study area.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in tidal perennial aquatic habitats. This activity could lead to increased soil erosion, turbidity and runoff entering tidal perennial aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and conservation sites. Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal perennial aquatic natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to tidal perennial aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with conservation activities.

- *Channel dredging.* Long-term operation of the Alternative 4A intakes on the Sacramento River and at Clifton Court Forebay would include periodic dredging of sediments that might accumulate in front of intake screens. The dredging would occur in tidal perennial aquatic natural community and would result in short-term increases in turbidity and disturbance of the substrate. These conditions would not eliminate the community, but would diminish its value for special-status and common species that rely on it for movement corridor or foraging area. The individual species effects are discussed in Section 4.3.8.2, *Wildlife Species*, of this RDEIR/SDEIS.

- *Habitat enhancement.* Alternative 4A includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For tidal perennial aquatic natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of tidal perennial aquatic natural community in the study area through changes in flow patterns and changes in water quality. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the alternative, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small reductions in acreage, these reductions would be greatly offset by restoration activities planned as part of *Environmental Commitment 4 Tidal Natural Communities Restoration*, and the restoration and expansion of this community at Clifton Court Forebay. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with tidal perennial aquatic habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be no adverse effect on the tidal perennial aquatic natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor losses in total acreage of tidal perennial aquatic natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Long-term restoration activities associated with *Environmental Commitment 4 Tidal Natural Communities Restoration* and enlargement of Clifton Court Forebay would greatly expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in the acreage or value of this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the tidal perennial aquatic natural community.

Tidal Brackish Emergent Wetland

Construction associated with Alternative 4A water conveyance facilities and the alternative's environmental commitments would not affect the tidal brackish emergent wetland natural community. Operation, maintenance, and management activities associated with the alternative could result in minor changes in total acreage of tidal brackish emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation.

As explained below, with the restoration and enhancement of tidal marsh as part of Alternative 4A, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Impact BIO-4: Changes in Tidal Brackish Emergent Wetland Natural Community as a Result of Implementing Alternative 4A

No tidal brackish emergent wetland would be lost or converted under Alternative 4A.

***NEPA Effects*:** No effect.

CEQA Conclusion: No impact.

Impact BIO-5: Modification of Tidal Brackish Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with water conveyance facilities and Environmental Commitment 4 of Alternative 4A are constructed and the water management practices associated with changed reservoir operations, diversions from the north Delta, and marsh restoration are in effect, there would be new ongoing and periodic actions that could affect tidal brackish emergent wetland natural community in the study area. The ongoing actions include water releases and diversions, access road and levee repair, and replacement of levee armoring, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversion from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of tidal brackish emergent wetland natural community in the study area. Flow levels in the upstream rivers would not directly affect this natural community because it does not exist upstream of the Delta. Increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in tidal brackish emergent wetland downstream of these diversions. Salinity levels in Suisun Marsh channels would be expected to increase with reduced Sacramento River outflows (see Section 4.3.4, *Water Quality*, of the RDEIR/SDEIS), but this change would not be sufficient to change the acreage of brackish marsh. This natural community persists in an environment that experiences natural fluctuations in salinity due to tidal ebb and flow. Reduced diversions from the south Delta channels would not create a reduction in this natural community.
- The increased diversion of Sacramento River flows in the north Delta would result in reductions in sediment load (annual mass) flowing into the central and west Delta, and Suisun Marsh. The reduction is estimated to be approximately 9% of the river's current sediment load for

Alternative 4A, which would have a north Delta diversion capacity of 9,000 cfs under Operational Scenario H (see Appendix 5.C, Attachment 5C.D, Section 5C.D.3.3, *Summary of Changes to Sediment Supply in the Plan Area Due to BDCP Shift in Export Location and Volume*, in the Draft BDCP for a detailed analysis of this issue). This would contribute to a decline in sediment reaching the Delta and Suisun Marsh that has been occurring over the past 50-plus years due to a gradual depletion of sediment from the upstream rivers. The depletion has been caused by a variety of factors, including depletion of hydraulic mining sediment in upstream areas, armoring of river channels and a cutoff of sediment due to dam construction on the Sacramento River and its major tributaries (Wright and Schoellhamer 2004; Barnard et al. 2013).

- Reduced sediment load flowing into the Delta and Suisun Marsh could have an adverse effect on tidal marsh, including tidal brackish emergent wetland. Sediment trapped by the marsh vegetation allows the emergent plants to maintain an appropriate water depth as water levels gradually rise from the effects of global warming (see Chapter 29, *Climate Change*, of the Draft EIR/EIS). The project proponents have incorporated an environmental commitment (see Appendix 3B, Section 3B.1.19, *Disposal and Reuse of Spoil, Reusable Tunnel Material and Dredged Material*, of the Draft EIR/EIS) into the project that would lessen this potential effect. The Sacramento River water diverted at north Delta intakes would pass through sedimentation basins before being discharged to water conveyance structures. The commitment states that sediment collected in these basins would be periodically removed and reused, to the greatest extent feasible, in the study area for a number of purposes, including marsh restoration, levee maintenance, subsidence reversal, flood response, and borrow area fill. The portion of the sediment re-introduced to the Delta and estuary for marsh restoration would remain available for marsh accretion. With this commitment to reuse in the study area, the removal of sediment at the north Delta intakes would not result in a net reduction in the acreage and value of this special-status marsh community. The effect would not be adverse (NEPA) and would be less than significant (CEQA).

- *Access road and levee repair.* Periodic repair of access roads and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in tidal brackish emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering these habitats. The activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan*. Any vegetation removal or earthwork adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment (Environmental Commitment 11), would be a periodic activity associated with the long-term maintenance of restoration sites. Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal brackish emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of Alternative 4A to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to levees associated with tidal wetland restoration activities.

- *Habitat enhancement.* Alternative 4A includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For tidal brackish emergent wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for special-status species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage and value of tidal brackish emergent wetland natural community in the study area through water operations, levee and road maintenance, and vegetation management in or adjacent to this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the alternative, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *Environmental Commitment 4 Tidal Natural Communities Restoration*. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with tidal brackish emergent wetland habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in the tidal brackish emergent wetland natural community within the study area. There would be no adverse effect on the tidal brackish emergent wetland natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of tidal brackish emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Restoration activities associated with *Environmental Commitment 4 Tidal Natural Communities Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact.

Tidal Freshwater Emergent Wetland

Construction, operation, maintenance and management associated with the environmental commitments of Alternative 4A would have no long-term adverse effects on the habitats associated with the tidal freshwater emergent wetland natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of small acreages of this community (see Table 12-4A-2). Small areas of this community could also be lost to the development of channel margin habitat associated with Environmental Commitment 6.

As explained below, with the restoration and enhancement of tidal habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-2. Changes in Tidal Freshwater Emergent Wetland Natural Community Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Water Conveyance Facilities	3	15
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	3	15

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-6: Changes in Tidal Freshwater Emergent Wetland Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities for Alternative 4A would permanently eliminate an estimated 3 acres and temporarily remove 15 acres of tidal freshwater emergent wetland natural community in the study area. These modifications represent less than 1% of the 8,856 acres of the community that is mapped in the study area. The majority of the permanent and temporary losses would happen during the first 14 years of Alternative 4A implementation, as water conveyance facilities are constructed. Smaller areas of this natural community could be affected by levee breaching, grading, and contouring associated with Environmental Commitment 4 and Environmental Commitment 6 restoration activities. Natural communities restoration would add at least 59 acres of tidal wetland during the course of project restoration activities, which would expand the area of that habitat and offset the losses.

The individual effects of water conveyance facilities, Environmental Commitment 4, and Environmental Commitment 6 are addressed below. A summary statement of the impacts and NEPA and CEQA conclusions follows the environmental commitment discussion.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would permanently remove 3 acres and temporarily remove 15 acres of tidal freshwater emergent wetland community. Most of the loss would occur along rivers and canals in the central Delta from barge unloading facility construction (Old River on the east side of Victoria Island and Connection Slough at the north end of Bacon Island), and from transmission line construction (San Joaquin River and Potato Slough at the south and north ends of Venice Island, Connection Slough at the north end of Bacon Island, and Railroad Slough at the north end of Woodward Island; see Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS). These losses would take place during the water conveyance facilities construction period.

- There is the potential for increased nitrogen deposition associated with construction vehicles during the construction phase of water conveyance facilities. Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities,* of the Draft BDCP addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing tidal freshwater emergent wetland natural community because the construction would occur primarily downwind of the natural community and the construction would contribute a negligible amount of nitrogen to regional projected emissions. No adverse effect is expected.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: The restoration activities associated with Environmental Commitment 4 would result in other effects that could alter the habitat value of tidal freshwater emergent wetland. Disturbances associated with levee breaching and grading or contouring would increase opportunities for the introduction or spread of invasive species. Implementation of Environmental Commitment 11 would limit this risk through invasive species control and wetland management and enhancement activities to support native species. Flooding of dry areas for tidal marsh creation could also increase the bioavailability of methylmercury, especially in the Cache Slough and Cosumnes/Mokelumne ROAs. Site-specific conditions would dictate the significance of this hazard to marsh vegetation and associated wildlife. A detailed review of the methylmercury issues associated with implementation of Alternative 4A is contained in Appendix D, *Substantive BDCP Revisions*. Site-specific restoration plans that address the creation and mobilization of mercury, and monitoring and adaptive management as described in *Environmental Commitment 12 Methylmercury Management*, would be available to address the uncertainty of methylmercury levels in restored tidal marsh. Water temperature fluctuations in newly created marsh is also an issue of concern that is difficult to quantify at the current stage of restoration design. None of these effects is expected to limit the extent or value of tidal freshwater emergent wetland in the study area.

- *Environmental Commitment 6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in filling of small amounts of tidal freshwater emergent wetland habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on narrow strips of habitat, including levees and channel banks. The improvements could occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A environmental commitments that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the construction phase of Alternative 4A, the project would affect the tidal freshwater emergent wetland natural community through water conveyance facilities construction losses (3 acres permanent and 15 acres temporary). These losses would occur in the central Delta from construction of barge unloading facilities and transmission lines on the fringes of Venice, Bacon and

Woodward Islands, and in various locations within the Yolo Bypass and the tidal restoration ROAs. An undetermined acreage would also be affected through channel margin habitat creation (Environmental Commitment 6) along the major Delta waterways.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with Alternative 4A environmental commitments. Loss of tidal freshwater emergent wetland natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the creation of 59 acres of tidal wetland as part of Environmental Commitment 4 during the construction phase of Alternative 4A would more than offset this loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 18 acres of restoration would be needed to offset (i.e., mitigate) the 18 acres of loss (the total permanent and temporary near-term effects listed in Table 12-4A-2).

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The creation of 59 acres of tidal wetland as part of Environmental Commitment 4 during the construction phase of Alternative 4A would more than offset the construction and restoration effects of implementing water conveyance facilities and Environmental Commitment 6, avoiding any adverse effect. Because of the 59 acres of tidal wetland restoration that would occur as part of Alternative 4A, the project would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would not be adverse.

CEQA Conclusion: Alternative 4A would result in the loss of approximately 18 acres of tidal freshwater emergent wetland natural community (permanent and temporary) due to construction of the water conveyance facilities. The construction losses would occur in primarily in the central Delta on the fringes of Venice, Bacon and Victoria Islands, and in the Yolo Bypass and various tidal restoration ROAs. An unknown amount of tidal freshwater emergent wetland could also be lost to channel margin habitat creation (Environmental Commitment 6).The losses would be spread across the Alternative 4A construction timeframe and would be offset by planned restoration of 59 acres of tidal wetland scheduled for the first 14 years of Alternative 4A implementation (Environmental Commitment 4). AMM1, AMM2, AMM6, AMM7, and AMM10 would also be implemented to minimize impacts. Because of these offsetting restoration activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration) would indicate that 18 acres of restoration would be needed to offset (i.e., mitigate) the 18 acres of loss. The restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community. The impact would be less than significant. No mitigation is required.

Impact BIO-7: Increased Frequency, Magnitude and Duration of Periodic Inundation of Tidal Freshwater Emergent Wetland Natural Community

Alternative 4A would not result in periodic effects on the tidal freshwater emergent wetland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-8: Modification of Tidal Freshwater Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect tidal freshwater emergent wetland natural community in the study area. The ongoing actions would include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Reduced diversions from the south Delta channels would not create a reduction in tidal freshwater emergent wetland in the study area. However, the periodic changes in flows in the Sacramento River, Feather River, and American River associated with modified reservoir operations, and the increased diversion of Sacramento River flows at north Delta intakes associated with Alternative 4A (Operational Scenario H) would affect salinity, water temperature, dissolved oxygen levels, turbidity, contaminant levels and dilution capacity in these rivers and Delta waterways. These changes are discussed in detail in Section 4.3.4, *Water Quality*, of the RDEIR/SDEIS. Potentially substantial increases in electrical conductivity (salinity) are predicted for the west Delta and Suisun Marsh as a result of these changed water operations. These salinity changes may alter the plant composition of tidal freshwater emergent wetland along the lower Sacramento and San Joaquin Rivers and west Delta islands. The severity and extent of these salinity changes would be complicated by anticipated sea level rise and the effects of downstream tidal restoration over the life of the project. There is the potential that some tidal freshwater marsh may become brackish. These potential changes are not expected to result in a significant reduction in the acreage and value of tidal freshwater emergent wetland natural community in the study area.
- The increased diversion of Sacramento River flows in the north Delta would result in reductions in sediment load (annual mass) flowing into the central and west Delta, and Suisun Marsh. The reduction is estimated to be approximately 9% of the river's current sediment load for Alternative 4A, which would have a north Delta diversion capacity of 9,000 cfs under Operational Scenario H (see Appendix 5.C, Attachment 5C.D, Section 5C.D.3.3, *Summary of Changes to Sediment Supply in the Plan Area Due to BDCP Shift in Export Location and Volume*, in the Draft BDCP for a detailed analysis of this issue). This would contribute to a decline in sediment reaching the Delta and Suisun Marsh that has been occurring over the past 50-plus years due to a gradual depletion of sediment from the upstream rivers. The depletion has been caused by a variety of factors, including depletion of hydraulic mining sediment in upstream areas, armoring of river channels and a cutoff of sediment due to dam construction on the

Sacramento River and its major tributaries (Wright and Schoellhamer 2004; Barnard et al. 2013).

- Reduced sediment load flowing into the Delta and Suisun Marsh could have an adverse effect on tidal marsh, including tidal freshwater emergent wetland. Sediment trapped by the marsh vegetation allows the emergent plants to maintain an appropriate water depth as water levels gradually rise from the effects of global warming (see Chapter 29, *Climate Change*, of the Draft EIR/EIS). The project proponents have incorporated an environmental commitment (see Appendix 3B, Section 3B.1.19, *Disposal and Reuse of Spoil, Reusable Tunnel Material and Dredged Material*, of the Draft EIR/EIS) into the project that would lessen this potential effect. The Sacramento River water diverted at north Delta intakes would pass through sedimentation basins before being discharged to water conveyance structures. The commitment states that sediment collected in these basins would be periodically removed and reused, to the greatest extent feasible, in the study area for a number of purposes, including marsh restoration, levee maintenance, subsidence reversal, flood response, and borrow area fill. The portion of the sediment re-introduced to the Delta and estuary for marsh restoration would remain available for marsh accretion. With this commitment to reuse in the study area, the removal of sediment at the north Delta intakes would not result in a net reduction in the acreage and value of this special-status marsh community. The effect would not be adverse (NEPA) and would be less than significant (CEQA).

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in or adjacent to tidal freshwater emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering tidal aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within emergent wetland habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (Environmental Commitment 11). Use of herbicides to control nuisance vegetation could pose a long-term hazard to tidal freshwater emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to tidal aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Channel dredging.* Long-term operation of the Alternative 4A intakes on the Sacramento River would include periodic dredging of sediments that might accumulate in front of intake screens. The dredging would occur in waterways adjacent to tidal freshwater emergent wetlands and would result in short-term increases in turbidity and disturbance of the substrate. These conditions would not eliminate the community, but would diminish its value for special-status and common species that rely on it for cover or foraging area. The individual species effects are discussed in Section 4.3.8.2, *Wildlife Species*, of this RDEIR/SDEIS.
- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For tidal freshwater emergent wetland community, a management plan would be prepared that specifies actions to improve the value of the habitats for special-status species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of tidal freshwater emergent wetland natural community in the study area through changes in flow patterns and resultant changes in water quality. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with Alternative 4A, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by restoration activities planned as part of *Environmental Commitment 4 Tidal Natural Communities Restoration*. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with tidal freshwater emergent wetland habitats by improving water movement.

NEPA Effects: Ongoing operation, maintenance, and management activities would not result in a net permanent reduction in the tidal freshwater emergent wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A, including changed water operations in the upstream reservoirs, would have the potential to create minor changes in total acreage of tidal freshwater emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Restoration activities associated with *Environmental Commitment 4 Tidal Natural Communities Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the tidal freshwater emergent wetland natural community.

Valley/Foothill Riparian

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the valley/foothill riparian natural community. Initial development and construction of water conveyance facilities, Environmental Commitment 4, and Environmental Commitment 6 would result in both permanent and temporary removal of this community (see Table 12-4A-3). Implementation of Alternative 4A would also include the following Environmental Commitments and Resource Restoration and Performance Principles over the term of the project to benefit the valley/foothill riparian natural community.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of mature riparian forest in either CZ 4 or CZ 7 (Resource Restoration and Performance Principle VFR2).
- The mature riparian forest intermixed with a portion of the early- to mid-successional riparian vegetation will be a minimum patch size of 50 acres and minimum width of 330 feet(Resource Restoration and Performance Principle VFR3).

As explained below, with the restoration and enhancement of these amounts of habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-3. Changes in Valley/Foothill Riparian Natural Community Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Water Conveyance Facilities	42	31
Environmental Commitment 4[a]	5	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	47	31

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-9: Changes in Valley/Foothill Riparian Natural Community as a Result of Implementing Alternative 4A

Construction, land grading and habitat restoration activities that would accompany the implementation of water conveyance facilities, Environmental Commitment 4, and Environmental

Commitment 6 would permanently eliminate an estimated 47 acres and temporarily remove 31 acres of valley/foothill riparian natural community in the study area. These modifications represent approximately 0.5% of the 17,966 acres of the community that is mapped in the study area. The majority of the permanent and temporary losses would happen during the construction of Alternative 4A and as habitat restoration is initiated. Valley/foothill riparian protection (103 acres) and restoration (251 acres) would be initiated during the same period, which would offset the losses.

The individual effects of each relevant environmental commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would permanently remove 42 acres and temporarily remove 31 acres of valley/foothill riparian natural community. The permanent losses would occur where Intakes 2, 3, and 5 encroach on the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees (acacia) and scrub vegetation (see Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS). Cottonwood, willow and mixed brambles would be permanently lost at manmade ponds located north and south of Twin Cities Road just west of Interstate 5, as these sites would be used to deposit reusable tunnel material. Some cottonwood and valley oak riparian would be lost due to construction of a permanent access road from the new forebay west to an RTM disposal area. Blackberry brambles would also be lost to deposit of reusable tunnel material at the east end of Bouldin Island. Smaller areas dominated by blackberry would be eliminated at the forebay site adjacent to Clifton Court Forebay and patches of willow and blackberry would be lost along the transmission line corridors where they cross waterways in the central and south Delta. Permanent losses would occur where the realigned SR 160 crosses Snodgrass Slough and along Lambert Road where temporary utility lines would be installed. Temporary losses would also occur adjacent to temporary intake work areas. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak, cottonwood, willow and scrub vegetation. These losses would take place during the Alternative 4A construction period.
- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Environmental Commitment 4 would permanently inundate or remove 5 acres of valley/foothill riparian community. The losses would occur in several of the ROAs established for tidal restoration (see Figure 12-1 in the Draft EIR/EIS). No losses would occur in the Suisun Marsh ROA. These ROAs support a mix of riparian vegetation types, including valley oak stands, extensive willow and cottonwood stringers along waterways, and areas of scrub vegetation dominated by blackberry. These areas are considered of low to moderate habitat value (see Section 5.4.5.1.1, *Permanent Loss and Fragmentation*, of the Draft BDCP). The actual loss of riparian habitat to marsh restoration would be expected to be smaller than predicted. As marsh restoration projects were identified and planned, sites could be selected that avoid riparian areas as much as possible.
- *Environmental Commitment 6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur

within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

- *Environmental Commitment 7 Riparian Natural Community Restoration:* The valley/foothill riparian natural community would be restored primarily in association with the tidal (Environmental Commitment 4) and channel margin (Environmental Commitment 6) enhancements. A total of 251 acres of this community would be restored and 103 acres would be protected during the construction period (14 years) of the project. A variety of successional stages would be sought to benefit the variety of sensitive plant and animal species that rely on this natural community in the study area.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4Aenviornmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Alternative 4A would affect the valley/foothill riparian natural community through water conveyance facilities construction losses (42 acres permanent and 31 acres temporary) and the Environmental Commitment 4 restoration actions (5 acres permanent). The water conveyance facilities losses would occur along the eastern bank of the Sacramento River at intake sites; along transmission lines in the central and south Delta and along Lambert Road; and at RTM storage sites near Twin Cities Road, Clifton Court Forebay, and on Bouldin Island. The 5 acres of Environmental Commitment 4 losses would occur in one or several of the ROAs mapped in Figure 12-1.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and protection/restoration actions associated with Alternative 4A environmental commitments described in Section 4.1.2.3, *Environmental Commitments*, of this RDEIR/SDEIS. Loss of valley/foothill riparian natural community would be considered a loss in acreage of a sensitive natural community, and could be considered a loss of wetlands as defined in Section 404 of the CWA. As indicated above, most of the losses would be in small patches or narrow strips along waterways, with limited structural complexity. However, the restoration of 251 acres and protection (including significant enhancement) of 103 acres of valley/foothill riparian natural community as part of Environmental Commitment 7 and Environmental Commitment 3 during the Alternative 4A construction period would minimize this loss, avoiding any adverse effect. The restoration areas would be large areas providing connectivity with existing riparian habitats and would include a variety of trees and shrubs to produce structural complexity. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 78 acres of protection and 78 acres of restoration would be needed to offset (i.e., mitigate) the 78 acres of loss (the combination of permanent and temporary losses listed in Table 12-4A-3). The combination of the two approaches (protection and restoration) are designed to avoid a temporal lag in the value of riparian habitat available to sensitive species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM10 Restoration of Temporarily Affected Natural Communities, and AMM18 Swainson's Hawk and White-Tailed Kite*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2, AMM6, and AMM18 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Implementation of Alternative 4A would result in the loss of approximately 0.5% of valley/foothill riparian natural community in the study area. These losses (47 acres of permanent and 31 acres of temporary) would be largely associated with construction of the water conveyance facilities and inundation during tidal marsh restoration (Environmental Commitment 4). Inundation losses would occur through the course of the project's tidal marsh restoration program at various tidal restoration sites throughout the study area. By the end of the project's construction period, a total of 251 acres of this natural community would be restored and 103 acres would be protected (Environmental Commitment 7 and Environmental Commitment 3, respectively), primarily in CZ 4 and CZ 7 in the Cosumnes/Mokelumne and South Delta ROAs (see Figure 12-1 in the Draft EIR/EIS).

NEPA Effects: The restoration of 251 acres and protection (including significant enhancement) of 103 acres of valley/foothill riparian natural community as part of Environmental Commitment 7 and Environmental Commitment 3 together with Resource restoration and performance principles VFR1-VFR3 during the construction period for Alternative 4A would minimize the loss of this community, avoiding any adverse effect. Because of the project's commitment to restoration of 251 acres and protection of 103 acres of valley/foothill riparian natural community during the course of the project, Alternative 4A would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would not be adverse.

CEQA Conclusion: Alternative 4A would result in the loss of approximately 78acres of valley/foothill riparian natural community due to construction of the water conveyance facilities and inundation during tidal marsh restoration (Environmental Commitment 4). The construction losses would occur primarily along the Sacramento River at intake sites; along transmission corridors in the central and south Delta and along Lambert Road; and at reusable tunnel material storage sites on Bouldin Island, Clifton Court Forebay and near Twin Cities Road, while inundation losses would occur at various tidal restoration sites throughout the study area. The construction losses would be spread across the 14-year construction time frame of the project. These losses would be minimized by planned restoration of 251 acres (Environmental Commitment 7) and protection (including significant enhancement) of 103 acres (Environmental Commitment 3) of valley/foothill riparian natural community scheduled for the construction period of Alternative 4A, which would be guided by Resource Restoration and Performance Principles VFR1-VFR3. AMM1, AMM2, AMM6, AMM7, AMM10, and AMM18 would also be implemented to minimize impacts. Because of these restoration and protection activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for protection and 1:1 for restoration) would indicate that 78 acres of protection and 78 acres of restoration would be needed to offset (i.e., mitigate) the 78 acres of loss. The combination of the two approaches (protection and restoration) is designed to avoid a temporal lag in the value of riparian habitat available to sensitive species. The restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community. Therefore, the impact would be less than significant.

Impact BIO-10: Increased Frequency, Magnitude and Duration of Periodic Inundation of Valley/Foothill Riparian Natural Community

Alternative 4A would not result in periodic effects on the valley/foothill riparian natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-11: Modification of Valley/Foothill Riparian Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect valley/foothill riparian natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, reduced diversions from south Delta channels, and recreational use of reserve areas. These actions are associated with water conveyance facilities and Environmental Commitment 11. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs.* Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would not affect valley/foothill riparian natural community. The anticipated water levels over time with Alternative 4A, as compared to no action, would be slightly lower in the October to May timeframe. The small changes in frequency of higher water levels in these lakes would not substantially reduce the small patches of riparian vegetation that occupy the upper fringes of the reservoir pools. Changes in releases that would influence downstream river flows are discussed below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area and their resultant changes in flows in the Sacramento, American and Feather Rivers (associated with Operational Scenario H) would not be expected to result in the permanent reduction in acreage of valley/foothill riparian natural community along these waterways. There is no evidence that flow levels in the upstream rivers would change such that the acreage of this community would be reduced on a permanent basis. Riparian habitats along the rivers of the Sacramento Valley have historically been exposed to significant variations in river stage. Based on modeling conducted for the BDCP (see Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis,* of the Draft EIR/EIS), flow levels in these upstream rivers could be reduced by as much as 19% in the July to November time frame when compared to No Action, while flow levels in the February to May time frame could increase as much as 48% with implementation of Alternative 4A. Similarly, increased diversions of Sacramento River flows in the north Delta would not be expected to result in a permanent reduction in valley/foothill riparian community downstream of these diversions, even though river flows are modeled to be reduced by 11–27% compared with No Action, depending on month and water-year type (see Appendix 11C, Section 11C.4, *Alternative 4*, in the Draft EIR/EIS). Reduced diversions from the south Delta channels would not create a reduction in this natural community.

- The periodic changes in flows in the Sacramento River, Feather River, and American River associated with modified reservoir operations, and the increased diversion of Sacramento River flows at north Delta intakes associated with Alternative 4A would affect salinity, water temperature, dissolved oxygen levels, turbidity, contaminant levels and dilution capacity in these rivers and Delta waterways. These changes are discussed in detail in Section 4.2.7, *Water Quality*, of the RDEIR/SDEIS. Potentially substantial increases in electrical conductivity (salinity) are predicted for the west Delta and Suisun Marsh as a result of these changed water operations. These salinity changes may alter the plant composition of riparian habitats along the lower Sacramento and San Joaquin Rivers and west Delta islands. The severity and extent of these salinity changes would be complicated by anticipated sea level rise and the effects of downstream tidal restoration over the life of the project. There is the potential that some valley/foothill riparian natural community may be degraded immediately adjacent to river channels. The riparian communities in the west Delta are dominated by willows, cottonwood and mixed brambles. These potential changes are not expected to result in a significant reduction in the acreage and value of valley/foothill riparian natural community in the study area.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in valley/foothill riparian habitats. This activity could lead to increased soil erosion, turbidity and runoff entering these habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within riparian habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces (*AMM10 Restoration of Temporarily Affected Natural Communities*). Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to valley/foothill riparian natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to riparian areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Channel dredging.* Operation of the Alternative 4A intakes on the Sacramento River would include periodic dredging of sediments that might accumulate in front of intake screens. The dredging could occur adjacent to valley/foothill riparian natural community. This activity should not adversely affect riparian plants as long as dredging equipment is kept out of riparian areas and dredge spoil is disposed of outside of riparian corridors.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the valley/foothill riparian natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

- *Recreation.* Alternative 4A would allow for certain types of recreation in and adjacent to valley/foothill riparian natural community. The activities could include wildlife and plant viewing and hiking. *Conservation Measure 11 Natural Communities Enhancement and Management* (on which Environmental Commitment 11 is based) describes this program and identifies applicable restrictions on recreation that might adversely affect riparian habitat (see Section 3.4.11, *Conservation Measure 11 Natural Communities Enhancement and Management*, of the Draft BDCP and Section 4.1.2.3, *Environmental Commitments*, of this RDEIR/SDEIS). The project also includes an avoidance and minimization measure (AMM37) that further dictates limits on recreation activities that might affect this natural community. Priority would be given to use of existing trails and roads, with some potential for new trails. Limited tree removal and limb trimming could also be involved.

The various operations and maintenance activities described above could alter acreage of valley/foothill riparian natural community in the study area through changes in flow patterns and resultant changes in water quality. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Recreation activities could encroach on riparian areas and require occasional tree removal. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration and protection activities planned as part of *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, AMM10, AMM18, and AMM37. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with riparian habitats by improving water movement in adjacent waterways and by eliminating competitive, invasive species of plants.

NEPA Effects**:** Ongoing operation, maintenance and management activities associated with implementation of Alternative 4A would not result in a net permanent reduction in the valley/foothill riparian natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion**:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of valley/foothill riparian natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, AMM10, and AMM18 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural*

Communities Enhancement and Management, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Restoration and protection activities associated with *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the valley/foothill riparian natural community.

Nontidal Perennial Aquatic

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the nontidal perennial aquatic natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of this community (see Table 12-4A-4). Channel margin habitat enhancement associated with Environmental Commitment 6 could also remove small areas of this natural community.

As explained below, with the restoration and enhancement of nontidal wetland habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-4. Changes in Nontidal Perennial Aquatic Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	59	9
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	59	9

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-12: Changes in Nontidal Perennial Aquatic Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities would permanently eliminate an estimated 59 acres and temporarily remove 9 acres of nontidal perennial aquatic natural community in the study area. These modifications represent approximately 1.2% of the 5,567 acres of the community that is mapped in the study area. Natural communities restoration would add 832 acres (Environmental Commitment 10) and protect 119 acres (Environmental Commitment 3) of nontidal marsh during the same period which would expand the area of that habitat and offset the losses. The nontidal marsh restoration would include a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities. The nontidal marsh would be restored in the vicinity of giant garter snake subpopulations identified in the recovery plan for this species (U.S. Fish and Wildlife Service 1998).

The individual effects of each relevant environmental commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of the Alternative 4A water conveyance facilities would permanently remove 59 acres and temporarily remove 9 acres of nontidal perennial aquatic community. Most of the permanent loss would occur at the linear manmade ponds located north and south of Twin Cities Road just west of I-5 and an RTM storage site on Bouldin Island (see Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS). Most of the temporary loss would occur where transmission line construction would cross Mandeville Island. These wetlands are linear ponds or small, isolated areas surrounded by agricultural land. These losses would take place during the Alternative 4A construction period.
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of nontidal perennial aquatic habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Nontidal marsh adjacent to these tidal areas could be affected. The improvements would be undertaken within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Environmental Commitment 10 would entail restoration of 832 acres of nontidal marsh in CZs 2, 4, and/or 5. The restoration would create a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent natural communities. This marsh restoration would occur in 25-acre or larger patches in or near giant garter snake occupied habitat and would be accompanied by adjacent grassland restoration or protection.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the Alternative 4A construction period, activities would affect the nontidal perennial aquatic community through water conveyance facilities construction losses (59 acres permanent and 9 acres temporary). Additional small losses could also occur during this time frame as channel margin habitat enhancement is implemented.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with Alternative 4A. Loss of nontidal perennial aquatic natural community would be considered both a loss in acreage of a sensitive natural community and a loss of waters of the United States as defined by Section 404 of the CWA. However, creating 832 acres of nontidal marsh as part of Environmental Commitment 10 during the Alternative 4A construction period would offset this loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate 68 acres of restoration and 68 acres of protection would be needed to offset (i.e., mitigate) the 68 acres of loss. The project also includes protection of 119 acres of nontidal marsh habitat (Environmental Commitment 3). The protection acreage exceeds the typical 1:1 protection requirement and fully compensates for the construction losses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils,* *Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Implementation of Alternative 4A would result in relatively minor (6%) losses of nontidal perennial aquatic community in the study area. These losses (59 acres of permanent and 9 acres of temporary loss) would be largely associated with construction of the water conveyance facilities. By the end of project construction, a total of 832 acres of nontidal marsh would be restored. The restoration would occur over a wide region of the study area, including within the Cosumnes/Mokelumne, Yolo Bypass, South Delta and East Delta ROAs (see Figure 12-1 in the Draft EIR/EIS).

***NEPA Effects*:** During the Alternative 4A construction period, creating 832 acres of nontidal marsh as part of Environmental Commitment 10 would offset the construction-related losses of 68 acres of nontidal perennial aquatic natural community. The effect would not be adverse.

***CEQA Conclusion*:** Alternative 4A would result in the loss of approximately 68 acres of nontidal perennial aquatic natural community due to construction of the water conveyance facilities. The construction losses would occur primarily at reusable tunnel material storage sites near Twin Cities Road and on Bouldin Island, and along the transmission corridor where it crosses Mandeville Island. The losses would be spread across the Alternative 4A construction period (14 years). These losses would be offset by planned restoration of 832 acres and protection of 119 acres of nontidal marsh during the same time period (Environmental Commitment 10 and Environmental Commitment 3). Also, AMM1, AMM2, AMM6, AMM7, and AMM10 would be implemented to minimize impacts. Because of these offsetting restoration activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 68 acres of restoration and 68 acres of protection would be needed to offset (i.e., mitigate) the 68 acres of loss. The project includes tidal marsh restoration (832 acres) and protection (119 acres) which is well in excess of the typical 1:1 restoration and protection acreages, and therefore compensates for all project-related losses. The restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community. Therefore, the impact would be less than significant. No mitigation is required.

Impact BIO-13: Increased Frequency, Magnitude and Duration of Periodic Inundation of Nontidal Perennial Aquatic Natural Community

Alternative 4A would not result in periodic effects on the nontidal perennial aquatic natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-14: Modification of Nontidal Perennial Aquatic Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect nontidal perennial aquatic natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions would be associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs.* Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would affect nontidal perennial aquatic natural community, in the form of the reservoir pools. The Alternative 4A operations scheme would alter the surface elevations of these reservoir pools as described in Section 4.3.2, *Surface Water*, of the RDEIR/SDEIS. These fluctuations would occur within historic ranges and would not adversely affect the natural community. Changes in releases that would influence downstream river flows are discussed below.
- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversion from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of the nontidal perennial aquatic natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of nontidal perennial aquatic community would be reduced on a permanent basis. Some minor increases and some decreases would be expected to occur along the major rivers during some seasons and in some water-year types, but there would be no permanent loss. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in nontidal perennial aquatic community downstream of these diversions. Nontidal wetlands below the diversions are not directly connected to the rivers, as this reach of the river is tidally influenced. Reduced diversions from south Delta channels would not create a reduction in this natural community.
- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in nontidal perennial aquatic habitats. This activity could lead to increased soil erosion, turbidity and runoff entering nontidal perennial aquatic habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.
- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management)*. Vegetation management is also the principal activity associated with *Environmental Commitment 13 Invasive Aquatic Vegetation Control.* Use of herbicides to

control nuisance vegetation could pose a long-term hazard to nontidal perennial aquatic natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to nontidal perennial aquatic areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For nontidal perennial aquatic natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of nontidal perennial aquatic natural community in the study area through changes in flow patterns and changes in periodic inundation of this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by restoration activities planned as part of *Environmental Commitment 10 Nontidal Marsh Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration*. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with nontidal perennial aquatic habitats by improving water movement.

***NEPA Effects*:** Ongoing operation, maintenance and management activities would not result in a net permanent reduction in the nontidal perennial aquatic natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of nontidal perennial aquatic natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in these habitats. Long-term restoration activities associated with *Environmental Commitment 10 Nontidal Marsh Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the nontidal perennial aquatic natural community.

Nontidal Freshwater Perennial Emergent Wetland

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the nontidal freshwater perennial emergent wetland natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of this community (see Table 12-4A-5). Small losses of this community could also occur with planned channel margin enhancement activities (Environmental Commitment 6).

As explained below, with the restoration and enhancement of nontidal marsh habitat, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-5. Changes in Nontidal Freshwater Perennial Emergent Wetland Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	2	6
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	2	6

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-15: Changes in Nontidal Freshwater Perennial Emergent Wetland Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities would permanently eliminate an estimated 2 acres and temporarily remove 6 acres of nontidal freshwater perennial emergent wetland natural community in the study area. These modifications represent approximately 0.5% of the 1,509 acres of the community that is mapped in the study area. Nontidal marsh restoration (Environmental Commitment 10) would add 832 acres of nontidal marsh and natural communities protection (Environmental Commitment 3) would protect 119 acres of nontidal marsh. These actions would be taken over the course of Alternative 4A marsh restoration activities, which would expand the area of that habitat and offset the losses. The nontidal marsh restoration would include a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland natural communities. The nontidal marsh protection would be designed to support tricolored blackbird and western pond turtle populations in the study area. The restoration would occur in blocks that are contiguous with or near giant garter snake subpopulations identified in the recovery plan for this species (U.S. Fish and Wildlife Service 1998), and in areas suitable for greater sandhill crane permanent roosting and foraging.

The individual effects of each relevant environmental commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would permanently remove 2 acres and temporarily remove 6 acres of tidal freshwater perennial emergent wetland community. The permanent losses would occur at the Clifton Court Forebay construction site and the RTM site on Bouldin Island (see Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS). The temporary loss would occur in a temporary work area and where temporary powerlines would be constructed across Mandeville Island. These wetlands are extremely small and remote water bodies, surrounded by agricultural operations. These losses would take place during the project's construction period.
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of nontidal freshwater perennial emergent wetland habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Nontidal marsh adjacent to these tidal areas could be affected. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Environmental Commitment 10 would entail restoration of 832 acres of nontidal marsh in CZs 2, 4, and/or 5. The restoration would create a mosaic of nontidal perennial aquatic and nontidal freshwater perennial emergent natural communities. Some of this marsh restoration would occur in 25-acre or larger patches in or near giant garter snake occupied habitat and would be accompanied by adjacent grassland restoration or protection.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the project's construction time frame, Alternative 4A would affect the nontidal freshwater perennial emergent wetland community through water conveyance facilities construction losses (2 acres permanent and 6 acres temporary). Small additional losses could result where channel margin habitat enhancement occurs along major Delta waterways (Environmental Commitment 6).

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with the project. Loss of nontidal freshwater perennial emergent wetland natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the combination of creating 832 acres and protecting 119 acres of nontidal perennial marsh as part of Environmental Commitment 3 and Environmental Commitment 10 during the construction of Alternative 4A would offset this loss, avoiding any adverse effect. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate 8 acres of restoration and 8 acres of protection would be needed to offset (i.e., mitigate) the 8 acres of loss. The project includes well in excess of the typical 1:1 restoration and protection acreages for this natural community.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Implementation of Alternative 4A would result in small (0.5%) losses of nontidal freshwater perennial emergent wetland community in the study area. These losses (2 acres of permanent and 6 acres of temporary loss) would be associated with construction of the water conveyance facilities. By the end of water conveyance facilities construction, a total of 832 acres of nontidal marsh would be restored and 119 acres would be protected. The restoration would occur near giant garter snake occupied habitat and greater sandhill crane roosting and foraging areas in the eastern Delta. Approximately half of the 119 acres of protection would occur in CZ 1, 2, 8, or 11 to provide nesting habitat for tri-colored blackbird (see Figure 12-1 in the Draft EIR/EIS).

NEPA Effects: The combination of creating 832 acres and protecting 119 acres of nontidal perennial marsh as part of Environmental Commitment 3 and Environmental Commitment 10 would offset the losses associated with construction of water conveyance facilities, avoiding any adverse effect. With 832 acres of nontidal marsh restoration and 119 acres of protection, Alternative 4A would not result in a net long-term reduction in the acreage of a sensitive natural community; the effect would not be adverse.

CEQA Conclusion: Alternative 4A would result in the loss of approximately 8 acres of nontidal freshwater perennial emergent wetland natural community due to construction of the water conveyance facilities. The construction losses would occur near Clifton Court Forebay and along transmission line construction areas on Mandeville Island. The losses would occur during the project construction timeframe. These losses would be offset by planned restoration of 832 acres and protection of 119 acres of nontidal marsh (Environmental Commitment 10 and Environmental Commitment 3). AMM1, AMM2, AMM6, AMM7, and AMM10 would also be implemented to minimize impacts. Typical project-level mitigation ratios (1:1 for restoration and 1:1 for protection) would indicate that 8 acres of restoration and 8 acres of protection would be needed to offset (i.e., mitigate) the 8 acres of loss. The project includes well in excess of the typical 1:1 restoration and protection acreages and therefore compensates for the construction-related losses. The restoration and protection would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species, and would result in a net gain in acreage of this sensitive natural community. Because of these offsetting restoration and protection activities and AMMs, impacts would be less than significant.

Impact BIO-16: Increased Frequency, Magnitude and Duration of Periodic Inundation of Nontidal Freshwater Perennial Emergent Wetland Natural Community

Alternative 4A would not result in periodic effects on the nontidal freshwater perennial emergent wetland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-17: Modification of Nontidal Freshwater Perennial Emergent Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect nontidal freshwater perennial emergent wetland natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified releases and water levels in upstream reservoirs.* Modified releases and water levels at Shasta Lake, Lake Oroville, Whiskeytown Lake, Lewiston Lake, and Folsom Lake would not affect the nontidal freshwater perennial emergent wetland natural community. These reservoirs do not support significant stands of freshwater emergent wetlands. Changes in releases that would influence downstream river flows are discussed below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of the nontidal freshwater perennial emergent wetland natural community in the study area. The majority of this wetland type exists outside of the levees of the larger rivers and would not be affected by flow changes in river or Delta channels. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in nontidal freshwater perennial emergent wetland community downstream of these diversions. Nontidal wetlands below the diversions are not directly connected to the rivers, as this reach of the river is tidally influenced. Reduced diversions from south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the project's actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in nontidal freshwater perennial emergent wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering nontidal freshwater perennial habitats. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within aquatic habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management).* Use of herbicides to control nuisance vegetation could pose a long-term hazard to nontidal freshwater perennial emergent wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to nontidal perennial wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of Alternative 4A to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For nontidal freshwater perennial emergent wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of nontidal freshwater perennial emergent wetland natural community in the study area through changes in flow patterns and facilities maintenance activities. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *Environmental Commitment 10 Nontidal Marsh Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration*. The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with nontidal freshwater perennial emergent wetland habitats by improving water movement.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in the nontidal freshwater perennial emergent wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of nontidal freshwater perennial emergent wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, and AMM5 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including improved water movement in and adjacent to these habitats. Long-term restoration activities associated with *Environmental Commitment 10 Nontidal Marsh Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would expand this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the nontidal freshwater perennial emergent wetland natural community.

Alkali Seasonal Wetland Complex

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the alkali seasonal wetland complex natural community. Initial development and construction of water conveyance facilities would result in a small permanent removal of this community (see Table 12-4A-6). Implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles over the term of the project to benefit the alkali seasonal wetland natural community.

- Restore vernal pool and alkali seasonal wetland complex to achieve no net loss of wetted acreage (Resource Restoration and Performance Principle VP/AW2).
- Increase the size and connectivity of protected vernal pool and alkali seasonal wetland complex in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principle VP/AW4).

As explained below, with the protection, restoration, and enhancement of the amounts of habitat proposed for Alternative 4A, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-6. Changes in Alkali Seasonal Wetland Complex Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	2	0
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	2	0

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-18: Changes in Alkali Seasonal Wetland Complex Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities under Alternative 4A would permanently eliminate an estimated 2 acres of alkali seasonal wetland complex natural community in the study area. There would be no temporary impacts to alkali seasonal wetlands. These modifications represent approximately 0.05% of the 3,723 acres of the community that is mapped in the study area. The combined vernal pool/alkali seasonal wetland complex protection (150 acres) and restoration (34 acres) would be initiated during project construction; these actions would offset the losses.

The effects associated with construction of water conveyance facilities are addressed below. A summary statement of the impacts and NEPA and CEQA conclusions follows the individual environmental commitment discussion.

- *Water Facilities and Operation*: Construction of the Alternative 4A transmission lines immediately west of Clifton Court Forebay would permanently affect 2 acres of alkali seasonal wetland complex natural community (see the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS). The alkali seasonal wetland complex at this location is scattered and significantly degraded by past agricultural and water development-related activities. It is surrounded by or adjacent to vernal pool complex natural community.

  The construction activity associated with water conveyance facilities also has the potential to lead to increased nitrogen deposition in alkali seasonal wetland habitats in the vicinity of Clifton Court Forebay. A significant number of cars, trucks, and land grading equipment involved in construction would emit small amounts of atmospheric nitrogen from fuel combustion; this material could be deposited in sensitive alkali seasonal wetland areas that are located west of the major construction areas at Clifton Court Forebay. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, in the Draft BDCP addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the alkali seasonal wetland complex in the construction area because the construction would occur primarily downwind of the natural community and the construction would contribute a negligible amount of nitrogen to regional projected emissions. No adverse effect is expected.

- *Environmental Commitment 3 Natural Communities Protection and Restoration:* Environmental Commitment 3 proposes to protect at least 150 acres of vernal pool/alkali seasonal wetland complex in the study area. The protection would occur in areas containing a mosaic of grassland and vernal pool complex in unfragmented natural landscapes supporting a diversity of native plant and wildlife species. These areas would be both protected and enhanced to increase the cover of alkali seasonal wetland plants relative to nonnative species.

- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Environmental Commitment 9 includes both vernal pool complex and alkali seasonal wetland complex restoration goals. The intent of the environmental commitment is to match the acreage of restoration with the actual acreage lost to other project measures (primarily water conveyance facilities). The current estimate for vernal pool/alkali seasonal wetland complex restoration is 34 acres. The goal is for no net loss of this natural community, consistent with the project's Resource Restoration and Performance Principles.

The following paragraphs summarize the combined effects discussed above and describe other project environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During project construction, Alternative 4A would affect the alkali seasonal wetland complex natural community through water conveyance facilities construction losses (2 acres permanent). These losses would occur on land immediately west of Clifton Court Forebay.

The construction losses of this special-status natural community would represent an adverse effect if they were not offset by avoidance and minimization measures and restoration actions associated with the project's environmental commitments. Loss of alkali seasonal wetland complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the protection of 150 acres of combined vernal pool/alkali seasonal wetland complex as part of Environmental Commitment 3, the restoration of 34 acres of these communities as part of Environmental Commitment 9, and the implementation of *AMM30 Transmission Line Design and Alignment Guidelines* would offset this loss, avoiding any adverse effect. AMM30 would require that transmission line construction avoid any losses of alkali seasonal wetland complex natural community (see Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP for a full description of AMM30). Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 4 acres of protection and 2 acres of restoration would be needed to offset (i.e., mitigate) the 2 acres of loss.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Implementation of Alternative 4A would result in very minor (0.05%) losses of alkali seasonal wetland natural community in the study area. These losses (2 acres) would be associated with construction of the project's water conveyance facility.

NEPA Effects: During the 14-year construction period for Alternative 4A, 150 acres of vernal pool/alkali seasonal wetland complex would be protected as part of Environmental Commitment 3 and 34 acres of these communities would be restored as part of Environmental Commitment 9, which would be guided by Resource Restoration and Performance Principles VP/AW2-VP/AW4. These environmental commitments would offset the loss of this community associated with water conveyance facilities, avoiding any adverse effect. The protection and restoration would occur primarily in the Clifton Court Forebay area. Therefore, Alternative 4A would not have an adverse effect on the alkali seasonal wetland complex natural community.

CEQA Conclusion: Alternative 4A would result in the permanent loss of approximately 2 acres of alkali seasonal wetland complex natural community due to water conveyance facility construction. The construction losses would occur primarily in the area adjacent to Clifton Court Forebay. The losses would occur during project construction.

The construction losses of this special-status natural community would represent a significant impact if they were not offset by avoidance and minimization measures and other actions associated with the project's environmental commitments. Loss of alkali seasonal wetland complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. However, the protection of 150 acres of combined vernal pool/alkali seasonal wetland complex as part of Environmental Commitment 3, the restoration of 34 acres of these communities as part of Environmental Commitment 9, Resource Restoration and Performance Principles VP/AW2-VP/AW4, and the implementation of *AMM30 Transmission Line Design and Alignment Guidelines* during construction of Alternative 4A would offset this loss, avoiding any significant impact. Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 4 acres of protection and 2 acres or restoration would be needed to offset (i.e., mitigate) the 2 acres of loss. AMM1, AMM2, AMM3, AMM4, and AMM10 would also be implemented to minimize impacts. Because of the offsetting protection and restoration activities and AMMs, impacts would be less than significant.

Impact BIO-19: Increased Frequency, Magnitude and Duration of Periodic Inundation of Alkali Seasonal Wetland Natural Community

Alternative 4A would not result in periodic effects on the alkali seasonal wetland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-20: Modification of Alkali Seasonal Wetland Complex Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A were constructed and the stream flow regime associated with changed water management was in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect alkali seasonal wetland complex natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, reduced diversions from south Delta channels, and recreation in and adjacent to Plan reserves. These actions are associated with water conveyance facilities and Environmental Commitment 11. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not affect alkali seasonal wetland natural community. This natural community does not exist within or adjacent to the active Sacramento River system channels and Delta waterways that would be affected by modified flow levels.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in or adjacent to alkali seasonal wetland complex habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within alkali seasonal wetland complex habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces as required by *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to alkali seasonal wetland complex natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to alkali seasonal wetland complex areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* Alternative 4A includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the alkali seasonal wetland complex natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

- *Recreation.* The project would allow for certain types of recreation in and adjacent to alkali seasonal wetland natural community in the reserve system. The activities could include wildlife and plant viewing and hiking. *Conservation Measure 11 Natural Communities Enhancement and Management* (on which Environmental Commitment 11 is based) describes this program and identifies applicable restrictions on recreation that might adversely affect alkali seasonal wetland habitat (see Section 3.4.11, *Conservation Measure 11 Natural Communities Enhancement and Management*, of the Draft BDCP). The project also includes an avoidance and minimization measure (AMM37) that further dictates limits on recreation activities that might affect this natural community. Most recreation would be docent-led wildlife and botanical tours, using existing trails and roads in the vicinity of the reserves. No new trails would be constructed.

The various operations and maintenance activities described above could alter acreage of alkali seasonal wetland complex natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by protection and restoration activities planned as part of *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, AMM10, and AMM37. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with alkali seasonal wetland complex habitats by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be no adverse effect on the alkali seasonal wetland complex natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of alkali seasonal wetland complex natural community in the study area, and could create temporary increases sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, AMM10, and AMM37 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would ensure that the acreage of this natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact on the alkali seasonal wetland complex natural community.

Vernal Pool Complex

Construction, operation, maintenance and management associated with the environmental commitments of Alternative 4A would have no long-term adverse effects on the habitats associated with the vernal pool complex natural community. Initial development and construction of water conveyance facilities would result in permanent removal of 28 acres of this community (see Table 12-4A-7). Implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles over the term of the project to benefit the vernal pool complex natural community.

- Protect existing vernal pool complex in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principle VP/AW1).
- Restore vernal pool and alkali seasonal wetland complex to achieve no net loss of wetted acreage (Resource Restoration and Performance Principle VP/AW2).
- Increase the size and connectivity of protected vernal pool and alkali seasonal wetland complex in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principle VP/AW4).

As explained below, with the protection, restoration and enhancement of the amounts of habitat proposed for Alternative 4A, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	28	3

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-21: Changes in Vernal Pool Complex Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities could permanently eliminate an estimated 28 acres and temporarily remove 3 acres of vernal pool complex natural community in the study area. These acreages are based on the proposed location of the water conveyance facilities construction footprint. The loss of this combined 31 acres would represent approximately 0.3% of the 12,133 acres of the community that is mapped in the study area. Vernal pool/alkali seasonal wetland complex protection (150 acres) and restoration (34 acres) would be initiated during the Alternative 4A construction period to counteract the loss of habitat. Because of the high sensitivity of this natural community and its shrinking presence in the study area, avoidance and minimization measures have been built into the project to eliminate the majority of this potential loss.

The individual effects of water conveyance facilities are addressed below. A summary statement of the impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation:* Construction of the Alternative 4A water conveyance facilities would directly affect 31 acres of vernal pool complex natural community, including 28 acres permanently affected and 3 acres temporarily affected. The permanent loss would occur along the southern edge of Clifton Court Forebay, where the forebay would be expanded to provide greater storage capacity and from the construction of permanent transmission lines. The temporary losses would occur in a temporary work area immediately adjacent to Clifton Court Forebay (see Figure 12-1 in the Draft EIR/EIS and the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS).

- Because of the close proximity of construction activity to adjacent vernal pool complex near Clifton Court Forebay, there is also the potential for indirect loss or damage to vernal pools from changes in pool hydrology or deposition of construction-related sediment. These potential indirect effects are discussed in detail in the vernal pool crustaceans impact analysis in Section 4.3.8.2, *Wildlife Species*, of this RDEIR/SDEIS.

- The construction activity associated with water conveyance facilities also has the potential to lead to increased nitrogen deposition in vernal pool complex habitats in the vicinity of Clifton Court Forebay and Stone Lakes National Wildlife Refuge. A significant number of cars, trucks, and land grading equipment involved in construction would emit small amounts of atmospheric nitrogen from fuel combustion; this material could be deposited in sensitive vernal pool areas that are located west of the major construction areas at Clifton Court Forebay and east of the construction areas adjacent to Stone Lakes NWR. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, of the Draft BDCP addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the vernal pool complex in the construction areas because the construction would contribute a negligible amount of nitrogen to regional projected emissions. Also, the construction at Clifton Court Forebay would occur primarily downwind of the natural community. At Stone Lakes National Wildlife Refuge, the USFWS refuge management undertakes active invasive species control, including use of grazing. No adverse effect is expected.

- *Environmental Commitment 3 Natural Communities Protection and Restoration:* Environmental Commitment 3 proposes to protect at least 150 acres of vernal pool complex, primarily in the Clifton Court Forebay area. The protection would occur in areas containing a mosaic of grassland and vernal pool complex in unfragmented natural landscapes supporting a diversity of native plant and wildlife species. These areas would be both protected and enhanced to increase the cover of vernal pool complex plants relative to nonnative species.

- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Environmental Commitment 9 includes both vernal pool complex and alkali seasonal wetland complex restoration goals. The current estimate for vernal pool/alkali seasonal wetland complex restoration is 34 acres. This restoration environmental commitment includes a “no net loss” policy normally applied to this natural community.

The following paragraphs summarize the combined effects discussed above and describe other project environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the project construction period (14 years), Alternative 4A could directly affect 28 acres of vernal pool complex natural community through construction-related losses in habitat from water conveyance facilities. This loss would occur in the vicinity of Clifton Court Forebay (see the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS).

The construction loss of this special-status natural community would represent an adverse effect if it were not offset by avoidance and minimization measures and restoration actions associated with the project's environmental commitments. Loss of vernal pool complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. The protection of 150 acres of vernal pool/alkali seasonal wetland complex as part of Environmental Commitment 3 and the restoration of up to 34 acres of these communities (including a commitment to have restoration keep pace with losses) as part of Environmental Commitment 9 during construction of Alternative 4A facilities would offset this loss. The project focuses this protection in the core vernal pool areas identified in the USFWS vernal pool recovery plan (U.S. Fish and Wildlife Service 2005). The core areas exist in CZ 1, CZ 8, and CZ 11 (see Figure 12-1 in the Draft EIR/EIS). Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 62 acres of protection and 31 acres of restoration would be needed to offset (i.e., mitigate) the 31 acres of loss.

To further avoid adverse effect, the project includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM12 Vernal Pool Crustaceans,* and *AMM30 Transmission Line Design and Alignment Guidelines.* All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and an updated version of AMM2 is described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS. With these AMMs in place, Alternative 4A would not adversely affect vernal pool complex natural community.

***NEPA Effects*:** The environmental commitments associated with Alternative 4A include protection of 150 acres (Environmental Commitment 3) and restoration of an estimated 34 acres (Environmental Commitment 9) of vernal pool/alkali seasonal wetland complex in the near-term time frame, which would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4. The project focuses the protection in the core vernal pool areas identified in the USFWS vernal pool recovery plan (U.S. Fish and Wildlife Service 2005). A core area exists in CZ 1 (see Figure 12-1 in the Draft EIR/EIS). With these environmental commitments and other AMMs in place, Alternative 4A would not adversely affect vernal pool complex natural community. With these environmental commitments and AMMs in effect through the entire project period, Alternative 4A would not have an adverse effect on the vernal pool complex natural community.

***CEQA Conclusion*:** During the 14-year construction period, Alternative 4A could result in the direct loss of approximately 31 acres of vernal pool complex natural community due to construction of the water conveyance facility. The losses would occur immediately adjacent to Clifton Court Forebay.

The construction-related loss of this special-status natural community would represent a significant impact if it were not offset by avoidance and minimization measures and other actions associated with Alternative 4A environmental commitments. Loss of vernal pool complex natural community would be considered both a loss in acreage of a sensitive natural community and a loss of wetland as defined by Section 404 of the CWA. The protection of 150 acres of vernal pool/alkali seasonal wetland complex as part of Environmental Commitment 3 and the restoration of an estimated 34 acres of this community (including a commitment to have restoration keep pace with losses) as part of Environmental Commitment 9 during the construction of Alternative 4A facilities would offset this near-term loss, Resource Restoration and Performance Principles VP/AW1-VP/AW4. Typical project-level mitigation ratios (2:1 for protection and 1:1 for restoration) would indicate 62 acres of protection and 34 acres of restoration would be needed to offset (i.e., mitigate) the 31 acres of loss. Alternative 4A also includes AMM1, AMM2, AMM3, AMM4, AMM10, AMM12, and AMM30 to minimize impacts. Because of the offsetting protection and restoration activities and implementation of AMMs, impacts would be less than significant.

Impact BIO-22: Increased Frequency, Magnitude and Duration of Periodic Inundation of Vernal Pool Complex Natural Community

Alternative 4A would not result in periodic effects on the vernal pool complex natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-23: Modification of Vernal Pool Complex Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the project facilities and conservation lands that could affect vernal pool complex natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, reduced diversions from south Delta channels, and recreation activities in project preserves. These actions are associated with water conveyance facilities and Environmental Commitment 11. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not affect vernal pool complex natural community. This natural community does not exist within or adjacent to the major Sacramento River system and Delta waterways.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the Alternative 4A actions have the potential to require removal of adjacent vegetation and could entail earth and rock work adjacent to vernal pool complex habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to vernal pool complex habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces as part of *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to vernal pool complex natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to vernal pool complex areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial or aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the vernal pool complex natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

- *Recreation.* Alternative 4A would allow for certain types of recreation in and adjacent to vernal pool complexes in the reserve system. The activities could include wildlife and plant viewing and hiking. *Conservation Measure 11 Natural Communities Enhancement and Management* (on which Environmental Commitment 11 is based) describes this program and identifies applicable restrictions on recreation that might adversely affect vernal pool habitat (see Section 3.4.11, *Conservation Measure 11 Natural Communities Enhancement and Management*, of the Draft BDCP). Alternative 4A also includes an avoidance and minimization measure (AMM37) that further dictates limits on recreation activities that might affect vernal pools. Recreational trails would be limited to existing trails and roads. New trail construction would be prohibited within the vernal pool complex reserves. It is expected that most activities would be docent-led tours of reserves, minimizing adverse effects.

The various operations and maintenance activities described above could alter acreage of vernal pool complex natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities*

Enhancement and Management, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be greatly offset by restoration activities planned as part of *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, AMM10, AMM12, AMM37, and AMM30. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with vernal pool complex habitats by eliminating competitive, invasive species of plants.

NEPA Effects: Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in the vernal pool complex natural community within the study area. Therefore, there would be no adverse effect on this natural community.

CEQA Conclusion: The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of vernal pool complex natural community in the study area, and could create temporary increases in sedimentation or damage from recreational activity. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, AMM10, AMM12, AMM37, and AMM30 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would ensure that the acreage of this natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact on the vernal pool complex natural community.

Managed Wetland

The construction of water conveyance facilities for Alternative 4A would reduce the acreage of managed wetland currently found in the study area. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of this community (see Table 12-4A-8).

Creation of similar habitat values by restoring nontidal marsh as part of Environmental Commitment 10 would offset the losses of managed wetland. The net effect would be a decrease in the amount of managed wetland, but an increase in similar habitat value for special-status and common species as cultivated land is converted to nontidal marsh. Impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes. Refer to Impacts BIO-178 through BIO-183 in the *Shorebirds and Waterfowl* discussion in Section 4.3.8.4, *General Terrestrial Biology*, of this RDEIR/SDEIS for further consideration of the effects of removing managed wetland natural community.

Table 12-4A-8. Changes in Managed Wetland Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	22	29
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	22	29

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-24: Changes in Managed Wetland Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities would permanently eliminate an estimated 22 acres and temporarily affect 29 acres of managed wetland in the study area. This modification represents approximately 0.07% of the 70,798 acres of managed wetland that is mapped in the study area. This loss would occur over the course of Alternative 4A construction (14 year period). Alternative 4A does not include protection or restoration actions directed specifically at managed wetland, but protection and restoration of nontidal wetland (119 acres and 832 acres, respectively) would replace the habitat values lost for special-status wildlife and plant species.

The individual effects of the relevant environmental commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of the Alternative 4A water conveyance facilities would permanently remove 22 acres and temporarily remove 29 acres of managed wetland community. The permanent losses would occur near the northeast corner of Clifton Court Forebay for the construction of a permanent shaft location and a permanent access road on Bouldin Island. Temporary impacts would occur in association with temporary work areas for a concrete batch plant on Mandeville Island and a tunnel muck conveyor facility near Clifton Court Forebay (see the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS). Smaller losses would occur from construction of the temporary transmission lines that parallel the tunnel alignment northwest of the intermediate forebay and across the length of Mandeville Island.
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in filling of small amounts of managed wetland habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur on the edges of tidal perennial aquatic habitat, including levees and channel banks. Managed wetland adjacent to these tidal areas could be affected. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

The following paragraphs summarize the combined effects discussed above and describe other project environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During construction of the water conveyance facility, Alternative 4A would permanently remove 22 acres and temporarily remove 29 acres of managed wetland. These losses would occur in various locations, but the majority would occur in the vicinity of Clifton Court Forebay.

The construction loss of this special-status natural community would represent an adverse effect if it were not offset by the environmental commitments described in Section 4.1.2.3 *Environmental Commitments* of this RDEIR/SDEIS. Loss of managed wetland natural community would be considered both a loss in acreage of a sensitive natural community and potentially a loss of wetland as defined by Section 404 of the CWA. Many managed wetland areas are interspersed with small natural wetlands that would be regulated under Section 404. The restoration of 832 acres of nontidal wetland (Environmental Commitment 10) and protection and enhancement of 119 acres (Environmental Commitment 3) of nontidal wetland during the Alternative 4A construction period would offset the loss of the habitat values associated with managed wetland associated with water conveyance facilities managed wetland loss. Typical project-level mitigation ratios (1:1 for protection) would indicate 51 acres of protection would be needed to offset the 51 acres of loss associated with water conveyance facilities. The protection and restoration of nontidal marsh associated with Alternative 4A would fully compensate for the loss in habitat value associated with the managed wetland loss.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and an updated versions of AMM2 is described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

In spite of the managed wetland protection, restoration and avoidance measures contained in Alternative 4A, there would be a net reduction in the acreage of this special-status natural community. This would be an adverse effect when judged by the significance criteria used for analysis of terrestrial biological resources (see Section 12.3.1.2, *Significance Criteria for Terrestrial Biological Resources*, of the Draft EIR/EIS). However, the creation of nontidal marsh habitats (832 acres) that support similar ecological functions would offset this adverse effect. Also, there are other environmental commitments contained in the project (Environmental Commitment 3 and Environmental Commitment 11) that would improve management and enhance existing habitat values, further offsetting the effects of managed wetland loss on special-status terrestrial species and on common species that rely on this natural community for some life phase. As a result, there would be no adverse effect.

NEPA Effects: Alternative 4A would result in a loss of 51 acres of managed wetland within the study area; however, it would also protect and enhance 119 acres and restore 832 acres of habitat (nontidal wetland) with similar wildlife values. Therefore, there would be no adverse effect on managed wetland natural community.

CEQA Conclusion: During the project's construction time frame (14 years), Alternative 4A would permanently remove 22 acres and temporarily remove 29 acres of managed wetland through construction-related losses in habitat from water conveyance facilities activities. The majority of the loss would be in the vicinity of Clifton Court Forebay.

The construction loss of this special-status natural community would represent a significant impact if it were not offset by other the environmental commitments described in Section 4.1.2.3, *Environmental Commitments,* of this RDEIR/SDEIS. Loss of managed wetland natural community would be considered both a loss in acreage of a sensitive natural community and potentially a loss of wetland as defined by Section 404 of the CWA. The restoration of 832 acres and protection and enhancement of 119 acres of nontidal marsh as part of Environmental Commitment 3 and Environmental Commitment 10 during construction of Alternative 4A would fully offset the losses in habitat value associated with water conveyance facilities. Typical project-level mitigation ratios (1:1 for protection) would indicate 51 acres of protection would be needed to offset the 51 acres of loss associated with water conveyance facilities. The combined protection and restoration proposed for nontidal marsh would offset the loss of wildlife habitat value. This acreage would significantly exceed the number of acres of managed wetland lost.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and an updated version of AMM2 is described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

In spite of the nontidal marsh protection and restoration contained in Alternative 4A, there would be a net reduction in the acreage of managed wetland special-status natural community. This would be a significant impact when judged by the significance criteria listed in Section 12.3.1.2, *Significance Criteria for Terrestrial Biological Resources*, of the Draft EIR/EIS. However, there are other environmental commitments contained in the project (Environmental Commitment 3, Environmental Commitment 10 and Environmental Commitment 11) that would improve management and enhance existing habitat values and expand habitat with similar values, further offsetting the impacts of managed wetland loss on special-status terrestrial species and on common species that rely on this natural community for some life phase. As a result, there would be a less-than-significant impact.

Impact BIO-25: Increased Frequency, Magnitude and Duration of Periodic Inundation of Managed Wetland Natural Community

Alternative 4A would not result in periodic effects on the managed wetland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-26: Modification of Managed Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the project facilities and conservation lands that could affect managed wetland natural community in the study area. The ongoing actions include changes in operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, reduced diversions from south Delta channels, and recreational use of reserve areas. These actions are associated with water conveyance facilities and Environmental Commitment 11. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not result in the reduction in acreage of the managed wetland natural community in the study area. Flow levels in the upstream rivers would not change to the degree that water levels in adjacent managed wetlands would be altered. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in the managed wetland community downstream of these diversions. The majority of the managed wetlands below the diversions is not directly connected to the rivers. Reduced diversions from the south Delta channels would not create a reduction in this natural community.
- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with Alternative 4 actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in managed wetland habitats. This activity could lead to increased soil erosion, turbidity and runoff entering managed wetlands. These activities would be subject to normal erosion, turbidity and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within managed wetland habitats would require use of sediment and turbidity barriers, soil stabilization and revegetation of disturbed surfaces. Proper implementation of these measures would avoid permanent adverse effects on this community.
- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to managed wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the community, or direct discharge of herbicides to managed wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in aquatic and terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the managed wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.
- *Recreation.* The project would allow hunting, fishing and hiking in managed wetland reserve areas. *Conservation Measure 11 Natural Communities Enhancement and Management* (on which Environmental Commitment 11 is based) describes this program and identifies applicable restrictions on recreation that might adversely affect managed wetland habitat (see Section 3.4.11, *Conservation Measure 11 Natural Communities Enhancement and Management*, of the Draft BDCP). The project also includes an avoidance and minimization measure (AMM37) that further dictates limits on recreation activities that might affect this natural community. Hunting would be the dominant activity in fall and winter months, while fishing and hiking would be allowed in non-hunting months.

The various operations and maintenance activities described above could alter acreage of managed wetland natural community in the study area through facilities maintenance, vegetation management, and recreation. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by restoration activities planned as part of *Environmental Commitment 10 Nontidal Marsh Restoration* and protection and restoration actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration*. Recreation activity effects would be minimized by AMM37 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). The management actions associated with levee repair and control of invasive plant species would also result in a long-term benefit to the species associated with managed wetland habitats by improving water movement.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in acreage of managed wetland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of managed wetland natural community in the study area, and could create temporary increases in turbidity and sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Hunting could intermittently reduce the availability of this community to special-status and common wildlife species. Implementation of environmental commitments and AMM2, AMM4, AMM5, and AMM37 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural*

Communities Enhancement and Management, would create positive effects, including improved water movement in and adjacent to these habitats. Long-term restoration activities associated with *Environmental Commitment 10 Nontidal Marsh Restoration* and protection and restoration actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would greatly expand the ecological functions of this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this sensitive natural community within the study area. Therefore, there would be a less-than-significant impact on the managed wetland natural community.

Other Natural Seasonal Wetland

The other natural seasonal wetlands natural community encompasses all the remaining natural (not managed) seasonal wetland communities other than vernal pools and alkali seasonal wetlands. These areas mapped by CDFW (Hickson and Keeler-Wolf 2007) and ICF biologists (the western area of additional analysis; see Figure 12-1 in the Draft EIR/EIS) consist of seasonally ponded, flooded, or saturated soils dominated by grasses, sedges, or rushes. The largest segments of this community in the study area are located along the Cosumnes River northeast of Thornton, and in the western extension of the study area northwest of Rio Vista. Most of the smaller mapped areas are located in the Suisun Marsh ROA on the western edge of the Montezuma Hills and in the interior of the Potrero Hills. There are also other natural seasonal wetlands mapped along Old River and Middle River in CZ 7. The only project conservation activity that would potentially affect this natural community is the channel margin enhancement measure (Environmental Commitment 6) (see Table 12-4A-9).

Table 12-4A-9. Changes in Other Natural Seasonal Wetland Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	0	0
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	UNK	UNK
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	0	0

UNK = unknown
[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-27: Modification of Other Natural Seasonal Wetland Natural Community as a Result of Implementing Alternative 4A

Because specific locations for implementing Alternative 4A's *Environmental Commitment 6 Channel Margin Enhancement* have not been identified, it is not known whether the creation of channel margin habitats along study area streams would remove other natural seasonal wetland community habitats. Several small patches of other natural seasonal wetland natural community are mapped along study area waterways. Because the areas of this community are small, and because their habitat values are also provided by other seasonal wetlands in the study area, the small potential that other natural seasonal wetland would be removed by channel margin enhancement is not expected to create an adverse effect on the special-status species that use this habitat.

***NEPA Effects*:** Alternative 4A environmental commitments would not adversely affect other natural seasonal wetland natural community because of the small potential for this community to be displaced.

***CEQA Conclusion*:** This community would not be significantly impacted because of the small potential for channel margin enhancement to displace other natural seasonal wetland acreage. There would be no substantial impact on the community. The impact would be less than significant.

Impact BIO-28: Modification of Other Natural Seasonal Wetland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the project facilities and conservation lands that could affect other natural seasonal wetland natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not affect other natural seasonal wetland natural community. The small areas mapped in the study area are not in or adjacent to streams that would experience changes in water levels as a result of these operations.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with the project actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in other natural seasonal wetland habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within other natural seasonal wetland habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces as required by *AMM10 Restoration of Temporarily Affected Natural Communities*. Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Communities Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to the other natural seasonal wetland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to wetland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of the project to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial or aquatic environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Habitat enhancement.* The project includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the other natural seasonal wetland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of other natural seasonal wetland natural community in the study area. Activities could introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the project, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be minor when compared to the restoration activities planned as part of *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, and AMM10. The vernal pool/alkali seasonal wetland complex environmental commitment (Environmental Commitment 9) includes restoration of 34 acres of seasonal wetlands with similar ecological values as the other natural seasonal wetland community. The management actions associated with control of invasive plant species would also result in a long-term benefit to the species associated with other natural seasonal wetland habitats by eliminating competitive, invasive species of plants.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be no adverse effect on the other natural seasonal wetland natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of other natural seasonal wetland natural community in the study area, and could create temporary increases in sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and*

Management, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Long-term restoration activities associated with *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* and protection actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would ensure that the ecological values provided by this small natural community would not decrease in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact on the other natural seasonal wetland natural community.

Grassland

Construction, operation, maintenance and management associated with Alternative 4A would have no long-term adverse effects on the habitats associated with the grassland natural community. Initial development and construction of water conveyance facilities would result in both permanent and temporary removal of this community (see Table 12-4A-10). Implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles over the term of the project to benefit the grassland natural community.

- Restore grasslands to connect fragmented patches of protected grassland and to provide upland habitat (Resource Restoration and Performance Principle G1).
- Restore and sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical sites (Resource Restoration and Performance Principle G3).
- Increase the extent, distribution, and density of native perennial grasses intermingled with other native species, including annual grasses, geophytes, and other forbs (Resource Restoration and Performance Principle G4).
- Maintain and enhance aquatic features in grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for covered amphibian and aquatic reptile species (Resource Restoration and Performance Principle G7).
- Protect grassland on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit (Resource Restoration and Performance Principle G8).
- Create or protect high-value upland giant garter snake habitat adjacent to the nontidal perennial aquatic habitat being restored and created (Resource Restoration and Performance Principle G9).
- Protect 647 acres of grassland in the Byron Hills area (Resource Restoration and Performance Principle G10).

As explained below, with the protection, restoration and enhancement of the amounts of habitat included in the project, in addition to implementation of AMMs, impacts on this natural community would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-10. Changes in Grassland Natural Community Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Water Conveyance Facilities	506	151
Environmental Commitment 4[a]	0	0
Environmental Commitment 7[a]	0	0
Environmental Commitment 10[a]	0	0
TOTAL IMPACTS	506	151

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-29: Changes in Grassland Natural Community as a Result of Implementing Alternative 4A

Construction and land grading activities that would accompany the implementation of water conveyance facilities would permanently eliminate an estimated 506 acres and temporarily remove 151 acres of grassland natural community in the study area. These modifications represent approximately 0.8% of the 78,047 acres of the community that is mapped in the study area.

The individual effects of each relevant environmental commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of the Alternative 4A water conveyance facilities would permanently remove 506 acres and temporarily remove 151 acres of grassland natural community. The permanent losses would occur where Intakes 2, 3, and 5 encroach on the Sacramento River's east bank between Clarksburg and Courtland; the rerouting of SR 160; construction of the intermediate forebay; a reusable tunnel material storage site on Bouldin Island; at a permanent pipeline shaft access road on the east side of Bacon Island; and at various permanent facility sites around Clifton Court Forebay, including a reusable tunnel material storage site, new canal connections from Clifton Court Forebay to the two aqueducts, and in the forebay expansion area on the south side of the existing forebay. Most of the permanent losses would be of ruderal and herbaceous grassland areas that exist in very narrow bands adjacent to waterways, levees and roads (see the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS). Some of the grassland lost at the sites of new canals south of Clifton Court Forebay is composed of larger stands of ruderal and herbaceous vegetation and California annual grassland. The temporary losses would be associated with construction of the temporary access roads along the Sacramento River; at work areas and barge offloading facility construction sites at the south end of Bouldin Island, at the north end of Bacon Island, and the south end of Venice Island and at the northwest corner of Victoria Island; at temporary access road sites on the northern and southern ends of Bacon Island and the northwest corner of Victoria Island; at temporary work areas on Mandeville and Bacon Islands; at the operable barrier construction site at the head of Old River, and various locations around Clifton Court Forebay. These losses would take place during the Alternative 4A construction period.
- The construction activity associated with water conveyance facilities also has the potential to lead to increased nitrogen deposition in grassland habitats in the vicinity of Clifton Court Forebay. A significant number of cars, trucks, and land grading equipment involved in construction in and around the forebay would emit small amounts of atmospheric nitrogen from

fuel combustion; this material could be deposited in sensitive grassland areas that are located west of the major construction areas at Clifton Court Forebay. Nitrogen deposition can pose a risk of adding a fertilizer to nitrogen-limited soils and their associated plants. Nonnative invasive species can be encouraged by the added nitrogen available. Appendix 5.J, Attachment 5J.A, *Construction-Related Nitrogen Deposition on BDCP Natural Communities*, of the Draft BDCP addresses this issue in detail. It has been concluded that this potential deposition would pose a low risk of changing the grassland in and adjacent to the construction areas because the construction would contribute a negligible amount of nitrogen to regional projected emissions and the existing grassland is dominated by nonnative invasive species of plants. Also, the construction at Clifton Court Forebay would occur primarily downwind of the natural community. No adverse effect is expected.

- *Environmental Commitment 3 Natural Community Protection and Restoration*: Approximately 1,060 acres of grassland natural community would be protected to restore and enhance aquatic and upland habitat for a number of amphibian, reptile and mammal special-status species.
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin habitat enhancement could result in removal of small amounts of grassland natural community along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where grassland habitat stringers exist, including along levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.
- *Environmental Commitment 8 Grassland Natural Community Restoration:* Up to 1,070 acres of grassland natural community would be restored primarily on the fringes of the Delta, where upland areas merge with Delta wetland and agricultural lands. Restoration would focus on CZ 1, CZ 8, and CZ 11, as proposed by the Draft BDCP.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Natural communities enhancement and management would include a wide range of activities designed to improve habitat conditions in restored and protected lands associated with the project. This measure also promotes sound use of pesticides, vector control activities, invasive species control and fire management in preserve areas. To improve the public’s ability to participate in recreational activities in and adjacent to restored and protected habitats, a system of trails is proposed. The location and extent of this system are not yet known; however, it is assumed that the trail system would be located entirely in grassland habitats.

The following paragraphs summarize the combined effects discussed above and describe other project environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

During the project’s construction timeframe, Alternative 4A would affect the grassland natural community through water conveyance facilities construction losses (506 acres permanent and 151 acres temporary). These losses would occur along the eastern bank of the Sacramento River at intake sites, adjacent to Clifton Court Forebay associated with forebay expansion, and at various permanent and temporary construction sites for barge unloading facilities and tunnel shaft sites through the central Delta.

The construction losses of this natural community would not represent an adverse effect based on the significance criteria used for this section because grassland is not considered a special-status or sensitive natural community. Most Central Valley grasslands are dominated by nonnative annual grasses and herbs. However, the importance of grassland as a habitat that supports life stages of numerous special-status plants and wildlife is well documented (see Chapter 3, *Conservation Strategy*, of the Draft BDCP). The significance of losses in grassland habitat is, therefore, discussed in more detail in species analyses in Section 4.3.8.2, *Wildlife Species*, of the RDEIR/SDEIS. The combination of restoring 1,070 acres grassland (Environmental Commitment 8), protecting and enhancing 1,060 acres (Environmental Commitment 3) of grassland natural community during the construction phase of the project (14 years), and the commitment to restore temporarily affected grassland (151 acres) to its pre-project condition within one year of completing construction as required by *AMM10 Restoration of Temporarily Affected Natural Communities*, would offset this construction loss, avoiding any loss in the value of this habitat for special-status species. The protected and restored habitat would be managed and enhanced to benefit special-status and common wildlife species (Environmental Commitment 3 and Environmental Commitment 11). Typical project-level mitigation ratios (2:1 for protection) would indicate that 1,314 acres of protection would be needed to offset (i.e., mitigate) the 657 acres of combined permanent and temporary loss. The combination of protection, along with the enhancement and management associated with Environmental Commitment 3 and Environmental Commitment 11 contained in the project, is designed to avoid a temporal lag in the value of grassland habitat available to sensitive species.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats at work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Implementation of Alternative 4A would result in the loss of 0.8% of the grassland natural community in the study area. These losses (506 acres of permanent and 151 acres of temporary loss) would be associated with construction of the water conveyance facilities.

NEPA Effects: By the end of the project's construction time frame, a total of 1,060 acres of grassland would be protected (Environmental Commitment 3) and 1,070 acres of grassland would be restored (Environmental Commitment 8), which would be guided by Resource Restoration and Performance Principles G1, G3, G4, and G7–G10. The protection would occur primarily in the west Delta and Clifton Court Forebay areas. Temporarily affected grassland would also be restored following construction activity as described in AMM10. There would be a permanent loss of 506 acres of grassland in the study area. However, the combination of restoration, protection and enhancement of grassland associated with Alternative 4A would replace the habitat lost and improve the habitat value of this community in the study area; there would not be an adverse effect on the grassland natural community.

CEQA Conclusion: Alternative 4A would result in the loss of approximately 657 acres of grassland natural community due to construction of the water conveyance facilities. The construction losses would occur along the eastern bank of the Sacramento River at intake sites, adjacent to Clifton Court Forebay associated with forebay expansion, and at various permanent and temporary construction sites for barge unloading facilities and tunnel shaft sites through the central Delta.

The construction losses of this natural community would not represent a significant impact based on the significance criteria used for this section because grassland is not considered a special-status or sensitive natural community. Nonetheless, these losses would be offset by planned restoration of 151 acres of temporarily affected grassland, the restoration of 1,070 acres of grassland, and protection of 1,060 acres of grassland natural community scheduled for the 14-year construction period of Alternative 4A, which would be guided by Resource Restoration and Performance Principles G1, G3, G4, and G7–G10. Also, AMM1, AMM2, AMM6, and AMM7 would be implemented to minimize impacts. Because of these offsetting restoration and protection activities and AMMs, impacts would be less than significant. Typical project-level mitigation ratios (2:1 for protection) would indicate that 1,314 acres of protection would be needed to offset (i.e., mitigate) the 657 acres of loss. The combined protection (1,060 acres) and restoration (1,070 acres) of 2,130 acres of grassland would more than offset the losses from the project. The combination of two approaches (protection and restoration) contained in the project environmental commitments and avoidance and minimization measures is designed to avoid a temporal lag in the value of grassland habitat available to special-status species. The protection and restoration would be initiated at the beginning of Alternative 4A implementation to minimize any time lag in the availability of this habitat to special-status species. Therefore, there would be a less-than-significant impact on the grassland natural community.

Impact BIO-30: Increased Frequency, Magnitude and Duration of Periodic Inundation of Grassland Natural Community

Alternative 4A would not result in periodic effects on grassland natural community type.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact BIO-31: Modification of Grassland Natural Community from Ongoing Operation, Maintenance and Management Activities

Once the physical facilities associated with Alternative 4A are constructed and the stream flow regime associated with changed water management is in effect, there would be new ongoing and periodic actions associated with operation, maintenance and management of the Alternative 4A facilities and conservation lands that could affect grassland natural community in the study area. The ongoing actions include modified operation of upstream reservoirs, the diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels. These actions are associated with water conveyance facilities. The periodic actions would involve access road and conveyance facility repair, vegetation management at the various water conveyance facilities and habitat restoration sites (Environmental Commitment 11), levee repair and replacement of levee armoring, channel dredging, and habitat enhancement in accordance with natural community management plans. The potential effects of these actions are described below.

- *Modified river flows upstream of and within the study area and reduced diversions from south Delta channels.* Changes in releases from reservoirs upstream of the study area, increased diversion of Sacramento River flows in the north Delta, and reduced diversions from south Delta channels (associated with Operational Scenario H) would not result in the permanent reduction in acreage of grassland natural community in the study area. Flow levels in the upstream rivers would not change such that the acreage of this community would be reduced on a permanent basis. The grassland along rivers upstream of planned north Delta diversions is primarily ruderal vegetation on levee banks and is dependent on winter and spring rains for germination and growth rather on than river levels. Similarly, increased diversions of Sacramento River flows in the north Delta would not result in a permanent reduction in grassland natural community downstream of these diversions. The reductions in flows below the intakes would occur primarily in the wet months when the existing nonnative annual grasslands along river levees are dormant, and like upstream grassland, this community is dependent on winter and spring rains for germination and growth in the winter and spring months, not on river stage. Anticipated small changes in river salinity in the west Delta and Suisun Marsh would not create a substantial change in grassland acreage in these areas. Reduced diversions from south Delta channels would not create a reduction in this natural community.

- *Access road, water conveyance facility and levee repair.* Periodic repair of access roads, water conveyance facilities and levees associated with project actions have the potential to require removal of adjacent vegetation and could entail earth and rock work in grassland habitats. This activity could lead to increased soil erosion and runoff entering these habitats. These activities would be subject to normal erosion and runoff control management practices, including those developed as part of *AMM2 Construction Best Management Practices and Monitoring* and *AMM4 Erosion and Sediment Control Plan.* Any vegetation removal or earthwork adjacent to or within grassland habitats would require use of sediment barriers, soil stabilization and revegetation of disturbed surfaces (*AMM10 Restoration of Temporarily Affected Natural Communities*). Proper implementation of these measures would avoid permanent adverse effects on this community.

- *Vegetation management.* Vegetation management, in the form of physical removal and chemical treatment, would be a periodic activity associated with the long-term maintenance of water conveyance facilities and restoration sites (*Environmental Commitment 11 Natural Community Enhancement and Management*). Use of herbicides to control nuisance vegetation could pose a long-term hazard to grassland natural community at or adjacent to treated areas. The hazard could be created by uncontrolled drift of herbicides, uncontrolled runoff of contaminated stormwater onto the natural community, or direct discharge of herbicides to grassland areas being treated for invasive species removal. Environmental commitments and *AMM5 Spill Prevention, Containment, and Countermeasure Plan* have been made part of Alternative 4A to reduce hazards to humans and the environment from use of various chemicals during maintenance activities, including the use of herbicides. These commitments, including the commitment to prepare and implement spill prevention, containment, and countermeasure plans and stormwater pollution prevention plans, are described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS. Best management practices, including control of drift and runoff from treated areas, and use of herbicides approved for use in terrestrial environments would also reduce the risk of affecting natural communities adjacent to water conveyance features and levees associated with restoration activities.

- *Channel dredging.* Long-term operation of the Alternative 4A intakes on the Sacramento River would include periodic dredging of sediments that might accumulate in front of intake screens. The dredging could occur adjacent to grassland natural community. This activity should not permanently reduce the acreage of grassland natural community because it is periodic in nature; the grassland in the vicinity of the proposed intakes is ruderal grasses and herbs with low habitat value.

- *Habitat enhancement.* The Alternative 4A includes a long-term management element for the natural communities within the study area (Environmental Commitment 11). For the grassland natural community, a management plan would be prepared that specifies actions to improve the value of the habitats for covered species. Actions would include control of invasive nonnative plant and animal species, fire management, restrictions on vector control and application of herbicides, and maintenance of infrastructure that would allow for movement through the community. The enhancement efforts would improve the long-term value of this community for both special-status and common species.

The various operations and maintenance activities described above could alter acreage of grassland natural community in the study area through changes in flow patterns and changes in periodic inundation of this community. Activities could also introduce sediment and herbicides that would reduce the value of this community to common and sensitive plant and wildlife species. Other periodic activities associated with the Plan, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would be undertaken to enhance the value of the community. While some of these activities could result in small changes in acreage, these changes would be offset by protection and enhancement activities planned as part of *Environmental Commitment 3 Natural Communities Protection and Restoration*, or minimized by implementation of AMM2, AMM4, AMM5, and AMM10. The management actions associated with levee repair, periodic dredging and control of invasive plant species would also result in a long-term benefit to the species associated with grassland habitats by improving water movement in adjacent waterways and by eliminating competitive, invasive species of plants.

***NEPA Effects*:** Ongoing operation, maintenance and management activities associated with Alternative 4A would not result in a net permanent reduction in grassland natural community within the study area. Therefore, there would be no adverse effect on this natural community.

***CEQA Conclusion*:** The operation and maintenance activities associated with Alternative 4A would have the potential to create minor changes in total acreage of grassland natural community in the study area, and could create temporary increases sedimentation. The activities could also introduce herbicides periodically to control nonnative, invasive plants. Implementation of environmental commitments and AMM2, AMM4, AMM5, and AMM10 would minimize these impacts, and other operations and maintenance activities, including management, protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* and *Environmental Commitment 11 Natural Communities Enhancement and Management*, would create positive effects, including reduced competition from invasive, nonnative plants in these habitats. Protection and enhancement actions associated with *Environmental Commitment 3 Natural Communities Protection and Restoration* would increase the value of this natural community in the study area. Ongoing operation, maintenance and management activities would not result in a net permanent reduction in this natural community within the study area. Therefore, there would be a less-than-significant impact on the grassland natural community.

Inland Dune Scrub

The inland dune scrub natural community is composed of vegetated, stabilized sand dunes associated with river and estuarine systems. In the study area, the inland dune scrub community consists of remnants of low-lying ancient stabilized dunes related to the Antioch Dunes formation located near the town of Antioch (CZ 10; see Figure 12-1 in the Draft EIR/EIS). While inland dune scrub is within the study area, none of the Alternative 4A actions is expected to affect this community.

Cultivated Lands

Cultivated lands is the major land cover type in the study area (487,106 acres, see Table 12-1 in the Draft EIR/EIS). The Delta, the Yolo Bypass and the Cache Slough drainage are dominated by various types of agricultural activities, with crop production the dominant element (see Figure 12-1 in the Draft EIR/EIS). Major crops and cover types in agricultural production include grain and hay crops (wheat, oats and barley), field crops (corn, beans and safflower), truck crops (tomatoes, asparagus and melons), pasture (alfalfa, native and nonnative pasture), rice, orchards, and vineyards. Tables 12-2 and 12-3 in the Draft EIR/EIS list special-status wildlife species supported by cultivated lands.

The effects of Alternative 4A on cultivated lands are discussed from various perspectives in this document. Section 4.3.10, *Agricultural Resources*, of the RDEIR/SDEIS includes a detailed analysis of cropland conversion as it relates to agricultural productivity. Many of the discussions of individual terrestrial plant and wildlife species in this section also focus on the relevance of cultivated land loss. Because cultivated lands is not a natural community and because the effects of its loss are captured in the individual species analyses, there is no separate analysis of this land cover type presented here. For Alternative 4A, the total loss (permanent and temporary) is estimated to be 7,314 acres. The majority of the permanent loss would be associated with tidal marsh restoration (Environmental Commitment 4; 54 acres), riparian natural community restoration (Environmental Commitment 7; 251 acres), nontidal marsh restoration (Environmental Commitment 10; 832 acres), and construction of the modified tunnel and associated water conveyance facilities (permanent removal of 3,768 acres and temporary removal 1,339 acres of cultivated lands). Of the 7,314 acres, 7,091 would be made up of croplands and the other 223 acres would be non-cropland agricultural areas.

Developed Lands

Additional lands in the study area that were not designated with a natural community type have been characterized as developed lands (90,660 acres). Developed lands include lands with residential, industrial, and urban land uses, as well as landscaped areas, riprap, road surfaces and other transportation facilities (see Figure 12-1 in the Draft EIR/EIS and the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS). Developed lands support some common plant and wildlife species, whose abundance and species richness vary with the intensity of development. One special-status species, the giant garter snake, is closely associated with a small element of developed lands; specifically, embankments and levees near water that are covered with riprap provide giant garter snake habitat.

As with cultivated lands, no effort has been made to analyze the effects of Alternative 4A activities on this land cover type because it is not a natural community. The effects of its conversion are discussed in Section 4.3.9, *Land Use*, of the RDEIR/SDEIS. Where the loss of developed lands may affect individual special-status species or common species, the impact analysis is contained in that species discussion.

Wildlife Species

Vernal Pool Crustaceans

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the environmental commitments, on vernal pool crustaceans (California linderiella, Conservancy fairy shrimp, longhorn fairy shrimp, midvalley fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp). The habitat model used to assess effects for the vernal pool crustaceans consists of: vernal pool complex, which consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly affected by agricultural or development practices; alkali seasonal wetlands in CZ 8; and degraded vernal pool complex, which consists of low-value ephemeral habitat ranging from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. For the purpose of the effects analysis, vernal pool complex is categorized as high-value for vernal pool crustaceans and degraded vernal pool complex is categorized as low-value for these species. Alkali seasonal wetlands in CZ 8 were included in the model as high-value habitat for vernal pool crustaceans. Also included as low-value habitat for vernal pool crustaceans are areas along the eastern boundary of CZ 11 that are mapped as vernal pool complex because they flood seasonally and support typical vernal pool plants, but which do not include topographic depressions that are characteristic of vernal pool crustacean habitat.

Alternative 4A would result in permanent losses (see Table 12-4A-11) and indirect conversions of vernal pool crustacean modeled habitat. Alternative 4A would also include the following environmental commitments and associated Resource Restoration and Performance Principles to benefit vernal pool crustaceans.

- Restore vernal pool complex and alkali seasonal wetland suitable for vernal pool crustaceans to achieve no net loss of wetted acreage (Environmental Commitment 9, Resource Restoration and Performance Principle VP/AW2).
- Increase size and connectivity of protected vernal pool complexes and alkali seasonal wetlands in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW3).
- Protect 150 acres of existing vernal pool complex (Environmental Commitment 3) in the greater Byron Hills area, primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principle VP/AW1).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principle VP/AW4).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs, impacts on vernal pool crustaceans would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-11. Changes in Vernal Pool Crustacean Modeled Habitat Associated with Alternative 4A (acres)[a]

Project Component	Habitat Type	Permanent	Temporary	Indirect
Water Conveyance Facilities	High-value	24	1	41
	Low-value	7	2	0
Total Impacts Water Conveyance Facilities		**31**	**3**	**41**
Environmental Commitments 4, 6–7, 9–11[a]	High-value	0	0	0
	Low-value	0	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**	**0**
TOTAL IMPACTS		**31**	**3**	**41**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-32: Loss or Conversion of Habitat for and Direct Mortality of Vernal Pool Crustaceans

Alternative 4A would result in the direct permanent and temporary loss combined of 34 acres of modeled vernal pool crustacean habitat from conveyance facilities construction. In addition, water conveyance facilities construction that causes hydrologic changes could result in the indirect conversion of an additional 41 acres of high-value vernal pool crustacean habitat. Construction of the water conveyance facilities may result in the modification of hardpan and changes to the perched water table, which could lead to alterations in the rate, extent, and duration of inundation of nearby vernal pool crustacean habitat. USFWS typically considers construction within 250 feet of vernal pool crustacean habitat to constitute a possible conversion of crustacean habitat unless more detailed information is provided to further refine the limits of any such effects. For the purposes of this analysis, the 250-foot buffer was applied to the water conveyance facilities work areas where surface and subsurface disturbance activities would take place. Habitat enhancement and management activities (Environmental Commitment 11), which include disturbance or removal of nonnative vegetation, could result in local adverse habitat effects.

Alternative 4A would also result in impacts on critical habitat for vernal pool fairy shrimp (195 acres). These impacts would be from water conveyance facilities construction west of Clifton Court Forebay. Of the 195 acres of vernal pool fairy shrimp critical habitat, only 8 acres consist of modeled habitat for vernal pool crustaceans, with the remainder consisting of cultivated lands.

As specified in *AMM12 Vernal Pool Crustaceans* and *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, restoration projects are designed such that no more than a total of 10 wetted acres of vernal pool crustacean habitat are permanently lost. AMM12 would also ensure that no more than 20 wetted acres of vernal pool crustacean habitat are indirectly affected by alterations to hydrology resulting from adjacent BDCP covered activities, in particular tidal restoration. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that temporary transmission lines avoid removal of wetted acres of vernal pools and alkali seasonal wetlands wetted acres of aquatic habitats to the maximum extent practicable. The term wetted acres refers to an area that would be defined by the three parameter wetland delineation method used by the U.S. Army Corps of Engineers to determine the limits of a wetland, which involve an evaluation of wetland soil, vegetation, and hydrology characteristics. This acreage differs from vernal pool complex acreages in that a vernal pool complex is composed of individual wetlands (vernal pools) and those upland areas that are in between and surrounding them, which provide the supporting hydrology (surface runoff and groundwater input), organic and nutrient inputs, and refuge for the terrestrial phase of some vernal pool species.

A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent and temporary combined loss of approximately 34 acres of vernal pool crustacean habitat, composed of 25 acres of high-value and 9 acres of low-value habitat (Table 12-4A-11). The construction of the conveyance facilities would result in the permanent loss of habitat associated with a vernal pool fairy shrimp CNDDB occurrence as a result of the expansion of Clifton Court Forebay. In addition, conveyance facility construction could result in the indirect conversion of 41 acres of high-value vernal pool crustacean habitat in the vicinity of Clifton Court Forebay. The indirect effects would result from the construction of permanent transmission lines, from the storage of RTM, and permanent access roads. There are records of vernal pool fairy shrimp and midvalley fairy shrimp in the vicinity of these areas (California Department of Fish and Game 2013). Alternative 4A would also result in the permanent loss of 195 acres of critical habitat for vernal pool fairy shrimp. The permanent impacts on critical habitat are associated with the RTM disposal areas and an associated access road west of Clifton Court Forebay (177 acres), a new transmission line (15 acres), and upgrades to a permanent access road just south of this area (3 acres). However, as discussed above, only 8 acres of this critical habitat consists of modeled habitat for vernal pool crustaceans and the remaining critical habitat consist of cultivated lands that are not suitable for the species. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that transmission lines are designed to avoid removal of aquatic habitats to the maximum extent feasible.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* The project's restoration/creation of vernal pools to achieve no net loss and the protection of 150 acres of vernal pool complex would benefit vernal pool crustaceans. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily affect vernal pool crustacean habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on vernal pool crustacean habitat and are expected to result in overall improvements to and maintenance of vernal pool crustacean habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

The proposed conservation efforts have been evaluated to determine whether they would provide sufficient habitat protection and restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA and would be less than significant under CEQA. Table 12-4A-11 lists the impacts on modeled vernal pool crustacean habitat that is based on the natural community mapping done within the study area. Table 12-4A-12 was prepared to further analyze the project's effects on vernal pool crustaceans using wetted acres of habitat in order to compare the effects of this alternative with the effect limits established in *AMM12 Vernal Pool Crustaceans*, which are measured in wetted acres of habitat. Wetted acres were estimated by using the Draft BDCP's assumption that restored vernal pool complexes would have a 15% density of vernal pools (i.e., of 100 acres of vernal pool complex 15 acres would constitute vernal pools and the remaining 85 acres supporting uplands). Based on an informal evaluation of aerial photographs of the project area it is likely that the actual densities within the project area are approximately 10%, but the 15% density value was chosen as a conservative estimate for determining effects.

Table 12-4A-12. Estimated Effects on Wetted Vernal Pool Crustacean Habitat under Alternative 4A (acres)

	Direct Loss	Indirect Conversion
AMM12 Impact Limit	10	20
Water Conveyance Facilities[a]	5.1	6.2
Environmental Commitments 4, 6–7, 9–11	0	0
Total	**5.1**	**6.2**

[a] These acreages were generated by assuming that the modeled habitat identified in Table 12-4A-12 has densities of wetted habitat at 15%. The direct effects numbers include permanent and temporary impacts.

Typical NEPA and CEQA project-level mitigation ratios for loss of vernal pools affected by Alternative 4A would be 1:1 for restoration and 2:1 for protection. Typically, indirect conversion impacts are mitigated by protecting vernal pools at a 2:1 ratio. Using these typical ratios would indicate that 5.1 wetted acres of vernal pool crustacean habitat (or 34 acres of vernal pool complex) should be restored and 22.6 wetted acres (or 150 acres of vernal pool complex) protected to mitigate Alternative 4A's direct and indirect effects on vernal pool crustacean habitat. With the implementation of AMM30 the effects on aquatic habitat would be avoided to the maximum extent feasible during the designing of the transmission line west of Clifton Court Forebay.

Project proponents would commit to protecting 150 acres of vernal pool complex by protecting at least 2 wetted acres of vernal pools for each wetted acre directly or indirectly affected. Alternative 4A has also committed to restoring/creating vernal pools and alkali seasonal wetlands such that there is no net loss of vernal pool acreage. The final amount of restoration would be determined during implementation based on the following criteria.

- If restoration is completed (i.e., restored natural community meets all success criteria) prior to impacts, then 1.0 wetted acre of vernal pools and/or alkali seasonal wetlands suitable for the species would be restored for each wetted acre directly affected (1:1 ratio).
- If restoration takes place concurrent with impacts (i.e., restoration construction is completed, but restored habitat has not met all success criteria, prior to impacts occurring), then 1.5 wetted acres of vernal pools and/or alkali seasonal wetlands suitable for the species would be restored for each wetted acre directly affected (1.5:1 ratio).

The protection and restoration efforts would include the following the Resource Restoration and Performance Principles.

- Protect existing vernal pool complex in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principle VP/AW1).
- Increase size and connectivity of protected vernal pool complexes and alkali seasonal wetlands in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW2).

- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM12 Vernal Pool Crustaceans, AMM30 Transmission Line Design and Alignment Guidelines,* and *AMM37 Recreation*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of vernal pool crustacean habitat under Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management and enhancement would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4, and by AMM1–AMM6, AMM10, AMM12, AMM30, and AMM37, which would be in place throughout the period of construction and operations. Considering these commitments, losses and conversion of vernal pool crustacean habitat under Alternative 4A would not be an adverse effect.

CEQA Conclusion: Alternative 4A would have significant impact on vernal pool crustacean habitat as a result of habitat modification of a special-status species and potential for direct mortality in the absence of the protection and restoration of habitat. However, the project proponents have committed to habitat protection, restoration, management and enhancement associated with Environmental Commitment 3, Environmental Commitment 9, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4 and effects would be avoided and minimized by AMM1–AMM6, AMM10, AMM12, AMM30, and AMM37, which would be in place throughout the period of construction and operations. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of vernal pool crustaceans. Therefore, Alternative 4A would have a less-than-significant impact on vernal pool crustaceans under CEQA.

Impact BIO-33: Indirect Effects of Alternative 4A on Vernal Pool Crustaceans

Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly affect vernal pool crustaceans and their habitat in the vicinity of construction and restoration areas, and maintenance activities. Ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into this habitat. Vernal pool crustaceans and their habitat could be periodically indirectly affected by maintenance activities at water conveyance facilities. Embankment maintenance activities around Clifton Court Forebay could result in the inadvertent discharge of sediments and hazardous materials into vernal pool crustacean habitat that occurs along the southern and western boundaries of the forebays.

NEPA Effects: Water conveyance facilities construction and restoration activities could indirectly affect vernal pool crustaceans and their habitat in the vicinity of construction areas. These potential effects would be avoided and minimized through AMM1–AMM6, AMM10, and AMM12, which would be in effect throughout the period of construction and operations. The indirect effects of Alternative 4A on vernal pool crustaceans and their habitat would not be adverse under NEPA.

***CEQA Conclusion*:** Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly impact vernal pool crustaceans and their habitat in the vicinity of these work areas. These potential impacts would be minimized or avoided through AMM1–AMM6, AMM10, and AMM12, which would be in effect throughout the period of construction and operations. The indirect impacts of Alternative 4A on vernal pool crustaceans would be less than significant under CEQA.

Impact BIO-34: Periodic Effects of Inundation of Vernal Pool Crustacean Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on vernal pool crustacean habitat.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Valley Elderberry Longhorn Beetle

The habitat model used to assess the effects for valley elderberry longhorn beetle is based on riparian habitat and nonriparian habitat (vernal pool complexes and grasslands within 200 feet of channels). Alternative 4A would result in both temporary and permanent losses of valley elderberry longhorn beetle modeled habitat as indicated in Table 12-4A-13. The majority of the losses would take place over an extended period of time as the restoration environmental commitments are being implemented. In addition, an estimated 5 elderberry shrubs that were previously mapped by DWR in the DHCCP Conveyance Planning Area could be impacted by the Alternative 4A water conveyance alignment. Full implementation of Alternative 4A would also include the following environmental commitments and associated Resource Restoration and Performance Principles to benefit valley elderberry longhorn beetle.

- Mitigate impacts on elderberry shrubs consistent with USFWS (1999) conservation guidelines for the species and planting shrubs in high-density cluster (Resource Restoration and Performance Principle VELB1).
- Site elderberry longhorn beetle habitat restoration with drainage immediately adjacent to or in the vicinity of occupied habitat (Resource Restoration and Performance Principle VELB2).
- Restore 251 acres of valley/foothill riparian (Environmental Commitment 7).
- Protect 103 acres of valley/foothill riparian (Environmental Commitment 3).

As explained below, with the restoration and protection of these amounts of habitat, impacts on valley elderberry longhorn beetle would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-13. Changes in Valley Elderberry Longhorn Beetle Modeled Habitat Associated with Alternative 4A (acres)[a]

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Riparian	42	31
	Nonriparian	211	86
Total Impacts Water Conveyance Facilities		**253**	**117**
Environmental Commitments 4, 6–7, 9–11[a]	Riparian	5	0
	Nonriparian	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11a		**5**	**0**
TOTAL IMPACTS		**258**	**117**

[a] See discussion below for a description of applicable Environmental Commitments.

Impact BIO-35: Loss of Valley Elderberry Longhorn Beetle Habitat

Alternative 4A would result in the permanent and temporary loss combined of up to 375 acres of modeled valley elderberry longhorn beetle habitat (78 acres of riparian habitat and 297 acres of nonriparian habitat), and an estimated 10 elderberry shrubs from water conveyance facilities, which represent potential habitat for the species (Table 12-4A-13). Due to the limitation of the habitat suitability model, all of these effects are assumed to be a large overestimate of the true effect on potential valley elderberry longhorn beetle habitat. Environmental commitments that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of RTM areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other project physical facilities could degrade or eliminate valley elderberry longhorn beetle habitat. Implementation of the habitat protection and restoration contained in Alternative 4A and implementation of AMMs committed to would result in no adverse effects under NEPA and less-than-significant impacts under CEQA. Each of these activities is described below.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent and temporary combined loss of approximately 370 acres of modeled valley elderberry longhorn beetle habitat, composed of 73 acres of riparian habitat and 297 acres of nonriparian habitat (Table 12-4A-13). In addition, an estimated 5 shrubs could be removed as a result of conveyance facilities construction. As noted in Section 12.3.2.3, *Methods Used to Assess Species Effects*, in the Draft EIR/EIS, elderberry shrubs were mapped in the DHCCP Conveyance Planning Area where accessible and thus the entire footprint of water conveyance facilities was not surveyed. In many cases, the data collected did not always specify the number of shrubs observed but rather the size class and a range of stem numbers. The exact number of shrubs to be impacted would be determined during pre-construction surveys of the footprints of the conveyance facility and associated work areas as part of the implementation of *AMM15 Valley Elderberry Longhorn Beetle*. Most of these impacts are associated with the intake and forebay construction in the north delta. There are no records of valley elderberry longhorn beetle within these impact areas. The portion of the above impacts that result from temporary habitat loss includes 117 acres of modeled valley elderberry longhorn beetle habitat (31 acres riparian and 86 acres nonriparian habitat). Elderberry shrubs could be affected from ground-disturbing activities associated with conveyance construction footprints, reusable tunnel material storage areas, geotechnical boring areas, temporary access roads, and staging areas.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the permanent loss of approximately 5 acres of riparian habitat. Elderberry shrubs could be affected from ground-disturbing activities associated with the re-contouring of surface topography, excavation or modification of channels, type conversion from riparian and grasslands to tidal habitat, levee removal and modification, and removal of riprap and other protections from channel banks.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Activities associated with natural communities enhancement and management, such as grazing practices and ground disturbance or herbicide use in the control of nonnative vegetation, intended to maintain and improve habitat functions of protected habitats for species could result in loss of elderberry shrubs and the potential for injury or mortality to beetles. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.
- Operations and maintenance: Post-construction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect valley elderberry beetle. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas could affect elderberry shrubs occupied by the species. These effects, however, would be reduced by AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe the environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Based on modeled habitat, the study area supports approximately 34,456 acres of modeled habitat (17,786 acres of riparian and 16,670 acres of nonriparian) for valley elderberry longhorn beetle. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 375 acres of modeled valley elderberry longhorn beetle habitat (78 acres of riparian habitat and 297 acres of nonriparian habitat) (1% of the modeled habitat in the study area). These losses would not fragment any known populations of valley elderberry longhorn beetle.

Typical NEPA and CEQA project-level mitigation ratios for riparian habitat affected by the project would be 1:1 for restoration and 1:1 for protection of riparian habitat. Using these typical ratios would indicate that 78 acres of the riparian habitat should be restored/created and 78 acres of existing riparian should be protected to mitigate project losses of valley elderberry longhorn beetle habitat.

Alternative 4A includes a commitment to restore/create 251 acres of riparian habitat and protect 103 acres of riparian habitat and in the project area. The Resource Restoration and Performance Principles identified under Alternative 4A for valley elderberry longhorn beetle conservation include implementing the USFWS (1999) conservation guidelines for the species (transplanting elderberry shrubs and planting elderberry seedlings and associated natives) (Resource Restoration and Performance Principle VELB1) and siting elderberry restoration within drainages immediately adjacent to or in the vicinity of sites confirmed to be occupied by valley elderberry longhorn beetle(Resource Restoration and Performance Principle VELB2). These Resource Restoration and Performance Principles would be met through the implementation of Environmental Commitment 7

Riparian Natural Community Restoration. *Environmental Commitment 7 Riparian Natural Community Restoration* specifically calls for the planting of elderberry shrubs in large, contiguous clusters with a mosaic of associated natives as part of riparian restoration consistent with USFWS (1999) conservation guidelines. The acres of riparian protection and restoration proposed would satisfy the typical mitigation requirements described in the previous paragraph. Though there are no restoration and preservation goals for the nonriparian habitat affected, the commitment to transplant shrubs and plant additional elderberry seedlings and associated natives would, together with the proposed restoration and protection of riparian (a higher quality habitat), would be more than adequate to compensate for the projects effects on the nonriparian habitat component of the modeled habitat for the species.

The project also includes commitments to implement AMM1 W*orker Awareness Training*, AMM2 C*onstruction Best Management Practices and Monitoring*, AMM3 *Stormwater Pollution Prevention Plan*, AMM4 *Erosion and Sediment Control Plan*, AMM5 *Spill Prevention, Containment, and Countermeasure Plan*, AMM6 *Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and AMM15 *Valley Elderberry Longhorn Beetle*. AMM15 requires surveys for elderberry shrubs within 100 feet of any ground disturbing activities, the implementation of avoidance and minimize measures for any shrubs that are identified within this 100-foot buffer, and transplanting shrubs that can't be avoided. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites.

Other factors relevant to effects on valley elderberry longhorn beetle include:

- Habitat loss is widely dispersed throughout the study area and would not be concentrated in any one location.
- There would be a temporal loss of riparian habitat, which is expected to result in a minimal effect on valley elderberry longhorn beetle because much of the riparian habitat in the project area is not known to be currently occupied by the species, because all elderberry shrubs that are suitable for transplantation would be moved to conservation areas in the project area, and because most of the affected community is composed of small patches of riparian scrub and herbaceous vegetation that are fragmented and distributed across the agricultural landscape of the project area and thus are likely to provide no or low-value habitat for the beetle.
- Temporarily disturbed areas would be restored within 1 year following completion of construction and management activities. Under AMM10, a restoration and monitoring plan would be developed prior to initiating any construction-related activities associated with the environmental commitments or other covered activities that would result in temporary effects on natural communities.

NEPA Effects: In the absence of actions to compensate and avoid and minimize effects, the losses of valley elderberry longhorn beetle habitat and potential for direct mortality of a special-status species associated with Alternative 4A would represent an adverse effect. However, with habitat protection and restoration associated with Environmental Commitment 7, Resource Restoration and Performance Principles VELB1 and VELB2, and by AMM1–AMM6, AMM10, and AMM15, the effects of Alternative 4A as a whole on valley elderberry longhorn beetle would not be adverse under NEPA.

CEQA Conclusion: Considering the protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, together with Resource Restoration and Performance Principles VELB1 and VELB2, implementation of Alternative 4A as a whole would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on valley elderberry longhorn beetle under CEQA.

Impact BIO-36: Indirect Effects on Valley Elderberry Longhorn Beetle and its Habitat

Construction activities associated with water conveyance facilities, habitat restoration, and habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic post-construction disturbances with localized impacts on valley elderberry longhorn beetle. Construction related effects could result from ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in dust and the inadvertent release of hazardous substances in areas where elderberry shrubs occur. A GIS analysis estimates that approximately 10 shrubs could be indirectly affected by conveyance facilities construction (see Section 12.3.2.3, *Methods Used to Assess Species Effects*, of the Draft EIR/EIS for a discussion of the methods used to make this estimate). Restoration activities could result in excavation or modification of channels, and type conversion from riparian and grasslands to other habitats, that occur within 100 feet of an elderberry shrubs. These potential effects would be minimized or avoided through AMM1–AMM6, AMM10, and AMM15.

***NEPA Effects*:** With the implementation of AMM1–AMM6, AMM10, and AMM15 as part of Alternative 4A construction, operations, and maintenance, substantial adverse indirect effects on valley elderberry longhorn beetle would be avoided and minimized. The indirect effects on valley elderberry longhorn beetle as a result of implementing Alternative 4A environmental commitments would not have an adverse effect on valley elderberry longhorn beetle under NEPA.

CEQA Conclusion: With the implementation of AMM1–AMM6, AMM10, and AMM15 as part of Alternative 4A construction, operation, and maintenance, substantial adverse indirect effects on valley elderberry longhorn beetle would be avoided and minimized. Furthermore, the impacts from project would not result in a substantial reduction in numbers or a restriction in the range of valley elderberry longhorn beetle. Therefore, the indirect effects under this alternative would have a less-than-significant impact on valley elderberry longhorn beetle under CEQA.

Impact BIO-37: Periodic Effects of Inundation of Valley Elderberry Longhorn Beetle Habitat as a Result of Implementation of Alternative 4A

Alternative 4A would not result in periodic effects on valley elderberry longhorn beetle.

***NEPA Effects*:** No effect.

CEQA Conclusion: No impact.

Nonlisted Vernal Pool Invertebrates

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the environmental commitments, on nonlisted vernal pool invertebrates that are not covered by the Plan (Blennosperma vernal pool andrenid bee, hairy water flea, Ricksecker's water scavenger beetle, curved-foot hygrotus beetle, molestan blister beetle). Little is known about the range of these species so it is assumed that they have potential to occur in the same areas described by the vernal pool crustacean modeled habitat. That habitat model consists of: vernal pool complex, which consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly affected by agricultural or development practices; alkali seasonal wetlands in CZ 8; and degraded vernal pool complex, which consists of low-value ephemeral habitat ranging from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, disking, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. For the purpose of the effects analysis, vernal pool complex is categorized as high-value and degraded vernal pool complex is categorized as low-value for these species. Alkali seasonal wetlands in CZ 8 were also included as high-value habitat for vernal pool crustaceans in the model. Also included as low-value for vernal pool habitat are areas along the eastern boundary of CZ 11 that are mapped as vernal pool complex because they flood seasonally and support typical vernal pool plants, but do not include topographic depressions that are characteristic of vernal pools.

Alternative 4A would result in permanent losses of habitat for nonlisted vernal pool invertebrates as indicated in Table 12-4A-14 and indirect conversions of vernal pool habitat. Alternative 4A would also include the following environmental commitments and associated Resource Restoration and Performance Principles that would benefit nonlisted vernal pool invertebrates.

- Protect 150 acres of existing vernal pool complex (Environmental Commitment 3) in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principles VP/AW1)
- Restore vernal pool complex and alkali seasonal wetland suitable for vernal pool invertebrates to achieve no net loss of wetted acreage (Environmental Commitment 9, Resource Restoration and Performance Principles VP/AW2).
- Increase size and connectivity of protected vernal pool complexes and alkali seasonal wetlands in the greater Byron Hill area (Resource Restoration and Performance Principles VP/AW3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principles VP/AW4).

As explained below, with the restoration and protection of these amounts of habitat, impacts on nonlisted vernal pool invertebrates would not be adverse for NEPA purposes and would be less-than significant for CEQA purposes.

Table 12-4A-14. Changes in Nonlisted Vernal Pool Invertebrate Habitat Associated with Alternative 4A (acres)[a]

Project Component	Habitat Type	Permanent	Temporary	Indirect
Water Conveyance Facilities	High-value (vernal pool complex)	24	1	41
	Low-value (degraded vernal pool complex)	7	2	0
Total Impacts Water Conveyance Facilities		**31**	**3**	**41**
Environmental Commitments 4, 6–7, 9–11[a]	High-value (vernal pool complex)	0	0	0
	Low-value (degraded vernal pool complex)	0	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**	**0**
TOTAL IMPACTS		**31**	**3**	**41**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-38: Loss or Conversion of Habitat for and Direct Mortality of Nonlisted Vernal Pool Invertebrates

Alternative 4A would result in the direct, permanent and temporary loss combined of 34 acres of vernal pool habitat from conveyance facilities construction. In addition, conveyance construction could result in the indirect conversion due to hydrologic alteration of an additional 41 acres of vernal pool complex. Construction of the water conveyance facilities may result in the modification of hardpan and changes to the perched water table, which could lead to alterations in the rate, extent, and duration of inundation of nearby vernal pool habitat. USFWS typically considers construction within 250 feet of vernal pools to constitute an indirect effect unless more detailed information is provided to further refine the limits of any such effects. For the purposes of this analysis, the 250-foot buffer was applied to the water conveyance facilities work areas where surface and subsurface disturbance activities would take place. Habitat enhancement and management activities (Environmental Commitment 11), which include disturbance or removal of nonnative vegetation, could result in local adverse habitat effects.

As specified in *AMM12 Vernal Pool Crustaceans* and *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, restoration projects would be designed such that no more than a total of 10 wetted acres of vernal pool crustacean habitat are permanently lost. AMM12 would also ensure that no more than 20 wetted acres of vernal pool crustacean habitat are indirectly affected by alterations to hydrology resulting from adjacent BDCP covered activities, in particular tidal restoration. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that temporary transmission lines avoid removal of wetted acres of vernal pools and alkali seasonal wetlands wetted acres of aquatic habitats to the maximum extent practicable. The term wetted acres refers to an area that would be defined by the three parameter wetland delineation method used by the U.S. Army Corps of Engineers to determine the limits of a wetland, which involve an evaluation of wetland soil, vegetation, and hydrology characteristics. This acreage differs from vernal pool complex acreages in that a vernal pool complex is composed of individual wetlands (vernal pools) and those upland areas that are in between and surrounding them, which provide the supporting hydrology (surface runoff and groundwater input), organic and nutrient inputs, and refuge for the terrestrial phase of some vernal pool species.

A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent and temporary combined loss of approximately 34 acres of vernal pool habitat, composed of 25 acres of high-value and 9 acres of low-value habitat (Table 12-4A-14). In addition, the conveyance facilities could result in the indirect conversion of 41 acres of vernal pool habitat in the vicinity of Clifton Court Forebay. The indirect effects would result from the construction of permanent transmission lines, from the storage of reusable tunnel material, and permanent access roads. *AMM30 Transmission Line Design and Alignment Guidelines* would ensure that temporary transmission lines are designed to avoid removal wetted acres of aquatic habitats to the maximum extent practicable. There are no records of these nonlisted vernal pool invertebrates at this location (California Department of Fish and Game 2013).
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Alternative 4A's restoration/creation of vernal pools to achieve no net loss and the protection of 150 acres of vernal pool complex would benefit vernal pool invertebrates. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance

wildlife values in protected habitats may result in localized ground disturbances that could temporarily affect vernal pool invertebrate habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on vernal pool invertebrate habitat and are expected to result in overall improvements to and maintenance of vernal pool habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

The proposed conservation efforts have been evaluated to determine whether they would provide sufficient habitat protection and restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA and would be less than significant under CEQA. Table 12-4A-14 above lists the impacts on nonlisted vernal pool invertebrate habitat that are based on the natural community mapping done within the study area. Table 12-4A-15 was prepared to further analyze the project's effects on vernal pool invertebrates using wetted acres of habitat in order to compare the effects of this alternative with the effect limits established in *AMM12 Vernal Pool Crustaceans*, which are measured in wetted acres of habitat. Wetted acres were estimated by using the Draft BDCP's assumption that restored vernal pool complexes would have a 15% density of vernal pools (i.e., of 100 acres of vernal pool complex 15 acres would constitute vernal pools and the remaining 85 acres supporting uplands). Based on an informal evaluation of aerial photographs of the project area, it is likely that the actual densities within the project area are approximately 10%, but the 15% density value was chosen as a conservative estimate for determining effects.

Table 12-4A-15. Estimated Effects on Wetted Vernal Pool Crustacean Habitat under Alternative 4A (acres)

	Direct Loss	Indirect Conversion
AMM12 Impact Limit	10	20
Water Conveyance Facilities[a]	5.1	6.2
Environmental Commitments 4, 6–7, 9–11	0	0
Total	**5.1**	**6.2**

[a] These acreages were generated by assuming that the modeled habitat identified in Table 12-4A-14 has densities of wetted habitat at 15%. The direct effects numbers include permanent and temporary impacts.

Typical NEPA and CEQA project-level mitigation ratios for loss of vernal pools affected by Alternative 4A would be 1:1 for restoration and 2:1 for protection. Typically, indirect conversion impacts are mitigated by protecting vernal pools at a 2:1 ratio. Using these typical ratios would indicate that 5.1 wetted acres of vernal pool habitat (34 acres of vernal pool complex) should be restored and 22.6 wetted acres of vernal pool habitat (150 acres of vernal pool complex) protected to mitigate Alternative 4A's direct and indirect effects on nonlisted vernal pool species habitat. With the implementation of AMM30 the effects on aquatic habitat would be avoided to the maximum extent feasible during the designing of the transmission line west of Clifton Court Forebay.

Project proponents would commit to protecting 150 acres of vernal pool complex by protecting at least 2 wetted acres of vernal pools protected for each wetted acre directly or indirectly affected. The Plan also includes a commitment to restore or create vernal pools such that the Plan results in no net loss of vernal pool acreage. The amount of restoration would be determined during implementation based on the following criteria, which would satisfy Resource Restoration and Performance Principle VP/AW2.

- If restoration is completed (i.e., restored natural community meets all success criteria) prior to impacts, then 1.0 wetted acre of vernal pools would be restored for each wetted acre directly affected (1:1 ratio).
- If restoration takes place concurrent with impacts (i.e., restoration construction is completed, but restored habitat has not met all success criteria prior to impacts occurring), then 1.5 wetted acres of vernal pools would be restored for each wetted acre directly affected (1.5:1 ratio).

The protection and restoration would be achieved by implementation of the following the Resource Restoration and Performance Principles.

- Protect existing vernal pool complex in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005) (Resource Restoration and Performance Principles VP/AW1).
- Increase size and connectivity of protected vernal pool complexes and alkali seasonal wetlands in the greater Byron Hill area (Resource Restoration and Performance Principles VP/AW3).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principles VP/AW4).

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM30 Transmission Line Design and Alignment Guidelines*, and *AMM37 Recreation*. *AMM12 Vernal Pool Crustaceans*, though developed for vernal pool crustaceans, includes measures to avoid and minimize direct and indirect effects on vernal pools and would thus be applicable to nonlisted vernal pool invertebrates as well. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

***NEPA Effects*:** The loss of vernal pool habitat under Alternative 4A would not be adverse under NEPA because project proponents would commit to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4, and by AMM1–AMM6, AMM10, AMM12, AMM30, and AMM37, which would be in place throughout the time period of construction and operations. Considering these commitments, losses and conversions of nonlisted vernal pool invertebrates habitat under Alternative 4A would not be adverse.

CEQA Conclusion**:** The effects on nonlisted vernal pool invertebrate habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of actions to compensate, avoid, and minimize impacts. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 9, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles VP/AW1-VP/AW4, and by AMM1–AMM6, AMM10, AMM12, AMM30, and AMM37, which would be in place throughout the period of construction and operations. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of nonlisted vernal pool invertebrates. Therefore, Alternative 4A would have a less-than-significant impact on nonlisted vernal pool invertebrates under CEQA.

Impact BIO-39: Indirect Effects of Alternative 4A on Nonlisted Vernal Pool Invertebrates

Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly affect nonlisted vernal pool invertebrates and their habitat in the vicinity of construction and restoration areas, and maintenance activities. Ground-disturbing activities, stockpiling of soils, and maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into this habitat. Vernal pools could be periodically indirectly affected by maintenance activities at water conveyance facilities. Embankment maintenance activities around Clifton Court Forebay could result in the inadvertent discharge of sediments and hazardous materials into nonlisted vernal pool invertebrate habitat that occurs along the southern and western boundaries of the forebays.

NEPA Effects**:** Water conveyance facilities construction and restoration activities could indirectly affect nonlisted vernal pool invertebrates and their habitat in the vicinity of construction areas. These potential effects would be avoided and minimized through AMM1–AMM6, and AMM10 which would be in effect throughout the period of construction and operations. The indirect effects of Alternative 4A on nonlisted vernal pool invertebrates would not be adverse under NEPA.

CEQA Conclusion: Construction and maintenance activities associated with water conveyance facilities, and restoration actions could indirectly impact nonlisted vernal pool invertebrates and their habitat in the vicinity of construction and restoration areas, and maintenance activities. These potential impacts would be minimized or avoided through AMM1–AMM6, and AMM10, which would be in effect throughout period of construction and operations. The indirect impacts of Alternative 4A on nonlisted vernal pool invertebrates would be less than significant under CEQA.

Impact BIO-40: Periodic Effects of Inundation of Nonlisted Vernal Pool Invertebrates' Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on nonlisted vernal pool invertebrates.

NEPA Effects**:** No effect.

CEQA Conclusion: No impact.

Sacramento and Antioch Dunes Anthicid Beetles

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the environmental commitments, on Sacramento and Antioch Dunes anthicid beetles. Potential habitat in the study area includes the inland dune scrub at Antioch Dunes NWR, sand bars along the Sacramento and San Joaquin Rivers, and sandy dredge spoil piles (California Department of Fish and Game 2006c and 2006d).

The construction, and operations and maintenance of the water conveyance facilities under Alternative 4A would not likely affect Sacramento and Antioch Dunes anthicid beetles. The construction of the water conveyance structure and associated infrastructure would generally avoid affects to channel margins where sand bars are likely to form. Conveyance construction would not affect inland dune scrub habitat at Antioch Dunes NWR. No dredge spoil areas that could be occupied by Sacramento anthicid beetle were identified within conveyance facilities footprints during a review of Google Earth imagery. Also, a review of the locations of the Alternative 4A water intake facilities on aerial imagery did not reveal any sandbars along the channel margins. These portions of the Sacramento River have steep, riprap lined channel banks that are likely not conducive to the formation of sandbars.

Implementation of Alternative 4A restoration measures could affect habitat for Sacramento and Antioch Dunes anthicid beetles. Both species are known to utilize interior sand dunes and sandbar habitat. The only interior sand dune habitat within the project area is at Antioch Dunes, which would not be impacted by the Alternative 4A environmental commitments. Both species are known to occur along the Sacramento River and San Joaquin Rivers. The implementation of Alternative 4A restoration actions could affect habitat for Sacramento and Antioch Dunes anthicid beetles along channels throughout the project area; however the extent of these habitats in the project area is unknown because these areas were not identified at the scale of mapping done within the study area. Because of current and historic channel modifications (channel straightening and dredging) and levee construction throughout the Delta, sandbar habitat is likely very limited and restricted to channel margins. The implementation of *Environmental Commitment 4 Tidal Natural Communities Restoration* and *Environmental Commitment 6 Channel Margin Enhancement* could impact sandbar habitat along the river channels and possibly sandy, dredge piles on Delta islands.

Alternative 4A would likely result in beneficial effects on Sacramento and Antioch Dunes anthicid beetles. The following Alternative 4A environmental commitments would generally increase opportunities for the formation of sandbars in the project area.

- As stated in Environmental Commitment 6, 4.6 miles of channel margin habitat would be enhanced.
- Restore 251 acres of riparian habitat (Environmental Commitment 7).
- Protect 103 acres of riparian habitat (Environmental Commitment 3).

These measures would improve shoreline conditions by creating benches along levees, shallow habitat along margins, and increasing shoreline vegetation, all of which would likely contribute to the formation of sandbars along Delta river channels where these measures would be implemented. Increasing the structural diversity of Delta river channel margins would create opportunities for sand to be deposited and for sandbars to subsequently form. As explained below, potential impacts on Sacramento and Antioch Dunes anthicid beetle would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-16. Changes in Sacramento and Antioch Dunes Anthicid Beetles' Habitat Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	unknown	unknown
TOTAL IMPACTS	**unknown**	**unknown**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-41: Loss or Conversion of Habitat for and Direct Mortality of Sacramento and Antioch Dunes Anthicid Beetles

Implementation of Alternative 4A environmental commitments could affect Sacramento and Antioch Dunes anthicid beetles and their habitat. As mentioned above, the full extent of this habitat in the study area is unknown but it is assumed that sand bars likely occur to some degree along the Sacramento and San Joaquin Rivers and that some islands in the Delta may contain sandy dredge spoil piles. A review of Google Earth imagery in the north Delta did identify three general areas that appear to have accumulations of sandy soils (with some vegetation), possibly from dredge disposal, are Decker Island, the western portion of Bradford Island, and the southwestern tip of Grand Island. A review of Google Earth imagery in the south Delta did identify sandbar habitat along the San Joaquin River from the southern end of the project area downstream to an area just west of Lathrop. An additional area along Paradise Cut was identified just north of I-5. Environmental commitments that could result in impacts on Sacramento and Antioch Dunes anthicid beetles are tidal habitat restoration (Environmental Commitment 4) and channel margin enhancement (Environmental Commitment 6). In addition, maintenance activities associated with the long-term operation of the water conveyance facilities could degrade or eliminate habitat for Sacramento and Antioch Dunes anthicid beetles. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration could impact the areas of sandy soils identified from aerial photographs on Decker Island, the western portion of Bradford Island, and on the southwestern tip of Grand Island because these areas fall within the West Delta Restoration Opportunity Area (ROA). The methods and techniques for tidal restoration may include the recontouring of lands so that elevations are suitable for the establishment of marsh plains and the eventual breaching of levees. There are three CNDDB records of Sacramento anthicid beetle (just north of Rio Vista, one just south of Rio Vista along the west shore of the Sacramento River, and one on Grand Island) and one CNDDB record of Antioch Dunes anthicid beetle (just north of Rio Vista) that fall within the West Delta ROA (California Department of Fish and Wildlife 2013). Tidal restoration actions in the West Delta ROA may eliminate potential habitat and impact occupied habitat of both Sacramento and Antioch Dunes anthicid beetles.
- *Environmental Commitment 6 Channel Margin Enhancement*: Channel margin enhancement could result in impacts on 4.6 miles of channel margin that could contain sandbars.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Alternative 4A could result in substantial effects on Sacramento and Antioch Dunes anthicid beetles because all of the habitat identifiable from aerial photo review falls within either the West Delta ROA, which may be considered for tidal restoration (Environmental Commitment 4). Furthermore, three of the records for Sacramento anthicid beetle within the study area fall within areas being considered for tidal restoration (Environmental Commitment 4), which represents approximately one quarter of the extant records for this species range wide (3 of 13). The only extant record for Antioch Dunes anthicid beetle, which represents one of five extant records range wide, falls within the West Delta ROA that is just north of Rio Vista. These occurrences could be affected if tidal restoration occurs in these areas. However, considering all of the environmental commitments under Alternative 4A, Sacramento and Antioch Dunes anthicid beetles would likely benefit from the project. Under Alternative 4A, Environmental Commitment 6, and Environmental Commitment 7, would generally contribute to the formation of sandbar habitat in the project area. These measures would improve shoreline conditions by creating benches along levees (Environmental Commitment 6) and increasing shoreline vegetation (Environmental Commitment 7), all of which would likely contribute to the formation of sandbars along Delta river channels where these measures would be implemented. Increasing the structural diversity of Delta river channel margins would create areas of slow water that would allow for sand to be deposited and for sandbars to subsequently form.

***NEPA Effects*:** The potential impacts on Sacramento and Antioch Dunes anthicid beetles associated with Alternative 4A as a whole would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other means to compensate for, avoid, and/or minimize impacts. However, considering the implementation of restoration associated with Environmental Commitment 6 and Environmental Commitment 7 the effects of Alternative 4A as a whole on Sacramento and Antioch Dunes anthicid beetles would not be adverse under NEPA.

***CEQA Conclusion*:** Alternative 4A would potentially impact Sacramento and Antioch Dunes anthicid beetles' habitat and could impact three occurrences of Sacramento anthicid beetle and one occurrence of Antioch Dunes anthicid beetle. However, the implementation of the environmental commitments would likely benefit Sacramento and Antioch Dunes anthicid beetles. Environmental Commitment 6 and Environmental Commitment 7 would generally contribute to the formation of sandbar habitat in the project area. Alternative 4A as a whole would not result in a substantial adverse effect though habitat modification and would not substantially reduce the number or restrict the range of these species. Therefore, the alternative would have a less-than-significant impact on Sacramento and Antioch Dunes anthicid beetles under CEQA.

Delta Green Ground Beetle

Suitable habitat in the study area would be vernal pool complexes and annual grasslands in the general Jepson Prairie area. The construction, and operations and maintenance of the water conveyance facilities under Alternative 4A would not affect delta green ground beetle because the facilities and construction area are outside the known range of the species. Implementation of Alternative 4A could affect delta green ground beetle through the potential protection of grasslands (Environmental Commitment 3) in the vicinity of Jepson Prairie and the subsequent implementation of habitat enhancement and management actions (Environmental Commitment 11) in these areas. In addition, tidal natural communities restoration (Environmental Commitment 4) could result in potential impacts on delta green ground beetle and its habitat. Alternative 4A could result in beneficial effects on delta green ground beetle through the protection of grasslands it occurs in CZ 1.

These areas could contain currently occupied habitat for delta green ground beetle and/or create conditions suitable for eventual range expansion. As explained below, potential impacts on delta green ground beetle would be adverse for NEPA purposes and would be significant for CEQA purposes. Mitigation Measure BIO-42 would reduce the effects under NEPA and reduce the impacts to a less-than-significant level under CEQA.

Table 12-4A-17. Changes in Delta Green Ground Beetle Habitat Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	unknown	unknown
TOTAL IMPACTS	**unknown**	**unknown**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-42: Loss or Conversion of Habitat for and Direct Mortality of Delta Green Ground Beetle

Alternative 4A environmental commitments could result in the conversion of habitat and/or direct mortality to delta green ground beetle. Environmental commitments that could affect delta green ground beetle include tidal natural communities habitat restoration (Environmental Commitment 4) and habitat enhancement and management activities (Environmental Commitment 11) in CZ 1. CZ 1 is the only portion of the project area that contains occupied and potential habitat for delta green ground beetle. The range of the delta green ground beetle is currently believed to be generally bound by Travis Air Force Base to the west, Highway 113 to the east, Hay Road to the north, and Creed Road to the south (Arnold and Kavanaugh 2007; USFWS 2009). Further discussion of this potential effect is provided below, and NEPA and CEQA conclusions follow.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal restoration in the Cache Slough ROA could result in the loss of delta green ground beetle habitat if restoration is planned in areas known to be or potentially occupied by the species. The tidal restoration methods and techniques identified in Environmental Commitment 4 include excavating channels; modifying ditches, cuts, and levees to encourage tidal circulation; and scalping higher elevation areas to create marsh plains. These disturbances could affect delta green ground beetle through habitat modification, either directly or indirectly through hydrologic modifications, and/or result in direct mortality to the species.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Grasslands would potentially be protected in CZ 1. Potential effects from Environmental Commitment 11 could include direct mortality to larvae and adults from the implementation of grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. In addition to these grassland management actions, Environmental Commitment 11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control, though some of these methods would be restricted in areas where rare plants occur or in critical habitat for vernal pool species. The creation of new recreation trails as part of Environmental Commitment 11 would result in impacts on grasslands within CZ 1, which could affect delta green ground beetle if present.

NEPA Effects: The potential protection of grassland in CZ 1 (Environmental Commitment 3) could benefit delta green ground beetle if these areas occur within the range of the species. The management of these grasslands according to *Environmental Commitment 11 Natural Communities Enhancement and Management* and the potential construction of recreational trails in CZ 1 has a potential to affect this species. AMM37 would ensure that new trails in vernal pool complexes be sited at least 250 feet from wetland features, or closer if site-specific information indicates that local watershed surrounding a vernal pools is not adversely affected. Direct mortality and/or the affects to delta green ground beetle habitat would be an adverse effect under NEPA. Implementation of mitigation measure BIO-42, *Avoid Impacts on Delta Green Ground Beetle and its Habitat*, would reduce this effect.

CEQA Conclusion: The implementation of grassland protection (Environmental Commitment 3), tidal natural communities restoration (Environmental Commitment 4), and recreational trail construction and subsequent enhancement and management actions (Environmental Commitment 11) could impact delta green ground beetle. Tidal restoration projects around Calhoun Cut and possible Lindsey Slough could affect habitat and result in direct mortality to the species from excavating channels; modifying ditches, cuts, and levees to encourage tidal circulation; and scalping higher elevation areas to create marsh plains. Potential impacts from Environmental Commitment 11 could include direct mortality to larvae and adults resulting from the implementation of recreation trail construction in grassland in CZ 1 and from grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. AMM37 would ensure that new trails in vernal pool complexes be sited at least 250 feet from wetland features, or closer if site-specific information indicates that local watershed surrounding a vernal pools is not adversely affected. Environmental Commitment 11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control, though some of these methods would be restricted in areas where rare plants occur and in critical habitat for vernal pool species. These actions could result in adverse effects through habitat modification and a possible reduction in the number of the species or restrict its range, and therefore result in significant impacts on delta green ground beetle. Implementation of Mitigation Measure BIO-42, *Avoid Impacts on Delta Green Ground Beetle and its Habitat*, would reduce these potential impacts to a less-than-significant level.

Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat

As part of the design of recreational trails in CZ 1, the development of tidal restoration plans, and site-specific management plans on protected grasslands in the area of Jepson Prairie, the project proponents will implement the following measures to avoid effects on delta green ground beetle.

- If recreational trail construction and/or habitat restoration or protection is planned for the lands adjacent to Calhoun Cut and noncultivated lands on the western side of Lindsey Slough, these area will be evaluated by a USFWS approved biologist for potential delta green ground beetle habitat (large playa pools, or other similar aquatic features, with low growing vegetation or bare soils around the perimeter). The biologist will have previous experience with identifying suitable habitat requirements for delta green ground beetle.
- Any suitable habitat identified by the biologist (with previous experience with delta green ground beetle) within the species current range will be considered potentially occupied and

all ground disturbing activities in these areas will be avoided, which for the project area is generally the area west of State Route 113.

- Any other areas identified as suitable habitat outside of the current range of the species will be surveyed by a biologist with previous experience in surveying for and identifying delta green ground beetle. No ground disturbing activities will be implemented in areas identified as occupied by delta green ground beetle.
- Based on the results of the habitat evaluations and surveys, recreational trail construction plans, and site-specific restoration and management plans will be developed so that they don't conflict with the recovery goals for delta green ground beetle in the USFWS's 2005 *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005). Plans will include measures to protect and manage for delta green ground beetle so that they continue to support existing populations or allow for future colonization.

Callippe Silverspot Butterfly

This section describes the effects of Alternative 4A on callippe silverspot butterfly. Suitable habitats are typically in areas influenced by coastal fog with hilltops that support the specie's host-plant, Johnny jump-ups. Preferred nectar flowers used by adults include thistles, blessed milk thistle, and coyote wild mint. Other native nectar sources include hairy false goldenaster, coast buckwheat, mourning bride, and California buckeye. Suitable habitat in the study area is located in CZ 11 in the Cordelia Hills west of I-680 and in the Potrero Hills on the northern edge of Suisun Marsh. The construction, and operations and maintenance of the water conveyance facilities under Alternative 4A would not result in impacts on callippe silverspot butterfly or its habitat. If Cordelia Hills and Potrero Hills are identified for grassland protection opportunities as part of *Environmental Commitment 3 Natural Communities Protection and Restoration* and the subsequent implementation of *Environmental Commitment 11 Natural Communities Enhancement and Management,* could affect callippe silverspot butterfly. Callippe silverspot butterfly has been documented in the western most portion of the project area (CZ 11) in the Cordelia Hills (Solano County Water Agency 2009). Potential habitat for the species (grassy hills with *Viola pedunculata*) is present in the Potrero Hills, but it has not been observed there (EDAW 2005, California Department of Fish and Wildlife 2013). Alternative 4A would protect up to 1,060 acres of grassland, some of which may occur in areas in CZ 11 that contain habitat for callippe silverspot butterfly. As explained below, potential impacts on callippe silverspot would be adverse for NEPA purposes and would be significant for CEQA purposes. Mitigation Measure BIO-43 would reduce the effects under NEPA and reduce the impacts to a less-than-significant level under CEQA.

Table 12-4A-18. Changes in Callippe Silverspot Butterfly Habitat Associated with Alternative 4A (acres)[a]

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	unknown	unknown
TOTAL IMPACTS	**unknown**	**unknown**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-43: Loss or Conversion of Habitat for and Direct Mortality of Callippe Silverspot Butterfly

Alternative 4A environmental commitments could result in the conversion of habitat and/or direct mortality to callippe silverspot butterfly. Only one environmental commitment was identified as potentially affecting Callippe silverspot butterfly, *Environmental Commitment 11 Natural Communities Enhancement and Management*, which could result in the disturbance of callippe silverspot butterfly habitat if such areas are acquired as part of grassland protection under *Environmental Commitment 3 Natural Communities Protection and Restoration*. Further discussion of this potential effect is provided below and NEPA and CEQA conclusions follow.

Up to 1,060 acres of grasslands would be protected in the project area, some of which may occur in CZ 11. If areas chosen for protection include Cordelia Hills or Potrero Hills, where there is known and potential habitat, respectively, then grassland enhancement and management actions could affect the callippe silverspot butterfly. Potential effects from Environmental Commitment 11 could include the loss of larval host and nectar sources and direct mortality to larvae and adults from the installation of artificial nesting burrows and structures and the implementation of grassland management techniques, which may include livestock grazing, prescribed burning, and mowing. In addition to these grassland management actions, Environmental Commitment 11 also includes guidelines and techniques for invasive plant control, which may include manual control (hand-pulling and digging), mechanical control (large equipment), and chemical control. Several of the preferred nectar sources are thistles, some of which have been identified by the California Invasive Plant Council as having limited to moderate ecological impacts (California Invasive Plant Council 2006).

***NEPA Effects*:** The protection of 1,060 acres of grassland some of which may occur within CZ 11 could benefit callippe silverspot butterfly if these protected areas include occupied and potential habitat on the hill tops in Cordelia Hills and Potrero Hills. However, the management of these grasslands according to *Environmental Commitment 11 Natural Communities Enhancement and Management* also has a potential to adversely affect this species. Direct mortality and/or the removal of larval host plants and nectar sources for adults would be an adverse effect under NEPA. Implementation of Mitigation Measure BIO-43, *Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat*, would ensure the effect is not adverse under NEPA.

CEQA Conclusion: If grasslands within the Cordelia Hills and Potrero Hills are protected as part of *Environmental Commitment 3 Natural Communities Protection and Restoration* then the subsequent management of these grasslands according to *Environmental Commitment 11 Natural Communities Enhancement and Management* has a potential to affect this species. These actions could result in adverse effects through habitat modification and a possible reduction in the number of the species or restrict its range and would therefore result in significant impact on the species under CEQA. However, callippe silverspot butterfly could benefit from the protection of occupied and potential habitat for the species with the implementation of Mitigation Measure BIO-43, which would avoid and minimize effects from management actions and thus reduce the potential impact to a less-than-significant level under CEQA.

Mitigation Measures BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat

As part of the development of site-specific management plans on protected grasslands in the Cordelia Hills and/or Potrero Hills, project proponents will implement the following measures to avoid and minimize the loss of callippe silverspot habitat.

- Hilltops in Cordelia Hills and Potrero Hills will be surveyed for callippe silverspot larval host plants (Johnny jump-ups) by a biologist familiar with identifying this plant species. These surveys should occur during the plant's blooming period (typically early January through April)
- If larval host plants are present, then presence/absence surveys for callippe silverspot butterfly larvae will be conducted according to the most recent USFWS approved survey methods by a biologist with previous experience in surveying for and identifying callippe larvae and/or signs of larval presence. These surveys should be conducted prior to the adult flight season, which usually starts in mid-May.
- If larvae are detected then no further surveys are necessary. If larvae are not detected then surveys for adults will be conducted by a biologist familiar with surveying for and identifying callippe silverspot. Surveys typically start in mid-May and continue weekly for 8 to 10 weeks.
- If callippe silverspot butterflies are detected, then the site-specific management plans will be written to include measures to protect and manage for larval host plants and nectar sources so that they continue to support existing populations and/or allow for future colonization. Mapping of both larval host plants and nectar sources will be incorporated into the management plans.

California Red-Legged Frog

Modeled California red-legged frog habitat in the study area is restricted to freshwater aquatic and grassland habitat, and immediately adjacent cultivated lands along the study area's southwestern edge in CZ 7, CZ 8, CZ 9, and CZ 11. Pools in perennial and seasonal streams and stock ponds provide potential aquatic habitat for this species. While stock ponds are underrepresented as a modeled habitat, none is expected to be affected by project actions.

Alternative 4A would result in both temporary and permanent losses of California red-legged frog modeled habitat as indicated in Table 12-4A-19. Factors considered in assessing the value of affected habitat for the California red-legged frog, to the extent that information is available, are presence of limiting habitat (aquatic breeding habitat), known occurrences and clusters of occurrences, proximity of the affected habitat to existing protected lands, and the overall degraded or fragmented nature of the habitat. The study area represents the extreme eastern edge of the species' coastal range, and species' occurrences are reported only from CZ 8 and CZ 11.

Alternative 4A would include the following environmental commitments and associated Resource Restoration and Performance Principles to benefit the California red-legged frog.

- Protect and improve habitat linkages that allow terrestrial species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2).

- Protect 647 acres of grassland in the Byron Hills area (Environmental Commitment 3, Resource Restoration and Performance Principle G10).
- Protect 150 acres and restore 34 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands (Environmental Commitment 3, Environmental Commitment 9, and Resource Restoration and Performance Principle VP/AW1) with the grassland portions expected to benefit California red-legged frog.
- Increase burrow availability for burrow-dependent species in grasslands surrounding all suitable aquatic habitat including stock ponds and vernal pool/alkali seasonal wetland complexes (Resource Restoration and Performance Principles G5, VP/AW6).
- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Resource Restoration and Performance Principle L3).
- Protect up to 6 acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Resource Restoration and Performance Principle G2).
- Maintain and enhance aquatic features in protected grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for covered amphibian and aquatic reptile species (Resource Restoration and Performance Principle G7).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs to reduce potential effects, impacts on California red-legged frog would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-44: Loss or Conversion of Habitat for and Direct Mortality of California Red-Legged Frog

Alternative 4A water conveyance facilities construction and environmental commitments would result in the permanent and temporary loss combined of up to 1 acre of modeled aquatic habitat and 68 acres of modeled upland habitat for California red-legged frog (Table 12-4A-19). Construction activities associated with the water conveyance facilities, including operation of construction equipment, could result in permanent and temporary effects on, as well as injury and mortality of, California red-legged frogs. In addition, natural enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Maintenance activities associated with the long-term operation of the water conveyance facilities and other project facilities could degrade or eliminate California red-legged frog habitat including injury and mortality of California red-legged frogs. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A would result in the permanent loss of up to 1 acre of aquatic habitat and 36 acres of upland habitat for California red-legged frog in CZ 8 (Table 12-4A-19). Permanent effects would be associated with RTM, grading, paving, excavating, extension and installation of cross culverts, installation of structural hardscape, and installation and relocation of utilities. Construction-related effects would temporarily disturb 32 acres of upland habitat for the California red-legged frog (Table 12-4A-19). Although there are no California red-legged frog occurrences that overlap with the water conveyance facilities construction footprint there are a number of occurrences approximately 0.5 mile to the west of Clifton Court Forebay.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Protection of 647 acres of grassland, protection of 150 acres and restoration of 34 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands, and protection and restoration of 6 acres of aquatic habitat would benefit California red-legged frog. Activities associated with natural communities enhancement and management in protected California red-legged frog habitat, such as ground disturbance or herbicide use to control nonnative vegetation, could result in local adverse habitat effects on, and injury or mortality of, California red-legged frogs. These effects would be avoided and minimized with implementation of the AMMs discussed below. Herbicides would only be used in California red-legged frog habitat in accordance with the written recommendation of a licensed, registered pest control advisor and in conformance with label precautions and federal, state, and local regulations in a manner that avoids or minimizes harm to the California red-legged frog. *AMM14 California Red-Legged Frog* would be implemented to ensure that California red-legged frog upland and aquatic habitats are avoided, as described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

- An unknown number of acres of upland cover and dispersal habitat for the California red-legged frog could be removed as a result of constructing trails and associated recreational facilities. Passive recreation in the reserve system could result in trampling and disturbance of egg masses in water bodies, degradation of water quality through erosion and sedimentation, and trampling of sites adjacent to upland habitat used for cover and movement. However, AMM37 Recreation requires protection of water bodies from recreational activities and requires trail setbacks from wetlands. With these restrictions, recreation related effects on California red-legged frog are expected to be minimal.

- Critical habitat: Several environmental commitments would be implemented in California red-legged frog habitat and designated critical habitat in CZ 8 and CZ 11. Approximately 2,460 acres of designated critical habitat for the California red-legged frog overlaps with the study area along the western edge of CZ 11 in critical habitat unit SOL-1. An additional 862 acres of designated critical habitat is also present along the western edge of CZ 8 in critical habitat unit ALA-2. Environmental commitments to protect and enhance grassland habitat for covered species, including California red-legged frog in CZ 8 could include acquisition and enhancement of designated critical habitat for the California red-legged frog and California tiger salamander. Any habitat enhancement actions for these species in designated critical habitat are expected to enhance the value of any affected designated critical habitat for conservation of California red-legged frog. These actions would result in an overall benefit to California red-legged frog within the study area through protection and management of grasslands with associated intermittent stream habitat and through restoration of vernal pool complex habitat and its associated grassland habitat.

- Operations and maintenance: Ongoing water conveyance facilities operation and maintenance is expected to have little if any adverse effect on the California red-legged frog. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic postconstruction disturbances that could affect California red-legged frog use of the surrounding habitat. Operation of maintenance equipment, including vehicle use along transmission corridors in CZ 8, could also result in injury or mortality of California red-legged frogs if present in work sites. Implementation environmental commitments and AMM1–AMM6, AMM10, AMM14, and AMM37, would reduce these effects.
- Injury and direct mortality: Construction activities associated with the water conveyance facilities, stock pond and vernal pool complex restoration, and habitat and management enhancement-related activities, including operation of construction equipment, could result in injury or mortality of California red-legged frogs. Breeding, foraging, dispersal, and overwintering behavior may be altered during construction activities, resulting in injury or mortality of California red-legged frog. Frogs occupying burrows could be trapped and crushed during ground-disturbing activities. Degradation and loss of estivation habitat is also anticipated to result from the removal of vegetative cover and collapsing of burrows. Injury or mortality would be avoided and minimized through implementation of seasonal constraints and preconstruction surveys in suitable habitat, collapsing unoccupied burrows, and relocating frogs outside of the construction area as described in AMM1–AMM6, AMM10, AMM14, and AMM37.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and associated Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

There are approximately 159 acres of modeled aquatic habitat and 7,766 acres of modeled upland habitat for California red-legged frog in the study area. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 1 acre of aquatic habitat and 68 acres of upland habitat for California red-legged frog (less than 1% of the total aquatic habitat and total upland habitat in the study area).

These effects would result from construction of the water conveyance facilities. The 1 acre of aquatic habitat that would be permanently lost is not known to be used for breeding. Most of the California red-legged frog upland habitat that would be removed consists of naturalized grassland or cultivated land in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay. The removed upland cover and dispersal habitat is within 0.5 mile of a cluster of known California red-legged frog occurrences to the west. However, this habitat consists mostly of cultivated lands and small patches of grasslands, and past and current surveys in this area have not found any evidence that this habitat is being used (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, of the Draft EIR/EIS).

With full implementation of Alternative 4A at least 647 acres of grassland would be protected, 150 acres of vernal pool/alkali seasonal wetland complexes with associated grasslands would be protected and 34 acres would be restored, and up to 6 acres of aquatic habitat would be protected and restored in the greater Byron Hills in CZ 8. Protection of grassland in CZ 8 west of Byron Highway would benefit the California red-legged frog by providing habitat in the portion of the study area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas. Six acres of ponds in the grasslands would also be protected to provide aquatic habitat for this species, and the surrounding grassland would provide dispersal and aestivation habitat. Aquatic features in the protected grasslands in CZ 8 would be maintained and enhanced to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding California red-legged frogs. Additionally, livestock exclusion from streams and ponds and other measures would be implemented as described in Environmental Commitment 11 to promote growth of aquatic vegetation with appropriate cover characteristics favorable to California red-legged frogs. Lands protected in CZ 8 would connect with lands protected under the *East Contra Costa County HCP/NCCP* and the extensive Los Vaqueros Watershed lands, including grassland areas supporting this species. This would ensure that California red-legged frog upland and associated aquatic habitats would be protected and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration and 1:1 for protection of nontidal wetlands and 2:1 for protection of grassland habitats. Using these ratios would indicate that 1 acre of aquatic habitat should be restored, 1 acre of aquatic habitat should be protected, and 136 acres of grassland should be protected for California red-legged frog.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM10 Restoration of Temporarily Affected Natural Communities, AMM14 California Red-Legged Frog, and AMM37 Recreation*. These AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2, AMM6, and AMM37 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on California red-legged frog habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, L3, VP/AW1, VP/AW6, G2, G7, and G10, and guided by AMM1–AMM6, AMM10, AMM14, and AMM37, which would be in place throughout the construction period, the effects of Alternative 4A as a whole on California red-legged frog would not be an adverse effect.

CEQA Conclusion: In the absence of actions to restore and protect habitat, the effects on California red-legged frog habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and

Performance Principles L2, L3, VP/AW1, VP/AW6, G2, G7, and G10, and guided by AMM1–AMM6, AMM10, AMM14, and AMM37, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on California red-legged frog would be less than significant.

Impact BIO-45: Indirect Effects of Alternative 4A on California Red-Legged Frog

Noise and visual disturbance outside the project footprint but within 500 feet of construction activities are indirect effects that could temporarily affect the use of California red-legged frog habitat, all of which is upland cover and dispersal habitat. The areas to be affected are near Clifton Court Forebay, and no California red-legged frogs were detected during recent surveys conducted by DWR in this area (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, of the Draft EIR/EIS).

Maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into species habitat. Increased sedimentation could reduce the suitability of California red-legged frog habitat downstream of the construction area by filling in pools and smothering eggs. Accidental spills of toxic fluids also could result in the subsequent loss of California red-legged frog if these materials enter the aquatic system. Hydrocarbon and heavy metal pollutants associated with roadside runoff also have the potential to enter the aquatic system, affecting water quality and California red-legged frog.

NEPA Effects: Implementation of AMM1–AMM6, AMM10, AMM14, and AMM37 as part of implementing Alternative 4A would avoid the potential for adverse effects on California red-legged frogs, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of California red-legged frogs, or restrict the species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on California red-legged frog.

CEQA Conclusion: Indirect effects from environmental commitment operations and maintenance, as well as construction-related noise and visual disturbances, could impact California red-legged frog in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact California red-legged frog or its prey. The inadvertent discharge of sediment or excessive dust adjacent to California red-legged frog habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM6, AMM10, AMM14, and AMM37, Alternative 4A construction, operation, and maintenance would avoid the potential for substantial adverse effects on California red-legged frog, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of California red-legged frogs. The indirect effects of Alternative 4A would have a less-than-significant impact on California red-legged frogs.

California Tiger Salamander

Modeled California tiger salamander habitat in the study area contains two habitat types: terrestrial cover and aestivation habitat, and aquatic breeding habitat and is restricted to CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11 (Figure 12-14). Modeled terrestrial cover and aestivation habitat contains all grassland types and alkali seasonal wetland with a minimum patch size of 100 acres and within a geographic area defined by species records and areas most likely to support the species. Patches of grassland that were below the 100-acre minimum patch size but were contiguous with grasslands outside of the study area boundary were included. Modeled aquatic breeding habitat for the California tiger salamander includes vernal pools and seasonal and perennial ponds.

California tiger salamander occurs within the study area in CZ 8 west of Clifton Court Forebay and in CZ 11 in the Potrero Hills (Figure 12-14). Potential habitat exists in vernal pool habitats in Yolo and Solano Counties (CZs 1, 2, and 3) west of Liberty Island and in the vicinity of Stone Lakes and the Cosumnes River Preserve in Sacramento County (CZ 4). DWR found California tiger salamander west of Clifton Court Forebay in the same vicinity as several of the CNNDB (California Department of Fish and Wildlife 2013) records (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, of the Draft EIR/EIS). There is also a small, isolated population near Manteca, south of Highway 120 in CZ 7.

Construction and restoration associated with Alternative 4A would result in temporary and permanent losses of upland habitat that California tiger salamander uses for cover and dispersal (Table 12-4A-20). Potential aquatic habitat for this species would not be affected. Factors considered in assessing the value of affected habitat for California tiger salamander, to the extent that information is available, include presence of limiting habitat (aquatic breeding habitat), known occurrences and clusters of occurrences, proximity of the affected habitat to existing protected lands, and the overall degraded or fragmented nature of the habitat. While environmental commitments implemented in other CZs could have potential effects on California tiger salamander, those activities in CZ 8 and CZ 11 are considered to have a proportionately larger effect due to their closer proximity to known occurrences of the species.

Alternative 4A would include the following environmental commitments and associated Resource Restoration and Performance Principles to benefit the California tiger salamander (see Chapter 3, *Conservation Strategy*, of the Draft EIR/EIS).

- Protect and improve habitat linkages that allow terrestrial species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2).
- Protect 647 acres of grassland in the Byron Hills area in CZ 8 (Environmental Commitment 3, Resource Restoration and Performance Principle G10).
- Protect 150 acres and restore 34 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands (Environmental Commitment 3, Environmental Commitment 9, and Resource Restoration and Performance Principle VP/AW1).
- Increase burrow availability for burrow-dependent species in grasslands surrounding all suitable aquatic habitat including stock ponds and vernal pool/alkali seasonal wetland complexes (Resource Restoration and Performance Principles G5, VP/AW6).
- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Resource Restoration and Performance Principle L3).
- Protect up to 6 acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Resource Restoration and Performance Principle G2).
- Maintain and enhance aquatic features in protected grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for

covered amphibian and aquatic reptile species (Resource Restoration and Performance Principle G7).

- Increase the size and connectivity of protected vernal pool complex within the project area and increase connectivity with protected vernal pool complex adjacent to the project area (Resource Restoration and Performance Principle VP/AW3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to the implementation of AMMs, impacts on California tiger salamander would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-20. Changes in California Tiger Salamander Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Aquatic	0	0
	Upland	29	32
Total Impacts Water Conveyance Facilities		**29**	**32**
Environmental Commitments 4, 6–7, 9–11[a]	Aquatic	0	0
	Upland	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**29**	**32**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-46: Loss or Conversion of Habitat for and Direct Mortality of California Tiger Salamander

Alternative 4A would result in the permanent and temporary loss combined of up to 61 acres of modeled upland habitat for California tiger salamander (Table 12-4A-20). There would be no effects on aquatic habitat. Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of RTM. In addition, natural enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Maintenance activities associated with the long-term operation of the water conveyance facilities and other project facilities could degrade or eliminate California tiger salamander habitat including injury and mortality of California tiger salamanders. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities, including transmission lines, would result in the permanent loss of 29 acres of upland habitat for California tiger salamander habitat, primarily in CZ 8 (Table 12-4A-20). Permanent effects would be associated with RTM, grading, paving, excavating, extension and installation of cross culverts, installation of structural hardscape, and installation and relocation of utilities. Construction-related effects would temporarily disturb 32 acres of upland habitat for the California tiger salamander (Table 12-4A-20). There is one California tiger salamander occurrence just south of the City of Byron that overlaps with the area of temporary effects. The area that would be affected by conveyance facilities construction is south of Clifton Court

Forebay, where modeled California tiger salamander habitat is of relatively low value in that it consists of fragmented patches of primarily terrestrial habitat surrounded by actively cultivated lands. The highest concentration of California tiger salamander occurrences are in CZ 8 and west of the conveyance facilities alignment, while lands to the east consist primarily of actively cultivated lands that are not suitable for the species. Habitat loss in this area is not expected to contribute to habitat fragmentation or impede important California tiger salamander dispersal.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Protection of 647 acres of grassland, protection of 150 acres and restoration of 34 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands, and protection and restoration of up to 6 acres of aquatic habitat would benefit California tiger salamander. Habitat enhancement- and management-related activities in protected California tiger salamander habitats would result in overall improvements to and maintenance of California tiger salamander habitat values. Activities associated with natural communities enhancement and management in protected California tiger salamander habitat, such as ground disturbance or herbicide use to control nonnative vegetation, could result in local adverse habitat effects and injury or mortality of California tiger salamander and disturbance effects if individuals are present in work sites. Implementation of AMM1–AMM6, AMM10, AMM13, and AMM37 would reduce these effects. Herbicides would only be used in California tiger salamander habitat in accordance with the written recommendation of a licensed, registered Pest Control Advisor and in conformance with label precautions and federal, state, and local regulations in a manner that avoids or minimizes harm to the California tiger salamander.

- An unknown number of acres of terrestrial cover and aestivation habitat for the California tiger salamander could be affected as a result of constructing trails and associated recreational facilities in CZ 8. Passive recreation in the reserve system could result in trampling and disturbance of eggs and larvae in water bodies, degradation of water quality through erosion and sedimentation, and trampling of sites adjacent to upland habitat used for cover and movement. However, *AMM37 Recreation* requires protection of water bodies from recreational activities and requires trail setbacks from wetlands. With these restrictions, recreation related effects on California tiger salamander are expected to be minimal.

- Critical habitat: Approximately 1,781 acres of designated Critical Habitat Unit 2, Jepson Prairie Unit, for California tiger salamander overlap the study area in CZ 1. While this area is located within the Cache Slough Complex, it is not expected to be affected by project restoration actions.

- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on the California tiger salamander. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect California tiger salamander use of the surrounding habitat. Operation of maintenance equipment, including vehicle use along transmission corridors in CZ 8, could also result in injury or mortality of California tiger salamanders if present in work sites. These effects, however, would be minimized with implementation of the California tiger salamander measures described in AMM1–AMM6, AMM10, AMM13, and AMM37.

- Injury and direct mortality: Construction activities associated with the water conveyance facilities, stock pond and vernal pool complex restoration, and habitat and management enhancement-related activities, including operation of construction equipment, could result in injury or mortality of California tiger salamanders. Foraging, dispersal, and overwintering behavior may be altered during construction activities, resulting in injury or mortality of California tiger salamander if the species is present. Salamanders occupying burrows could be trapped and crushed during ground-disturbing activities. Degradation and loss of estivation habitat is also anticipated to result from the removal of vegetative cover and collapsing of burrows. Injury or mortality would be avoided and minimized through implementation of seasonal constraints and preconstruction surveys in suitable habitat, collapsing unoccupied burrows, and relocating salamanders outside of the construction area as described in AMM1–AMM6, AMM10, AMM13, and AMM37.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and associated Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and CEQA conclusions are also included.

There are approximately 8,273 acres of aquatic and 29,459 acres of upland modeled habitat for California tiger salamander in the study area. Alternative 4A as a whole would result in the permanent loss of, and temporary effects combined on 61 acres of upland habitat for California tiger salamander for the term of the plan (less than 1% of the total upland habitat in the study area). These effects would result from construction of the water conveyance facilities. There would be no effects on aquatic habitat.

With full implementation of Alternative 4A at least 647 acres of grassland would be protected, 150 acres of vernal pool/alkali seasonal wetland complexes with associated grasslands would be protected and 34 would be restored, and up to 6 acres of aquatic habitat would be protected and restored in the greater Byron Hills in CZ 8. Protection of grassland in CZ 8 west of Byron Highway would benefit the California tiger salamander by providing habitat in the portion of the study area with the highest long-term conservation value for the species based on known species occurrences and large, contiguous habitat areas. Six acres of ponds in the grasslands would also be protected or restored to provide aquatic habitat for this species, and the surrounding grassland would provide dispersal and aestivation habitat. Aquatic features in the protected grasslands in CZ 8 would be maintained and enhanced to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding California tiger salamanders. Additionally, livestock exclusion from streams and ponds and other measures would be implemented as described in Environmental Commitment 11 to promote growth of aquatic vegetation with appropriate cover characteristics favorable to California tiger salamanders. Lands protected in CZ 8 would connect with lands protected under the *East Contra Costa County HCP/NCCP* and the extensive Los Vaqueros Watershed lands, including grassland areas supporting this species. This would ensure that California tiger salamander upland and associated aquatic habitats would be protected and enhanced in the largest possible patch sizes adjacent to occupied habitat within and adjacent to the study area.

Typical NEPA and CEQA project-level mitigation ratios of 2:1 for protected grassland habitats would indicate that 122 acres of grassland should be protected for California tiger salamander to mitigate the project losses.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged*

Material, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM13 California Tiger Salamander, and AMM37 Recreation*. These AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2, AMM6, and AMM37 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on California tiger salamander habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, L3, VP/AW1, VP/AW3, VP/AW6, G2, G7, and G10, and guided by AMM1–AMM6, AMM10, AMM13, and AMM37, which would be in place throughout the construction period and operations, the effects of Alternative 4A as a whole on California tiger salamander would not be an adverse effect.

CEQA Conclusion: In the absence of actions to restore and protect habitat, the effects on California tiger salamander habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, L3, VP/AW1, VP/AW3, VP/AW6, G2, G7, and G10, and by AMM1–AMM6, AMM10, AMM13, and AMM37, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on California tiger salamander would be less than significant.

Impact BIO-47: Indirect Effects of Alternative 4A on California Tiger Salamander

Indirect effects could occur outside of the construction footprint but within 500 feet of California tiger salamander habitat. Activities associated with conveyance construction, restoration, and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances with localized effects on California tiger salamander and its habitat, and temporary noise and visual disturbances. Most of the areas indirectly affected are associated with the construction of Byron Forebay in CZ 8.

Maintenance and refueling of heavy equipment could result in the inadvertent release of sediment and hazardous substances into species habitat. Increased sedimentation could reduce the suitability of California tiger salamander habitat downstream of the construction area by filling in pools and smothering eggs. Accidental spills of toxic fluids into the aquatic system could result in the subsequent loss of California tiger salamander habitat. Hydrocarbon and heavy metal pollutants associated with roadside runoff also have the potential to enter the aquatic system, affecting water quality and California tiger salamander.

NEPA Effects: Implementation of AMM1–AMM6, AMM10, AMM13, and AMM37 under Alternative 4A would avoid or minimize the potential for adverse effects on California tiger salamanders, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of California tiger salamanders or restrict the species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on California tiger salamander.

CEQA Conclusion: Indirect effects resulting from project operations and maintenance as well as construction-related noise and visual disturbances could impact California tiger salamander in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact California tiger salamander or its prey. The inadvertent discharge of sediment or excessive dust adjacent to California tiger salamander habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM6, AMM10, AMM13, and AMM37 as part of Alternative 4A, the project would avoid the potential for substantial adverse effects on California tiger salamander, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of California tiger salamanders. The indirect effects of Alternative 4A would have a less-than-significant impact on California tiger salamander.

Impact BIO-48: Periodic Effects of Inundation of California Tiger Salamander Habitat as a Result of Implementation of Alternative 4A

There would be no periodic effects on California tiger salamander.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Giant Garter Snake

The habitat model used to assess effects for the giant garter snake is based on aquatic habitat and upland habitat. Modeled aquatic habitat is composed of tidal perennial aquatic, tidal freshwater perennial emergent wetland, nontidal freshwater emergent wetland, and nontidal perennial aquatic natural communities; rice fields; and artificial canals and ditches. Modeled upland habitat is composed of all nonwetland and nonaquatic natural communities (primarily grassland and cropland) within 200 feet of modeled aquatic habitat features. The modeled upland habitat is ranked as high-, moderate-, or low-value based on giant garter snake associations between vegetation and cover types (U.S. Fish and Wildlife Service 2012) and historical and recent occurrence records (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, of the Draft EIR/EIS), and presence of features necessary to fulfill the species' life cycle requirements. Modeled habitat is expressed in acres for aquatic and upland habitats, and in miles for linear movement corridors in aquatic habitat. Other factors considered in assessing the value of affected habitat for the giant garter snake, to the extent that information is available, are proximity to conserved lands and recorded occurrences of the species, proximity to giant garter snake subpopulations (Yolo Basin/Willow Slough and Coldani Marsh/White Slough) in the study area that are identified in the draft recovery plan for this species (U.S. Fish and Wildlife Service 1999b), and contribution to connectivity between giant garter snake subpopulations.

Construction and restoration associated with Alternative 4A would result in both temporary and permanent losses of giant garter snake modeled habitat as indicated in Table 12-4A-21. Alternative 4A would include the following environmental commitments and associated Resource Restoration and Performance Principles to benefit the giant garter snake.

- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Resource Restoration and Performance Principle L3).

- Protect 1,060 acres and restore 1,070 acres of grassland (Environmental Commitment 3 and Environmental Commitment 8).
- Protect 843 acres of high-value upland giant garter snake habitat adjacent to suitable aquatic habitat (Environmental Commitment 3, Resource Restoration and Performance Principle GGS4).
- Restore 255 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, with suitable habitat characteristics for giant garter snake and western pond turtle in CZ 4 and CZ 5 (Environmental Commitment 10).
- Protect 11,870 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species, of which 255 acres of rice land or equivalent-value habitat would be protected for giant garter snake and connected to the restored 255 acres of aquatic habitat in nontidal marsh for giant garter snake in CZ 4 or CZ 5 (Environmental Commitment 3, Resource Restoration and Performance Principles GGS1 and GGS3).
- Protect and improve habitat linkages that allow terrestrial species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2)
- Target cultivated land conservation to provide connectivity between other conservation lands (Resource Restoration and Performance Principle CL2).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).
- Protect giant garter snakes on restored and protected nontidal marsh and adjacent uplands from incidental injury or mortality by establishing 200-foot buffers between protected giant garter snake habitat and roads (other than those roads primarily used to support adjacent cultivated lands and levees). Establish giant garter snake reserves at least 2,500 feet from urban areas or areas zoned for urban development (Resource Restoration and Performance Principle GGS2).
- Create connections from the Coldani Marsh/White Slough subpopulation to other areas in the giant garter snake's historical range in the Stone Lakes vicinity by protecting 255 acres of rice land or equivalent-value habitat (e.g., perennial wetland) for the giant garter snake in CZ 4 and/or CZ 5. Any portion of the 255 acres may consist of muted tidal freshwater emergent wetland and may overlap with the 160 acres of tidally restored freshwater emergent wetland if it meets specific giant garter snake habitat criteria (Resource Restoration and Performance Principle GGS5).

As explained below, with the restoration or protection of these amounts of habitat, in addition to the implementation of AMMs, impacts on giant garter snake would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-21. Changes in Giant Garter Snake Modeled Habitat Associated with Alternative 4A

Project Component	Habitat Type [b]	Permanent	Temporary
Water Conveyance Facilities	Aquatic (acres)	217	120
	Upland (acres)	455	193
	Aquatic (miles)	13	7
Total Impacts Water Conveyance Facilities (acres)		**672**	**313**
Environmental Commitments 4, 6–7, 9–11[a]	Aquatic (acres)	0	0
	Upland (acres)	0	0
	Aquatic (miles)	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a] (acres)		0	0
TOTAL IMPACTS (acres)		**672**	**313**

[a] See discussion below for a description of applicable environmental commitments.
[b] Aquatic acres represent tidal and nontidal habitat combined, and upland acres represent low-, moderate-, and high-value acreages combined.

Impact BIO-49: Loss or Conversion of Habitat for and Direct Mortality of Giant Garter Snake

Alternative 4A would result in the permanent and temporary loss combined of up to 337 acres of modeled aquatic habitat (tidal and nontidal combined), up to 648 acres of modeled upland habitat, and up to 20 miles of channels providing aquatic movement habitat for the giant garter snake (Table 12-4A-21). Project measures that would result in these losses are water conveyance facilities and transmission line construction, geotechnical investigation, and establishment and use of RTM. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available giant garter snake habitat and are expected to result in overall improvements to and maintenance of giant garter snake habitat values. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities would degrade or eliminate giant garter snake habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent loss of approximately 672 acres of modeled giant garter snake habitat, composed of 217 acres of aquatic habitat and 455 acres of upland habitat (Table 12-4A-21). The 455 acres of upland habitat that would be removed for the construction of the conveyance facilities consists of 130 acres of high-, 292 acres of moderate-, and 33 acres of low-value habitat. In addition, approximately 13 miles of channels providing giant garter snake movement habitat would be removed as a result of conveyance facilities construction. Development of the water conveyance facilities would also result in the temporary removal of up to 120 acres of giant garter snake aquatic habitat and up to 193 acres of adjacent upland habitat in areas near construction and geotechnical investigation in CZ 5 and CZ 6 (see Table 12-4A-21 and Terrestrial Biology Map Book). In addition, approximately 7 miles of channels providing giant garter snake movement habitat would be temporarily removed as a result of conveyance facilities construction. There are three giant garter snake occurrences in the vicinity of the water conveyance facilities construction footprint in Snodgrass Slough and Middle River.

Most of the habitat to be lost is in CZ 6 on Mandeville Island. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 4A construction locations. Water facilities construction and operation is expected to have low to moderate potential for adverse effects on giant garter snake aquatic habitat on Mandeville Island because it is not located near or between populations identified in the draft recovery plan. An estimated 301 of the 672 acres would be lost as storage areas for reusable tunnel material, which would likely be moved to other sites for use in levee build-up and restoration, and the affected area would likely be restored: while this effect is categorized as permanent because there is no assurance that the material would eventually be moved, the effect would likely be temporary. Furthermore, the amount of storage area needed for reusable tunnel material is flexible and the footprint used in the effects analysis is based on a worst case scenario: the actual area to be affected by reusable tunnel material storage would likely be less than the estimated acreage.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of giant garter snake habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available giant garter snake habitat and are expected to result in overall improvements to and maintenance of giant garter snake habitat values. These effects cannot be quantified, but are expected to be minimal because vegetation removal would occur around existing infrastructure and roads where giant garter snake are not as likely to be present. Any of these minor impacts would be avoided and minimized by the AMMs listed below.

  Passive recreation in the reserve system could result in human disturbance of giant garter snakes basking in upland areas and compaction of upland burrow sites used for brumation. However, AMM37, described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS, requires setbacks for trails in giant garter snake habitat. With this measure in place, recreation-related effects on giant garter snake are expected to be minimal.

- Operations and maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect giant garter snake use of the surrounding habitat in the Cache Slough area, and the north and south Delta (CZ 1, CZ 2, CZ 3, CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8). Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be reduced by AMMs and environmental commitments as described below.

- Injury and direct mortality: Construction vehicle activity may cause injury or mortality of the giant garter snake. If snakes reside where activities take place (most likely in the vicinity of the Coldani Marsh/White Slough subpopulation [CZ 4]), the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or mortality of giant garter snakes. This risk is highest from late fall through early spring, when the snakes are dormant. Increased vehicular traffic associated construction and restoration could contribute to a higher incidence of road kill. However, preconstruction surveys would be implemented after the project planning phase and prior to any ground-disturbing activity. Any disturbance to suitable aquatic and upland sites in or near the project footprint would be avoided to the extent feasible, and the loss of aquatic habitat and grassland vegetation would be minimized through adjustments to project design, as practicable. Construction monitoring and other measures would be implemented to avoid and minimize injury or mortality of this species during construction as described in *AMM16 Giant Garter Snake*.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A environmental commitments that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

There are approximately 31,281 acres of aquatic and 53,285 acres of upland modeled habitat for giant garter snake in the study area. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 337 acres of aquatic habitat and 648 acres of upland habitat for giant garter snake during the term of the plan (1% of the total aquatic and upland modeled habitat in the study area).

With full implementation of Alternative 4A there would be protection of 1,060 acres and restoration of 1,070 acres of grassland, protection of 11,870 acres of cultivated lands, 119 acres of nontidal wetlands, and restoration of 832 acres of nontidal wetlands in the study area. Lands to be protected and restored specifically for the giant garter snake total 1,353 acres (255 acres nontidal marsh, 843 acres of grassland, 255 acres of cultivated lands (rice or habitat of equivalent value in CZ 4, and CZ 5). In addition to the 1,353 acres of high-value habitat targeted specifically for giant garter snake, the protection and restoration of other natural communities is expected to provide additional restoration and protection of garter snake habitat. An unknown number of irrigation and drainage ditches located in cultivated lands and suitable for giant garter snake movement would be maintained and protected within the reserve system, which would include isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands.

Protection and management of cultivated lands (Environmental Commitment 11) would also benefit the giant garter snake by providing connectivity and maintaining irrigation and drainage channels that provide aquatic habitat for the snake. Giant garter snake habitat would be restored and protected specifically to conserve and expand the Coldani Marsh/White Slough subpopulation of the giant garter snake. Protecting and expanding existing giant garter snake subpopulations, and providing connectivity between protected areas, is considered the most effective approach to giant garter snake conservation in the study area. The Coldani Marsh/White Slough and Yolo Basin/Willow Slough subpopulations are the only known subpopulations of giant garter snakes in the study area and are identified as important for the recovery of the species in the draft recovery plan for the species (U.S. Fish and Wildlife Service 1999b). Implementation actions that target giant garter snake habitat would focus on these two important subpopulations.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration and 1:1 for protection of aquatic habitats and 2:1 for protection of upland habitats. Using these ratios would indicate that 337 acres of aquatic habitat should be restored, 337 acres of aquatic habitat should be protected, and 1,296 acres of upland habitat should be protected for giant garter snake.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, AMM10 Restoration of Temporarily Affected Natural*

Communities, AMM16 Giant Garter Snake, and AMM37 Recreation. All of these AMMs include elements that avoid or minimize the risk of activities affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2, AMM6, and AMM37 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on giant garter snake habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles GGS1-GGS5, L2, L3, CL1, and CL2, and guided by AMM1–AMM7, AMM10, AMM16, and AMM37, which would be in place throughout the construction period and operations, the effects of Alternative 4A as a whole on giant garter snake would not be an adverse effect.

CEQA Conclusion: In the absence of actions to restore and protect habitat, the effects on giant garter snake habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles GGS1-GGS5, L2, L3, CL1, and CL2, and guided by AMM1–AMM7, AMM10, AMM16, and AMM37, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on giant garter snake would not result in a substantial reduction in numbers or a restriction in the range of giant garter snakes. Therefore, the effects of Alternative 4A would have a less-than-significant impact on giant garter snakes.

Impact BIO-50: Indirect Effects of Alternative 4A on Giant Garter Snake

Construction activities outside the project footprint but within 200 feet of construction associated with water conveyance facilities, habitat restoration, and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances with localized effects on giant garter snake habitat, and temporary noise and visual disturbances. These potential effects would be minimized or avoided through AMM1–AMM7, AMM10, AMM16, and AMM37, which would be in effect during all project activities.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect giant garter snake or its aquatic prey. The inadvertent discharge of sediment or excessive dust adjacent to giant garter snake habitat could also have a negative effect on the species or its prey. AMM1–AMM6 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment or dust on giant garter snake or its prey.

Covered activities have the potential to exacerbate bioaccumulation of mercury in covered species that feed on aquatic species, including giant garter snake. The operational impacts of new flows under water conveyance facilities were analyzed to assess potential effects on mercury concentration and bioavailability. Results indicated that changes in total mercury levels in water and fish tissues due to future operational conditions were insignificant (see Draft BDCP Appendix 5.D, *Contaminants*).

Marsh (tidal and nontidal) restoration also has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes. Thus, restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community restoration may indirectly affect giant garter snake, which feeds on small fishes, tadpoles, and small frogs, especially introduced species, such as small bullfrogs (*Rana catesbeiana*) and their larvae, carp (*Cyprinus carpio*), and mosquitofish (*Gambusia affinis*). In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Along with minimization and mitigation measures and adaptive management and monitoring, *Environmental Commitment 12 Methylmercury Management* is expected to reduce the amount of methylmercury resulting from the restoration of natural communities.

Extant populations of giant garter snake within the study area are known only from the upper Yolo Basin and at the Coldani Marsh/White Slough area. Davis et al. (2007) found mercury concentrations in fish at White Slough (and the central Delta in general) to be relatively low compared to other areas of the Delta. No restoration activities involving flooding (and subsequent methylation of mercury) are planned within the known range of the Coldani Marsh/White Slough giant garter snake population. Yolo Basin is where some of the highest concentrations of mercury and methylmercury have been documented (Foe et al. 2008); however, there would be no construction or restoration in this area. Effects from exposure to methylmercury may include decreased predator avoidance, reduced success in prey capture, difficulty in shedding, and reduced ability to move between shelter and foraging or thermoregulation areas (Wylie et al. 2009). The potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. Measures described in *Environmental Commitment 12 Methylmercury Management* include provisions for project-specific Mercury Management Plans. Along with avoidance and minimization measures and adaptive management and monitoring, Environmental Commitment 12 is expected to reduce the effects of methylmercury resulting from natural communities and floodplain restoration on giant garter snake.

NEPA Effects: Implementation of the AMMs listed above and *Environmental Commitment 12 Methylmercury Management* as part of implementing Alternative 4A would avoid the potential for substantial adverse effects on giant garter snakes, either indirectly or through habitat modifications. These AMMs and Environmental Commitment would also avoid and minimize effects that could substantially reduce the number of giant garter snakes or restrict the species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on giant garter snake.

CEQA Conclusion: Indirect effects from project operations and maintenance as well as construction-related noise and visual disturbances could impact giant garter snake in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact giant garter snake or its prey. The inadvertent discharge of sediment or excessive dust adjacent to giant garter snake habitat could also have a negative impact on the species or its prey. With implementation of AMM1–AMM7, AMM10, AMM16, and AMM37 and *Environmental Commitment 12 Methylmercury Management* as part of Alternative 4A construction, operation and maintenance, the project would avoid or minimize the potential for substantial adverse effects on giant garter snakes, either indirectly or through habitat modifications. Therefore, the indirect effects of Alternative 4A would have a less-than-significant impact on giant garter snakes.

Impact BIO-50a: Loss of Connectivity among Giant Garter Snakes in the Coldani Marsh/White Slough Subpopulation, Stone Lakes National Wildlife Refuge, and the Delta

Implementation of Alternative 4A would not introduce a substantial barrier to the movement among giant garter snakes in the Coldani Marsh/White Slough subpopulation, Stone Lakes National Wildlife Refuge, and the Delta in the study area.

***NEPA Effects*:** Alternative 4A would not adversely affect connectivity among giant garter snakes in the Coldani Marsh/White Slough subpopulation, Stone Lakes National Wildlife Refuge, and the Delta in the study area.

***CEQA Conclusion*:** Alternative 4A would have a less-than-significant impact on connectivity among giant garter snakes in the study area and therefore no mitigation is required.

Impact BIO-51: Periodic Effects of Inundation of Giant Garter Snake Habitat as a Result of Implementation of Alternative 4A

There would be no periodic effects on giant garter snake.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Western Pond Turtle

The habitat model used to assess effects on the western pond turtle is based on aquatic and upland nesting and overwintering habitat. Further details regarding the habitat model, including assumptions on which the model is based, are provided in Draft BDCP Appendix 2.A, *Species Accounts*, Section 2A.29, *Western Pond Turtle.* The model quantified two types of upland nesting and overwintering habitat, including upland habitat in natural communities as well as upland in agricultural areas adjacent to aquatic habitats. Both of these upland habitat types are combined for this analysis. Factors considered in assessing the value of affected aquatic habitat are natural community type and availability of adjacent nesting and overwintering habitat. The highest value aquatic habitat types in the study area consist of nontidal freshwater perennial emergent wetlands and ponds adjacent to suitable nesting and overwintering habitat (Patterson pers. comm.). Less detail is provided on effects on dispersal habitat because, although dispersal habitat is important for maintaining and increasing distribution and genetic diversity, turtles have been known to travel over many different land cover types; therefore, this habitat type is not considered limiting. The value of dispersal habitat depends less on the habitat type itself than on the proximity of that habitat type to high-value aquatic and nesting and overwintering habitat.

Alternative 4A would result in both temporary and permanent losses of western pond turtle modeled habitat, as indicated in Table 12-4A-22. The majority of these losses would take place over an extended period of time as tidal marsh is restored in the study area.

Alternative 4A would include the following environmental commitments and Resource Restoration and Performance Principles to benefit the western pond turtle.

- Protect 103 acres and restore 251 acres of valley/foothill riparian habitat (Environmental Commitments 3 and 7).
- Protect 119 acres and restore 832 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, which will

include suitable habitat characteristics for western pond turtle (Environmental Commitments 3 and 10, Resource Restoration and Performance Principle WPT1).

- Protect 1,060 acres and restore 1,070 acres of grassland (Environmental Commitments 3 and 8).
- Protect up to 6 acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Resource Restoration and Performance Principle G2).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs, impacts on western pond turtle would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-22. Changes in Western Pond Turtle Modeled Habitat Associated with Alternative 4A

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Aquatic (acres)	264	2,102
	Upland (acres)	286	77
	Aquatic (miles)	7	5
Total Impacts Water Conveyance Facilities (acres)		**550**	**2,179**
Environmental Commitments 4, 6–7, 9–11[a]	Aquatic (acres)	0	0
	Upland (acres)	5	0
	Aquatic (miles)	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a] (acres)		**5**	
TOTAL IMPACTS (acres)		**555**	**2,179**

[a] See discussion below for a description of applicable environmental commitments.

[b] Upland acres represent upland nesting and overwintering habitat acreages combined for both natural communities and agricultural lands adjacent to aquatic habitats.

Impact BIO-52: Loss or Conversion of Habitat for and Direct Mortality of Western Pond Turtle

Alternative 4A would result in the permanent and temporary loss of up to 2,366 acres of aquatic habitat and 368 acres of upland nesting and overwintering habitat (Table 12-4A-22). Activities that would result in the temporary and permanent loss of western pond turtle modeled habitat are conveyance facilities and transmission line construction, geotechnical investigations, and establishment and use of RTM, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), such as ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate western pond turtle habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent loss of approximately 264 acres of aquatic habitat and 286 acres of upland nesting and overwintering habitat for the western pond turtle in the study area (Table 12-4A-22). Development of the water conveyance facilities would also result in the temporary removal of up to 2,102 acres of aquatic habitat and 77 acres of upland nesting and overwintering habitat for the western pond turtle in the study area (see Table 12-4A-22). Approximately 7 miles of channels providing western pond turtle movement habitat would be removed and 5 miles would be temporarily disturbed. Permanent effects on an estimated 162 of the total 550 aquatic and upland acres combined and 4 of the 7 miles would be lost as storage areas for RTM, which would likely be moved to other sites for use in levee build-up and restoration. The affected area would likely be restored. Although this effect is categorized as permanent because there is no assurance that the material would eventually be moved, the effect would likely be temporary. Furthermore, the amount of storage area needed for RTM is flexible and the footprint used in the effects analysis is based on a worst case scenario. The actual area to be affected by RTM storage would likely be less than the estimated acreage.

  The majority of the permanent loss of aquatic habitat and upland nesting and overwintering habitat would be near Clifton Court Forebay in CZ 8. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 4A construction locations. The aquatic habitat in the Clifton Court Forebay area is considered to be of reasonably high-value because it consists of agricultural ditches in or near known species occurrences. The nesting and overwintering habitat that would be lost consists primarily of cultivated lands with some small portion of ruderal grassland habitat. Except for remnant, uncultivated patches, the cultivated lands are not suitable for nesting and overwintering unless left fallow. Construction of the water conveyance facilities would also affect dispersal habitat, which is primarily cultivated lands. Although there are western pond turtle occurrences scattered throughout CZ 3, CZ 4, CZ 5, and CZ 6, this effect is widely dispersed because of the long, linear nature of the pipeline footprint.

  There are four western pond turtle occurrences that overlap with the water conveyance facilities footprint in CZ 2, one occurrence that overlaps with an RTM area on the southern tip of Bouldin Island in CZ 5, and one occurrence that overlaps with an RTM area along Twin Cities Road in CZ 4.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the conversion of approximately 5 acres of upland nesting and overwintering habitat for western pond turtle to tidal marsh. Tidal habitat restoration is expected to change existing salinity and flow conditions rather than lead to complete loss of aquatic habitat. Restoration of tidal flow where habitat consists of the calm waters of managed freshwater ponds and wetlands could have an adverse effect on the western pond turtle. Tidal restoration is likely to create suitable, slow-moving freshwater slough and marsh habitat suitable for western pond turtle. The habitat affected would be in the interior Delta (West Delta and South Delta) which is of low value, consisting of levees and intensively farmed cultivated lands, while the Cache Slough and Cosumnes-Mokelumne ROAs are less intensively farmed and have higher-value habitat for the turtle. Because the estimates of the effect of tidal inundation are based on projections of where restoration may occur, actual effects are expected to be lower because sites would be selected to minimize effects on western pond turtle habitat (see AMM17 in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP).

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of western pond turtle habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor adverse effects on available western pond turtle habitat and are expected to result in overall improvements to and maintenance of western pond turtle habitat values. In addition, effects would be avoided and minimized by the AMMs listed below.

- Passive recreation in the reserve system could result in human disturbance of western pond turtles basking in upland areas and compaction of upland burrow sites used for nesting. However, AMM37, described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS, requires setbacks for trails in western pond turtle habitat. With this measure in place, recreation-related effects on western pond turtle are expected to be minimal.
- Operations and maintenance: Ongoing maintenance of facilities is expected to have little if any adverse effect on the western pond turtle. Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western pond turtle use where there is suitable habitat in the study area. Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized by AMMs and environmental commitments described below.
- Injury and direct mortality: Construction vehicle activity may cause injury to or mortality of western pond turtles. If turtles reside where environmental commitments are implemented (most likely in the vicinity of aquatic habitats in the study area), the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or mortality of western pond turtles. However, to avoid injury or mortality, preconstruction surveys would be conducted in suitable aquatic or upland habitat for the western pond turtle, and turtles found would be relocated outside the construction areas, as required by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Based on the habitat model, the study area supports approximately 81,666 acres of aquatic and 28,864 acres of upland habitat for western pond turtle. Alternative 4A as a whole would remove 2,366 acres of aquatic habitat and 368 acres of upland nesting and overwintering habitat for western pond turtle (3% of the total aquatic habitat and 1% of the total upland habitat in the study area).

These effects would result from water conveyance facilities construction (2,366 acres of aquatic and 363 acres of upland habitats), tidal habitat restoration (Environmental Commitment 4, 5 acres of upland habitat). Most of the impacts (2,102 acres) from water conveyance facilities would be temporary in the vicinity of Clifton Court Forebay and are expected to return to suitable aquatic habitat once construction is completed. Therefore the following analysis addresses the permanent loss of 264 acres of aquatic habitat.

Implementation of Alternative 4A as a whole would increase the extent and distribution of high-value aquatic and upland nesting and overwintering habitat for western pond turtle in the study area. The conservation strategy for western pond turtle involves restoration and protection of aquatic and adjacent upland habitat, and establishment of an interconnected reserve system that provides for western pond turtle dispersal. The project proponents have committed to protection and restoration of up to 957 acres of aquatic habitat including 951 acres of nontidal wetland and up to 6 acres of stock ponds. In addition, there would be 354 acres of valley/foothill riparian habitat and 2,130 acres of grasslands habitat. The most beneficial restoration would occur in the 832 acres of freshwater emergent wetland consisting of slow-moving slough and marsh adjacent to protected, undisturbed grassland of which 77 acres would be protected and 77 acres restored with suitable habitat characteristics for western pond turtle. Aquatic features (e.g., ditches and ponds) and adjacent uplands that are preserved and managed as part of the 11,870 acres of protected cultivated lands described above for giant garter snake are also expected to benefit the species and to help offset the loss of aquatic habitat. Additionally, basking platforms would be installed as needed in restored freshwater marsh to benefit the western pond turtle.

Riparian restoration would potentially increase the quantity and value of aquatic and nesting and overwintering habitat. Where riparian vegetation is restored adjacent to slower-moving channels, sloughs, and ponds, downed trees can provide important basking habitat and cover habitat for turtles. Riparian restoration in those more interior portions of Old and Middle Rivers that would be managed for riparian brush rabbit habitat have potential to benefit resident western pond turtles as riparian-adjacent grassland is an important habitat characteristic for the rabbit.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected for western pond would be 1:1 for restoration and 1:1 for protection of aquatic habitats and 2:1 for protection of upland habitats. Using these ratios would indicate that 246 acres of aquatic habitat should be restored, 246 acres of aquatic habitat should be protected, and 736 acres of upland habitat should be protected for western pond turtle. Alternative 4A also contains commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM10 Restoration of Temporarily Affected Natural Communities, and AMM17 Western Pond Turtle*. These AMMs include elements that would avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on western pond turtle would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles WPT1, G2, and CL1, and guided by AMM1–AMM6, AMM10, AMM17, and AMM37, the effects of Alternative 4A as a whole on western pond turtle would not be an adverse effect.

CEQA Conclusion: In the absence of actions to restore and protect habitat, the effects on western pond turtle habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles WPT1, G2, and CL1, and guided by AMM1–AMM6, AMM10, AMM17, and AMM37, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on western pond turtle would be less than significant.

Impact BIO-53: Indirect Effects of Alternative 4A on Western Pond Turtle

Indirect effects on western pond turtle within 200 feet of construction activities could temporarily affect the use of aquatic habitat and upland nesting and overwintering habitat for the western pond turtle. Construction activities outside the construction footprint but within 200 feet of water conveyance facilities, habitat restoration, and ongoing habitat enhancement, as well as operation and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances with localized impacts on western pond turtle habitat, and temporary noise and visual disturbances.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western pond turtle or its aquatic prey. The inadvertent discharge of sediment or excessive dust adjacent to western pond turtle aquatic habitat could also have a negative effect on the species or its prey. AMM1–AMM6, and AMM10 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment or dust on western pond turtle or its prey.

***NEPA Effects*:** With implementation of AMM1–AMM6, AMM10, and AMM17 as part of Alternative 4A, the project would avoid the potential for substantial adverse effects on western pond turtles, either directly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of western pond turtles or restrict the species range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on western pond turtle.

***CEQA Conclusion*:** Indirect effects resulting from project operations and maintenance as well as construction-related noise and visual disturbances could impact western pond turtle in aquatic and upland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could affect western pond turtle or its prey. The inadvertent discharge of sediment or excessive dust adjacent to western pond turtle habitat could also have a negative effect on the species or its prey. With implementation of AMM1–AMM6, AMM10, and AMM17 as part of Alternative 4A construction, operation, and maintenance, the Alternative 4A would avoid the potential for substantial adverse effects on western pond turtles, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of western pond turtles. The indirect effects of Alternative 4A would have a less-than-significant impact on western pond turtles.

Impact BIO-54: Periodic Effects of Inundation of Western Pond Turtle Habitat as a Result of Implementation of Alternative 4A

There would be no periodic effects on western pond turtle.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Silvery Legless Lizard, San Joaquin Coachwhip, and Blainville's Horned Lizard

This section describes the effects of Alternative 4A on the silvery legless lizard, San Joaquin coachwhip and Blainville's horned lizard (special-status reptiles). The habitat types used to assess effects on silvery legless lizard are limited to inland sand dunes near Antioch (CZ 9 and CZ 10)

(Figure 12-17). There are isolated patches of sandy habitat in the vicinity of Oakley and along the railroad in the East Bay Regional Park Legless Lizard Preserve that are not shown in Figure 12-17 because project mapping was not available at this level of detail. Furthermore, none of these areas would be affected by construction or restoration activities and this species is not discussed any further.

The habitat types used to assess effects on the San Joaquin coachwhip are alkali seasonal wetland complex, grassland, and inland dune scrub west of Byron Highway (CZ 7)and west of Old River and West Canal (CZ 8). The habitat types used to assess effects on the Blainville's horned lizard are the same as those for the whipsnake in CZ 7 and CZ 8. There is also potential habitat for the horned lizard to occur in grassland habitat around Stone Lake (CZ 4). Although the expected range for San Joaquin coachwhip and Blainville's horned lizard extends into the study area, there are no records for either of these species within the study area (California Department of Fish and Wildlife 2013

Construction associated with Alternative 4A environmental commitments would result in both temporary and permanent removal of habitat that special-status reptiles use for cover and dispersal (Table 12-4A-23).

Alternative 4A would also include the following environmental commitments and associated Resource Restoration and Performance Principles to benefit special-status reptiles.

- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Resource Restoration and Performance Principle L1).
- Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species (Resource Restoration and Performance Principle L3).
- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2).
- Protect 150 acres and restore 34 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands (Environmental Commitment 3).
- Protect 1,060 acres and restore 1,070 acres of grassland (Environmental Commitments 3 and 8).

As explained below, with the restoration or protection of these amounts of habitat, in addition to implementation of AMMs, impacts on special-status reptiles would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-23. Changes in Special-Status Reptile Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type[b]	Permanent	Temporary
Water Conveyance Facilities	Grassland	291	89
Total Impacts Water Conveyance Facilities		**291**	**89**
Environmental Commitments 4, 6–7, 9–11[a]	Grassland	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**291**	**89**

[a] See discussion below for a description of applicable environmental commitments.
[b] Grassland impacts include alkali seasonal wetland complex, grassland, and inland dune scrub natural communities.

Impact BIO-55: Loss or Conversion of Habitat for and Direct Mortality of Special-Status Reptiles

Alternative 4A would result in the permanent and temporary loss of 380 acres of habitat for special-status reptiles (Table 12-4A-23). Water conveyance facilities and transmission line construction, including establishment and use of RTM and geotechnical investigations would cause the loss of special-status reptile habitat. In addition, habitat enhancement and management activities (Environmental Commitment 11), such as ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects for special-status reptiles. For purposes of this analysis, the acres of total effects are considered the same for both San Joaquin coachwhip and Blainville's horned lizard, even though there would be slightly more acres of permanent effect on the San Joaquin coachwhip resulting from water conveyance facilities activities in CZ 4.

In addition to habitat loss and conversion, construction activities, such as grading, the movement of construction vehicles or heavy equipment, and the installation of water conveyance facilities components and new transmission lines, may result in the direct mortality, injury, or harassment of special-status reptiles, including the potential crushing of individuals and disruption of essential behaviors. Construction of access roads could fragment suitable habitat, impede upland movements in some areas, and increase the risk of road mortality. Construction activities related to environmental commitments could have similar effects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Development of the conveyance facilities would result in the permanent loss of approximately 291 acres of habitat for special-status reptiles in the vicinity of Clifton Court Forebay. Construction-related effects would temporarily disturb 89 acres of suitable habitat for special-status reptiles in the study area. There are no occurrences of either species within the construction footprint for water conveyance facilities.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in *Environmental Commitment 11* that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of special-status reptile habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor adverse effects on available special-status reptile habitat and are expected to result in overall improvements to and maintenance of species

habitat values. These effects cannot be quantified, but are expected to be minimal and would be reduced through implementation of Mitigation Measure BIO-55 *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs.*

- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on special-status reptiles. Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect special-status reptiles' use of suitable habitat in the study area. These effects, however, would be minimized with implementation of Mitigation Measure BIO-55.
- Injury and direct mortality: Construction vehicles may cause injury to or mortality of special-status reptiles. The operation of equipment for land clearing, construction, operation and maintenance, and restoration, enhancement, and management activities could result in injury or mortality. This risk is highest from late fall through early spring, when special-status reptiles are not as active. Increased vehicular traffic associated with project actions could contribute to a higher incidence of road kill. However, conducting construction during the late-spring through early fall periods when feasible and implementation of Mitigation Measure BIO-55 would avoid and minimize injury or mortality of special-status reptiles during construction.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and associated Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Alternative 4A would remove 380 acres of grassland habitat for special-status reptiles as a result of water conveyance facilities.

Effects of water conveyance facilities construction on special-status reptiles would be offset through the project's protection of 1,060 acres and restoration of 1,070 acres of grassland, and grassland associated with protection and restoration of up to 184 acres of vernal pool/alkali seasonal wetland complex. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8. This area connects to more than 620 acres of existing habitat that is protected under the East Contra Costa County HCP/NCCP. The projects commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of vernal pool/alkali seasonal wetland complexes) in CZ 8 would sufficiently offset the adverse effects resulting from water conveyance facilities construction.

The typical NEPA and CEQA project-level mitigation ratio (2:1 for protection) for this natural community would indicate that 760 acres should be protected in the near-term to offset water conveyance facilities losses.

NEPA Effects: In the absence of actions to restore and protect habitat, the effects on special-status reptile habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L1-L3, and by Mitigation Measure BIO-55, which would be in place throughout the construction period and operations, the effects of Alternative 4A as a whole on special-status reptiles would not be an adverse effect.

CEQA Conclusion: In the absence of other actions to restore and protect habitat, the effects on special-status reptile habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L1–L3, and by Mitigation Measure BIO-55, which would be in place throughout the construction period and operations, the impact of Alternative 4A as a whole on special-status reptiles would be less than significant.

Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs

DWR will retain a qualified biologist to conduct a habitat assessment in areas that are relatively undisturbed or have a moderate to high potential to support noncovered special-status reptiles (Blainville's horned lizard and San Joaquin coachwhip) in CZ 4, CZ 7, and CZ 8. The qualified biologist will survey for noncovered special-status reptiles in areas of suitable habitat concurrent with the preconstruction surveys for covered species in CZ 4, CZ 7, and CZ 8. If special-status reptiles are detected, the biologist will passively relocate the species out of the work area prior to construction if feasible.

In addition, *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM10 Restoration of Temporarily Affected Natural Communities*, will be implemented for all noncovered special-status reptiles adversely affected by the project to avoid, minimize, or compensate for impacts.

Impact BIO-56: Indirect Effects of Alternative 4A on Special-Status Reptile Species

Construction activities associated with water conveyance facilities, environmental commitments, and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on special-status reptiles and their habitat.

In addition, construction activities could indirectly affect special-status reptiles if construction resulted in the introduction of invasive weeds that create vegetative cover that is too dense for the species to navigate. Construction vehicles and equipment can transport in their tires and various parts under the vehicles invasive weed seeds and vegetative parts from other regions to construction sites, resulting in habitat degradation. These potential effects would be reduced through implementation of AMM10. Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove special-status reptile habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual special-status reptiles, if present.

***NEPA Effects*:** Implementation of the Mitigation Measure BIO-55, *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs* would avoid the potential for substantial adverse effects on these species, either indirectly or through habitat modifications. The mitigation measure would also avoid and minimize effects that could substantially reduce the number of special-status reptiles, or restrict either species' range. Therefore, with implementation of Mitigation Measure BIO-55, the indirect effects of Alternative 4A on special-status reptiles would not be adverse under NEPA.

***CEQA Conclusion*:** Indirect effects from project operations and maintenance as well as construction-related noise and visual disturbances could impact special-status reptiles. In addition, construction activities could indirectly affect special-status reptiles if construction resulted in the introduction of invasive weeds that create vegetative cover that is too dense for the species to navigate. Water conveyance facilities operations and maintenance activities, such as vegetation and weed control, and road maintenance, are not expected to remove special-status reptile habitat, but operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual special-status reptiles, if present. These activities could result in a significant impact.

With implementation of Mitigation Measure BIO-55, *Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs* as part of Alternative 4A construction, operation, and maintenance, the project would avoid the potential for significant effects on special-status reptile species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of either species. With implementation of Mitigation Measure BIO-55, the indirect effects of Alternative 4A would have a less-than-significant impact on special-status reptiles.

Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs

See description of Mitigation Measure BIO-55 under Impact BIO-55.a

California Black Rail

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on California black rail. The habitat model used to assess effects for the California black rail is based on primary breeding habitat and secondary habitat. Primary (breeding) habitat for this species within the Delta includes all *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acre (essentially instream islands of the San Joaquin River and its tributaries and White Slough Wildlife Area). In Suisun Marsh, primary habitat includes all *Schoenoplectus* and *Typha*-dominated, and *Salicornia*-dominated patches greater than 0.55 acre, with the exception that all low marsh habitats dominated by *Schoenoplectus acutus* and *S. californicus* and all managed wetlands, in general, are considered secondary habitat with lesser ecological value. Upland transitional zones that provide refugia during high tides within 150 feet of the tidal wetland edge were also included as secondary habitat. Secondary habitats generally provide only a few ecological functions such as foraging (low marsh and managed wetlands) or extreme high tide refuge (upland transition zones), while primary habitats provide multiple functions, including breeding, effective predator cover, and valuable foraging opportunities.

Alternative 4A would result in both temporary and permanent losses of California black rail modeled habitat as indicated in Table 12-4A-24. Full implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles that would benefit the California black rail.

- At the ecotone that would be created between restored tidal wetlands and transitional uplands (Environmental Commitment 4), provide for at least 22 acres of California black rail habitat (*Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the central Delta) consisting of shallowly inundated emergent vegetation at the upper edge of the marsh (within 50 meters of upland refugia habitat) with adjacent riparian or other shrubs that will provide upland refugia, and other moist soil perennial vegetation. If feasible, create the 22 acres of tidal habitat in a single patch in a location that is contiguous with occupied California black rail habitat (Resource Restoration and Performance Principle CBR1).
- Create topographic heterogeneity in restored tidal wetlands (Environmental Commitment 4, Resource Restoration and Performance Principle CBR2).

California black rail is a fully protected species and take of California black rail individuals is prohibited under section 3511 of the Fish and Game Code. With the implementation of *AMM38 California Black Rail*, construction activities would not result in take and effects on the species would be avoided. As explained below, with the restoration and protection of tidal wetland habitat, in addition to natural community enhancement and management commitments (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM38 California Black Rail*, and *AMM27 Selenium Management*, impacts on the California black rail would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-24. Changes in California Black Rail Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Primary	1	21
	Secondary	0	0
Total Impacts Water Conveyance Facilities		**1**	**21**
Environmental Commitments 4, 6–7, 9–11[a]	Primary	0	0
	Secondary	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**1**	**21**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-57: Loss or Conversion of Habitat for and Direct Mortality of California Black Rail

Alternative 4A would result in the combined permanent and temporary loss of 22 acres of modeled primary habitat for California black rail (Table 12-4A-24). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of RTM areas. Habitat enhancement and management activities (Environmental Commitment 11) which include ground disturbance or removal of nonnative vegetation could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other Alternative 4A physical facilities could degrade or eliminate California black rail habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the permanent loss of up to 1 acre and the temporary loss of up to 21 acres of modeled primary California black rail habitat (Table 12-4A-24). The construction of a temporary transmission line in the central Delta that extends from Bouldin Island to Victoria Island would impact modeled habitat on Mandeville Island, the north end of Bacon Island, and on in-channel islands along the transmission line alignment. Other temporary impacts on modeled habitat would result from a temporary barge unloading facility and a temporary access road along the north end of Bacon Island, and from a temporary work area on Mandeveille Island. Geotechnical exploration could also impact black rail habitat on an in-channel island east of Bacon Island. Up to 1 acre of habitat would be permanently lost from the construction of a permanent transmission line at the northeast corner of Clifton Court Forebay in CZ 8. The water conveyance facilities footprint intersects with one California black rail occurrence on Mandeville Island, from the footprint of the temporary transmission line.

  Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: California black rail modeled habitat would be not be affected by tidal marsh restoration. The restoration of 22 acres of tidal wetlands in the central Delta would benefit California black rail. The primary habitat for the species in the Delta consists of in-channel islands, which are in areas that are most vulnerable to the effects of sea level rise in the study area. Tidal restoration under Environmental Commitment 4 would ensure that land is protected adjacent to current habitat in the delta with the consideration of sea level rise. Tidal restoration for the California black rail would include an ecotone between wetlands and transitional uplands which would provide upland refugia for the species.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions associated with natural communities enhancement, that are designed to enhance wildlife values in restored tidal wetland habitats may result in localized ground disturbances that could temporarily remove small amounts of California black rail habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities are expected to have minor adverse effects on available California black rail habitat and are expected to result in overall improvements and maintenance of California black rail habitat values. Noise and visual disturbances during implementation of habitat management actions could also result in temporary disturbances that affect California black rail use of the surrounding habitat. These effects cannot be quantified, but would be avoided and minimized by the AMMs listed below (AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP. *AMM38 California Black Rail* and an updated version of AMM6 *Disposal and Reuse of Spoils, Reusable Tunnel Material and Dredged Material* are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). The implementation of *AMM38 California Black Rail* would avoid disturbance and take by requiring restrictions on construction activities during the breeding season and establishing nodisturbance buffers around California black rail territories. In addition, construction would be avoided altogether if breeding territories cannot be accurately delimited. Environmental Commitment 11 would also include the control of nonnative predators through habitat manipulation techniques or trapping to reduce nest predation on California black rail if needed.

Water Facility Operations and Maintenance: Post construction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect California black rail use of the central Delta. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by the AMMs listed below (AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP. *AMM38 California Black Rail* and an updated version of *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material and Dredged Material* are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).Injury and Direct Mortality: California black rail is a fully protected species and take is prohibited under Section 3511 of the Fish and Game Code. If rails are present adjacent to covered activities, the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or take of California black rail. Increased vehicular traffic associated with construction and maintenance of water conveyance facilities could also contribute to a higher potential for take. The implementation of *AMM38 California Black Rail* would avoid disturbance and take of California black rail individuals by restricting construction activities during the breeding season and establishing 500-foot no-disturbance buffers around identified territorial calling centers. If the 500-foot buffer does not provide complete avoidance of take, a CDFW-approved biologist would monitor construction activities to ensure that black rail individuals are not harmed. If breeding territories cannot be accurately delimited construction would not occur in order to avoid impacts (*AMM38 California Black Rail* is described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

The following paragraphs summarize the combined effects discussed above and describe environmental commitments that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 7,467 acres of primary and 17,915 acres of secondary habitat for California black rail. Alternative 4A would result in the permanent loss of 1 acre and temporary effects on up to 21 acres of primary California black rail habitat (much less than 1% of the total primary habitat in the study area) as a result of water conveyance facilities construction. The typical NEPA and CEQA project-level mitigation ratio for the tidal wetlands that would be affected by the project would be 1:1 for restoration/creation of tidal wetlands. Using this ratio would indicate that 22 acres of tidal freshwater emergent wetland should be restored/created to mitigate the losses of California black rail habitat.

The project includes measures to improve habitat for California black rail to offset the habitat that is permanently and temporarily lost. Conservation commitments under Alternative 4A through *Environmental Commitment 4 Tidal Natural Communities Restoration* would restore or create 22 acres of tidal wetlands in the central Delta.

Upland refugia for California black rail would be created between the restored tidal wetlands and transitional uplands to provide cover from predators (*Environmental Commitment 4 Tidal Natural Communities Restoration*/Resource Restoration and Performance Principle CBR1). In addition, nonnative predators would be controlled to reduce nest predation if necessary through *Environmental Commitment 11 Natural Communities Enhancement and Management*. These wetlands would consist of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acre, which would provide primary habitat for the black rail. If feasible, the 22 acres of tidal restoration would occur in a single patch at a location adjacent to occupied California black rail habitat. Upland refugia for California black rail would be created between the restored tidal freshwater emergent wetlands and transitional uplands to provide cover from predators (Environmental Commitment 4/Resource Restoration and Performance Principle CBR1). In addition, nonnative predators would be controlled to reduce nest predation if necessary through *Environmental Commitment 11 Natural Communities Enhancement and Management*.

The project also includes commitments to implement the following avoidance and minimization measures that will help to avoid and minimize adverse effects on California black rail: *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, and *AMM38 California Black Rail*. *AMM38 California Black Rail* requires surveys for California black rail and the implementation of avoidance and minimization measures including the establishment of a 500 foot no disturbance buffer around any identified calling stations. All of these AMMs include elements that avoid or minimize the risk of affecting habitat and avoid the risk of take of California black rail in or adjacent to work areas and RTM storage sites.

***NEPA Effects*:** In the absence of environmental commitments and AMMs, the losses of California black rail habitat and potential for take of a special-status species associated with Alternative 4A would represent an adverse effect. However, with habitat protection and restoration associated with Environmental Commitment 4, guided by Resource Restoration and Performance Principles CBR1 and CBR2, and AMM1–AMM7, and *AMM38 California Black Rail*, the effects of Alternative 4A as a whole on California black rail would not be adverse under NEPA.

***CEQA Conclusion*:** In the absence of other environmental commitments and AMMs, the losses of California black rail habitat and potential for take of a special-status species associated with Alternative 4A in the late long-term would represent a significant impact. Considering the restoration provisions, which would provide acreages of new tidal marsh habitat in amounts necessary to compensate for habitats lost to construction and restoration activities guided by Resource Restoration and Performance Principles CBR1 and CBR2, and the implementation of AMM1–AMM7 and *AMM38 California Black Rail*, implementation of Alternative 4A as a whole would not result in a substantial adverse effect through habitat modifications and would avoid take of California black rail individuals. Therefore, the alternative would have a less-than-significant impact on California black rail under CEQA.

Impact BIO-58: Effects on California Black Rail Associated with Electrical Transmission Facilities

A variety of rail species are known to suffer take from transmission line collision, likely associated with migration and flights between foraging areas (Eddleman et. al.1994). Due to their wing shape and body size, rails have low to moderate flight maneuverability (Bevanger 1998), increasing susceptibility to collision mortality. However, there are relatively few records of California black rail collisions with overhead wires.

California black rails exhibit daytime site fidelity and a lack of long-distance night migration, two factors which are associated with low collision risk in avian species (Eddleman et al. 1994). California black rail movements in the study area are likely short, seasonal, and at low altitudes, typically less than 16 feet (5 meters) (Eddleman et al, 1994). There are numerous occurrences within 1 mile of the proposed temporary transmission line which extends north-south between Bouldin Island and Clifton Court Forebay. However, although the species may have low to moderate flight maneuverability, the bird's behavior (e.g., sedentary, nonmigratory, ground-nesting and foraging, solitary, no flocking, secretive) reduces potential exposure to overheard wires and vulnerability to collision mortality (see Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*, of the Draft BDCP). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters which would substantially reduce any potential for take of California black rail individuals from powerline collisions.

Transmission line poles and towers also provide perching substrate for raptors, which are predators on California black rail. Although there is potential for temporary transmission lines to increase perching opportunities for raptors and result in increased predation pressure on local black rails, little is currently known about the seasonal movements of black rails or the potential for increased predation on rails near power poles. Therefore, because of the limited area over which poles are installed relative to the amount of California black rail habitat in the Delta, it is assumed that the increase in predation risk on California black rail from an increase in raptor perching opportunities is negligible.

***NEPA Effects*:** The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the species' flight behaviors. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further eliminate or the risk of take from bird strike for California black rails from the project. The increase in predation risk on California black rail from an increase in raptor perching opportunities is considered negligible because of the limited area over which poles are installed relative to the amount of California black rail habitat in the Delta. Therefore, the construction and operation of new transmission lines would not result in an adverse effect on California black rail.

***CEQA Conclusion*:** The construction and presence of new transmission lines would not result in "take" of California black rail per Section 86 of the California Fish and Game Code because the risk of bird strike is considered to be minimal based on the species' flight behaviors. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further eliminate risk of take from bird strike for California black rails from the project. The increase in predation risk on California black rail from an increase in raptor perching opportunities is considered negligible when considering the limited area over which poles would be installed relative to the amount of California black rail habitat in the Delta. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on California black rail.

Impact BIO-59: Indirect Effects of Alternative 4A on California Black Rail

Indirect construction-related effects: Both primary and secondary habitat for California black rail within the vicinity of proposed construction areas could be indirectly affected by construction activities. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 500 feet from the construction edge. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there is no available data to determine the extent to which these noise levels could affect California black rail. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect California black rail in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to California black rail habitat could also affect the species.

If construction occurs during the nesting season, these indirect effects could result in the loss or abandonment of nests, and take of any eggs and/or nestlings. in the implementation of *AMM38 California Black Rail* (as described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) would avoid disturbance and take of individuals by requiring preconstruction surveys of potential breeding habitat, establishment of a 500-foot no-disturbance buffer, and the presence of an onsite monitor during the breeding season. In addition, construction would be avoided altogether if breeding territories cannot be accurately delimited.

Salinity: Water operations ranging between Operational Scenarios H3 and H4 would have an effect on salinity gradients in Suisun Marsh. It is expected that the salinity of water in Suisun Marsh would generally increase as a result of water operations and operations of salinity-control gates to mimic a more natural water flow. This would likely encourage the establishment of tidal wetland plant communities tolerant of more brackish environments, which should be beneficial to California black rail because its historical natural Suisun Marsh habitat was brackish tidal marsh.

Methylmercury Exposure: The modeled primary habitat for California black rail includes tidal brackish emergent wetland and tidal freshwater emergent wetland in Suisun Marsh and the Delta west of Sherman Island, and instream islands and White Slough Wildlife Area in the central Delta. Black rails typically occur in the high marsh zone near the upper limit of tidal flooding in salt and brackish habitats. Low marsh, managed wetlands, and the upland fringe are considered secondary habitat. California black rails are a top predator in the benthic food chain; they nest and forage in dense vegetation and prey on isopods, insects and arthropods from the surface of mud and vegetation They also consume insects and seeds from bulrushes (*Schoenoplectus* spp.) and cattails (*Typha* spp.) (Eddleman et al. 1994).

Largemouth bass was used as a surrogate species for analysis (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species would overestimate the effects on black rail. Organisms feeding within pelagic-based (algal) food webs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic food webs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Modeled effects of mercury concentrations from changes in operations of water conveyance facilities on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that black rail mercury tissue concentrations would not measurably increase as a result of water conveyance facilities implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes (primary black rail habitat) that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have existing elevated mercury tissue levels, these low level increases could result in some level of effects. Environmental Commitment 12, described below, would be implemented to address this risk of low level increases in methylmercury which could add to the current elevated tissue concentrations.

Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management,* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including California black rail. Tidal and nontidal marsh restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, tidal marsh restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative.

There could be an effect on California black rail from increases in selenium associated with tidal restoration activities (Environmental Commitment 4); however, effects on the California black rail population would be expected to be minimal as the amount of tidal restoration would total up to 22 acres. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of project design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design.

***NEPA Effects*:** Noise and visual disturbances related to construction-related activities from environmental commitments could reduce California black rail use of modeled habitat adjacent to work sites. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect use of the surrounding habitat by California black rail. Potential effects of noise and visual disturbances on California black rail individuals would be avoided with *AMM38 California Black Rail*. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on habitat for the species.

Implementation of operations ranging between Operational Scenarios H3 and H4, including operation of salinity-control gates are expected to increase water salinity in Suisun Marsh because they will create conditions more similar to historic conditions.

Tidal habitat restoration could result in increased exposure of California black rail to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the California black rail population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations would not be expected to result in increased mercury bioavailability to California black rail. Restoration actions that would create high and low tidal marsh, which is California black rail habitat, could provide biogeochemical conditions for methylation of mercury in the in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the amount of tidal restoration would total up to 22 acres, and potential exposure to methylmercury resulting from these acres of restoration would not be expected to adversely affect the California black rail population. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for any effects of increased methylmercury exposure.

With the above measures in place, the indirect effects of Alternative 4A implementation would not result in take of California black rail individuals, nor would it result in a substantial adverse effect on the species through habitat modification. Therefore, the indirect effects of Alternative 4A implementation would not have adverse effect on California black rail.

***CEQA Conclusion*:** Noise and visual disturbances related to construction-related activities and other environmental commitments could reduce California black rail use of modeled habitat adjacent to work sites. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect use of the surrounding habitat by California black rail. Potential effects of noise and visual disturbance on California black rail individuals would be avoided with *AMM38 California Black Rail*. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects on dust on habitat for the species.

Implementation of Operational Scenarios H3 and H4, including operation of salinity-control gates, are expected to increase water salinity in Suisun Marsh. These salinity gradient changes should have a beneficial impact on California black rail because they will create conditions more similar to historic conditions.

Tidal habitat restoration could result in increased exposure of California black rail to selenium; however, the amount of tidal restoration would total up to 22 acres, and potential exposure to selenium resulting from these acres of restoration would not be expected to adversely affect the California black rail population. Any effects would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. With implementation of AMM27, potential for increased selenium exposure would result in no adverse effect on the species.

Changes in water operations would not be expected to result in increased mercury bioavailability to California black rail. Restoration actions that would create high and low tidal marsh, which is California black rail habitat, could provide biogeochemical conditions for methylation of mercury in the in the newly inundated soils. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the amount of tidal restoration would total up to 22 acres, and potential exposure to methylmercury resulting from these acres of restoration would not be expected to adversely affect the California black rail population. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for any effects of increased methylmercury exposure.

With these measures in place, indirect effects of Alternative 4A implementation would not result in take of California black rail individuals, nor would it result in a substantial adverse effect on the species through habitat modification. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on California black rail.

Impact BIO-60: Fragmentation of California Black Rail Habitat as a Result of Project Implementation

Restoration activities may temporarily fragment existing wetlands and could create temporary barriers to California black rail movements. Grading, filling, contouring and other initial ground-disturbing activities could remove habitat along movement corridors used by individuals and potentially temporarily reduce access to adjacent habitat areas. The temporary adverse effects of fragmentation of tidal freshwater emergent wetland habitat for California black rail or restoration activities resulting in barriers to movement would be minimized through sequencing of *Environmental Commitment 4 Tidal Natural Community Restoration* activities to allow for recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38 California Black Rail* would avoid and minimize effects on California black rail.

NEPA Effects: The fragmentation of existing wetlands and creation of temporary barriers to movement would not represent an adverse effect on California black rail as a result of habitat modification of a special-status species because *Environmental Commitment 4 Tidal Natural Communities Restoration* would be phased to allow for the recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38 California Black Rail* would avoid and minimize effects on California black rail.

CEQA Conclusion: The fragmentation of existing wetlands and creation of temporary barriers to movement would represent a less-than-significant impact on California black rail as a result of habitat modification of a special-status species because *Environmental Commitment 4 Tidal Natural Communities Restoration* would be phased to allow for the recovery of some areas before restoration actions are initiated in other areas. In addition, *AMM38California Black Rail* would avoid and minimize impacts on California black rail.

Impact BIO-61: Periodic Effects of Inundation of California Black Rail Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects of inundation on California black rail.

NEPA Effects: There would be no periodic effects of inundation on California black rail.

CEQA Conclusion: There would be no periodic impacts of inundation on California black rail.

California Clapper Rail [1]

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on California clapper rail. California clapper rail modeled habitat includes primarily middle marsh habitat with select emergent wetland plant alliances. High marsh is also used if it is of high value, and low marsh provides foraging habitat for the species. California clapper rail secondary habitats generally provide only a few ecological functions such as foraging (low marsh) or high-tide refuge (upland

[1] Based on recent genetic studies by Maley and Brumfield (2013) and Chesser et al. (2014), the “California” (*Rallus longirostris obsoletus*), “Yuma” (*R. l. yumanensis*), and “light-footed” (*R. l. levipes*) subspecies of clapper rail are now recognized by the American Ornithologists’ Union (AOU) as a separate species: Ridgway’s rail (*Rallus obsoletus*). Consequently, the taxon formerly known as California clapper rail (*R. l. obsoletus*) is now California Ridgway’s rail (*R. o. obsoletus*). For the purposes of this document, the “California clapper rail” common name has been retained due to its use in previous BDCP documents.

transition zones), while primary habitats provide multiple functions including breeding, effective predator cover, and foraging opportunities.

Alternative 4A would occur outside of the current range of the species and would not result in effects on modeled California clapper rail habitat as indicated in Table 12-4A-25. There is no modeled habitat for the species in the water conveyance facilities footprint and tidal restoration under Alternative 4A would not take place in Suisun Marsh.

Table 12-4A-25. Changes in California Clapper Rail Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Primary	0	0
	Secondary	0	0
Total Impacts Water Conveyance Facilities		**0**	**0**
Environmental Commitments 4, 6–7, 9–11[a]	Primary	0	0
	Secondary	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**0**	**0**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-62: Loss or Conversion of Habitat for and Direct Mortality of California Clapper Rail

No habitat would be lost or converted and there would be no direct take of California clapper rail under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects**:** There would be no effects on California Clapper Rail habitat.

CEQA Conclusion: There would be no impacts on California Clapper Rail habitat.

Impact BIO-63: Indirect Effects of the Project on California Clapper Rail

No indirect effects on California clapper rail were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects**:** There would be no indirect effects on California Clapper Rail.

CEQA Conclusion**:** There would be no indirect impacts on California Clapper Rail.

Impact BIO-64: Effects on California Clapper Rail Associated with Electrical Transmission Facilities

Isolated patches of suitable California clapper rail habitat may occur in the study area as far east as (but not including) Sherman Island. Home range and territory of the California clapper rail is not known, but in locations outside of California, clapper rail territory ranges 0.3 acre to 8 acres (0.1 to

3.2 hectares) (Rush et al. 2012), indicating that known occurrences are not likely to intersect with the proposed lines (BDCP Attachment 5J.C*, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). The location of the current population and suitable habitat for the species make collision with the proposed transmission lines highly unlikely.

NEPA Effects: The construction and presence of new transmission lines would not have an adverse effect on California clapper rail because the location of the current population and suitable habitat for the species would make collision with the proposed transmission lines highly unlikely.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on California clapper rail because the location of the current population and suitable habitat for the species would make collision with the proposed transmission lines highly unlikely.

Impact BIO-65: Fragmentation of California Clapper Rail Habitat as a Result of Project Implementation

No effects of fragmentation of California clapper rail were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

NEPA Effects: There would be no effects of fragmentation on California Clapper Rail habitat.

CEQA Conclusion: There would be no impacts of fragmentation on California Clapper Rail habitat.

California Least Tern

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on California least tern. California least tern modeled habitat identifies foraging habitat as all tidal perennial aquatic natural community in the study area. Breeding habitat is not included in the model because most of the natural shoreline in the study area that historically provided nesting sites has been modified or removed. Least terns currently nest on artificial fill adjacent to tidal perennial aquatic habitat in the vicinity of Suisun Marsh and west Delta, and additional nesting could occur at the edge of tidal perennial waters whenever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). The study area is outside of the primary range of California least tern, although there are two CNDDB occurrences, one in Suisun Marsh (CZ 11), and one in Pittsburg (CZ 10).

Alternative 4A would result in both temporary and permanent losses of California least tern modeled foraging habitat as indicated in Table 12-4A-26.

California least tern is a fully protected species and "take" of individuals, per Section 86 of the California Fish and Game Code, is prohibited. With the implementation of *AMM20 Greater Sandhill Crane*, and Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized,* construction activities would not result in take of the species, which would avoid take per Section 86 of the California Fish and Game Code[2]. As explained below, with the expansion of aquatic foraging habitat in Clifton Court Forebay, in addition to natural community enhancement and management commitments (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM27 Selenium Management*, and mitigation to avoid impacts on terns should they nest in the study area, impacts on the California least tern would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-26. Changes in California Least Tern Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Foraging	207	2,098
Total Impacts Water Conveyance Facilities		**207**	**2,098**
Environmental Commitments 4, 6–7, 9–11[a]	Foraging	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**207**	**2,098**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-66: Loss or Conversion of Habitat for and Direct Mortality of California Least Tern

Alternative 4A would result in the combined permanent and temporary loss of up to 2,367 acres of modeled foraging habitat for California least tern (Table 12-4A-26). The project components that would result in these losses are construction of water conveyance facilities and operation. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities could degrade or eliminate California least tern foraging habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,305 acres of modeled California least tern aquatic foraging habitat (Table 12-4A-26). Of these acres, 207 acres would be a permanent loss the majority of which would occur where new facilities are constructed at Clifton Court Forebay. A smaller portion of the permanent loss would occur where Intakes 2, 3, and 5 encroach on the Sacramento River's east bank between Clarksburg and Courtland. Permanent losses would also occur where new control structures would be built into the California Aqueduct and the Delta Mendota Canal adjacent to Clifton Court Forebay where Clifton Court Forebay levees are modified. The temporary effects on tidal perennial aquatic habitats would occur at numerous locations, with the largest affect occurring at Clifton Court Forebay, where the entire forebay would be dredged to provide additional storage capacity. Other temporary effects would occur in the Sacramento River at Intakes 2, 3, and 5, and at temporary barge unloading facilities established at three locations along the tunnel route. The water conveyance facilities footprint does not overlap with any California least tern occurrences. Refer to the

[2] Section 86 of the California Fish and Game Code defines take as "hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill." The project proponents do not propose to hunt, pursue, catch, or capture California least tern. Killing would be avoided through AMM20.

Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Noise and visual disturbances during implementation of habitat management actions could result in temporary disturbances that affect California least tern use of the surrounding habitat. These effects cannot be quantified, but are expected to be minimal because few management activities would be implemented in aquatic habitat and because terns are not expected to nest on protected lands. Surveys would be conducted prior to ground disturbance in any areas that have suitable nesting substrate for California least tern (flat, unvegetated areas near aquatic foraging habitat) and take and other effects on nesting terns would be avoided and minimized by the AMMs and Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, described below.
- *Water Facilities Operations and Maintenance*: Post construction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic postconstruction disturbances, localized impacts on California least tern foraging habitat, and temporary noise and disturbances over the term of the project. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas which could be adjacent to California least tern foraging habitat. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: California least terns currently nest in the vicinity of potential restoration sites in the west Delta area (CZ 10). New nesting colonies could establish if suitable nesting habitat is created during restoration activities (e.g., placement of unvegetated fill to raise surface elevations prior to breaching levees during restoration efforts). If nesting occurs where covered activities are undertaken, the operation of equipment for land clearing, construction, conveyance facilities operation and maintenance, and habitat restoration, enhancement, and management could result in injury or take of California least tern. Risk of injury or disturbance would be greatest to eggs and nestlings susceptible to land-clearing activities, abandonment of nests and nesting colonies, or increased exposure to the elements or to predators. Injury to adults or fledged juveniles is less likely as these individuals would be expected to avoid contact with construction equipment. However, injury or take would be avoided through planning and preconstruction surveys to identify nesting colonies, the design of projects to avoid locations with least tern colonies, and the provision for 500-foot buffers as required by Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*.

The following paragraph summarizes the combined effects discussed above and describes environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

With Alternative 4A implementation, there would be a permanent loss of 207 acres of modeled foraging habitat for California least tern in the study area. The permanent loss would occur primarily from the expansion of the Clifton Court Forebay and, a lesser amount would be lost along the Sacramento River. In addition, 2,098 acres would be temporarily unavailable from the dredging of the Clifton Court Forebay. The temporary loss of habitat would not be expected to adversely affect California least tern as the impact area is outside of their primary range.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected by water conveyance facilities would be 1:1 for restoration/creation of tidal perennial aquatic habitat. Using this ratio would indicate that 207 acres of the tidal perennial aquatic natural community should be restored/created to compensate for the permanent loss of potential California least tern habitat from the construction of the water conveyance facilities. Part of the project includes the permanent expansion of the Clifton Court Forebay, which would create approximately 450 acres of aquatic habitat, which would be available for the California least tern if they were to forage in the area. This habitat creation would occur within the same timeframe as the construction temporary and permanent losses, thereby avoiding adverse effects on California least tern from loss of foraging habitat. In addition, 37 acres of tidal wetlands would be restored in the north delta, which would provide foraging opportunities for the species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM*2 *Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats at or adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Although nesting by California least tern is not expected to occur, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). If nesting were to occur, construction activities could have an adverse effect on California least tern. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies Will be Minimized*, would be available to address this adverse effect on nesting California least terns.

NEPA Effects: The potential for take of California least tern associated with Alternative 4A would represent an adverse effect in the absence of the mitigation measure and AMMs described below. Although nesting by California least tern is not expected to occur in the study area, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). If nesting were to occur, construction activities could have an adverse effect on California least tern. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized*, would be available to address this effect on nesting California least terns. Temporary impacts on tidal perennial aquatic habitat in Clifton Court Forebay associated with dredging would not be expected to impact California least tern, as this region of the study area is outside of their primary range. The restoration of aquatic habitat associated with the expansion of the Clifton Court Forebay (water conveyance facilities), and Environmental Commitment 4 (tidal restoration) would be sufficient to compensate for permanent impacts on California least tern foraging habitat. With these acres of restoration, in addition to the implementation of *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*, which would be in place during all project activities, the effects of Alternative 4A as a whole on California least tern would not be adverse.

CEQA Conclusion: The potential take of California least tern associated with Alternative 4A would represent an adverse effect in the absence of the Mitigation Measure and AMMs described below as a result of potential for take of a special-status species. Although nesting by California least tern is not expected to occur in the study area, restoration sites could attract individuals wherever disturbed or artificial sites mimic habitat conditions sought for nesting (i.e., sandy or gravelly substrates with sparse vegetation). Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall be Avoided and Indirect Effects on Colonies will be Minimized*, would avoid the potential for take of California least tern individuals and reduce this effect to a less-than-significant impact.

Temporary impacts on tidal perennial aquatic habitat in Clifton Court Forebay associated with dredging would not be expected to impact California least tern, as this region of the study area is outside of their primary range. The restoration of aquatic habitat associated with the expansion of the Clifton Court Forebay (water conveyance facilities), and *Environmental Commitment 4 Tidal Natural Communities Restoration* would be sufficient to compensate for permanent impacts on California least tern foraging habitat. With these acres of restoration, in addition to the implementation of *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*, which would be in place during all project activities, the effects of Alternative 4A as a whole on California least tern would not result in a substantial adverse effect through habitat modifications and would avoid take of individuals. Therefore, the implementation of Alternative 4A would have a less-than-significant impact on California least tern.

Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

If suitable nesting habitat for California least tern (flat unvegetated areas near aquatic foraging habitat) is identified during planning level surveys, DWR will ensure that a qualified biologist with experience observing the species and its nests conducts at least three preconstruction surveys for this species during the nesting season. DWR will design projects to avoid the loss of California least tern nesting colonies. No construction will take place within 500 feet California least tern nests during the nesting season (April 15 to August 15 or as determined through surveys). Only inspection, maintenance, research, or monitoring activities may be performed during the least tern breeding season in areas within or adjacent to least tern breeding habitat with USFWS and CDFW approval under the supervision of a qualified biologist.

Impact BIO-67: Indirect Effects of the Project on California Least Tern

Indirect construction- and operation-related effects: Indirect effects associated with construction that could affect California least tern include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 500 feet from the construction edge. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect California least tern. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect

California least tern or their prey species in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to foraging habitat could also affect the species. Noise and visual disturbance is not expected to have an adverse effect on California least tern foraging behavior. As described in Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, if least tern nests were found during planning or preconstruction surveys, no construction would take place within 500 feet of active nests. In addition, AMM1–AMM7, including construction best management practices, would minimize the likelihood of spills or excessive dust being created during construction. Should a spill occur, implementation of these AMMs would greatly reduce the likelihood of individuals being affected.

Methylmercury Exposure: Covered activities have the potential to exacerbate the bioaccumulation of mercury in the California least tern. The operational impacts of new flows with water conveyance facilities were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability. Largemouth bass were used as a surrogate species for this analysis and results would be expected to be similar or lower for the California least tern. Results indicated that changes in total mercury levels in water and largemouth bass tissues were insignificant (see Appendix 5.D, *Contaminants*, of the Draft BDCP).

Marsh (tidal and nontidal) restoration also has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community restoration may indirectly affect California least tern, via uptake through consumption of prey (as described in the, Appendix 5.D, *Contaminants*, of the Draft BDCP).

Schwarzbach and Adelsbach (2003) investigated mercury exposure in 15 species of birds inhabiting the Bay-Delta ecosystem. Among the species studied, the highest concentrations of mercury were found in the eggs of piscivorous birds (terns and cormorants) that bioaccumulate mercury from their fish prey. The very highest concentrations were found in Caspian and Forster's terns, especially those inhabiting South San Francisco Bay. Based on three California least tern eggs collected from Alameda Naval Air Station in the San Francisco Central Bay, concentrations in California least tern eggs were a third (0.3 ppm) those of the eggs of the other two terns. Because of the small sample size, there is a high degree of uncertainty regarding the levels of mercury that may be present in California least tern eggs. If the mercury levels measured at Alameda Naval Air Station are representative of the population in the San Francisco Bay, they would not be expected to result in adverse effects on tern hatchlings. Hatching and fledging success were not reduced in common tern eggs in Germany with mercury concentrations of 6.7 ppm (Hothem and Powell 2000).

Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels pre-Alternative 4A, these low level increases could result in some level of effects. Environmental Commitment 12, described below, would be implemented to address this risk of low level increases in methylmercury which could add to the current elevated tissue concentrations.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.

- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including California least tern. Marsh (tidal and nontidal) restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 4, Environmental Commitment 5) would lead to adverse effects on California least tern.

Because of the uncertainty that exists with respect to specific siting of tidal restoration areas, there could be a substantial effect on California least tern from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects**:** Noise and visual disturbances within 500 feet of construction-related activities from the environmental commitments could disturb California least tern foraging habitat adjacent to work sites. Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, would avoid this potential adverse effect.

AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species.

Tidal habitat restoration could result in increased exposure of California least tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations under water conveyance facilities would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1–7, AMM12, AMM27, and Environmental Commitment 12 in place, in addition to the implementation of Mitigation Measure BIO-66, the indirect effects of Alternative 4A, implementation would not result in an adverse effect on California least tern.

Mitigation Measure BIO-66, California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

See Mitigation Measure BIO-66 under Impact BIO-66.

CEQA Conclusion**:** Noise and visual disturbances within 500 feet of construction-related activities from the environmental commitments would not be expected to disturb California least tern foraging habitat adjacent to work sites. If terns were to nest in newly graded restoration sites during construction activities, Mitigation Measure BIO-66, *California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized*, would avoid the potential for disturbance and take of California least tern individuals.

AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of spills from occurring and ensure that measures were in place to prevent runoff from the construction area and to avoid negative effects of dust on the species.

Tidal habitat restoration could result in increased exposure of California least tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations under water conveyance facilities would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1–7, AMM12, AMM27, and Environmental Commitment 12 in place, in addition to the implementation of Mitigation Measure BIO-66, the indirect effects of Alternative 4A implementation would not result in take of California least tern individuals, nor would it result in a substantial adverse effect on the species through habitat modification. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on California least tern.

Mitigation Measure BIO-66, California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized

See Mitigation Measure BIO-66 under Impact BIO-66.

Impact BIO-68: Effects on California Least Tern Associated with Electrical Transmission Facilities

The risk of take of California least tern from the construction of new transmission lines is considered to be minimal based on tern flight behaviors and its unlikely use of habitats near the transmission line corridors. Terns exhibit low wing loading and high aspect-ratio wings and as a result can maneuver relatively quickly around an obstacle such as a transmission line. Their wing structure and design allows for rapid flight and quick, evasive actions (see Draft BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to California least terns and would further eliminate potential for powerline collisions.

NEPA Effects: The construction and presence of new transmission lines would not represent an adverse effect on California least tern as a result of take of a special-status species because they are uncommon in the vicinity of proposed transmission lines and because the probability of bird-powerline strikes is highly unlikely due to tern flight behaviors. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would not result in an adverse effect on California least tern.

CEQA Conclusion: The construction and presence of new transmission lines would represent a less-than-significant impact on California least tern as a result of take of a special-status species because they are uncommon in the vicinity of proposed transmission lines and because the probability of bird-powerline strikes is highly unlikely due to tern flight behaviors. *AMM20 Greater Sandhill Crane* contains the commitment for all new transmission lines constructed as a result of the project to be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, there would be no take of California least tern from the project per Section 86 of the California Fish and Game Code, and the construction and operation of transmission lines would result in a less-than-significant impact on California least tern.

Greater Sandhill Crane

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on greater sandhill crane. Greater sandhill cranes in the study area are almost entirely dependent on privately owned agricultural lands for foraging. Long-term sustainability of the species is thus dependent on providing a matrix of compatible crop types that afford suitable foraging habitat and maintaining compatible agricultural practices, while sustaining and increasing the extent of other essential habitat elements such as night roosting habitat. The habitat model for greater sandhill crane includes permanent and temporary “roosting and foraging” and “foraging” habitat. These habitat types include certain agricultural types, specific grassland types, irrigated pastures and hay crops, managed seasonal wetland, and other natural seasonal wetland. Roosting and foraging habitat includes known, traditional roost sites that also provide foraging habitat (see Appendix 2.A *Covered Species Accounts*, of the Draft BDCP). Both temporary and permanent roost sites were identified for greater Sandhill crane. Permanent roosting and foraging sites are those used regularly, year after year, while temporary roosting and foraging sites are those only used in some years. Factors included in assessing the loss of foraging habitat for the greater sandhill crane includes the relative habitat value of specific crop or land cover types, and proximity to known roost sites. Foraging habitat for greater sandhill crane included crop types and natural communities up to 4 miles from known roost sites, within the boundary of the winter crane use area (see Appendix 2.A, *Covered Species Accounts*, of the Draft BDCP).

Alternative 4A would result in both temporary and permanent losses of foraging and roosting habitat for greater sandhill crane as indicated in Table 12-4A-27. Full implementation of Alternative 4A would also include the following Resource Restoration and Performance Principles that would benefit the greater sandhill crane.

- Protect at least 3,892 acres of high- to very high-value habitat for greater sandhill crane, with at least 80% maintained in very high-value types in any given year. This protected habitat will be within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6 and will consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss. Patch size of protected cultivated lands will be at least 160 acres (Resource Restoration and Performance Principle GSC1).

- Create at least 320 acres of managed wetlands (part of the nontidal wetland restoration acreage) in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands will be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands (Resource Restoration and Performance Principle GSC2).

- Create at least two 90-acre wetland complexes within the Stone Lakes National Wildlife Refuge project boundary. The complexes will be no more than 2 miles apart and will help provide connectivity between the Stone Lakes and Cosumnes River Preserve greater sandhill crane populations. Each complex will consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and will be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes National Wildlife Refuge for greater sandhill crane (Resource Restoration and Performance Principle GSC3).
- Create an additional 95 acres of roosting habitat within 2 miles of existing permanent roost sites. The habitat will consist of active cornfields that are flooded following harvest to support roosting cranes and that provide highest-value foraging habitat. Individual fields will be at least 40 acres and can shift locations throughout the Greater Sandhill Crane Winter Use Area, but will be sited with consideration of the location of roosting habitat loss and will be in place prior to roosting habitat loss (Resource Restoration and Performance Principle GSC4).

Greater sandhill crane is a fully protected species and “take” of individuals, per Section 86 of the California Fish and Game Code, is prohibited. With the implementation of *AMM20 Greater Sandhill Crane*, construction activities would not result in take of the species, which would avoid take per Section 86 of the California Fish and Game Code[3]. As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and *AMM30 Transmission Line Design and Alignment Guidelines*, impacts on the greater sandhill crane would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

[3] Section 86 of the California Fish and Game Code defines take as “hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill.” The project proponents do not propose to hunt, pursue, catch, or capture greater sandhill cranes. Killing would be avoided through AMM20.

Table 12-4A-27. Changes in Greater Sandhill Crane Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Roosting and Foraging–Permanent	0	3
	Roosting and Foraging–Temporary	16	85
	Foraging	1,799	850
Total Impacts Water Conveyance Facilities		**1,815**	**938**
Environmental Commitments 4, 6–7, 9–11[a]	Roosting and Foraging–Permanent	0	0
	Roosting and Foraging–Temporary	0	0
	Foraging	1,985	0
Total Impacts Environmental Commitments 4, 6–9–11[a]		**1,985**	**0**
Total Roosting/Foraging–Permanent		**0**	**3**
Total Roosting/Foraging–Temporary		**16**	**85**
Total Foraging		**3,784**	**850**
TOTAL IMPACTS		**3,800**	**938**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-69: Loss or Conversion of Habitat for and Direct Mortality of Greater Sandhill Crane

Alternative 4A would result in the combined permanent and temporary loss of up to 104 acres of modeled roosting and foraging habitat (16 acres of permanent loss, 88 acres of temporary loss) and 4,634 acres of foraging habitat for greater sandhill crane (3,784 of permanent loss, 850 acres of temporary loss; see Table 12-4A-27). Project measures that would result in these losses are water conveyance facilities and transmission line construction, establishment and use of reuseable tunnel material areas, *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 8 Grassland Natural Communities Restoration*, *Environmental Commitment 10 Nontidal Marsh Natural Community Restoration*, and *Environmental Commitment 11 Natural Communities Enhancement and Management*. The majority of habitat loss would result from water conveyance facility construction and conversion of habitat to nontidal wetland through Environmental Commitment 10. Habitat enhancement and management activities through Environmental Commitment 11, which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate greater sandhill crane modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities as they are currently designed would result in the combined permanent loss of up to 1,815 acres of modeled greater sandhill crane habitat. This would consist of the permanent removal of 16 acres of temporary roosting and foraging habitat, and 1,799 acres of foraging habitat (Table 12-4A-27). Foraging habitat that would be permanently impacted by water conveyance facilities would consist of 474 acres of very high-value, 202 acres of high-value, 579 acres of medium-value, and 544 acres of low-value foraging habitat (Table 12-4A-28). In addition, 3 acres of permanent roosting and foraging habitat, 85 acres of temporary roosting and foraging habitat, and 850 acres of foraging habitat would be temporarily removed (Table 12-4A-27, Table 12-4A-28). The temporarily removed habitat would consist primarily of cultivated lands and it would be restored within one year following construction; however, it would not necessarily be restored to its original topography and it could be restored as grasslands in the place of cultivated lands. Water conveyance facilities activities that would result in temporary impacts would include temporary access roads, reusable tunnel material sites, and work areas for construction.

The acres of roosting and foraging habitat that would be removed would occur from the construction of a temporary transmission line on Zacharias Island, Bouldin Island, and Venice Island and from the construction of a temporary concrete batch plant and a permanent access road on Bouldin Island; however, the implementation of *AMM20 Greater Sandhill Crane* would require that water conveyance facilities activities be designed to avoid direct loss of crane roost sites. This includes a provision that the final transmission line alignment would be designed to avoid crane roost sites. Avoidance of crane roost sites would be accomplished either by siting activities outside of identified roost sites or by relocating the roost site if it consisted of cultivated lands (roost sites consisting of wetlands would not be subject to re-location). Relocated roost sites would be established prior to construction activities affecting the original roost site, as described in *AMM20 Greater Sandhill Crane* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed. The potential for greater sandhill crane bird strike on electrical transmission facilities is addressed below under Impact BIO-70.

Approximately 1,480 acres of the permanent loss of foraging habitat would be from the storage of reusable tunnel material. This material would likely be moved to other sites for use in levee build-up and restoration, and the affected area would likely eventually be restored. This effect is categorized as permanent because there is no assurance that the material would eventually be moved. The implementation of *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) would require that the areas used for reusable tunnel material storage be minimized in crane foraging habitat and completely avoid crane roost sites.

Construction-related activities would not be expected to result in take of greater sandhill crane if they were present in the study area, because cranes would be expected to avoid contact with construction and other equipment. The potential for greater sandhill crane bird strike on electrical transmission lines is discussed below under Impact BIO-70.

The effects of noise and visual disturbance from water conveyance facilities construction activities are discussed under Impact BIO-71. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

Table 12-4A-28. Value of Greater Sandhill Crane Foraging Habitat affected by Alternative 4A

Foraging Habitat Value Class	Land Cover Type	Amount Affected by Water Conveyance Facilities permanent [temporary] (acres)	Amount Affected by Environmental Commitments (permanent acres)
Very high	Corn, rice	474 [224]	524
High	Wheat, managed wetlands,	202 [95]	222
Medium	Alfalfa and alfalfa mixtures, irrigated mixed pasture, irrigated native pasture, irrigated pasture, irrigated other pasture, grain and hay crops, miscellaneous grain and hay, mixed grain and hay, nonirrigated mixed grain and hay, other grain crops, sudan, miscellaneous grasses, grassland, alkali seasonal wetlands, vernal pool complex	579 [273]	638
Low	Other irrigated crops, idle cropland, blueberries, asparagus, clover, cropped within the last 3 years, grain sorghum, green beans, miscellaneous truck, miscellaneous field, new lands being prepped for crop production, nonirrigated mixed pasture, nonirrigated native pasture, onions, garlic, peppers, potatoes, safflower, sugar beets, tomatoes (processing), melons squash and cucumbers all types, artichokes, beans (dry), native vegetation	544 [257]	601
Total		**1,799 [850]**	**1,985**

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 59 acres of greater sandhill crane foraging habitat in the north Delta. Loss of foraging habitat from Environmental Commitment 4 would consist of 16 acres of very high-value, 7 acres of high-value, 19 acres of medium-value, and 18 acres of low-value foraging habitat.
- *Environmental Commitment 7 Riparian Natural Communities Restoration*: This activity would result in the permanent loss of approximately 251 acres of greater sandhill crane foraging habitat. Loss of foraging habitat from Environmental Commitment 4 would consist of 66 acres of very high-value, 28 acres of high-value, 81 acres of medium-value, and 76 acres of low-value foraging habitat.
- *Environmental Commitment 8 Grassland Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 843 acres of cultivated lands that comprise greater sandhill crane foraging habitat. Loss of foraging habitat from Environmental Commitment 4 would consist of 222 acres of very high-value, 94 acres of high-value, 271 acres of medium-value, and 255 acres of low-value foraging habitat.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would result in the permanent conversion of approximately 832 acres of modeled foraging habitat for the greater sandhill crane. Impacts would consist of approximately 219 acres of very high-value, 93 acres of high-value, 268 acres of medium-value, and 252 acres of low-value foraging habitat (Table 12-4A-28). A portion of the restored nontidal marsh would be expected to provide roosting and foraging habitat value for the greater sandhill crane. However, some of this

restored marsh would be unsuitable as it would lack emergent vegetation and consist of open water that would be too deep to provide suitable roosting or foraging habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values. The potential for these activities to result in take of greater sandhill crane would be minimized with the implementation of *AMM20 Greater Sandhill Crane*. Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Chapter 4, *Covered Activities and Associated Federal Actions*, of the Draft BDCP). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.
- *Water Facilities Operations and Maintenance:* Post construction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect greater sandhill crane use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects could be adverse as sandhill cranes are sensitive to disturbance. However, potential impacts would be reduced by the AMMs listed below. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2, AMM6 and AMM20 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

The following paragraphs summarize the combined effects discussed above and describe Alternative 4A environmental commitments that offset or avoid these effects. NEPA effects and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 104 acres roosting and foraging habitat (16 acres of permanent loss, 88 acres of temporary loss) from the construction of the water conveyance facilities. In addition, 4,634 acres of foraging habitat would be removed or converted (Water Conveyance Facilities—2,649 acres; *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration,* and *Environmental Commitment 10 Nontidal Marsh Restoration*—1,985 acres). Of these acres of foraging habitat impact, 2,598 acres would be medium- to very high-value habitat (Table 12-4A-28).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 protection and 1:1 restoration for loss of roost sites and 1:1 protection of high- to very high-value foraging habitat for loss of foraging habitat. Using these ratios would indicate that 104 acres of greater sandhill crane roosting habitat should be restored/created and 104 acres should be protected to compensate for the losses of greater sandhill crane roosting and foraging habitat. In addition, 4,634 acres of high- to very high-value foraging habitat should be protected to mitigate the water conveyance facilities losses of greater sandhill crane foraging habitat.

The implementation of *AMM20 Greater Sandhill Crane* (Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) would require that no greater sandhill crane roost sites were directly impacted by water conveyance facilities covered activities (including transmission lines and their associated footprints). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed, which would avoid the water conveyance facilities impact on 104 acres of roosting and foraging habitat. Indirect effects of construction-related noise and visual disturbance are discussed below under Impact BIO-71.

Under Alternative 4A, project proponents would commit to creating up to 95 acres of roosting habitat within 2 miles of existing permanent roost sites Resource Restoration and Performance Principle GSC4). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, and would be in place prior to roosting habitat loss. In addition, 320 acres of roosting habitat would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Resource Restoration and Performance Principle GSC2). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that will protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The creation of 180 acres of crane roosting habitat would be constructed within the Stone Lakes NWR project boundary (see Figure 3.3-7 in the Draft BDCP) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Resource Restoration and Performance Principle GSC3). The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of greater sandhill crane wintering habitat.

At least 4,811 acres of cultivated lands that provide high- to very high-value foraging habitat would be protected. This habitat would occur within 2 miles of known roost sites and at least 80% would be maintained in very high-value habitat types in any given year (see Table 12-4-28 for greater sandhill crane foraging habitat values).

The Plan also includes commitments to implement the following avoidance and minimization measures that will help to avoid and minimize adverse effects on greater sandhill crane: *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM30 Transmission Line Design and Alignment Guidelines*. All of these AMMs include elements that would avoid or minimize the risk of affecting greater sandhill crane habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of greater sandhill crane habitat under Alternative 4A would not be adverse under NEPA because Alternative 4A has committed the project proponents to avoiding and minimizing effects and to restoring and protecting acreages that are greater than the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles GSC1–GSC4, and by AMM1–AMM6, *AMM20 Greater Sandhill Crane*, and AMM30 *Transmission Line Design and Alignment Guidelines,* which would be in place during all project activities. Construction activities would not be expected to result in greater sandhill crane take because foraging and roosting individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas. Considering these commitments, the implementation of Alternative 4A would not result in an adverse effect on greater sandhill crane.

CEQA Conclusion: The effects on greater sandhill crane habitat under Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species in the absence of other environmental commitments, Resource Restoration and Performance Principles GSC1–GSC4, and AMMs. However, the project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 10 that are greater than the mitigation ratios described above. These conservation actions would be guided by AMM1–AMM6, *AMM20 Greater Sandhill Crane*, and *AMM30 Transmission Line Design and Alignment Guidelines*, which would be in place during all project activities. Construction activities would not be expected to result in greater sandhill crane take because foraging and roosting individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications. Therefore, Alternative 4A would have a less-than-significant impact on greater sandhill cranes under CEQA.

Impact BIO-70: Effects on Greater Sandhill Crane Associated with Electrical Transmission Facilities

Greater sandhill cranes are susceptible to collision with power lines and other structures during periods of inclement weather and low visibility (Avian Power Line Interaction Committee 1994, Brown and Drewien 1995, Manville 2005). There are extensive existing transmission and distribution lines in the sandhill crane winter use area. These include a network of distribution lines that are between 11- and 22-kV. In addition, there are two 115-kV lines that cross the study area, one that overlaps with the greater sandhill crane winter use area between Antioch and I-5 east of Hood, and one that crosses the northern tip of the crane winter use area north of Clarksburg. There are 69-kv lines within the study area that parallel Twin Cities Road, Herzog Road, Lambert Road, and the Southern Pacific Dredge Cut in the vicinity of Stone Lakes National Wildlife Refuge. At the south end of the winter use area, there are three 230-kV transmission lines that follow I-5, and then cut southwest through Holt, and two 500-kV lines cross the southwestern corner of the winter use area. This existing network of power lines in the study currently poses a collision and electrocution risk for sandhill cranes, because they cross over or surround sandhill crane roost sites in the study area.

Both permanent and temporary electrical transmission lines would be constructed to supply construction and operational power to Alternative 4A facilities, as described below. The potential take of greater sandhill crane in the area of the proposed transmission lines was estimated for the Draft BDCP using collision mortality rates developed by Brown and Drewien (1995) and an estimate of potential crossings along the proposed lines (See Draft BDCP Appendix 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). This analysis concluded that risk of take could be substantially reduced by marking new transmission lines to increase their visibility to sandhill cranes.

Alternative 4A substantially reduced the length of permanent and temporary transmission lines as compared to the Draft BDCP, substantially reducing the likelihood of crane collisions. Under Alternative 4A, no permanent transmission lines would be constructed within the greater sandhill crane winter use area. In addition, no new transmission lines (permanent or temporary) would be constructed in the vicinity of Staten Island which is one of the most important wintering sites for greater sandhill cranes in the Delta. The Alternative 4A transmission line alignment within the greater sandhill crane winter use area would be limited to three segments of temporary transmission lines: a temporary 11-mile segment extending north and south between Intake 2 and the intermediate forebay, a temporary 9-mile segment extending east and west between the intermediate forebay and the SMUD/WAPA substation, and an 11-mile segment extending north and south between Bouldin Island and Victoria Island. These three temporary lines would be removed after construction of the water conveyance facilities, after 10–14 years. Limiting the proposed transmission line footprint to temporary lines and siting these lines away from the highest use areas by greater sandhill cranes, substantially reduces the potential for sandhill crane bird strike in Alternative 4A as compared to the Draft BDCP.

In addition, after the BDCP Draft EIR/EIS was issued in December of 2013, additional avoidance features were added to *AMM20 Greater Sandhill Crane*. *AMM20 Greater Sandhill Crane* requires that Alternative 4A meets the performance standard of no take of greater sandhill crane associated with the new facilities. This would be achieved by implementing one or any combination of the following: (1) siting new transmission lines in lower bird strike risk zones; (2) removing, relocating or undergrounding existing lines where feasible; (3) using natural gas generators in lieu of installing transmission lines in high-risk zones of the greater sandhill crane winter use area (4) undergrounding new lines in high-risk zones of the greater sandhill crane winter use area, (5) permanently installing flight diverters on existing lines over lengths equal to or greater than the length of the new temporary transmission lines in the crane winter use area; and/or (6) for areas outside of the Stone Lakes National Wildlife Refuge project boundary, shifting locations of flooded areas that provide crane roosts to lower risk areas. These measures are described in detail in *AMM20 Greater Sandhill Crane* (Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

The implementation of the measures described above under *AMM20 Greater Sandhill Crane*, in addition to the project design changes to avoid high crane use areas, would not result in “take” of greater sandhill crane per Section 86 of the California Fish and Game Code. Potential measures include using natural gas generators in lieu of transmission lines or undergrounding new lines in high-risk zones in the greater sandhill crane winter use area. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality, including for sandhill cranes (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new temporary transmission lines would be fitted with flight diverters. The installation of flight diverters on existing permanent lines would be prioritized in the highest risk zones for greater sandhill crane (as described in Draft BDCP Appendix 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*) and diverters would be installed in a configuration that research indicates would reduce bird strike risk by at least 60%. Diverters would be installed on existing lines at a rate of one foot of existing transmission line for every one foot of new project transmission line constructed, in an area with equal or higher greater sandhill crane bird strike risk. Placing diverters on existing lines would be expected to reduce existing take in the Plan Area and therefore result in a net benefit to the greater sandhill crane population because these flight diverters would be maintained in perpetuity. Considering that the temporary lines would be removed within the first 10–14 years of Alternative 4A implementation, and with the implementation of one or a combination of the measures described under *AMM20 Greater Sandhill Crane*, there would be no take of greater sandhill crane from the project per Section 86 of the California Fish and Game Code.

NEPA Conclusion: Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for sandhill cranes. Under Alternative 4A, proposed transmission lines have been designed to substantially reduce the likelihood of a crane collision with transmission lines. New transmission lines constructed as part of the project would be limited to temporary lines which would be removed within the first 10–14 years of Alternative 4A implementation. In addition, no new transmission lines would be sited in the vicinity of Staten Island, which has the highest crane-use in the greater sandhill crane winter use area. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By incorporating one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 4A would not result in an adverse effect on greater sandhill crane.

CEQA Conclusion: Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for sandhill cranes. Under Alternative 4A, proposed transmission lines have been designed to substantially reduce the likelihood of a crane collision with transmission lines. New transmission lines constructed as part of the project would be limited to temporary lines which would be removed within the first 10–14 years of Alternative 4A implementation. In addition, no new transmission lines would be sited in the vicinity of Staten Island, which has the highest crane-use in the greater sandhill crane winter use area. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By incorporating one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, there would be no take of greater sandhill crane from the project per Section 86 of the California Fish and Game Code, and the construction and operation of transmission lines under Alternative 4A would have a less-than-significant impact on greater sandhill crane.

Impact BIO-71: Indirect Effects of the Project on Greater Sandhill Crane

Indirect construction-and operation-related effects: Sandhill cranes are sensitive to disturbance. Noise and visual disturbances from the construction of water conveyance facilities and other environmental commitments could reduce greater sandhill crane use of modeled habitat adjacent to work areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet of the construction edge. Furthermore, maintenance of the aboveground water conveyance facilities could result in ongoing but periodic postconstruction noise and visual disturbances that could affect greater sandhill crane use of surrounding habitat. These effects could result from periodic vehicle use along the conveyance corridor, inspection and maintenance of aboveground facilities, and similar activities. These potential effects would be minimized with implementation of *AMM20 Greater Sandhill Crane* described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

The Draft BDCP includes an analysis of the indirect effects of noise and visual disturbance that would result from the construction of the Alternative 4 water conveyance facilities on greater sandhill crane (see Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). The analysis addressed the potential noise effects on cranes, and concluded that as much as 20,243 acres of crane habitat could potentially be affected by general construction noise (including pile driving) above baseline level (50–60 dBA; Table 12-4A-29). This would include 1,008 acres of permanent crane roosting habitat, 1,909 acres of temporary crane roosting habitat, and 17,327 acres of crane foraging habitat. The analysis was conducted based on the assumption that there would be direct line-of-sight from sandhill crane habitat areas to the construction site, and, therefore, provides a worst-case estimate of effects. In many areas the existing levees would partially or completely block the line-of-sight and would function as effective noise barriers, substantially reducing noise transmission. However, there is insufficient data to assess the effects that increased noise levels would have on sandhill crane behavior.

Table 12-4A-29. Greater Sandhill Crane Habitat Affected by General Construction and Pile Driving Noise Under Alternative 4A (acres)

	General Construction	
Habitat Type	Above 60 dBA	Above 50 dBA
Permanent Roosting	196	1,008
Temporary Roosting	810	1,909
Foraging	7,676	17,327
Total Habitat	8,681	20,243

Evening and nighttime construction activities would require the use of extremely bright lights. Nighttime construction could also result in headlights flashing into roost sites when construction vehicles are turning onto or off of construction access routes. Proposed surge towers would require the use of safety lights that would alert low-flying aircraft to the presence of these structures because of their height. Little data is available on the effects of impact of artificial lighting on roosting birds. Direct light from automobile headlights has been observed to cause roosting cranes to flush and it is thought that they may avoid roosting in areas where lighting is bright (see Chapter 5, *Effects Analysis*, of the Draft BDCP). If the birds were to roost in a brightly lit site, they may be vulnerable to sleep-wake cycle shifts and reproductive cycle shifts. Potential risks of visual impacts from lighting include a reduction in the cranes' quality of nocturnal rest, and effects on their sense of photo-period which might cause them to shift their physiology towards earlier migration and breeding (see Chapter 5, *Effects Analysis*, of the Draft BDCP). Effects such as these could prove detrimental to the cranes' overall fitness and reproductive success (which could in turn have population-level impacts). A change in photo-period interpretation could also cause cranes to fly out earlier from roost sites to forage and might increase their risk of power line collisions if they were to leave roosts before dawn (see Chapter 5, *Effects Analysis*, of the Draft BDCP).

The effects of noise and visual disturbance on greater sandhill crane would be minimized through the implementation of *AMM20 Greater Sandhill Crane* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Activities within 0.75 mile of crane roosting habitat would reduce construction noise during night time hours (from one hour before sunset to one hour after sunrise) such that construction noise levels do not exceed 50 dBA L_{eq} (1 hour) at the nearest temporary or permanent roosts during periods when the roost sites are available (flooded). In addition, the area of crane foraging habitat that would be affected during the day (from one hour after sunrise to one hour before sunset) by construction noise exceeding 50 dBA L_{eq} (1 hour) would also be minimized. Unavoidable noise related effects would be compensated for by the enhancement of 0.1 acre of foraging habitat for every acre indirectly affected within the 50 dBA L_{eq} (1 hour) construction noise contour. With these measures in place, indirect effects of noise and visual disturbance from construction activities are not expected to reduce the greater sandhill crane population in the study area.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect greater sandhill crane in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to greater sandhill crane habitat could also affect the species. The implementation of AMM1–AMM6 (Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP; updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and negative effects of dust on foraging habitat.

Methylmercury Exposure: Changes in water operations from the construction of the water conveyance facilities and the implementation of Environmental Commitment 10 (Nontidal Marsh Restoration) have the potential to exacerbate bioaccumulation of mercury in greater sandhill crane. Largemouth bass was used as a surrogate species for analysis of impacts from changes in operations from the construction of the water conveyance facilities (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species overestimate the effects on greater sandhill crane because of their position in the food web. Organisms feeding within pelagic-based (algal) food webs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic food webs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Potential indirect effects of increased mercury exposure are likely low for greater sandhill crane because they primarily forage on waste grains and, to a lesser extent, invertebrates associated with cultivated crops. The modeled effects of mercury concentrations from changes in water operations with water conveyance facilities on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that greater sandhill crane tissue concentrations would not measurably increase as a result of water conveyance facilities construction.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with Environmental Commitment 10 (Nontidal Marsh Restoration) may indirectly affect greater sandhill crane via uptake in lower tropic levels (see Appendix 5.D, *Contaminants*, of the Draft BDCP). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury.

Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability

- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including greater sandhill crane. Environmental Commitment 10 (Nontidal Marsh Restoration) has the potential to mobilize selenium, and therefore increase greater sandhill crane exposure from ingestion of prey items (waste grain and associated invertebrates) with elevated selenium levels. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 10) would lead to adverse effects on greater sandhill crane.

Because of the uncertainty that exists with respect to the location of nontidal restoration activities, there could be an effect on greater sandhill crane from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal and nontidal habitats (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the restoration design.

***NEPA Effects*:** Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for greater sandhill crane. *AMM20 Greater Sandhill Crane* would include requirements (described above) to minimize the effects of noise and visual disturbance on greater sandhill cranes and to compensate for affected habitat.

The implementation of Environmental Commitment 10 (Nontidal Marsh Restoration) could result in increased exposure of greater sandhill crane to methylmercury and selenium. The potential indirect effect of increased mercury exposure is likely low for greater sandhill crane because they primarily forage on cultivated crops and associated invertebrates. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure. The potential effect of selenium exposure would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in restored habitats.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of greater sandhill cranes. Therefore, the indirect effects of Alternative 4A implementation on greater sandhill crane would not be adverse under NEPA.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of greater sandhill cranes. Therefore, the indirect effects of Alternative 4A implementation would not result in an adverse effect on greater sandhill crane under NEPA.

***CEQA Conclusion*:** Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for greater sandhill crane. This would be a significant impact. *AMM20 Greater Sandhill Crane* would include requirements (described above) to minimize the effects of noise and visual disturbance on greater sandhill cranes and to mitigate for affected habitat.

The implementation of Environmental Commitment 10 (Nontidal Marsh Restoration) could result in increased exposure of greater sandhill crane to methylmercury and selenium. This would be a significant impact. The potential indirect effect of increased mercury exposure is likely low for greater sandhill crane because they primarily forage on cultivated crops and associated invertebrates. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure. The potential effect of selenium exposure would be addressed through the implementation of *AMM27*

Selenium Management, which would provide specific restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in restored habitats.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of greater sandhill cranes. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on greater sandhill crane under CEQA.

Lesser Sandhill Crane

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on lesser sandhill crane. Lesser sandhill cranes in the study area are almost entirely dependent on privately owned agricultural lands for foraging. Long-term sustainability of the lesser sandhill crane is thus dependent on providing a matrix of compatible crop types that afford suitable foraging habitat and maintaining compatible agricultural practices, while sustaining and increasing the extent of other essential habitat elements such as night roosting habitat. The habitat model for lesser sandhill crane includes "roosting and foraging" and "foraging" habitat. Suitable roosting and foraging habitat in the study area includes certain agricultural types, specific grassland types, irrigated pastures and hay crops, managed seasonal wetland, and other natural seasonal wetland. Roosting and foraging habitat includes traditional roost sites that are known to be used by sandhill cranes (both greater and lesser) and that also provide foraging habitat. Detail regarding the roosting and foraging modeled habitat for both subspecies of sandhill crane is included in the BDCP (see Appendix 2.A, *Covered Species Accounts*, of the Draft BDCP). Both temporary and permanent roost sites were identified for sandhill cranes. Permanent roosting and foraging sites are those used regularly, year after year, while temporary roosting and foraging sites are those used in some years. Factors included in assessing the loss of foraging habitat for the lesser sandhill crane considers the relative habitat value of specific crop or land cover types. Although both the greater and the lesser sandhill crane use similar crop or land cover types, these provide different values of foraging habitat for the two subspecies based on proportional use of these habitats. Lesser sandhill cranes are less traditional than greater sandhill cranes and are more likely to move between different roost site complexes and different wintering regions (Ivey pers. comm.) The wintering range is ten times larger than the greater sandhill crane and their average foraging flight radius from roost sites is twice that of greater sandhill cranes. Because of this higher mobility, lesser sandhill cranes are more flexible in their use of foraging areas than the greater sandhill crane.

Alternative 4A would result in both temporary and permanent losses of foraging and roosting habitat for lesser sandhill crane as indicated in Table 12-4A-30. Full implementation of Alternative 4A would include the following Resource Restoration and Performance Principles for greater sandhill crane that would similarly benefit the lesser sandhill crane.

- Protect at least 3,892 acres of high- to very high-value habitat for greater sandhill crane, with at least 80% maintained in very high-value types in any given year. This protected habitat will be within 2 miles of known roosting sites in CZs 3, 4, 5, and/or 6 and will consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss. Patch size of protected cultivated lands will be at least 160 acres (Resource Restoration and Performance Principles GSC1).

- Create at least 320 acres of managed wetlands in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands will be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands (Resource Restoration and Performance Principles GSC2).
- Create at least two 90-acre wetland complexes within the Stone Lakes National Wildlife Refuge project boundary. The complexes will be no more than 2 miles apart and will help provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations. Each complex will consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and will be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes National Wildlife Refuge for greater sandhill crane (Resource Restoration and Performance Principles GSC3).
- Create an additional 95 acres of roosting habitat within 2 miles of existing permanent roost sites. The habitat will consist of active cornfields that are flooded following harvest to support roosting cranes and that provide highest-value foraging habitat. Individual fields will be at least 40 acres and can shift locations throughout the Greater Sandhill Crane Winter Use Area, but will be sited with consideration of the location of roosting habitat loss and will be in place prior to roosting habitat loss (Resource Restoration and Performance Principles GSC4).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments (including *Environmental Commitment 12 Methylmercury Management*) and implementation of AMM1–AMM7, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and *AMM30 Transmission Line Design and Alignment Guidelines*, impacts on the lesser sandhill crane would be less than significant for CEQA purposes, and would not be adverse for NEPA purposes.

Table 12-4A-30. Changes in Lesser Sandhill Crane Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Roosting and Foraging–Permanent	0	3
	Roosting and Foraging–Temporary	16	85
	Foraging	1,838	988
Total Impacts Water Conveyance Facilities		**1,854**	**1,076**
Environmental Commitments 4, 6––11[a]	Roosting and Foraging–Permanent	0	0
	Roosting and Foraging–Temporary	0	0
	Foraging	1,985	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**1,985**	**0**
Total Roosting/Foraging–Permanent		**0**	**3**
Total Roosting/Foraging–Temporary		**16**	**85**
Total Foraging		**3,823**	**988**
TOTAL IMPACTS		**3,839**	**1,076**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-72: Loss or Conversion of Habitat for and Direct Mortality of Lesser Sandhill Crane

Alternative 4A would result in the combined permanent and temporary loss of up to 104 acres of modeled roosting and foraging habitat (16 acres of permanent loss, 88 acres of temporary loss) and 4,811 acres of foraging habitat (3,823 acres of permanent loss, 988 acres of temporary loss, Table 12-4A-30). Project measures that would result in these losses are water conveyance facilities and transmission line construction, establishment and use of reusable tunnel material areas, *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Communities Restoration*, *Environmental Commitment 8 Grassland Natural Communities Restoration*, *Environmental Commitment 10 Nontidal Marsh Natural Community Restoration*, and *Environmental Commitment 11 Natural Communities Enhancement and Management*. The majority of habitat loss would result from water conveyance facility construction and conversion of foraging habitat to nontidal natural communities through Environmental Commitment 10. Habitat enhancement and management activities through Environmental Commitment 11, which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate lesser sandhill crane modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent loss of up to 2,930 acres of modeled lesser sandhill crane habitat. This would consist of the permanent removal of 16 acres of temporary roosting and foraging habitat, and 1,838 acres of foraging habitat. Foraging habitat that would be permanently impacted by water conveyance facilities would consist of 1,049 acres of very high-value, 144 acres of high-value, and 325 acres of medium-value foraging habitat (Table 12-4A-31). In addition, 3 acres of permanent roosting and foraging habitat, 85 acres of temporary roosting and foraging habitat, and 988 acres of foraging habitat would be temporarily removed (Table 12-4A-30). The temporarily removed habitat would consist primarily of cultivated lands and it would be restored within 1 year following construction. However, it would not necessarily be restored to its original topography and it could be restored as grasslands. Water conveyance facilities activities that would result in temporary impacts would include temporary access roads, reusable tunnel material sites, and work areas for construction.

- The acres of roosting and foraging habitat that would be permanently removed is located on Bouldin Island, from the construction of a permanent access road. Temporary impacts on roosting and foraging habitat would occur on Bouldin Island from the construction of a temporary concrete batch plant and a fuel station. Temporary losses would also occur from the construction of temporary transmission lines between the Lambert Road vent shaft and the intermediate forebay, and on Venice Island. However, the implementation of *AMM20 Greater Sandhill Crane* would require that water conveyance facilities activities be designed to avoid direct loss of crane roost sites. This includes a provision that the final transmission line alignment would be designed to avoid crane roost sites. Avoidance of crane roost sites would be accomplished either by siting activities outside of identified roost sites or by relocating the roost site if it consisted of cultivated lands (roost sites consisting of wetlands would not be subject to re-location). Relocated roost sites would be established prior to construction activities affecting the original roost site, as described in *AMM20 Greater Sandhill Crane* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Therefore, there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed.

- Approximately 1,480 acres of the permanent loss of foraging habitat would be from the storage of reusable tunnel material. This material would be stored on Bouldin Island, Zacharias Island and parcels south of Lambert Road and north of the Cosumnes River. The reusable tunnel material would likely be moved to other sites for use in levee build-up and restoration, and the affected areas would likely eventually be restored. This effect is categorized as permanent because there is no assurance that the material would eventually be moved. The implementation of *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material and Dredged Material* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS), would require that the areas used for reusable tunnel material storage be minimized in crane foraging habitat and completely avoid crane roost sites.

  Construction-related activities would not be expected to result in direct mortality of lesser sandhill crane if they were present in the study area, because cranes would be expected to avoid contact with construction and other equipment. The potential for lesser sandhill crane bird strike on electrical transmission lines is discussed below under Impact BIO-73.

The effects of noise and visual disturbance from water conveyance facilities construction activities are discussed under Impact BIO-74. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

Table 12-4A-31. Value of Lesser Sandhill Crane Foraging Habitat Affected By Alternative 4A Water Conveyance Facilities

Foraging Habitat Value Class	Land Cover Type	Water Conveyance Facilities Permanent [Temporary] (acres)
Very high	Corn, alfalfa and alfalfa mixtures	1,049 [448]
High	Mixed pasture, native pasture, other pasture, irrigated pasture, native vegetation, rice	144 [43]
Medium	Grain and hay crops, miscellaneous grain and hay, mixed grain and hay, unirrigated mixed grain and hay, other grain crops, miscellaneous grasses, grassland, wheat, other grain crops, managed wetlands	325 [245]
Low	Other irrigated crops, idle cropland, blueberries, asparagus, clover, cropped within the last 3 years, grain sorghum, green beans, miscellaneous truck, miscellaneous field, new lands being prepped for crop production, nonirrigated mixed pasture, nonirrigated native pasture, onions, garlic, peppers, potatoes, safflower, sudan, sugar beets, tomatoes (processing), melons squash and cucumbers all types, artichokes, beans (dry)	292 [244]
None	Vineyards, orchards	28 [8]

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 59 acres of lesser sandhill crane foraging habitat in the north Delta.
- *Environmental Commitment 7 Riparian Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 251 acres of lesser sandhill crane foraging habitat in the north Delta.
- *Environmental Commitment 8 Grassland Natural Communities Restoration*: This activity would result in the permanent loss or conversion of approximately 843 acres of lesser sandhill crane foraging habitat in the north Delta.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would result in the permanent conversion of approximately 832 acres of modeled foraging habitat for the lesser sandhill crane. A portion of the restored nontidal marsh would be restored to provide roosting and foraging habitat value for sandhill cranes. However, some of this restored marsh would be unsuitable as it would lack emergent vegetation and consist of open water that would be too deep to provide suitable roosting or foraging habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in *Environmental Commitment 11* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values. The potential for these activities to result in direct mortality of lesser sandhill crane would be

minimized with the implementation of *AMM20 Greater Sandhill Crane*. Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.

- *Water Facilities Operations and Maintenance*: Post construction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect lesser sandhill crane use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, could be adverse as sandhill cranes are sensitive to disturbance. However, potential impacts would be reduced by the AMMs listed below. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of *AMM2 Construction Best Management Practices and Monitoring, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material,* and *AMM20 Greater Sandhill Crane* are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

The following paragraphs summarize the combined effects discussed above and describe Alternative 4A environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA effects and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 104 acres roosting and foraging habitat (16 acres of permanent loss, 88 acres of temporary loss) from the construction of the water conveyance facilities. In addition, 4,811 acres of foraging habitat would be removed or converted (Water Conveyance Facilities—2,826 acres; *Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration* and *Environmental Commitment 10 Nontidal Marsh Restoration*—1,985 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 protection and 1:1 restoration for loss of roost sites and 1:1 protection for loss of foraging habitat. Using these ratios would indicate that 104 acres of sandhill crane roosting habitat should be restored/created and 104 acres should be protected to compensate for the losses of lesser sandhill crane roosting and foraging habitat. In addition, 4,811 acres of high- to very high-value foraging habitat should be protected to mitigate the water conveyance facilities losses of lesser sandhill crane foraging habitat.

The implementation of *AMM20 Greater Sandhill Crane* (Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) would require that no sandhill crane roost sites were directly impacted by water conveyance facilities covered activities (including transmission lines and their associated footprints). Therefore there would be no loss of crane roosting and foraging habitat as a result of water conveyance facility construction once the facilities were fully designed, which would avoid the water conveyance facilities impact on 104 acres of roosting and foraging habitat once the project design is final. Indirect effects of construction-related noise and visual disturbance are discussed below under Impact BIO-74.

Alternative 4A also includes the following performance standards for the greater sandhill crane which would also benefit the lesser sandhill crane, as they utilize similar habitats and face similar threats within their winter use areas.

Project proponents would commit to creating up to 95 acres of roosting habitat within 2 miles of existing permanent roost sites (Resource Restoration and Performance Principle GSC4). These roosts would consist of active cornfields that are flooded following harvest to support roosting cranes and also provide the highest-value foraging habitat for the species. Individual fields would be at least 40 acres could shift locations throughout the Greater Sandhill Crane Winter Use Area, and would be in place prior to roosting habitat loss. In addition, 320 acres of roosting habitat would be created in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6 (Resource Restoration and Performance Principle GSC2). Restoration sites would be identified with consideration of sea level rise and local seasonal flood events. These wetlands would be created within 2 miles of existing permanent roost sites and protected in association with other protected natural community types at a ratio of 2:1 upland to wetland habitat to provide buffers that would protect cranes from the types of disturbances that would otherwise result from adjacent roads and developed areas (e.g., roads, noise, visual disturbance, lighting). The creation of 180 acres of crane roosting habitat would be constructed within the Stone Lakes NWR project boundary (see Figure 3.3-7 in the Draft BDCP) and would be designed to provide connectivity between the Stone Lakes and Cosumnes greater sandhill crane populations (Resource Restoration and Performance Principle GSC3). The large patch sizes of these wetland complexes would provide additional conservation to address the threats of vineyard conversion, urbanization to the east, and sea level rise to the west of sandhill crane wintering habitat.

At least 4,811 acres of cultivated lands that provide high- to very high-value foraging habitat would be protected. This habitat would occur within 2 miles of known roost sites and at least 80% would be maintained in very high-value habitat types for greater sandhill crane in any given year (which would be high- to very high-value crop types for the lesser sandhill crane; see Table 12-4-28 and Table 12-4-32 for sandhill crane foraging habitat values).The Plan also includes commitments to implement the following avoidance and minimization measures that will help to avoid and minimize adverse effects on lesser sandhill crane: *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM30 Transmission Line Design and Alignment Guidelines*. All of these AMMs include elements that would avoid or minimize the risk of affecting lesser sandhill crane habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

***NEPA Effects*:** The loss of lesser sandhill crane habitat under Alternative 4A would not be adverse under NEPA because Alternative 4A has committed the project proponents to avoiding and minimizing effects and to restoring and protecting acreages that meet the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles GSC1–GSC4, and by AMM1–AMM6, *AMM20 Greater Sandhill Crane*, and AMM30 *Transmission Line Design and Alignment Guidelines,* which would be in place during all project activities. Considering these commitments, the implementation of Alternative 4A would not result in an adverse effect on lesser sandhill crane.

CEQA Conclusion: The effects on lesser sandhill crane habitat under Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species in the absence of environmental commitments, Resource Restoration and Performance Principles GSC1-GSC4 for greater sandhill crane (which would also benefit lesser sandhill crane), and AMMs. However, the project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 10 that are greater than the mitigation ratios described above. These conservation actions would be guided by AMM1–AMM6, *AMM20 Greater Sandhill Crane*, and *AMM30 Transmission Line Design and Alignment Guidelines*, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of lesser sandhill cranes. Therefore, Alternative 4A would have a less-than-significant impact on lesser sandhill cranes under CEQA.

Impact BIO-73: Effects on Lesser Sandhill Crane Associated with Electrical Transmission Facilities

Sandhill cranes are susceptible to collision with power lines and other structures during periods of inclement weather and low visibility (Avian Power Line Interaction Committee 1994, Brown and Drewien 1995, Manville 2005). There are extensive existing transmission and distribution lines in the sandhill crane winter use area. These include a network of distribution lines that are between 11- and 22-kV. In addition, there are two 115-kV lines that cross the study area, one that overlaps with the greater sandhill crane winter use area between Antioch and I-5 east of Hood, and one that crosses the northern tip of the crane winter use area north of Clarksburg. There are 69-kv lines within the study area that parallel Twin Cities Road, Herzog Road, Lambert Road, and the Southern Pacific Dredge Cut in the vicinity of Stone Lakes National Wildlife Refuge. At the south end of the winter use area, there are three 230-kV transmission lines that follow I-5, and then cut southwest through Holt, and two 500-kV lines cross the southwestern corner of the winter use area. This existing network of power lines in the study currently poses a collision and electrocution risk for sandhill cranes, because they cross over or surround sandhill crane roost sites in the study area.

Both permanent and temporary electrical transmission lines would be constructed to supply construction and operational power to Alternative 4A facilities, as described below. The potential mortality of greater sandhill crane in the area of the proposed transmission lines was estimated for the Draft BDCP using collision mortality rates developed by Brown and Drewien (1995) and an estimate of potential crossings along the proposed lines (See Draft BDCP Appendix 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). This analysis concluded that mortality risk could be substantially reduced by marking new transmission lines to increase their visibility to sandhill cranes. Mortality risk would be similarly reduced for lesser sandhill cranes by marking new transmission lines.

The transmission line footprint for Alternative 4A was changed substantially from the Draft BDCP to reduce potential risk of greater sandhill crane collisions. The following changes also reduce potential risk of lesser sandhill crane collisions:

Alternative 4A substantially reduced the length of permanent and temporary transmission lines as compared to the Draft BDCP, substantially reducing the likelihood of crane collisions. Under Alternative 4A, no permanent transmission lines would be constructed within the greater sandhill crane winter use area. In addition, no new transmission lines (permanent or temporary) would be constructed in the vicinity of Staten Island which is one of the most important wintering sites for greater sandhill cranes in the Delta. The Alternative 4A transmission line alignment within the greater sandhill crane winter use area would be limited to three segments of temporary transmission lines: a temporary 11-mile segment extending north and south between Intake 2 and the intermediate forebay, a temporary 9-mile segment extending east and west between the intermediate forebay and the SMUD/WAPA substation, and an 11-mile segment extending north and south between Bouldin Island and Victoria Island. These three temporary lines would be removed after construction of the water conveyance facilities, after 10–14 years. Limiting the proposed transmission line footprint to temporary lines and siting these lines away from the highest use areas by both greater and lesser sandhill cranes, substantially reduces the potential for sandhill crane bird strike in Alternative 4A as compared to the Draft BDCP.

In addition, after the BDCP Draft EIR/EIS was issued in December of 2013, additional avoidance features were added to *AMM20 Greater Sandhill Crane*. *AMM20 Greater Sandhill Crane* requires that Alternative 4A meets the performance standard of no mortality of greater sandhill crane associated with the new facilities. This would be achieved by implementing one or any combination of the following: (1) siting new transmission lines in lower bird strike risk zones; (2) removing, relocating or undergrounding existing lines where feasible; (3) using natural gas generators in lieu of installing transmission lines in high-risk zones of the greater sandhill crane winter use area (4) undergrounding new lines in high-risk zones of the greater sandhill crane winter use area, (5) permanently installing flight diverters on existing lines over lengths equal to or greater than the length of the new temporary transmission lines in the crane winter use area; and/or (6) for areas outside of the Stone Lakes National Wildlife Refuge project boundary, shifting locations of flooded areas that provide crane roosts to lower risk areas. These measures are described in detail in *AMM20 Greater Sandhill Crane* (Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

The implementation of the measures described above under *AMM20 Greater Sandhill Crane*, in addition to the project design changes to avoid high crane use areas, would substantially reduce potential collisions of lesser sandhill cranes with transmission lines. Potential measures include using natural gas generators in lieu of transmission lines or undergrounding new lines in high-risk zones in the greater sandhill crane winter use area. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality, including for sandhill cranes (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new temporary transmission lines would be fitted with flight diverters. The installation of flight diverters on existing permanent lines would be prioritized in the highest risk zones for greater sandhill crane (as described in Draft BDCP Appendix 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*) and diverters would be installed in a configuration that research indicates would reduce bird strike risk by at least 60%. Diverters would be installed on existing lines at a rate of one foot of existing transmission line for every one foot of new project transmission line constructed, in an area with equal or higher greater sandhill crane bird strike risk. Placing diverters on existing lines would be expected to reduce existing lesser and greater sandhill crane mortality in the Plan Area and therefore result in a net benefit to the lesser sandhill crane population because these flight diverters would be maintained in perpetuity.

NEPA Conclusion: Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for lesser sandhill cranes. Under Alternative 4A, proposed transmission lines have been designed to substantially reduce the likelihood of a crane collision with transmission lines. New transmission lines constructed as part of the project would be limited to temporary lines which would be removed within the first 10–14 years of Alternative 4A implementation. In addition, no new transmission lines would be sited in the vicinity of Staten Island, which has high use by wintering lesser sandhill cranes. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By incorporating one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 4A would not result in an adverse effect on lesser sandhill crane.

***CEQA Conclusion*:** Sandhill cranes are known to be susceptible to collision with overhead wires. The existing network of power lines in the study area currently poses a risk for lesser sandhill cranes. Under Alternative 4A, proposed transmission lines have been designed to substantially reduce the likelihood of a crane collision with transmission lines. New transmission lines constructed as part of the project would be limited to temporary lines which would be removed within the first 10–14 years of Alternative 4A implementation. In addition, no new transmission lines would be sited in the vicinity of Staten Island, which has high use by wintering lesser sandhill cranes. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By incorporating one or a combination of the measures to greatly reduce the risk of bird strike described in *AMM20 Greater Sandhill Crane*, described in *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines under Alternative 4A would have a less-than-significant impact on lesser sandhill crane.

Impact BIO-74: Indirect Effects of the Project on Lesser Sandhill Crane

Indirect construction-and operation-related effects: Sandhill cranes are sensitive to disturbance. Noise and visual disturbances from the construction of water conveyance facilities and other environmental commitments could reduce lesser sandhill crane use of modeled habitat adjacent to work areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet of the construction edge. Furthermore, maintenance of the aboveground water conveyance facilities could result in ongoing but periodic postconstruction noise and visual disturbances that could affect lesser sandhill crane use of surrounding habitat. These effects could result from periodic vehicle use along the conveyance corridor, inspection and maintenance of aboveground facilities, and similar activities. These potential effects would be minimized with implementation of *AMM20 Greater Sandhill Crane* described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

The BDCP includes an analysis of the indirect effects of noise and visual disturbance that would result from the construction of the Alternative 4 water conveyance facilities on greater sandhill crane (see Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). The analysis addressed the potential noise effects on cranes, and concluded that as much as 20,243 acres of crane habitat could potentially be affected by general construction noise (including pile driving) above baseline level (50–60 dBA; Table 12-4A-29). This would include 1,008 acres of permanent crane roosting habitat, 1,909 acres of temporary crane roosting habitat, and 17,327 acres of crane foraging habitat. The analysis was conducted based on the assumption that there would be direct line-of-sight from sandhill crane habitat areas to the construction site, and, therefore, provides a worst-case estimate of effects. In many areas the existing levees would partially or completely block the line-of-sight and would function as effective noise barriers, substantially reducing noise transmission. However, there is insufficient data to assess the effects that increased noise levels would have on sandhill crane behavior. Similar acreages of lesser sandhill crane habitat would be expected to be indirectly affected. However, lesser sandhill cranes are less traditional in their winter roost sites and may be more likely to travel away from disturbed areas to roost and forage in more suitable habitat.

Evening and nighttime construction activities would require the use of extremely bright lights. Nighttime construction could also result in headlights flashing into roost sites when construction vehicles are turning onto or off of construction access routes. Proposed surge towers would require the use of safety lights that would alert low-flying aircraft to the presence of these structures because of their height. Little data is available on the effects of impact of artificial lighting on roosting birds. Direct light from automobile headlights has been observed to cause roosting cranes to flush and it is thought that they may avoid roosting in areas where lighting is bright (see Chapter 5, *Effects Analysis*, of the Draft BDCP). If the birds were to roost in a brightly lit site, they may be vulnerable to sleep-wake cycle shifts and reproductive cycle shifts, and be more vulnerable to predators. Potential risks of visual impacts from lighting include a reduction in the cranes' quality of nocturnal rest, and effects on their "sense of photo-period which might cause them to shift their physiology towards earlier migration and breeding." (see Chapter 5 of the Draft BDCP). Effects such as these could prove detrimental to the cranes' overall fitness and reproductive success (which could in turn have population-level impacts). A change in photo-period interpretation could also cause cranes to fly out earlier from roost sites to forage and might increase their risk of power line collisions if they were to leave roosts before dawn (see Chapter 5 of the Draft BDCP).

The effects of noise and visual disturbance on lesser sandhill crane would be minimized through the implementation of AMM20 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Activities within 0.75 mile of crane roosting habitat would reduce construction noise during night time hours (from one hour before sunset to one hour after sunrise) such that construction noise levels do not exceed 50 dBA L_{eq} (1 hour) at the nearest temporary or permanent roosts during periods when the roost sites are available (flooded). In addition, the area of crane foraging habitat that would be affected during the day (from one hour after sunrise to one hour before sunset) by construction noise exceeding 50 dBA L_{eq} (1 hour) would also be minimized. Unavoidable noise related effects would be compensated for by the enhancement of 0.1 acre of foraging habitat for every acre indirectly affected within the 50 dBA L_{eq} (1 hour) construction noise contour. With these measures in place, indirect effects of noise and visual disturbance from construction activities are not expected to reduce the lesser sandhill crane population in the study area.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect lesser sandhill cranes in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to lesser sandhill crane habitat could also affect the subspecies. The implementation of AMM1–AMM6 (Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP; updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and negative effects of dust on foraging habitat.

Methylmercury Exposure: Changes in water operations from the construction of the water conveyance facilities and the implementation of Environmental Commitment 10 (Nontidal Marsh Restoration) have the potential to exacerbate bioaccumulation of mercury in lesser sandhill cranes. Largemouth bass was used as a surrogate species for analysis of impacts from changes in operations from the construction of the water conveyance facilities (see Appendix D, *Substantive BDCP Revisions*, in this RDEIR/SDEIS). Results of the quantitative modeling of mercury effects on largemouth bass as a surrogate species overestimate the effects on lesser sandhill crane because of their position in the food web. Organisms feeding within pelagic-based (algal) food webs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic food webs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). Potential indirect effects of increased mercury exposure are likely low for lesser sandhill crane because they primarily forage on waste grains, other cultivated crops, and associated invertebrates. The modeled effects of mercury concentrations from changes in water conveyance facilities operations on largemouth bass did not differ substantially from existing conditions; therefore, results also indicate that lesser sandhill crane tissue concentrations would not measurably increase as a result of water conveyance facilities construction.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with Environmental Commitment 10 (Nontidal Marsh Restoration) may indirectly affect lesser sandhill crane via uptake in lower tropic levels (see Appendix 5.D, *Contaminants, of the Draft BDCP*). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury.

Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At

Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including the lesser sandhill crane. Environmental Commitment 10 (Nontidal Marsh Restoration) has the potential to mobilize selenium, and therefore increase lesser sandhill crane exposure from ingestion of prey items with elevated selenium levels. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 10) would lead to adverse effects on lesser sandhill crane.

Because of the uncertainty that exists with respect to the location of nontidal restoration activities, there could be an effect on lesser sandhill crane from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) which would provide specific habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal and nontidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the restoration design.

***NEPA Effects*:** Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). However, lesser sandhill cranes are less traditional in their winter roost sites than greater sandhill cranes and may be more likely to travel away from disturbed areas to roost in more suitable habitat. Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for lesser sandhill crane. *AMM20 Greater Sandhill Crane*, which would include requirements (described above) to minimize the effects of noise and visual disturbance on sandhill cranes and to compensate for affected habitat.

The implementation of Environmental Commitment 10 (Nontidal Marsh Restoration) could result in increased exposure of lesser sandhill crane to selenium which could result in the mortality of a special status species. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of lesser sandhill crane to methylmercury and selenium. methylmercury and selenium. The potential indirect effect of increased mercury exposure is likely low for lesser sandhill crane because they primarily forage on waste grains, other cultivated crops, and associated invertebrates. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure. The potential effect of selenium exposure would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in restored habitats.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of lesser sandhill crane. Therefore, the indirect effects of Alternative 4A implementation on lesser sandhill crane would not be adverse under NEPA.

CEQA Conclusion**:** Crane habitat could potentially be affected by general construction noise above baseline level (50–60 dBA). However, lesser sandhill cranes are less traditional in their winter roost sites and may be more likely to travel away from disturbed areas to roost in more suitable habitat. Construction in certain areas would take place 7 days a week and 24 hours a day and evening and nighttime construction activities would require the use of extremely bright lights, which could adversely affect roosting cranes by impacting their sense of photo-period and by exposing them to predators. Effects of noise and visual disturbance could substantially alter the suitability of habitat for lesser sandhill crane. This would be a significant impact. With *AMM20 Greater Sandhill Crane* in place, would include requirements (described above) to minimize the effects of noise and visual disturbance on sandhill cranes and to mitigate for affected habitat, there would not be an adverse effect on lesser sandhill crane.

The implementation of Environmental Commitment 10 (Nontidal Marsh Restoration) could result in increased exposure of lesser sandhill crane to methylmercury and selenium. This would be a significant impact. The potential indirect effect of increased mercury exposure is likely low for lesser sandhill crane because they primarily forage on cultivated crops and associated invertebrates. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure. The potential effect of selenium exposure would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in restored habitats.

With AMM1–AMM6, *AMM20 Greater Sandhill Crane*, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of lesser sandhill cranes. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on lesser sandhill crane.

Least Bell's Vireo and Yellow Warbler

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on least Bell's vireo and yellow warbler. Least Bell's vireo and yellow warbler modeled habitat identifies suitable nesting and migratory habitat as those plant alliances from the valley/foothill riparian modeled habitat that contain a dense shrub component, including all willow-dominated alliances.

Alternative 4A would result in both temporary and permanent losses of least Bell's vireo and yellow warbler modeled habitat as indicated in Table 12-4A-32. Full implementation of Alternative 4A would also include the following environmental commitments and Resource Restoration and Performance Principles that would benefit least Bell's vireo and yellow warbler.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7 (Resource Restoration and Performance Principle VFR2).
- The mature riparian forest will be intermixed with a portion of the early- to mid-successional riparian vegetation and will be a minimum width of 330 feet (Resource Restoration and Performance Principle VFR3).

As explained below, with the restoration and protection of these amounts of habitat, in addition to natural community enhancement and management commitments and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, and Mitigation Measure BIO-75, impacts on least Bell's vireo and yellow warbler would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-32. Changes in Least Bell's Vireo and Yellow Warbler Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Migratory and breeding	32	27
Total Impacts Water Conveyance Facilities		**32**	**27**
Environmental Commitments 4, 6–7, 9–11[a]	Migratory and breeding	5	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**5**	**0**
TOTAL IMPACTS		**37**	**27**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-75: Loss or Conversion of Habitat for and Direct Mortality of Least Bell's Vireo and Yellow Warbler

Alternative 4A would result in the combined permanent and temporary loss of 64 acres of modeled habitat (37 acres of permanent loss and 27 acres of temporary loss) for least Bell's vireo and yellow warbler (Table 12-4A-32). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas and *Environmental Commitment 4 Tidal Natural Communities Restoration*. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could also result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate least Bell's vireo and yellow warbler habitat. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 59 acres of modeled least Bell's vireo and yellow warbler habitat (Table 12-4A-32). Of the 59 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 32 acres would be a permanent loss and 27 acres would be a temporary loss of habitat. Activities that would impact modeled habitat consist of the construction of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, and temporary barge unloading facilities and work areas. Impacts from water conveyance facilities would occur in the central Delta in CZs 3, 4, 5, 6, and 8. Permanent habitat loss would result from the construction of Intakes 2, 3, and 5 on the east bank of the Sacramento River between Freeport and Courtland. Some habitat would also be impacted by the construction of a permanent access road from the new forebay west to a reusable tunnel material disposal area and where the realigned SR 160 would cross Snodgrass Slough. Additional losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of habitat would resulted from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described *in AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require a period of time for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, restored riparian vegetation can have the habitat structure to support breeding vireos within 3 to 5 years, particularly if the restored vegetation is adjacent to established riparian areas (Kus 2002), and similar habitat would be suitable for yellow warbler. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete. There are no occurrences of least Bell's vireo or yellow warbler that intersect with the water conveyance facilities footprint. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove approximately 5 acres of modeled least Bell's vireo and yellow warbler habitat.

- *Environmental Commitment 6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat protection and management activities that could be implemented in protected least Bell's vireo and yellow warbler habitats are expected to maintain and improve the functions of the habitat. Least Bell's vireo and yellow warbler would be expected to benefit from the increase in protected habitat, which would maintain conditions favorable for future species establishment in the study area. If least Bell's vireo and yellow warbler established breeding populations in restored riparian habitats in the study area, occupied habitat would be monitored to determine if there were a need to implement controls on brood parasites (brown-headed cowbird) or nest predators. If implemented, these actions would be expected to benefit the least Bell's vireo and yellow warbler by removing a potential stressor that could, if not addressed, adversely affect the stability of newly established populations.

  Habitat management- and enhancement-related activities could disturb least Bell's vireo and yellow warbler nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in direct mortality of least Bell's vireo or yellow warbler would be minimized with the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least Bell's vireo and yellow warbler use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: Nesting of least Bell's vireo and yellow warbler has not been confirmed in the study area. Although there have been recent occurrences of least Bell's vireo in the Yolo Bypass and of both least Bell's vireo and yellow warbler at the San Joaquin River National Wildlife Refuge, the reestablishment of a breeding population of either species unlikely over the term of the project (14 years). If present in the study area, construction-related activities would not be expected to result in direct mortality of least Bell's vireo or yellow warbler because adults and fledged young would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo.* In addition, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to address adverse effects on nesting yellow warblers.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 14,850 acres of modeled habitat for least Bell's vireo and yellow warbler. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 64 acres of habitat for these species during the term of the Plan (<1% of the total habitat in the study area). These losses would occur from the construction of the water conveyance facilities and from *Environmental Commitment 4 Tidal Natural Communities Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of dense shrubby successional valley/foothill riparian habitat. Using these ratios would indicate that 64 acres of valley/foothill riparian habitat should be restored/created and 64 acres should be protected to compensate for the losses of least Bell's vireo and yellow warbler habitat.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create 251 acres and protect 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1). A single, contiguous patch of 100 acres of mature riparian forest would be maintained within either CZ 4 (in the vicinity of Cosumnes River Preserve) or CZ 7 (in the vicinity of San Joaquin National Wildlife Refuge and Caswell State Memorial Park) (Resource Restoration and Performance Principle VFR2). The mature riparian forest would be intermixed with a portion of the early- to mid-successional riparian vegetation and would be a minimum width of 330 feet (Resource Restoration and Performance Principle VFR3).

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of least Bell's vireo and yellow warbler habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VFR1-VFR3, and by AMM1–AMM7, and AMM22. Mitigation Measure BIO-75 would be available to address potential adverse effects on nesting yellow warblers. Environmental commitments and AMMs would be in place during all project activities. However, neither species is an established breeder in the study area and impacts would likely be limited to loss of migratory habitat. Considering these commitments, losses and conversions of least Bell's vireo and yellow warbler habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The loss of least Bell's vireo and yellow warbler habitat from Alternative 4A would represent an adverse effect in the absence of other conservation actions as a result of habitat modification and potential for direct mortality of a special-status species. However, neither species is an established breeder in the study area and impacts would likely be limited to loss of migratory habitat. In addition, habitat protection and restoration associated with Environmental Commitment 3 and Environmental Commitment 7, guided by Resource Restoration and Performance Principles VFR1-VFR3 and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, would be in place during all project activities. Considering these commitments, in addition to Mitigation Measure BIO-75, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of least Bell's vireo or yellow warbler. Therefore, Alternative 4A would have a less-than-significant impact on least Bell's vireo and yellow warbler under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

To reduce impacts on nesting birds, DWR will implement the measures listed below.

- To the maximum extent feasible, vegetation (trees, shrubs, ruderal areas) removal and trimming will be scheduled during the nonbreeding season of birds (September 1–January 31). If vegetation removal cannot be removed in accordance with this timeframe, preconstruction/preactivity surveys for nesting birds and additional protective measures will be implemented as described below.

- A qualified wildlife biologist with knowledge of the relevant species will conduct nesting surveys before the start of construction. A minimum of three separate surveys will be conducted within 30 days prior to construction, with the last survey within 3 days prior to construction. Surveys will include a search of all suitable nesting habitat (trees, shrubs, ruderal areas, field crops) in the construction area. In addition, a 500-foot area around the project area will be surveyed for nesting raptors, and a 500-foot buffer area will be surveyed for other nesting birds. If no active nests are detected during these surveys, no additional measures are required.

- If active nests are found in the survey area, no-disturbance buffers will be established around the nest sites to avoid disturbance or destruction of the nest site until the end of the breeding season (approximately September 1) or until a qualified wildlife biologist determines that the young have fledged and moved out of the project area (this date varies by species). A qualified wildlife biologist will monitor construction activities in the vicinity of the nests to ensure that construction activities do not affect nest success. The extent of the buffers will be determined by the biologists in coordination with USFWS and CDFW and will depend on the level of noise or construction disturbance, line-of-sight between the nest and the disturbance, ambient levels of noise and other disturbances, and other topographical or artificial barriers. Suitable buffer distances may vary between species.

Impact BIO-76: Fragmentation of Least Bell's Vireo and Yellow Warbler Habitat

Grading, filling, contouring, and other initial ground-disturbing operations may temporarily fragment modeled least Bell's vireo and yellow warbler habitat. This could temporarily reduce the affected habitat's extent and functions, including exposure to cowbird parasitism, a nest parasite of both species. Because there are only two recent occurrences of least Bell's vireo within the study area, and no occurrences of yellow warbler breeding in the study area, future occupancy would likely consist of only a small number of individuals, and any such habitat fragmentation is expected to have no or minimal effect on the species. Preconstruction surveys under *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* and Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would identify any nesting pairs and the potential for habitat fragmentation to affect either species. If a nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under Environmental Commitment 11 which includes the control of nonnative predators through habitat manipulation techniques or trapping to reduce nest predation.

***NEPA Effects*:** Because there are only two recent occurrences of least Bell's vireo within the study area, and no occurrences of yellow warbler breeding in the study area, habitat fragmentation resulting from ground-disturbing operations is not expected to affect either species. If nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under Environmental Commitment 11. Therefore, the effect of habitat fragmentation would not have an adverse effect on least Bell's vireo or yellow warbler.

***CEQA Conclusion*:** Because there are only two recent occurrences of least Bell's vireo within the study area, and no occurrences of yellow warbler breeding in the study area, habitat fragmentation resulting from ground-disturbing operations would not be expected to substantially modify habitat or result in the direct mortality of special status species. If nesting pairs of either species were detected where fragmentation has occurred, nests would be monitored for edge effects or other effects caused by the disturbance. The habitat would be adaptively managed to avoid or minimize impacts (e.g., cowbird control) under Environmental Commitment 11. Therefore, the effect of habitat fragmentation, as a result of Alternative 4A would have a less-than-significant impact on least Bell's vireo and yellow warbler.

Impact BIO-77: Effects on Least Bell's Vireo and Yellow Warbler Associated with Electrical Transmission Facilities

Both least Bell's vireo and yellow warbler typically occur in early to mid-successional riparian habitat, which is used to meet all of its life requisites. Least Bell's vireo are rarely observed in open habitats away from riparian vegetation. Neither species form flocks and individuals generally remain at or below the riparian canopy, below the height of proposed transmission lines (see Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*, of the Draft BDCP). The lack of occurrences in the study area, and the behavior and habitat requirements of least Bell's vireo and yellow warbler make collision with the proposed transmission lines highly unlikely. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and

Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters which would substantially reduce any potential for mortality of least Bell's vireo or yellow warbler individuals from powerline collisions.

***NEPA Effects*:** Installation and presence of new transmission lines would not result in an adverse effect on least Bell's vireo or yellow warbler because the probability of bird-powerline strikes is unlikely due to the lack of occurrences in the study area and the behavior and habitat requirements of these species. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would substantially reduce the risk of mortality from bird strike for least Bell's vireo and yellow warbler from the project. Therefore, the construction and operation of new transmission lines would not result in an adverse effect on least Bell's vireo or yellow warbler.

***CEQA Conclusion*:** Installation and presence of new transmission lines would result in less-than-significant impact on least Bell's vireo or yellow warbler because the probability of bird-powerline strikes is unlikely due to the lack of occurrences in the study area and the behavior and habitat requirements of these species. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would substantially reduce the risk of mortality from bird strike for least Bell's vireo and yellow warbler from the project. Therefore, the construction and operation of new transmission lines would result in a less-than-significant impact on least Bell's vireo or yellow warbler.

Impact BIO-78: Indirect Effects of The Project on Least Bell's Vireo and Yellow Warbler

Indirect construction- and operation-related effects: If least Bell's vireo or yellow warbler were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect least Bell's vireo or yellow warbler. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would reduce the potential for adverse effects of construction-related activities on survival and productivity of nesting least Bell's vireo and a 500 foot no-disturbance buffer would be established around the active nest. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to reduce the potential for adverse effects of construction-related activities on nesting yellow warbler. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect least Bell's vireo and yellow warbler in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including the least Bell's vireo and yellow warbler. Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least Bell's vireo and yellow warbler, via uptake in lower tropic levels (as described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

The potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

NEPA Effects: Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities on least Bell's vireo would not be adverse with the implementation of AMM1–AMM7, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo.* Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting yellow warblers. The implementation of tidal natural communities restoration could result in increased exposure of least Bell's vireo and yellow warbler to methylmercury. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

CEQA Conclusion: Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would have an adverse effect on least Bell's vireo and yellow warbler in the absence of environmental commitments and AMMs as a result of habitat modification and potential for direct mortality of special-status species. With the implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and *AMM2 Construction Best Management Practices and Monitoring* in place, the effect would not be adverse. The implementation of tidal natural communities restoration could result in increased exposure of least Bell's vireo and yellow warbler to methylmercury. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

With AMM1–AMM7, AMM22, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of least Bell's vireo or yellow warbler. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on least Bell's vireo or yellow warbler.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-79: Periodic Effects of Inundation of Least Bell's Vireo and Yellow Warbler Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on least Bell's vireo or yellow warbler.

NEPA Effects: No effect.

***CEQA Conclusion*:** No impact.

Suisun Song Sparrow and Saltmarsh Common Yellowthroat

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on Suisun song sparrow and saltmarsh common yellowthroat. The habitat model used to assess effects on Suisun song sparrow and saltmarsh common yellowthroat is based on primary breeding habitat and secondary habitat. Suisun song sparrow and saltmarsh common yellowthroat primary habitat consists of all *Salicornia*-dominated tidal brackish emergent wetland and all *Typha*-, *Scirpus*-, and *Juncus*-dominated tidal freshwater emergent wetland in the study area west of Sherman Island, with the exception that *Scirpus acutus* and *S. californicus* plant communities (low marsh) and all of the plant communities listed below that occur in managed wetlands were classified as secondary habitat. Upland transitional zones, providing refugia during high tides, within 150 feet of the wetland edge were also included as secondary habitat. Secondary habitats generally provide only a few ecological functions such as foraging (low marsh and managed wetlands) or extreme high tide refuge (upland transition zones), while primary habitats provide multiple functions, including breeding, effective predator cover, and high-value forage.

Alternative 4A would result in no effects on modeled Suisun song sparrow and saltmarsh common yellowthroat modeled habitat as indicated in Table 12-4A-33. There is no modeled habitat for Suisun song sparrow and saltmarsh common yellowthroat in the water conveyance facilities footprint and tidal restoration under Alternative 4A would not take place in Suisun Marsh.

Table 12-4A-33. Changes in Suisun Song Sparrow Saltmarsh Common Yellowthroat Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Primary	0	0
	Secondary	0	0
Total Impacts Water Conveyance Facilities		**0**	**0**
Environmental Commitments 4, 6–7, 9–11[a]	Primary	0	0

Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**0**	**0**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-80: Loss or Conversion of Habitat for and Direct Mortality of Suisun Song Sparrow and Saltmarsh Common Yellowthroat

No habitat would be lost or converted and there would be no direct mortality of Suisun song sparrow or saltmarsh common yellowthroat under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species are known to occur.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Impact BIO-81: Indirect Effects of Alternative 4A on Suisun Song Sparrow and Saltmarsh Common Yellowthroat

No indirect effects on Suisun song sparrow and saltmarsh common yellowthroat were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where these species are known to occur.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No Impact.

Impact BIO-82: Effects on Suisun Song Sparrow and Saltmarsh Common Yellowthroat Associated with Electrical Transmission Facilities

The range of the Suisun song sparrow extends eastward into the study area to approximately Kimball Island. There are several reported occurrences from Kimball Island, Browns Island, and in the Suisun Marsh in the western portion of the study area. The easternmost range of the saltmarsh common yellowthroat also ends in Suisun Marsh. These species ranges, along with areas of suitable habitat, are far from the proposed transmission line routes (BDCP Attachment 5.J-2*, Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Location of the current populations, species ranges, and suitable habitat in the study area make collision with the proposed transmission lines highly unlikely. Therefore the construction and presence of new transmission lines would not have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat.

NEPA Effects: The construction and presence of new transmission lines would not have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat because the location of the current populations, species ranges, and suitable habitat for the species make collision with the proposed transmission lines highly unlikely.

CEQA Conclusion: The construction and presence of new transmission lines would not be expected to have an adverse effect on Suisun song sparrow and saltmarsh common yellowthroat because the location of the current populations, species ranges, and suitable habitat for the species make collision with the proposed transmission lines highly unlikely. Therefore, the construction and presence of new transmission lines under Alternative 4A would have a less-than-significant impact on Suisun song sparrow and saltmarsh common yellowthroat.

Swainson's Hawk

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on Swainson's hawk. The habitat model used to assess impacts on Swainson's hawk includes plant alliances and land cover types associated with Swainson's hawk nesting and foraging habitat. Alternative 4A would result in both temporary and permanent losses of Swainson's hawk modeled habitat as indicated in Table 12-4A-34. The majority of the losses would occur from the construction of the water conveyance facilities. Although protection and restoration for the loss of nesting and foraging habitat would be initiated in the same timeframe as the losses, it could take one or more decades (for nesting habitat) for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized through specific requirements of *AMM18 Swainson's Hawk*, including transplanting mature trees in the near-term time period. Full implementation of Alternative 4A would also include the following environmental commitments and Resource Restoration and Performance Principles which would benefit the Swainson's hawk.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principles VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7. The mature riparian forest intermixed with a portion of the early- to mid-successional riparian vegetation will be a minimum width of 330 feet (Resource Restoration and Performance Principles VFR1 and VFR2).
- Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in minimum patch sizes of 40 acres (Resource Restoration and Performance Principle SH1).
- Protect Swainson's hawk foraging habitat above 1 foot above mean sea level with at least 50% in very high-value habitat (see Table 12-4A-35 for a definition habitat value) production (Resource Restoration and Performance Principle SH2).

- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM18 Swainson's Hawk* to minimize potential effects, impacts on Swainson's hawk would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-34. Changes in Swainson's Hawk Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary

TOTAL IMPACTS		**5,652**	**1,191**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-83: Loss or Conversion of Habitat for and Direct Mortality of Swainson's Hawk

Alternative 4A would result in the combined permanent and temporary loss of up to 6,843 acres of modeled habitat (38 acres of nesting habitat and 6,805 acres of foraging habitat) for Swainson's hawk (Table 12-4A-34). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could affect Swainson's hawk modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 33 acres of Swainson's hawk nesting habitat (20 acres of permanent loss habitat and 13 acres of temporary loss). In addition, 4,593 acres of foraging habitat would be removed (3,415 acres of permanent loss, 1,178 acres of temporary loss; Table 12-4A-34). Activities that would impact modeled Swainson's hawk habitat consist of tunnel, forebay, and intake construction, temporary access roads, and construction of transmission lines. Most of the permanent loss of nesting habitat would occur where Intakes 2, 3, and 5 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some nesting habitat would be lost due to construction of a permanent access road from the new forebay west to a reusable tunnel material disposal area and where the realigned SR 160 would cross Snodgrass Slough. Permanent losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of nesting habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. There are at least 12 occurrences of nesting Swainson's hawk that overlap with the construction footprint of water conveyance facilities, primarily from the construction of intakes 2, 3, and 5, and the construction footprint for the permanent and temporary transmission lines. The implementation of *AMM18 Swainson's Hawk*, would minimize the effects of construction on nesting Swainson's hawks if present in the area (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Impacts on foraging habitat would occur throughout the central Delta in CZs 3–6, and CZ 8. Permanent foraging habitat impacts would include 883 acres of very high-value habitat (Table 12-4A-35). Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

Table 12-4A-35. Acres of Impacted Foraging Habitat by Value Classes for Swainson's Hawk

Foraging Habitat Value Class	Cultivated Land and Other Land Cover Types	Water Conveyance Facilities Permanent (temporary)	Environmental Commitments permanent (temporary)
Very high	Alfalfa hay	883 (174)	549 (0)
Moderate	Irrigated pasture, other hay crops	1,456 (529)	1,121 (0)
Low	Other irrigated field and truck/berry crops	92 (67)	256 (0)
Very low	Safflower, sunflower, corn, grain sorghum	986 (408)	286 (0)

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 5 acres of Swainson's hawk nesting habitat and 54 acres of foraging habitat. Because the species is highly mobile and wide-ranging, habitat fragmentation is not expected to reduce the use of remaining cultivated lands or preclude access to surrounding lands. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of Swainson's hawk foraging habitat.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands that provide Swainson's hawk foraging habitat to grassland.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of Swainson's hawk foraging habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb Swainson's hawk nests if they were present near work sites. A variety of habitat management actions that are designed to enhance wildlife values in Alternative 4A-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of Swainson's hawk habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available Swainson's hawk habitat and are expected to result in overall improvements to and maintenance of habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below (AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP. *AMM18 Swainson's Hawk* and updated versions of *AMM2 Construction Best Management Practices and Monitoring and AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material and Dredged Material* are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.

- Permanent and temporary nesting habitat losses from the above environmental commitments, would primarily consist of small, fragmented riparian stands. Temporarily affected nesting habitat would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. The restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Swainson's hawks. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees and planting of trees near high-value foraging habitat. The functions of cultivated lands and grassland communities that provide foraging habitat for Swainson's hawk are expected to be restored relatively quickly (within 10–14 years of Alternative 4A implementation).

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Swainson's hawk use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and *AMM18 Swainson's Hawk* described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Swainson's hawk if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. However, if Swainson's hawk were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the incorporation of *AMM18 Swainson's Hawk* into the Alternative 4A.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments and Resource Restoration and Performance Principles that offset or avoid these effects. NEPA and CEQA conclusions are also provided at the end of the section.

The study area supports approximately 9,796 acres of modeled nesting habitat and 477,879 acres of modeled foraging habitat for Swainson's hawk. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 38 acres of potential nesting habitat (<1% of the potential nesting habitat in the study area) and 6,805 acres of foraging habitat (1% of the foraging habitat in the study area).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, and 1:1 protection for foraging habitat. Using these ratios would indicate that 38 acres of nesting habitat should be restored/ created and 38 acres should be protected to compensate for the losses of Swainson's hawk nesting habitat. In addition, 6,805 acres of foraging habitat should be protected to mitigate the losses of Swainson's hawk foraging habitat.

Project proponents would commit to conserving 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat (Resource Restoration and Performance Principle SH1). These acres of cultivated lands and grasslands would be located above 1 foot above sea level, and at least 50% would be in very high-value production (Resource Restoration and Performance Principle SH2). These Resource Restoration and Performance Principles would be associated with Environmental Commitment 3 and would occur in the same timeframe as the construction and early restoration losses.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create 251 acres and protect 103 acres of valley/foothill riparian woodland, which would provide nesting habitat for Swainson's hawk. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. A single, contiguous patch of 100 acres of mature riparian forest would be maintained in either CZ 4 or CZ 7, ensuring that acres of restored and protected habitat provide habitat for nesting raptors. In addition, small but essential nesting habitat for Swainson's hawk associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Environmental Commitment 3).

The 251 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Swainson's hawks. This time lag between the removal and restoration of nesting habitat could have a substantial impact on Swainson's hawk in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active Swainson's hawk nests within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least 5 trees (five gallon container size) would be planted for every tree anticipated to be removed by construction during the near-term period that was suitable for nesting by Swainson's hawks (20 feet or taller). A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted in areas that support high-value foraging habitat in clumps of at least 3 trees each at appropriate sites within or adjacent to conserved cultivated lands, or they could be incorporated as a component of the riparian restoration (Environmental Commitment 7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the lands protected as foraging habitat for Swainson's hawk. To enhance Swainson's hawk and reproductive output until the replacement nest trees become suitable for nesting, 100 acres of high-quality foraging habitat (alfalfa rotation) would be protected in the near-term for each potential nest site removed (a nest site is defined as a 125-acre block in which more than 50% of nest trees are 20 feet or greater in height) as a result of construction activity during the near-term. The foraging habitat to be protected would be within 6 kilometers of the removed tree within an otherwise suitable foraging landscape and on land not subject to threat of seasonal flooding, construction disturbances, or other conditions that would reduce the foraging value of the land.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of Swainson's hawk nesting and foraging habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets or exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VFR1, VFR2, SH1, SH2, and CL1, and by AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. Considering these commitments, losses and conversions of Swainson's hawk habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on Swainson's hawk habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11 that meet or exceed the typical mitigation ratios described above. These conservation activities would be guided by Resource Restoration and Performance Principles VFR1, VFR2, SH1, SH2, and

CL1s, and by AMM1–AMM6, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Swainson's hawk. Therefore, Alternative 4A would have a less-than-significant impact on Swainson's hawk under CEQA.

Impact BIO-84: Effects on Swainson's Hawk Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that Swainson's hawks could be subject to power line strikes, which could result in injury or mortality of Swainson's hawks. However, this species would be at low risk of bird strike mortality based on factors assessed in the bird strike vulnerability analysis (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Factors analyzed include the height of the new transmission lines and the flight behavior of the species. The existing network of transmission lines in the study area currently poses the same small risk for Swainson's hawk, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to Swainson's hawks and would further reduce any potential for powerline collisions.

***NEPA Effects*:** New transmission lines would minimally increase the risk for Swainson's hawk power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would not result in an adverse effect on Swainson's hawk.

***CEQA Conclusion*:** New transmission lines would minimally increase the risk for Swainson's hawk power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would result in a less-than-significant impact on Swainson's hawk.

Impact BIO-85: Indirect Effects of The Project on Swainson's Hawk

Noise and visual disturbances from the construction of water conveyance facilities and other environmental commitments could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4). However, there are no available data to determine the extent to which these noise levels could affect Swainson's hawk. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. Swainson's hawks are seasonally abundant across much of the study area wherever adequate nest trees occur within a cultivated landscape that supports suitable foraging habitat. There would be a potential for noise and visual disturbances associated with Alternative 4A actions to temporarily displace Swainson's hawks and temporarily reduce the use of suitable habitat adjacent to construction areas. These adverse effects would be minimized with the implementation of *AMM18 Swainson's Hawk*.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect Swainson's hawk foraging in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on habitat.

NEPA Effects**:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would not have an adverse effect on Swainson's hawk with the implementation of AMM1–AMM7, and *AMM18 Swainson's Hawk.*

CEQA Conclusion**:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Swainson's hawk use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Swainson's hawk use of the surrounding habitat. The effects of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would result in a less-than-significant impact on Swainson's hawk with the implementation of AMM1–AMM7, and *AMM18 Swainson's Hawk.*

Impact BIO-86: Periodic Effects of Inundation of Swainson's Hawk Nesting and Foraging Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on Swainson's hawk.

NEPA Effects**:** No effect.

CEQA Conclusion**:** No impact.

Tricolored Blackbird

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on tricolored blackbird. The habitat model used to assess effects for tricolored blackbird is based on breeding habitat and nonbreeding habitat. Although nesting colonies have been documented along the fringe of Suisun Marsh, in the Yolo Bypass, along the southwestern perimeter of the study area, and in the southeast corner of the study area near the San Joaquin River, breeding colonies are uncommon in the study area. Modeled breeding habitat includes bulrush/cattail wetlands and shrub communities that may provide suitable nesting substrate, and adjacent high-value foraging areas that occur within 5 miles of nesting colonies documented in the study area. The nesting component consists of nontidal freshwater perennial emergent marsh, and valley foothill riparian natural communities that occur within 5 miles of breeding colonies documented between 1998 and 2012. The foraging component includes cultivated lands and noncultivated land cover types known to support abundant insect populations such as grasslands, pasturelands (including alfalfa), natural seasonal wetlands, and sunflower croplands. The Delta is recognized as a major wintering area for tricolored blackbird (Hamilton 2004, Beedy 2008). Modeled nonbreeding habitat includes emergent wetlands and shrub stands that provide suitable roosting habitat, as well as cultivated lands and noncultivated lands that provide foods sought by tricolored blackbirds during the winter. Outside of the breeding season, tricolored blackbirds are primarily granivores that forage opportunistically across the study area in grasslands, pasturelands, croplands, dairies, and livestock feed lots. Factors considered in assessing the value of affected habitat for the tricolored blackbird, include patch size, suitability of vegetation, and proximity to recorded occurrences.

Alternative 4A would result in both temporary and permanent losses of tricolored blackbird modeled breeding and nonbreeding habitat as indicated in Table 12-4A-36. Full implementation of Alternative 4A would also include the following environmental commitments and Resource Restoration and Performance Principles to benefit the tricolored blackbird.

- Protect and manage occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat located within 3 miles of high-value foraging habitat in Conservation Zones 1, 2, 8, or 11. Nesting habitat will be managed to provide young, lush stands of bulrush/cattail emergent vegetation and prevent vegetation senescence. If sufficient acres of protection are not available, create suitable nesting habitat at a ratio of 1:1 (Resource Restoration and Performance Principle TB1).
- Protect high- to very high-value breeding-foraging habitat (as defined in Table 12-4A-37 (within 5 miles of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat. At least 130 acres will be within 5 miles of the 42 acres of nontidal wetland nesting habitat protected (Resource Restoration and Performance Principle TB2).
- Protect moderate-, high-, or very high-value cultivated lands (as defined in Table 12-4A-37) as nonbreeding foraging habitat, at least 50% of which is of high- or very high-value (Resource Restoration and Performance Principle TB3).
- Protect 119 acres and restore 832 acres of nontidal wetland (Environmental Commitment 3 and Environmental Commitment 10).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7 and *AMM21 Tricolored Blackbird,* impacts on tricolored blackbird would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-36. Changes to Tricolored Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type		Permanent	Temporary
Water Conveyance Facilities	Breeding	Nesting	16	4
		Foraging-cultivated	1,430	190
		Foraging-noncultivated	311	92

TOTAL IMPACTS			**4,955**	**917**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-87: Loss or Conversion of Habitat for and Direct Mortality of Tricolored Blackbird

Alternative 4A would result in the combined permanent and temporary loss of up to 5,872 acres of modeled habitat (2,767 acres of breeding habitat and up to 3,105 acres of nonbreeding habitat) for tricolored blackbird (Table 12-4A-36). Project components that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, tidal habitat restoration (Environmental Commitment 4), riparian restoration (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate tricolored blackbird habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the permanent loss of 1,757 acres of tricolored blackbird breeding habitat (16 acres nesting habitat, 1,430 acres of cultivated lands, and 311 acres of noncultivated lands suitable for foraging) and 1,296 acres of nonbreeding habitat (10 acres roosting habitat, 1,088 acres of cultivated lands, and 198 acres of noncultivated lands suitable for foraging, Table 12-4A-36). Approximately 771 of the 1,757 acres permanently impacted would be lost as reusable tunnel material storage areas, which would likely be moved to other sites for use in levee build-up and restoration, and the affected area would likely be restored. This effect is categorized as permanent because there is no assurance that the material would eventually be moved. In addition, water conveyance facilities would result in the temporary removal of 631 acres of breeding habitat (4 acres nesting habitat, 190 acres of cultivated lands, and 92 acres of noncultivated lands suitable for foraging) and 631 acres of nonbreeding habitat (31 acres roosting habitat, 543 acres of cultivated lands, and 57 acres of noncultivated lands suitable for foraging, Table 12-4A-36). *AMM21 Tricolored Blackbird* (described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) would minimize the effects of construction on nesting tricolored blackbirds if present in the area. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within 10–14 years.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal natural communities restoration would result in the inundation of approximately 59 acres of nonbreeding habitat (all acres consisting of cultivated lands suitable for foraging).
- *Environmental Commitment 7 Riparian Natural Communities Restoration*: Riparian natural communities restoration could remove approximately 251 acres of nonbreeding foraging habitat consisting of cultivated lands.
- *Environmental Commitment 8 Grassland Natural Communities Restoration*: Grassland natural communities restoration would convert approximately 407 acres of breeding foraging habitat and 663 acres of nonbreeding foraging habitat consisting of cultivated lands to grasslands. Grassland provides high-value foraging habitat for tricolored blackbird during the breeding season. Therefore, while impacted habitat may be temporarily unavailable, restored grasslands would be expected to provide foraging habitat for the species if in the vicinity of breeding colonies.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Marsh restoration activities would result in the permanent removal or conversion of approximately 316 acres of breeding foraging habitat and 516 acres of nonbreeding foraging habitat (all cultivated lands suitable for foraging). Some portion of the restored nontidal marsh would be open water, and the remainder would support emergent wetland vegetation that could provide roosting habitat for tricolored blackbird depending on vegetation density and composition.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions that are designed to enhance wildlife values in protected habitats could result in localized ground disturbances that could temporarily remove small amounts of tricolored blackbird habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, would be expected to have minor effects on available tricolored blackbird habitat and are expected to result in overall improvements to and maintenance of tricolored blackbird habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below (AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of *AMM2 Construction Best Management Practices and Monitoring* and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material and*

Dredged Material is described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). Trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. Surveys would be conducted under *AMM21 Tricolored Blackbird* to ensure that areas identified for recreational development did not contain active breeding or foraging tricolored blackbirds (Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect tricolored blackbird use of the surrounding habitat in or adjacent to work areas. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Operation of construction equipment may cause injury to or mortality of tricolored blackbirds. Risk would be greatest to eggs and nestlings susceptible to land clearing activities, nest abandonment, or increased exposure to the elements or to predators. Injury to or mortality of adults and fledged juveniles would not be expected as individuals would be expected to avoid contact with construction equipment. Construction activities could temporarily fragment existing tricolored blackbird habitat during grading, filling, contouring, and other initial ground-disturbing operations that could temporarily reduce the extent and functions supported by the affected habitat. To the maximum extent practicable, construction activity will be avoided up to 1,300 feet, but not less than a minimum of 300 feet, from an active tricolored blackbird nesting colony. If monitoring determines an activity is adversely affecting a nesting colony, construction will be modified, as practicable, by either delaying construction until the colony site is abandoned or until the end of the breeding season, whichever occurs first, by temporarily relocating staging areas, or temporarily rerouting access to the construction site. These measures to avoid injury or mortality of nesting tricolored blackbirds are described in *AMM21 Tricolored Blackbird* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Table 12-4A-37. Tricolored Blackbird Foraging Habitat Value Classes

Foraging Habitat Value Class	Agricultural Crop Type/Habitats	
	Breeding Season[a] Foraging Habitat	Nonbreeding Season Foraging Habitat
Very high	Native pasture, nonirrigated native pasture, annual grasslands, vernal pool grasslands, alkali grasslands, unsprayed alfalfa, unsprayed sunflower, unsprayed mixed alfalfa	Livestock feed lots
High	Sunflower, alfalfa and mixed alfalfa, mixed pasture, induced high water table native pasture, nonirrigated mixed pasture, dairies	Corn, sunflower, alfalfa and mixed alfalfa, mixed pasture, native pasture, nonirrigated native pasture, rice, dairies, annual grasslands, vernal pool grasslands, alkali grasslands, native vegetation[b],
Moderate	Miscellaneous grasses, fallow lands cropped within 3 years, new lands prepped for crop production, livestock feed lots, organic rice	Miscellaneous grass pasture, nonirrigated mixed pasture, fallow lands cropped within 3 years, new lands prepped for crop production
Low	Mixed grain and hay crops, farmsteads, unirrigated mixed grain and hay, farm residences	Wheat, oats, mixed grain and hay, farmsteads, unirrigated mixed grain and hay, and on-irrigated misc. grain and hay
Marginal	Rice	None
None	All remaining crop types	All remaining crop types

[a] Generally March through August; occasional breeding in fall (September through November).

[b] Native vegetation is a land use designation within the California Department of Water Quality crop type dataset (2007). For the purposes of incorporating native vegetation classes into the correct species models, and, when applicable, assigning habitat foraging values, the management on these lands most resembles that of grassland or a nonirrigated pasture type.

Based on the habitat model, the study area approximately 164,947 acres of breeding and 259,093 acres of nonbreeding habitat for tricolored blackbird. The Delta is an important wintering area for the tricolored blackbird (Hamilton 2004, Beedy 2008). Although there is a large acreage of modeled breeding habitat available, the study area does not currently support many nesting tricolored blackbirds with the exception of a few occurrences on the fringes of the Suisun Marsh, in the Yolo Bypass, and along the southwestern perimeter of the study area. Alternative 4A would result in the combined permanent and temporary loss of up to 5,872 acres of modeled habitat (2,767 acres of breeding habitat and up to 3,105 acres of nonbreeding habitat) for tricolored blackbird (2% of the total breeding habitat in the study area and 1% of the total nonbreeding habitat in the study area). These impacts would consist of 20 acres of nesting habitat, 41 acres of roosting habitat, 657 acres of noncultivated foraging habitat, and 5,463 acres of cultivated lands suitable for foraging.

Typical NEPA and CEQA project-level mitigation ratios would be 2:1 for protection of nesting habitat, 1:1 creation and 1:1 protection of roosting wetland habitat, 2:1 protection for loss of noncultivated lands suitable for foraging (for the breeding and nonbreeding season), and 1:1 protection for the loss of cultivated lands.

Project proponents would commit to protecting and managing 42 acres of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat located within 3 miles of high-value foraging habitat in Conservation Zones 1, 2, 8, or 11. Nesting habitat would be managed to provide young, lush stands of bulrush/cattail emergent vegetation and prevent vegetation senescence (Resource Restoration and Performance Principle TB1). These acres would compensate for impacts on 20 acres of tricolored blackbird nesting habitat. An additional 41 acres of nontidal wetland would be protected and 41 acres would be restored which would provide sufficient compensation for impacts on 41 acres of roosting habitat. Alternative 4A would also commit to protecting 1,620 acres of high- to very high-value breeding-foraging habitat (as defined in Table 4A-38) within 5 miles of occupied or recently occupied - within the last 15 years - tricolored blackbird nesting habitat. At least 130 acres would be within 5 miles of the 42 acres of nontidal wetland nesting habitat protected (Resource Restoration and Performance Principle TB2). In addition, 5,463 acres of moderate-, high-, or very high-value cultivated lands (as defined in Table 4A-38) would be protected as nonbreeding foraging habitat, at least 50% of which would be of high- or very high-value (Resource Restoration and Performance Principle TB3). These acres would be sufficient to compensate for impacts on tricolored blackbird foraging habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of tricolored blackbird breeding and nonbreeding habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting acreages that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles TB1–TB4, and by AMM1–AMM7, and *AMM21 Tricolored Blackbird*, which would be in place during all project activities. Considering these commitments, losses and conversions of tricolored blackbird habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on tricolored blackbird habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles TB1–TB4, and by AMM1–AMM6, and *AMM21 Tricolored Blackbird*, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of tricolored blackbird. Therefore, Alternative 4A would have a less-than-significant impact on tricolored blackbird under CEQA.

Impact BIO-88: Effects on Tricolored Blackbird Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that tricolored blackbirds could be subject to power line strikes, which could result in injury or mortality of individuals. Tricolored blackbirds would have the potential to intersect the proposed transmission lines largely due to winter movements throughout the study area, when individuals are migrating in large flocks and dense fog is common in the area. Although migratory movements and daily flights between roosting and foraging habitat make tricolored blackbird vulnerable to collision with transmission lines, daily flights associated with winter foraging likely occurs in smaller flocks at heights that are lower than the transmission lines (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters which would further reduce any potential for tricolored blackbird collision with transmission lines.

Transmission line poles and towers provide perching substrate for raptors, which are predators on tricolored blackbird. Although there is potential for transmission lines to result in increased perching opportunities for raptors and result in increased predation pressure on tricolored blackbirds, the existing network of transmission lines in the study area currently poses these risks and any incremental risk associated with the new power line corridors would not be expected to affect the study area population. Therefore, it is assumed that the increase in predation risk on tricolored blackbird from an increase in raptor perching opportunities is minimal.

***NEPA Effects*:** New transmission lines would increase the risk for tricolored blackbird powerline strikes, primarily in winter during daily flights between roosting and foraging sites and during migration movements. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on tricolored blackbird. The increase in predation risk on tricolored blackbird from an increase in raptor perching opportunities is considered minimal. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on tricolored blackbird.

***CEQA Conclusion*:** New transmission lines would increase the risk for tricolored blackbird powerline strikes, primarily in winter during daily flights between roosting and foraging sites and during migration movements. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on tricolored blackbird. The increase in predation risk on tricolored blackbird from an increase in raptor perching opportunities is considered minimal. The construction and operation of new transmission lines under Alternative 4A would not substantially reduce the number or restrict the range of the species and would therefore result in a less-than-significant impact on tricolored blackbird.

Impact BIO-89: Indirect Effects of the Project on Tricolored Blackbird

Indirect construction- and operation-related effects: Tricolored blackbird nesting habitat within the vicinity of proposed construction areas that could be indirectly affected by construction activities. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect tricolored blackbird. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. Construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. *AMM21 Tricolored Blackbird* would require preconstruction surveys, and if detected, covered activities would be avoided within a minimum 300 feet of an active nesting colony and up to 1,300 feet where practicable until breeding has ceased. In addition, monitoring would be implemented to ensure that construction does not adversely affect the nesting colony. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect tricolored blackbird in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to tricolored blackbird habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including tricolored blackbird. Tidal and nontidal marsh restoration also have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury.

Breeding tricolored blackbirds are not thought to be highly susceptible to methylmercury exposure because tidal wetlands are not expected to be a major foraging area for the species. However, species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects and increased methylmercury associated with natural community restoration could indirectly affect tricolored blackbird, via uptake in lower tropic levels (as described in the, Appendix 5.D, *Contaminants*, of the Draft BDCP). A detailed review of the methylmercury issues associated with implementation of the Alternative 4A is contained in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS. The review includes an overview of the project-related mechanisms that could result in increased mercury in the food web, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase.

Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including tricolored blackbird. Tidal and nontidal marsh restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 4 and Environmental Commitment 5) would lead to adverse effects on tricolored blackbird.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on tricolored blackbird from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see

Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** The effects of noise, potential spills of hazardous material, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would not be adverse with the implementation of AMM1–AMM7 and *AMM21 Tricolored Blackbird*.

Tidal habitat restoration could result in increased exposure of tricolored blackbird to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of tricolored blackbird to methylmercury. It is unlikely that breeding tricolored blackbird would be highly susceptible to methylmercury exposure because tidal wetlands are not expected to be a major foraging area for the species. However, it is unknown what concentrations of methylmercury are harmful to this species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on tricolored blackbird.

***CEQA Conclusion*:** Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would be less than significant with the implementation of *AMM21 Tricolored Blackbird* and AMM1–AMM7.

Tidal habitat restoration could result in increased exposure of tricolored blackbird to selenium. This impact would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

The implementation of tidal natural communities restoration could result in increased exposure of tricolored blackbird to methylmercury. It is unlikely that breeding tricolored blackbird would be highly susceptible to methylmercury exposure because tidal wetlands are not expected to be a major foraging area for the species. However, it is unknown what concentrations of methylmercury are harmful to this species. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on tricolored blackbird.

Therefore, with AMM1–AMM7, AMM21, AMM27, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modification or potential mortality. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on tricolored blackbird.

Impact BIO-90: Periodic Effects of Inundation of Tricolored Blackbird Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on tricolored blackbird.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Western Burrowing Owl

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on western burrowing owl. Western burrowing owl modeled habitat consisted of high- and low-value habitat for nesting and foraging. High-value habitat consists of plant alliances within the grassland and vernal pool natural communities and pasture. Low-value habitat includes plant alliances and crop types from managed wetland, alkali seasonal wetland, and cultivated lands. Value was determined through reported species use patterns from the literature.

Alternative 4A would result in both temporary and permanent losses of western burrowing owl modeled habitat as indicated in Table 12-4A-38. Full implementation of Alternative 4A would also include the following environmental commitments Resource Restoration and Performance Principles which would benefit the western burrowing owl.

- Protect 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3). The following Swainson's hawk Resource Restoration and Performance Principles would be implemented as part of these acres and would also benefit western burrowing owl:
  - Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in a minimum of 40-acre patches (Resource Restoration and Performance Principle SH1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7, and *AMM23 Western Burrowing Ow*l, impacts on western burrowing owl would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-38. Changes in Western Burrowing Owl Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	High-value	920	220
	Low-value	2,403	747
Total Impacts Water Conveyance Facilities		**3,323**	**967**
Environmental Commitments 4, 6–7, 9–11[a]	High-value	2,212	0
	Low-value	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,212**	**0**
Total High-value		**3,132**	**220**
Total Low-value		**2,403**	**747**
TOTAL IMPACTS		**5,535**	**967**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-91: Loss or Conversion of Habitat for and Direct Mortality of Western Burrowing Owl

Alternative 4A would result in the combined permanent and temporary loss of up to 6,502 acres of modeled habitat for western burrowing owl (of which 3,352 acres is of high-value and 3,150 acres is of low value, Table 12-4A-38). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Community Restoration*, *Environmental Commitment 8 Grassland Restoration*, *Environmental Commitment 10 Nontidal Marsh Restoration*, and *Environmental Commitment 11 Natural Communities Enhancement and Management.* Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate western burrowing owl habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 1,140 acres of acres of modeled high-value western burrowing owl habitat (920 acres of permanent loss, 220 acres of temporary loss) from CZs 3–6 and CZ 8. In addition, 3,150 acres of low-value burrowing owl habitat would be removed (2,403 acres of permanent loss, 747 acres of temporary loss). The majority of high-value grassland habitat that would be removed would be in CZ 8, from the construction of the new forebay in CZ 8. There is a high concentration of CNDDB and DHCCP survey records for western burrowing owls in CZ 8 to the west and the south of the Clifton Court Forebay. The loss of high-value habitat from facility construction and the establishment of the forebay reusable tunnel material storage area could remove occupied habitat, displace nesting and wintering owls, and fragment occupied burrowing owl habitat.
- The reusable tunnel material storage area overlaps with six occurrences of western burrowing owl and there are also several occurrences west of the new forebay control structure that could be indirectly affected by construction activities. The amount of storage area needed for reusable

tunnel material is flexible (dependent on storage pile height and other factors) and the footprint used in the effects analysis is based on a worst case scenario. However, the actual area to be affected by reusable tunnel material storage would likely be less than the estimated acreage. The implementation of *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material* and *AMM23 Western Burrowing Owl* would require that to the extent practicable, the reusable tunnel material storage area footprint avoided locations where active burrows are present. The footprints of a permanent transmission line and a permanent access road, both located west of the Clifton Court Forebay overlap with an additional 8 occurrences of western burrowing owl. Preconstruction surveys would be conducted prior to any construction activities under *AMM23 Western Burrowing Owl* during the nonbreeding and the breeding season. If avoidance was not possible, passive relocation would be considered in consultation with CDFW. If owls were to be excluded from existing burrows, artificial burrows would be used if it were possible for them to be installed within 100 meters from the existing burrows on protected lands. A substantial portion of the high-value grassland protection and enhancement under *Environmental Commitment 8 Grassland Natural Community Restoration* would be expected to occur to the west and to the south of these occurrences in CZ 8, which would provide high-value protected lands in close proximity to the disturbed habitat.

- Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 59 acres of high-value western burrowing owl habitat.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of high-value western burrowing owl habitat.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would permanently remove approximately 1,070 acres of high-value western burrowing owl habitat.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Implementation would result in the permanent removal of 832 acres of high-value western burrowing owl habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of western burrowing owl habitat. The burrowing owl's fossorial habits make the species more sensitive to the effects of ground disturbance than other raptors. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available western burrowing owl habitat and would be expected to result in overall improvements to and maintenance of habitat values. Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.

- Habitat management- and enhancement-related activities and equipment operation could destroy nests burrows, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in nest failure and mortality or other adverse effects on western burrowing owl would be avoided or minimized with the incorporation of *AMM23 Western Burrowing Owl* which would require surveys to determine presence or absence and the establishment of no-disturbance buffers around active sites.
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western burrowing owl use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of western burrowing owl. However, if nest burrows were occupied in the vicinity of construction activities, equipment operation could destroy nests and noise and visual disturbances could lead to abandonment. *AMM23 Western Burrowing Owl* would ensure that preconstruction surveys detected any occupied burrows and no-disturbance buffers would be implemented.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Based on the habitat model, the study area supports approximately 152,014 acres of high-value and 254,352 acres of low-value habitat for western burrowing owl. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 3,352 acres of high-value habitat (2% of the habitat in the study area) and 3,150 acres of low-value western burrowing owl habitat (<2% of the habitat in the study area). These effects would result from the construction of the water conveyance facilities and implementing other environmental commitments (*Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 2:1 protection of high-value habitat, and 1:1 protection of low-value habitat. Using these typical ratios would indicate that 6,704 acres should be protected to compensate for the loss of high-value habitat and 3,150 acres should be protected to compensate for the loss of low-value habitat.

Project proponents would commit to protect 1,060 acres of grassland and 11,870 acres of cultivated lands, which would be sufficient to compensate for impacts on western burrowing owl habitat. As part of these acres of protection, Alternative 4A would conserve 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat (which would also benefit western burrowing owl), which would total 6,805 acres. These acres would be sufficient to compensate for impacts on western burrowing owl habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged*

Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of western burrowing owl habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle SH1, and by AMM1–AMM7, and *AMM23 Western Burrowing Owl*, which would be in place during all project activities. Considering these commitments, losses and conversions of western burrowing owl habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on western burrowing owl habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle SH1, and by AMM1–AMM6 and *AMM23 Western Burrowing Owl*, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of western burrowing owl. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on western burrowing owl under CEQA.

Impact BIO-92: Effects on Western Burrowing Owl Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes and/or electrocution, which could result in injury or mortality of western burrowing owl. The species is large-bodied but with relatively long and rounded wings, making it moderately maneuverable. While burrowing owls may nest in loose colonies, they do not flock or congregate in roosts or foraging groups. Collectively, the species' keen eyesight and largely ground-based hunting behavior make it a relatively low-risk species for powerline collision. While the species in not widespread in the study area, it may become more widely distributed as grassland enhancement improves habitat for the species. Even so, the risk of effects on the population are low, given its physical and behavioral characteristics (BDCP Attachment 5.J-2*, Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*) and new transmission lines would not be expected to have an adverse effect on the species. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would make transmission lines highly visible to western burrowing owls and would further reduce any potential for powerline collisions.

NEPA Effects: The construction and presence of new transmission lines would not result in an adverse effect on western burrowing owl because the risk of bird strike is considered to be minimal based on the owl's physical and behavioral characteristics. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60%, which would further reduce any potential for powerline collisions.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on western burrowing owl because the risk of bird strike is considered to be minimal based on the owl's physical and behavioral characteristics. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60%, which would further reduce any potential for powerline collisions.

Impact BIO-93: Indirect Effects of the Project on Western Burrowing Owl

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect western burrowing owl use of up to 13,922 acres of modeled burrowing owl habitat (6,113 acres of high-value habitat) within 500 feet of covered activities will temporarily be made less suitable as a result of construction noise and visual disturbances adjacent to proposed construction areas. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Any disturbance within 250 feet of a burrow occupied by burrowing owl during the breeding season (February 1–August 31) and within 160 feet during the nonbreeding season (September 1–January 31) could potential displace winter owls or cause abandonment of active nests. These potential effects would be minimized with incorporation of *AMM23 Western Burrowing Owl* into Alternative 4A, which would require preconstruction surveys and establish no-disturbance buffers around active burrows. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect western burrowing owl.

The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western burrowing owl in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to western burrowing owl habitat could also affect the species. AMM1–AMM7 in addition to *AMM23 Western Burrowing Owl* would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests.

***NEPA Effects*:** Indirect effects on western burrowing owl as a result of Alternative 4A implementation could have adverse effects on this species through the modification of habitat and potential for direct mortality. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting owls or active burrows in the high-value grassland habitat surrounding Clifton Court Forebay and adjacent to work area. With the implementation of AMM1–AMM7, and *AMM23 Western Burrowing Owl*, the indirect effects from Alternative 4A implementation would not be adverse under NEPA.

***CEQA Conclusion*:** Indirect effects on western burrowing owl as a result of Alternative 4A implementation could have significant impacts on these species through the modification of habitat and potential for direct mortality. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting owls or active burrows in the high-value grassland habitat surrounding Clifton Court Forebay and adjacent to work areas. With the implementation of AMM1–AMM7 and *AMM23 Western Burrowing Owl*, the indirect effects resulting from Alternative 4A implementation would have a less-than-significant impact on western burrowing owl.

Impact BIO-94: Periodic Effects of Inundation on Western Burrowing Owl Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on western burrowing owl.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Western Yellow-Billed Cuckoo

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on western yellow-billed cuckoo. The habitat model for Western yellow-billed cuckoo includes potential breeding habitat, which includes plant alliances from the valley/foothill riparian modeled habitat that contain a dense forest canopy for foraging with understory willow for nesting, and a minimum patch size of 50 acres, and migratory habitat, which includes the same plant alliances as breeding habitat without the minimum 50 acres patch size requirement.

The western yellow-billed cuckoo is uncommon in the study area at present, and the likelihood that it would be found using the modeled habitat is low relative to more abundant riparian species. Nesting of the species in the study area has not been confirmed for approximately 100 years. Western yellow-billed cuckoo was detected in the study area during 2009 DHCCP surveys, but nesting was not confirmed and the bird is suspected to have been a migrant (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, of the Draft EIR/EIS). Alternative 4A would result in both temporary and permanent losses of Western yellow-billed cuckoo modeled habitat as indicated in Table 12-4A-39. Full implementation Alternative 4A would also include the following environmental commitments and Resource Restoration and Performance Principles which would benefit the western yellow-billed cuckoo.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7. The mature riparian forest will be intermixed with a portion of the early- to mid-successional riparian vegetation and will be a minimum width of 330 feet (Resource Restoration and Performance Principles VFR2 and VFR3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities,* and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, impacts on Western yellow-billed cuckoo would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-39. Changes in Western Yellow-Billed Cuckoo Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Breeding	6	4
	Migratory	18	19
Total Impacts Water Conveyance Facilities		**24**	**23**
Environmental Commitments 4, 6–7, 9–11[a]	Breeding	1	0
	Migratory	4	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**5**	**0**
Total Breeding		**7**	**4**
Total Migratory		**22**	**19**
TOTAL IMPACTS		**29**	**23**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-95: Loss or Conversion of Habitat for and Direct Mortality of Western Yellow-Billed Cuckoo

Alternative 4A would result in the combined permanent and temporary loss of up to 52 acres of modeled habitat for western yellow-billed cuckoo (11 acres of breeding habitat, 41 acres of migratory habitat, Table 12-4A-39). Project components that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate western yellow-billed cuckoo modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 10 acres of breeding habitat (6 acres of permanent loss, 4 acres of temporary loss) for yellow-billed cuckoo. In addition, 37 acres of migratory habitat would be removed (18 acres of permanent loss, 19 acres of temporary loss, see Table 12-4A-39). Activities that would impact modeled habitat consist of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, and temporary barge unloading facilities and work areas. Impacts from water conveyance facilities would occur in the central Delta in CZs 3–6, and 8. Permanent habitat loss would occur from the construction of Intakes 2, 3, and 5 on the east bank of the Sacramento River between Freeport and Courtland. Some habitat would also be impacted by the construction of a permanent access road from the new forebay west to a reusable tunnel material disposal area and where the realigned SR 160 would cross Snodgrass Slough. Additional losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. Permanent and temporary habitat losses from the above environmental commitments, would primarily consist of small, fragmented riparian stands in CZ 2–CZ 8 that do not provide high-value habitat for the species. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete.

There are no extant occurrences of yellow-billed cuckoo nests in the study area; however, habitat loss from the construction of water conveyance facilities would have the potential to displace individuals, if present, and remove the functions and value of modeled habitat for nesting, protection, or foraging. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, would minimize the effects of construction on nesting cuckoos if present in the area (see Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP). Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 1 acres of modeled yellow-billed cuckoo breeding habitat and 4 acres of modeled migratory habitat. There are no extant nesting records of yellow-billed cuckoo in the study area. However, a yellow-billed cuckoo detection was recorded during DHCCP surveys in 2009 (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, in the Draft EIR/EIS) in CZ 5 between Twin Cities Road and Walnut Grove.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Habitat protection and management activities that could be implemented in protected western yellow-billed cuckoo habitats would maintain and improve the functions of the habitat. With conditions favorable for its future establishment in the study area, western yellow-billed cuckoo would be expected to benefit from the increase in protected habitat. However, habitat management- and enhancement-related activities could disturb western yellow-billed cuckoo nests if they were present near work sites. Environmental Commitment 11 actions designed to enhance wildlife values in restored riparian habitats may result in localized ground disturbances that could temporarily remove small amounts of western yellow-billed cuckoo habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available western yellow-billed cuckoo habitat and would be expected to result in overall improvements and maintenance of western yellow-billed cuckoo habitat values.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect western yellow-billed cuckoo use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: Western yellow-billed cuckoo nesting has not been confirmed in the Delta for approximately 100 years. However, an unconfirmed breeding detection during 2009 DHCCP surveys (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, of the Draft EIR/EIR) and the presence of suitable habitat indicate that the species is potentially breeding in the study area, or may nest there in the future. Construction-related activities would not be expected to result in direct mortality of adult or fledged western yellow-billed cuckoo if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. Although there is minimal habitat in the Plan Area that is of appropriate width, and suitable understory to support nesting cuckoos, if western yellow-billed cuckoo were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the incorporation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the Alternative 4A.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The habitat model indicates that the study area supports approximately 12,395 acres of modeled breeding and migratory habitat for yellow-billed cuckoo. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 52 acres of modeled habitat (<1% of the modeled habitat in the study area). These losses would occur from the construction of the water conveyance facilities and from *Environmental Commitment 4 Tidal Natural Communities Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 52 acres of valley/foothill riparian habitat should be restored/created and 52 acres should be protected to compensate for the losses of western yellow-billed cuckoo habitat.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create 251 acres and protect 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1). A single, contiguous patch of 100 acres of mature riparian forest would be maintained within either CZ 4 (in the vicinity of Cosumnes River Preserve) or CZ 7 (in the vicinity of San Joaquin National Wildlife Refuge and Caswell State Memorial Park) to ensure that restored and protected riparian would be of sufficient size to provide suitable habitat for yellow-billed cuckoo (Resource Restoration and Performance Principle VFR2). The mature riparian forest would be intermixed with a portion of the early- to mid-successional riparian vegetation and would be a minimum width of 330 feet (Resource Restoration and Performance Principle VFR3).

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of western yellow-billed cuckoo habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VFR1-VFR3, and by AMM1–AMM7, AMM10, and AMM22. These environmental commitments and AMMs would be in place during all project activities. Considering these commitments, losses and conversions of western yellow-billed cuckoo habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The loss of western yellow-billed cuckoo habitat from Alternative 4A would represent an adverse effect in the absence of environmental commitments and AMMs as a result of habitat modification and potential for direct mortality of a special-status species. However, habitat protection and restoration associated with Environmental Commitment 3 and Environmental Commitment 7, guided by Resource Restoration and Performance Principles VFR1-VFR3 and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of western yellow-billed cuckoo. Therefore, Alternative 4A would have a less-than-significant impact on western yellow-billed cuckoo under CEQA.

Impact BIO-96: Fragmentation of Western Yellow-Billed Cuckoo Habitat as a Result of Constructing the Water Conveyance Facilities

Grading, filling, contouring, and other initial ground-disturbing operations for water conveyance facilities construction may temporarily fragment modeled western yellow-billed cuckoo habitat. This could temporarily reduce the extent and functions supported by the affected habitat. Because western yellow-billed cuckoo is not currently known to breed in the study area, and the protection and restoration of riparian habitat will expand contiguous habitat block requirements, habitat fragmentation would have a minimal effect on the species.

NEPA Effects: Because western yellow-billed cuckoo is not currently known to breed in the study area and the protection and restoration of riparian habitat will expand contiguous habitat block requirements, fragmentation of habitat would not have an adverse effect on western yellow-billed cuckoo.

CEQA Conclusion: Because western yellow-billed cuckoo is not currently known to breed in the study area and the protection and restoration of riparian habitat will expand contiguous habitat block requirements, fragmentation of habitat would have a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-97: Effects on Western Yellow-Billed Cuckoo Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of western yellow-billed cuckoo. Because the western yellow-billed cuckoo uses riparian forests to meet all of its breeding and wintering life requisites, the species remains primarily within the canopy of riparian forests and rarely ventures into open spaces except during migration, limiting its opportunity to encounter the proposed transmission lines. As a summer resident, if the species were to occur in the study area it would be during periods of relatively high visibility and clear weather conditions, thus further reducing collision risk from daily use patterns or seasonal migration flights. Finally, western yellow-billed cuckoo wing shape is characterized by low wing loading and a moderate aspect ratio, making the species moderately maneuverable and presumably able to avoid collisions, especially during high-visibility conditions (BDCP Attachment 5.J-2*, Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*).

Transmission line poles and towers also provide perching substrate for raptors, which are predators on western yellow-billed cuckoo. Although there is potential for transmission lines to result in increased perching opportunities for raptors, the existing network of transmission lines in the study area currently poses these risks and any incremental risk associated with the new power line corridors would not be expected to affect the population. In addition, the transmission lines that would be constructed in the vicinity of modeled western yellow-billed cuckoo habitat would be temporary and would be removed within 10–14 years of Alternative 4A implementation. Because there is low probability for the species to occur in the study area, and because the transmission lines that would be constructed near modeled habitat would be temporary, any increase in predation risk on western yellow-billed cuckoo from an increase in raptor perching opportunities is minimal.

NEPA Effects: The risk of bird-strike is considered to be minimal based on the species' rarity in the study area, its proclivity to remain in the riparian canopy, its presence in the study area during periods of relative high visibility, and its overall ability to successfully negotiate around overhead wires that it may encounter. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. However, because there is a low probability for the species to occur in the study area, and because the transmission lines that would be constructed near modeled habitat would be temporary, any increase in predation risk on western yellow-billed cuckoo from an increase in raptor perching opportunities is minimal. Therefore the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on western yellow-billed cuckoo.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on western yellow-billed cuckoo because the risk of bird-strike is considered to be minimal based on the species' rarity in the study area, its proclivity to remain in the riparian canopy, its presence during periods of relative high visibility, and its overall ability to successfully negotiate around overhead wires that it may encounter. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. However, because there is a low probability for the species to occur in the study area, and because the transmission lines that would be constructed near modeled habitat would be temporary, any increase in predation risk on western yellow-billed cuckoo from an increase in raptor perching opportunities is minimal. Therefore the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-98: Indirect Effects of the Project on Western Yellow-Billed Cuckoo

Construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect western yellow-billed cuckoo use of modeled habitat adjacent to proposed construction areas. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect western yellow-billed cuckoo. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If western yellow-billed cuckoo were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. These potential effects would be minimized with incorporation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the Alternative 4A. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western yellow-billed cuckoo in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to western yellow-billed cuckoo habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, in addition to *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize the likelihood of such spills from occurring and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests.

***NEPA Effects*:** Indirect effects on western yellow-billed cuckoo as a result of Alternative 4A implementation could have adverse effects on the species through the modification of habitat and potential for direct mortality. However, due to the species' minimal presence in the study area, and with the incorporation of AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the Alternative 4A, indirect effects would not have an adverse effect on western yellow-billed cuckoo.

***CEQA Conclusion*:** Indirect effects on western yellow-billed cuckoo as a result of Alternative 4A implementation could have a significant impact on the species from modification of habitat. With the incorporation of AMM1–AMM7 and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the Alternative 4A, indirect effects as a result of Alternative 4A implementation would have a less-than-significant impact on western yellow-billed cuckoo.

Impact BIO-99: Periodic Effects of Inundation of Western Yellow-Billed Cuckoo Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on western yellow-billed cuckoo.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

White-Tailed Kite

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on white-tailed kite. The habitat model used to assess impacts on white-tailed kite includes nesting habitat and foraging habitat. Most white-tailed kites in the Sacramento Valley are found in oak and cottonwood riparian forests, valley oak woodlands, or other groups of trees and are usually associated with compatible foraging habitat for the species in patches greater than 1,500 square meters (Erichsen et al. 1996). Modeled foraging habitat for white-tailed kite consists of pasture and hay crops, compatible row and grain crops and natural vegetation such as seasonal wetlands and annual grasslands (Erichsen et al. 1995).

Alternative 4A would result in both temporary and permanent losses of white-tailed kite modeled habitat as indicated in Table 12-4A-402. The majority of the losses would result from the construction of the water conveyance facilities. Although restoration for the loss of nesting and foraging habitat would be initiated in the same timeframe as the losses, it could take one or more decades (for nesting habitat) for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM39 White-Tailed Kite*, including the planting of mature trees in the near-term time period. Full implementation of Alternative 4A would also include the following environmental commitments and Resource Restoration and Performance Principles which would benefit the white-tailed kite.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).
- Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7.The mature riparian forest will be intermixed with a portion of the early- to mid-successional riparian vegetation will be a minimum width of 330 feet (Resource Restoration and Performance Principles VFR2 and VFR3).
- Protect 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3). The following Swainson's hawk Resource Restoration and Performance Principles would be implemented as part of these acres and would also benefit white-tailed kite:

- Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in minimum patch sizes of 40 acres (as part of the total cultivated lands protected) (Resource Restoration and Performance Principle SH1).
- Protect Swainson's hawk foraging habitat above 1 foot above mean sea level with at least 50% in very high-value habitat (see Table 12-4A-35 for a definition habitat value) (Resource Restoration and Performance Principle SH2).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

White-tailed kite is a fully protected species and take of white-tailed kite individuals is prohibited under Section 3511 of the Fish and Game Code. With the implementation of *AMM39 White-Tailed Kite*, construction activities would not result in take and effects on the species would be avoided. As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM39 White-Tailed Kite,* impacts on white-tailed kite would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-40. Changes in White-Tailed Kite Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	31	21
	Foraging	3,420	1,181
Total Impacts Water Conveyance Facilities		**3,451**	**1,202**

	Foraging	2,212	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,217**	**0**
Total Nesting		**36**	**21**
Total Foraging		**5,632**	**1,181**
TOTAL IMPACTS		**5,668**	**1,202**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-100: Loss or Conversion of Habitat for and Direct Mortality of White-Tailed Kite

Alternative 4A would result in the combined permanent and temporary loss of up to 6,870 acres of modeled habitat (57 acres of nesting habitat and 6,813 acres of foraging habitat) for white-tailed kite (Table 12-4A-40). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could affect white-tailed kite modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 52 acres of white-tailed kite nesting habitat (31 acres of permanent loss and 21 acres of temporary loss). In addition, 4,601 acres of foraging habitat would be removed (3,420 acres of permanent loss, 1,181 acres of temporary loss). Activities that would impact modeled white-tailed kite habitat consist of tunnel, forebay, and intake construction, temporary access roads, and construction of transmission lines. Most of the permanent loss of nesting habitat would occur where Intakes 1–3 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some nesting habitat would be lost due to construction of a permanent access road from the new forebay west to a reusable tunnel material disposal area and where the realigned SR 160 would cross Snodgrass Slough. Permanent losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of nesting habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. There are no occurrences of nesting white-tailed kite that overlap with the construction footprint of water conveyance facilities. White-tailed kite is a fully protected species and take is prohibited under Section 3511 of the Fish and Game Code. If white-tailed kite were to nest in or adjacent to work areas, the implementation of *AMM39 White-Tailed Kite* would avoid disturbance and nest abandonment, mortality of eggs, nestlings, or fledglings by restricting construction activities during the breeding season or establishing suitable buffers around active nests. (*AMM39 White-Tailed Kite* is described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Impacts on foraging habitat would occur throughout the central Delta in CZs 3–6, and CZ 8. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 5 acres of white-tailed kite nesting habitat and 59 acres of foraging habitat. The conversion of cultivated lands to tidal wetlands over fairly broad areas within the tidal restoration footprints could result in the removal or abandonment of nesting territories that occur within or adjacent to the restoration areas. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated.

- *Environmental Commitment 7 Riparian Natural Community Restoration:* Riparian restoration would permanently remove approximately 251 acres of white-tailed kite foraging habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration:* Grassland restoration would permanently convert approximately 1,070 acres of cultivated lands suitable for foraging by white-tailed kite to grassland.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent conversion of 832 acres of cultivated lands to nontidal marsh. This would not result in a loss of foraging habitat as both natural communities are foraging habitat for white-tailed kite. Small patches of riparian vegetation that support White-tailed kite nesting habitat may develop along the margins of restored nontidal marsh restoration would also provide foraging habitat for the species.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Habitat management- and enhancement-related activities could disturb white-tailed kite nests if they were present near work sites. A variety of habitat management actions that are designed to enhance wildlife values in Alternative 4A-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of white-tailed kite habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available white-tailed kite habitat and are expected to result in overall improvements to and maintenance of habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below (AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP. *AMM39 White-Tailed Kite* and updated versions of *AMM2 Construction Best Management Practices and Monitoring* and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material and Dredged Material* are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). The implementation of *AMM39 White-Tailed Kite* would avoid disturbance and nest abandonment by requiring restrictions on construction activities during the breeding season or establishing nodisturbance buffers. Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.

- Permanent and temporary white-tailed kite nesting habitat losses from the above environmental commitments would primarily consist of small, fragmented riparian stands. Temporarily affected nesting habitat would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. The restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kite. *AMM39 White-Tailed Kite* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees and planting of trees near high-value foraging habitat. The functions of agricultural and grassland communities that provide foraging habitat for white-tailed kite are expected to be restored relatively quickly.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect white-tailed kite use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. Effects of operations and maintenance activities on active white-tailed kite nests would be avoided by the implementation of *AMM39 White-Tailed Kite* which would restriction activities during the breeding season or require a construction buffer to minimize disturbance. If emergency repairs were required during the breeding season that could potentially result in take, CDFW consultation would be initiated (*AMM39 White-Tailed Kite* is described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

- Injury and Direct Mortality: Construction-related activities would not be expected to result in take of adult or fledged white-tailed kite if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. However, if white-tailed kite were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment. White-tailed kite is a fully protected species and take is prohibited under Section 3511 of the Fish and Game Code. If active nests were present in or adjacent to work areas, the implementation of *AMM39 White-Tailed Kite*, would restrict construction activities during the breeding season, or require a construction buffer that would avoid disturbance and nest abandonment, mortality of eggs, nestlings, or fledglings (*AMM39 White-Tailed Kite* is described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 14,069 acres of modeled nesting habitat and 507,922 acres of modeled foraging habitat for white-tailed kite. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 57 acres of potential nesting habitat (<1% of the potential nesting habitat in the study area) and the loss or conversion of 6,813 acres of foraging habitat (1% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual environmental commitments.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, and 1:1 protection for foraging habitat. Using these ratios would indicate that 57 acres of nesting habitat should be restored/ created and 57 acres should be protected to mitigate the losses of white-tailed kite nesting habitat. In addition, 6,813 acres of foraging habitat of should be protected to compensate for the losses of white-tailed kite foraging habitat.

A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected through Alternative 4A. Project proponents would commit to conserving 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat which would protect a total of 6,805 acres of white-tailed kite foraging habitat (Resource Restoration and Performance Principle SH1). These acres of cultivated lands and grasslands would be located above -1 foot above mean sea level. At least 50% of these lands would be in very high-value production for the Swainson's hawk (alfalfa) (Resource Restoration and Performance Principle SH2). These Swainson's hawk Resource Restoration and Performance Principles would be associated with Environmental Commitment 3 and would occur in the same timeframe as the construction and early restoration losses and would compensate for effects on white-tailed kite foraging habitat.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create 251 acres and protect 103 acres of valley/foothill riparian woodland, which would provide nesting habitat for white-tailed kite. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1). A single, contiguous patch of 100 acres of mature, riparian forest would be maintained in either CZ 4 or CZ 7 (Resource Restoration and Performance Principle VFR2), as part of the acres of restoration and protection under Environmental Commitment 7. In addition, small but essential nesting habitat for white-tailed kite associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Environmental Commitment 3).

The 251 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kite. This time lag between the removal and restoration of nesting habitat could have a substantial impact on white-tailed kite in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active white-tailed kite nests within the study area until restored riparian habitat is sufficiently developed.

AMM39 White-Tailed Kite would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the Alternative 4A reserve system for every tree 20 feet or taller anticipated to be removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the Alternative 4A reserve system in areas that support high-value foraging habitat in clumps of at least three trees each at appropriate sites within or adjacent to conserved cultivated lands, or they could be incorporated as a component of the riparian restoration (Environmental Commitment 7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout the lands protected as foraging habitat for white-tailed kite.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. The implementation of these AMMs, in addition to *AMM39 White-Tailed Kite*, would avoid the risk of take of individuals in habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP; AMM2, AMM6 and AMM39 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of white-tailed kite nesting and foraging habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles VFR1-VFR3, SH1, SH2, and CL1, AMM1–

AMM7, AMM10, and *AMM39 White-Tailed Kite*, which would restrict construction activities during the breeding season and would avoid disturbance and nest abandonment, mortality of eggs, nestlings, or fledglings and would be in place during all project activities. Considering these commitments, losses and conversions of white-tailed kite habitat under Alternative 4A would not be adverse.

***CEQA Conclusion*:** The effects on white-tailed kite habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for take in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles VFR1–VFR3, SH1, SH2, and CL1, AMM1–AMM6, AMM10, and *AMM39 White-Tailed Kite*, which would restrict construction activities during the breeding season and would avoid disturbance and nest abandonment, mortality of eggs, nestlings, or fledglings and would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not result in "take" of white-tailed kite per Section 86 of the California Fish and Game Code. Therefore, Alternative 4A would have a less-than-significant impact on white-tailed kite under CEQA.

Impact BIO-101: Effects on White-Tailed Kite Associated with Electrical Transmission Facilities

There are several known occurrences of nesting white-tailed kite within 5 miles of the proposed transmission line alignment. While white-tailed kite flight behavior puts them regularly within the range of heights proposed for the new transmission lines (50 to 110 feet), their keen vision and high maneuverability substantially reduce powerline collision risk for the species. Like other diurnal raptors, white-tailed kites have highly developed eyesight (Jones et al. 2007), allowing them to detect small prey while hunting from relatively high altitudes. Keen eyesight also allows for detection and avoidance of other aerial objects, including above-ground utility lines. Like many other falcons, the white-tailed kite has long, narrow, tapered wings and body size that allow for efficient soaring flight and highly developed aerial maneuverability. White-tailed kite are at low risk of take from bird strike from the construction of new transmission lines based on its general maneuverability, its keen eyesight, and lack of flocking behavior (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters, which would substantially reduce any risk of collision with lines.

***NEPA Effects*:** The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the species' general maneuverability, keen eyesight, and lack of flocking behavior. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further eliminate risk of take from bird strike for white-tailed kite from the project. Therefore, the construction and operation of new transmission lines would not result in an adverse effect on white-tailed kite.

CEQA Conclusion: The construction and presence of new transmission lines would not result in "take" of white-tailed kite per Section 86 of the California Fish and Game Code because the risk of bird strike is considered to be minimal based on the species' general maneuverability, keen eyesight, and lack of flocking behavior. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further eliminate any risk of take from bird strike for white-tailed kite from the project. Therefore, the construction and operation of new transmission lines would result in a less-than-significant impact on white-tailed kite.

Impact BIO-102: Indirect Effects of the Project on White-Tailed Kite

White-tailed kite nesting habitat within the vicinity of proposed construction areas could be indirectly affected by construction activities. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect white-tailed kite. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If white-tailed kite were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. The implementation of *AMM39 White-Tailed Kite* would avoid the risk of take of individual white-tailed kites in habitats in or adjacent to work areas by restricting construction activities during the breeding season or establishing nodisturbance buffers around active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect white-tailed kite in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to white-tailed kite habitat could also affect the species. AMM1–AMM7, and *AMM39 White-tailed Kite*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including white-tailed kite. Marsh (tidal and nontidal) an restoration also has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Increased methylmercury associated with natural community restoration may indirectly affect white-tailed kite (see Appendix 5.D, *Contaminants*, of the Draft BDCP). However, the potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. Due to the complex and very site-specific factors that would determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including white-tailed kite. Marsh (tidal and nontidal) restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 4, Environmental Commitment 5) would lead to adverse effects on white-tailed kite.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on white-tailed kite from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27*

Selenium Management, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*: **Noise and visual disturbances from the construction of water conveyance facilities could reduce white-tailed kite use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect use of the surrounding habitat by white-tailed kite. Noise, potential spills of hazardous materials, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would not have an adverse effect on white-tailed kite with the implementation of AMM1–AMM7, and *AMM39 White-Tailed Kite* which would avoid the risk of take of individuals*.* Tidal habitat restoration could result in increased exposure of white-tailed kite to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The indirect effects associated with noise and visual disturbances, potential spills of hazardous material, and increased exposure to selenium from Alternative 4A implementation would not have an adverse effect on white-tailed kite. Tidal habitat restoration is unlikely to have an adverse effect on white-tailed kite through increased exposure to methylmercury, as kites currently forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in *Environmental Commitment 12 Methylmercury Management,* would address the uncertainty of methylmercury levels in restored tidal marsh. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for white-tailed kite, once site specific sampling and other information could be developed.

***CEQA Conclusion*: **Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would have a less-than-significant impact on white-tailed kite with the implementation of AMM1–AMM7, and *AMM39 White-Tailed Kite*, which would avoid the risk of take of individuals. Tidal habitat restoration could result in increased exposure of white-tailed kite to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration could result in increased exposure of white-tailed kite to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to this species. *Environmental Commitment 12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in Environmental Commitment 12, would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area on white-tailed kite. With these measures in place, the indirect effects associated with noise and visual disturbances, potential spills of hazardous material, and increased exposure to selenium from Alternative 4A implementation would have a less-than-significant impact on white-tailed kite.

Impact BIO-103: Periodic Effects of Inundation of White-Tailed Kite Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on white-tailed kite.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Yellow-Breasted Chat

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on yellow-breasted chat. Yellow-breasted chat modeled habitat includes suitable nesting and migratory habitat as those plant alliances from the valley/foothill riparian modeled habitat that contain a shrub component and an overstory component. Primary nesting and migratory habitat is qualitatively distinguished from secondary habitat in Delta areas as those plant associations that support a greater percentage of a suitable shrub cover, particularly blackberry, and California wild rose, and have an open to moderately dense overstory canopy, using data from Hickson and Keeler-Wolf (2007). No distinction is made between primary and secondary habitat for Suisun Marsh/Yolo Basin habitats because supporting information is lacking.

Alternative 4A would result in both temporary and permanent losses of yellow-breasted chat modeled habitat as indicated in Table 12-4A-41. Full implementation of Alternative 4A would also include the following environmental commitments and Resource Restoration and Performance Principles which would benefit the yellow-breasted chat.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities* and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, impacts on yellow-breasted chat would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-41. Changes in Yellow-Breasted Chat Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Nesting and Migratory Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Primary	16	16
	Secondary	17	10
Total Impacts Water Conveyance Facilities		**33**	**26**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-104: Loss or Conversion of Habitat for and Direct Mortality of Yellow-Breasted Chat

Alternative 4A would result in the combined permanent and temporary loss of up to 64 acres of modeled nesting and migratory habitat for yellow-breasted chat (38 acres of permanent loss, 26 acres of temporary loss, Table 12-4A-41). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate yellow-breasted chat habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 32 acres of primary habitat (16 acres of permanent loss, 16 acres of temporary loss). In addition, 27 acres of secondary habitat would be removed (17 acres of permanent loss, 10 acres of temporary loss, Table 12-4A-41). Activities that would impact modeled habitat consist of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, barge unloading facilities and temporary work areas. Impacts from water conveyance facilities would occur in the central Delta in CZs 3–6, and 8. Most of the permanent loss of habitat would occur where Intakes 2, 3, and 5 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some habitat would be lost due to construction of a permanent access road from the new forebay west to a reusable tunnel material disposal area and where the realigned SR 160 would cross Snodgrass Slough. Permanent habitat loss would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary loss of habitat would occur from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation.

- Habitat loss from water conveyance facilities activities would have the potential to displace individuals, if present, and remove the functions and value of modeled habitat for nesting, protection, or foraging. There are no occurrences of yellow-breasted chat that overlap with the water conveyance facilities construction footprint. The implementation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize the effects of construction on nesting yellow-breasted chats if they were to occur in the area (see Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP). Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 5 acres of modeled yellow-breasted chat migratory habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat protection and management activities that could be implemented in protected yellow-breasted chat habitats would be expected to maintain and improve the functions of the habitat. Yellow-breasted chat would be expected to benefit from the increase in protected habitat, which would maintain conditions favorable for the chat's use of the study area.

  Habitat management- and enhancement-related activities could disturb yellow-breasted chat nests if they are present near work sites. Equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would ensure that these activities do not result in direct mortality of yellow-breasted chat or other adverse effects.

  Occupied habitat would be monitored to determine if there is a need to implement controls on brood parasites (brown-headed cowbird) or nest predators. If implemented, these actions would be expected to benefit the yellow-breasted chat by removing a potential stressor that could, if not addressed, adversely affect the stability of newly established populations.

  A variety of habitat management actions included in *Environmental Commitment 11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored riparian habitats may result in localized ground disturbances that could temporarily remove small amounts of yellow-breasted chat habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor adverse effects on available yellow-breasted chat habitat and are expected to result in overall improvements to and maintenance of yellow-breasted chat habitat values.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect yellow-breasted chat use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: Construction is not expected to result in direct mortality of yellow-breasted chat because adults and fledged young are expected to occur only in very small numbers and, if present, would avoid contact with construction and other equipment. If yellow-breasted chat were to nest in the vicinity of construction activities, equipment operation could destroy nests and noise and visual disturbances could lead to nest abandonment. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would avoid and minimize this effect.

- Permanent and temporary habitat losses from the above environmental commitments would primarily consist of small, fragmented riparian stands in CZ 2–CZ 8 that do not provide high-value habitat for the species. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The habitat model indicates that the study area supports approximately 14,547 acres of modeled nesting and migratory habitat for yellow-breasted chat. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 64 acres of modeled habitat (less than 1% of the modeled habitat in the study area). These losses would occur from the construction of the water conveyance facilities and from *Environmental Commitment 4 Tidal Natural Communities Restoration*. The locations of these losses would be in fragmented riparian habitat throughout the study area.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of dense shrubby successional valley/foothill riparian habitat. Using these ratios would indicate that 64 acres of valley/foothill riparian habitat should be restored/created and 64 acres should be protected to compensate for the losses of yellow-breasted chat habitat.

Alternative 4A includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create 251 acres and protect 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western*

Yellow-Billed Cuckoo. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of yellow-breasted chat habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM7, AMM10, and AMM22. These environmental commitments and AMMs would be in place during all project activities. Considering these commitments, losses and conversions of yellow-breasted chat habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The loss of yellow-breasted chat habitat from Alternative 4A would represent an adverse effect in the absence of environmental commitments and AMMs as a result of habitat modification and potential for direct mortality of a special-status species. However, habitat protection and restoration associated with Environmental Commitment 3 and Environmental Commitment 7, guided by Resource Restoration and Performance Principle VFR1 and by *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities* and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo*, would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of yellow-breasted chat. Therefore, Alternative 4A would have a less-than-significant impact on yellow-breasted chat under CEQA.

Impact BIO-105: Fragmentation of Yellow-Breasted Chat Habitat as a Result of Constructing the Water Conveyance Facilities

Grading, filling, contouring, and other initial ground-disturbing activities for water conveyance facilities construction may temporarily fragment modeled yellow-breasted chat habitat. This could temporarily reduce the extent of and functions supported by the affected habitat. Any such habitat fragmentation is expected to have no or minimal effect on the species.

NEPA Effects: Temporary fragmentation of habitat would not result in an adverse effect on yellow-breasted chat. Any such habitat fragmentation is expected to have no or minimal effect on the species.

CEQA Conclusion: Temporary fragmentation of habitat would have a less-than-significant impact on yellow-breasted chat. Any such habitat fragmentation is expected to have no or minimal effect on the species.

Impact BIO-106: Effects on Yellow-Breasted Chat Associated with Electrical Transmission Facilities

Yellow-breasted chats are migratory and usually arrive at California breeding grounds in April from their wintering grounds in Mexico and Guatemala. Departure for wintering grounds occurs from August to September. These are periods of relative high visibility when the risk of powerline collisions will be low. The species' small, relatively maneuverable body; its foraging behavior; and its presence in the project area during the summer contribute to a low risk of collision with the proposed transmission lines (BDCP Attachment 5.J-2*, Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters. Bird flight diverters would further reduce any potential for powerline collisions.

NEPA Effects: The construction and presence of new transmission lines would not result in an adverse effect on yellow-breasted chat because the risk of bird strike is considered to be minimal based on the species' small, relatively maneuverable body; its foraging behavior; and its presence in the project area during the summer during periods of high visibility. Under *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with bird diverters which would further reduce any potential for powerline collisions.

CEQA Conclusion: The construction and presence of new transmission lines would have a less-than-significant impact on yellow-breasted chat because the risk of bird strike is considered to be minimal based on the species' small, relatively maneuverable body; its foraging behavior; and its presence in the project area during the summer during periods of high visibility. Under *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with bird diverters which would further reduce any potential for powerline collisions.

Impact BIO-107: Indirect Effects of the Project on Yellow-Breasted Chat

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-breasted chat use of modeled habitat adjacent to proposed construction areas. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect yellow-breasted chat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If yellow-breasted chat were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. These potential effects would be minimized with incorporation of *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the Alternative 4A, which would ensure 250 foot no-disturbance buffers were established around active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect yellow-breasted chat in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to yellow-breasted chat habitat could also affect the species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, in addition to *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would minimize the likelihood of such spills from occurring and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests. If present, yellow-breasted chat individuals could be temporarily affected by noise and visual disturbances adjacent to water conveyance construction sites, reducing the use of an estimated 59 acres of modeled primary nesting and migratory habitat and 119 acres of secondary nesting and migratory habitat. *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* would avoid and minimize this effect on the species.

NEPA Effects: The potential for noise and visual disturbance, hazardous spills, increased dust and sedimentation, and the potential impacts of operations and maintenance of the water conveyance facilities would not result in an adverse effect on yellow-breasted chat with the incorporation of AMM1–AMM7, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the Alternative 4A.

CEQA Conclusion: The potential for noise and visual disturbance, hazardous spills, increased dust and sedimentation, and the potential impacts of operations and maintenance of the water conveyance facilities would have a less-than-significant impact on yellow-breasted chat with the incorporation of AMM1–AMM7, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo* into the Alternative 4A.

Impact BIO-108: Periodic Effects of Inundation of Yellow-Breasted Chat Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on yellow-breasted chat.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Cooper's Hawk and Osprey

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on Cooper's hawk and osprey. Although osprey often nest on manmade structures such as telephone poles, and Cooper's hawk will nest in more developed landscapes, modeled nesting habitat for these species is restricted to valley/foothill riparian forest.

Alternative 4A would result in both temporary and permanent losses of Cooper's hawk and osprey modeled habitat as indicated in Table 12-4A-42. Although restoration for the loss of nesting habitat would be initiated in the same timeframe as the losses, it could take one or more decades for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM18 Swainson's Hawk*, including the planting of mature trees in the near-term time period. Full implementation of Alternative 4A would include the following environmental commitments and Resource Restoration and Performance Principles which would also benefit Cooper's hawk and osprey.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).

- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7. As explained below, with the acres of restoration or protection included in the project, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities, AMM18 Swainson's Hawk*, and Mitigation Measure BIO-75, impacts on Cooper's hawk and osprey would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-42. Changes in Cooper's Hawk and Osprey Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	31	21
Total Impacts Water Conveyance Facilities		**31**	**21**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	5	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**5**	**0**
TOTAL IMPACTS		**36**	**21**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-109: Loss or Conversion of Habitat for and Direct Mortality of Cooper's Hawk and Osprey

Alternative 4A would result in the combined permanent and temporary loss of up to 57 acres (36 acres of permanent loss, 21 acres of temporary loss) of modeled nesting habitat for Cooper's hawk and osprey (Table 12-4A-42). Project measures that would result in these losses are water facilities and operation (which would involve construction of water conveyance facilities and transmission lines and establishment and use of reusable tunnel material areas), and tidal restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), which would include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other Alternative 4A physical facilities could affect Cooper's hawk and osprey modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 52 acres of modeled Cooper's hawk and osprey habitat (Table 12-4A-42). Of the 52 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 31 acres would be a permanent loss and 21 acres would be a temporary loss of habitat. Activities that would impact modeled habitat consist of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, barge unloading facilities and work areas. Most of the permanent loss of nesting habitat would occur where Intakes 1–3 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some nesting habitat would be lost due to construction of a permanent access road from the new forebay west to an reusable tunnel material disposal area and where the realigned SR 160 would cross Snodgrass Slough. Permanent losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of nesting habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. Impacts from water conveyance facilities would occur in the central Delta in CZ 3, CZ 4, CZ 5, CZ 6, and CZ 8. These losses would have the potential to displace individuals, if present, and remove the functions and value of potentially suitable habitat. There are no occurrences of Cooper's hawk or osprey that overlap with the construction footprint for water conveyance facilities; however, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize impacts on Cooper's hawk and osprey if they were to nest in the vicinity of construction activities. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration would permanently remove up to 5 acres of potential Cooper's hawk and osprey nesting habitat. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Habitat management- and enhancement-related activities could disturb Cooper's hawk and osprey nests if they were present near work sites. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in Alternative 4A-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of Cooper's hawk and osprey habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available Cooper's hawk and osprey habitat and are expected to result in overall improvements to and maintenance of habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below (AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP. *AMM18 Swainson's Hawk* and updated versions of *AMM2 Construction Best Management Practices and Monitoring* and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material and Dredged Material* are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

- Permanent and temporary habitat losses from the above environmental commitments would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Cooper's hawk or osprey. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Cooper's hawk or osprey use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Cooper's hawk or osprey if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If Cooper's hawk or osprey were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects on Cooper's hawk and osprey.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 14,069 acres of modeled nesting habitat for Cooper's hawk and osprey. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 57 acres of potential nesting habitat (less than 1% of the potential nesting habitat in the study area).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat. Using these ratios would indicate that 57 acres of nesting habitat should be restored/ created and 57 acres should be protected to mitigate the losses of Cooper's hawk and osprey nesting habitat.

The 251 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Cooper's hawk or osprey. This time lag between the removal and restoration of nesting habitat could have a substantial impact on white-tailed kite in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active Cooper's hawk or osprey nests within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the Alternative 4A reserve system for every tree 20 feet or taller anticipated to be removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the Alternative 4A reserve system in areas that support high-value foraging habitat in clumps of at least three trees each at appropriate sites within or adjacent to conserved cultivated lands, or they could be incorporated as a component of the riparian restoration (Environmental Commitment 7).

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of Cooper's hawk and osprey nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents committed to avoiding and minimizing effects from and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM7, AMM10, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of Cooper's hawk and osprey habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on Cooper's hawk and osprey habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM6, AMM10, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Cooper's hawk and osprey. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on Cooper's hawk and osprey under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-110: Effects on Cooper's Hawk and Osprey Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Cooper's hawk and osprey. However, the flight behavior of these species, their keen vision, and high maneuverability substantially reduce the risk of powerline collisions. The existing network of transmission lines in the project area currently poses the same small risk for Cooper's hawk and osprey, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters, which would further reduce any risk of collision with lines.

NEPA Effects: The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the general maneuverability and keen eyesight of Cooper's hawk and osprey. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce any risk of mortality from bird strike for Cooper's hawk and osprey from the project. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on Cooper's hawk and osprey.

CEQA Conclusion: The construction and presence of new transmission lines would not represent an adverse effect because the risk of bird strike is considered to be minimal based on the general maneuverability and keen eyesight of Cooper's hawk and osprey. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would further reduce any risk of mortality from bird strike for Cooper's hawk and osprey from the project. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on Cooper's hawk and osprey.

Impact BIO-111: Indirect Effects of the Project on Cooper's Hawk and Osprey

Indirect construction- and operation-related effects: Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect Cooper's hawk or osprey. If Cooper's hawk or osprey were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting Cooper's hawk and osprey. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect Cooper's hawk and osprey in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including Cooper's hawk and osprey. Future operational impacts under water conveyance facilities were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability resulting from proposed flows. Subsequently, a regression model was used to estimate fish-tissue concentrations under these future operational conditions (evaluated starting operations or ESO). Results indicated that changes in total mercury levels in water and fish tissues due to ESO were insignificant (see Draft BDCP Appendix 5.D, *Contaminants*, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community restoration could indirectly affect cooper's hawk and osprey, via uptake in lower tropic levels (as described in Appendix 5.D, *Contaminants*, of the Draft BDCP).

The potential mobilization or creation of methylmercury within the project area varies with site-specific conditions and would need to be assessed at the project level. Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management,* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability.
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

NEPA Effects**:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Cooper's hawk and osprey use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could adversely affect Cooper's hawk and osprey use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, in addition to AMM1–AMM7, would be available to address this adverse effect. The implementation of tidal natural communities restoration could result in increased exposure of Cooper's hawk or osprey to methylmercury, through the ingestion of fish or small mammals in tidally restored areas. However, it is currently unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Cooper's hawk and osprey.

***CEQA Conclusion*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Cooper's hawk and osprey use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Cooper's hawk and osprey use of the surrounding habitat. Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would have a less-than-significant impact on Cooper's hawk and osprey with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. The implementation of tidal natural communities restoration could result in increased exposure of Cooper's hawk or osprey to methylmercury, through the ingestion of fish or small mammals in tidally restored areas. This would be a significant impact. However, it is currently unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Cooper's hawk and osprey.

With AMM1–AMM7 and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of Cooper's hawk or osprey. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on Cooper's hawk or osprey.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-112: Periodic Effects of Inundation of Cooper's Hawk and Osprey Nesting Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on Cooper's hawk and osprey.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Golden Eagle and Ferruginous Hawk

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on golden eagle and ferruginous hawk. Modeled foraging habitat for these species consists of grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Alternative 4A would result in both temporary and permanent losses of golden eagle and ferruginous hawk modeled foraging habitat as indicated in Table 12-4A-43. Full implementation of

Alternative 4A would include the following environmental commitments that would benefit golden eagles or ferruginous hawk.

- Protect 1,060 acres of grassland (Environmental Commitment 3).
- Protect 11,870 acres of cultivated lands (Environmental Commitment 3).

Golden eagle is a fully protected species and "take" of individuals, per Section 86 of the California Fish and Game Code, is prohibited. With the implementation of *AMM20 Greater Sandhill Crane*, construction activities would not result in mortality of the species, which would avoid take per Section 86 of the California Fish and Game Code[4]. As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, impacts on golden eagle and ferruginous hawk would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-43. Changes in Golden Eagle and Ferruginous Hawk Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Foraging	1,967	503
Total Impacts Water Conveyance Facilities		**1,967**	**503**
Environmental Commitments 4, 6–7, 9–11[a]	Foraging	2,212	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,212**	**0**
TOTAL IMPACTS		**4,179**	**503**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-113: Loss or Conversion of Habitat for and Direct Mortality of Golden Eagle and Ferruginous Hawk

Alternative 4A would result in the combined permanent and temporary loss of up 4,682 acres of modeled foraging habitat for golden eagle and ferruginous hawk (4,179 acres of permanent loss and 503 of temporary loss, Table 12-4A-43). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate golden eagle foraging habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,470 acres of modeled golden eagle

[4] Section 86 of the California Fish and Game Code defines take as "hunt, pursue, catch, capture, or kill, or attempt to hunt, pursue, catch, capture, or kill." The Lead Agencies do not propose to hunt, pursue, catch, or capture golden eagles and ferruginous hawk. Killing would be avoided through AMM20.

and ferruginous hawk habitat (1,967 acres of permanent loss, 503 acres of temporary loss). Impacts would occur from the construction of Intakes 2, 3, and 5 and associated temporary work areas and access roads in CZ 4 between Clarksburg and Courtland; the rerouting of SR 160; construction of the intermediate forebay; and from an reusable tunnel material storage area on Bouldin Island. The construction of the permanent and temporary transmission line corridors through CZs 4–6 and 9 would also remove suitable foraging habitat for the species. Approximately 796 acres would be affected by placement of a reusable tunnel material area west of the Clifton Court Forebay in CZ 8. In addition, permanent habitat loss would result from the construction of the new forebay south of the existing Clifton court Forebay in CZ 8. Some of the grassland habitat lost at the sites of new canals south of Clifton Court Forebay is composed of larger stands of ruderal and herbaceous vegetation and California annual grassland, which is also suitable foraging habitat for the species. There are no occurrences of golden eagle or ferruginous hawk that intersect with the water conveyance facilities footprint. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 59 acres of modeled golden eagle and ferruginous hawk habitat. The majority of the acres lost would consist of cultivated lands in the West Delta ROA.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of Golden eagle and foraging habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for foraging raptors but would not permanently reduce foraging habitat for either species.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of Swainson's hawk foraging habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of golden eagle and ferruginous hawk foraging habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities would be expected to have minor adverse effects on available habitat for these species. Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect golden eagle and ferruginous hawk use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of golden eagle and ferruginous hawk because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 4,682 acres of modeled golden eagle and ferruginous hawk foraging habitat. These effects would result from the construction of the water conveyance facilities and implementing other environmental commitments (*Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration, and Environmental Commitment 10 Nontidal Marsh Restoration*).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 9,364 acres should be protected to compensate for the losses of golden eagle and ferruginous hawk habitat. Project proponents would commit to protect 1,060 acres of grassland and 11,870 acres of cultivated lands, which would provide suitable habitat for golden eagle and ferruginous hawk.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of golden eagle and ferruginous hawk foraging habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by and by AMM1–AMM7, which would be in place during all project activities. Considering these commitments, losses and conversions of mountain plover habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on golden eagle and ferruginous hawk foraging habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 11. These conservation activities would be guided by and by AMM1–AMM7, which would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications. Therefore, Alternative 4A would have a less-than-significant impact on golden eagle and ferruginous hawk under CEQA.

Impact BIO-114: Effects on Golden Eagle and Ferruginous Hawk Associated with Electrical Transmission Facilities

Golden eagle and ferruginous hawk would be at low risk of bird strike mortality from the construction of new transmission lines based on their maneuverability, their keen eyesight, their lack of flocking behavior, and other factors assessed in the bird strike vulnerability analysis (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines would be fitted with flight diverters which would substantially reduce any potential for powerline collisions.

***NEPA Effects*:** Golden eagle and ferruginous hawk are already at a low risk of bird strike mortality based on their general maneuverability, keen eyesight and lack of flocking behavior. All new transmission lines constructed as a result of the project would be fitted with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, the construction and operation of transmission lines would not result in an adverse effect on golden eagle or ferruginous hawk.

***CEQA Conclusion*:** Golden eagle and ferruginous hawk are already at a low risk of bird strike mortality based on their general maneuverability, keen eyesight and lack of flocking behavior. In addition, *AMM20 Greater Sandhill Crane* contains the commitment to fit new transmission lines constructed as a result of the project with bird diverters, which have been shown to reduce avian mortality by 60%. By implementing *AMM20 Greater Sandhill Crane*, there would be no take of golden eagle from the project per Section 86 of the California Fish and Game Code, and the construction and operation of transmission lines would not result in an adverse effect on golden eagle or ferruginous hawk.

Impact BIO-115: Indirect Effects of the Project on Golden Eagle and Ferruginous Hawk

Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for golden eagle and ferruginous hawk. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect golden eagle or ferruginous hawk. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to golden eagle and ferruginous hawk grassland habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

***NEPA Effects*:** Indirect effects on golden eagle and ferruginous hawk as a result of Alternative 4A implementation could have adverse effects on these species through the modification of habitat.

With the incorporation of AMM1–AMM7 into the Alternative 4A, indirect effects as a result of Alternative 4A implementation would not have an adverse effect on golden eagle and ferruginous hawk.

***CEQA Conclusion*:** Indirect effects on golden eagle and ferruginous hawk as a result of Alternative 4A implementation could have a significant impact on the species from modification of habitat. With the incorporation of AMM1–AMM7 into the Alternative 4A, indirect effects as a result of Alternative 4A implementation would have a less-than-significant impact on golden eagle and ferruginous hawk.

Impact BIO-116: Periodic Effects of Inundation on Golden Eagle and Ferruginous Hawk Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on golden eagle and ferruginous hawk.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Cormorants, Herons and Egrets

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron. Modeled breeding habitat for these species consists of valley/foothill riparian forest.

Alternative 4A would result in both temporary and permanent losses of cormorant, heron, and egret modeled habitat as indicated in Table 12-4A-44. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although restoration for the loss of nesting habitat would be initiated in the same timeframe as the losses, it could take one or more decades for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of *AMM18 Swainson's Hawk*, including the planting of mature trees in the near-term time period. Full implementation of Alternative 4A would include the following environmental commitments and Resource Restoration and Performance Principles which would benefit cormorants, herons, and egrets.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, *AMM10 Restoration of Temporarily Affected Natural Communities, AMM18 Swainson's Hawk*, Mitigation Measure BIO-75, and Mitigation Measure BIO-117, impacts on cormorants, herons, and egrets would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-44. Changes in Cormorant, Heron and Egret Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting (Rookeries)	42	31
Total Impacts Water Conveyance Facilities		**42**	**31**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting (Rookeries)	5	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**5**	**0**
TOTAL IMPACTS		**47**	**31**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-117: Loss or Conversion of Nesting Habitat for and Direct Mortality of Cormorants, Herons and Egrets

Alternative 4A would result in the combined permanent and temporary loss of up to 78 acres of modeled nesting habitat (47 acres of permanent loss, 31 acres of temporary loss) for double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron (Table 12-4A-44). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal natural communities restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11) which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate cormorant, heron, and egret modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 73 acres of modeled nesting habitat for cormorants, herons, and egrets. (Table 12-4A-44). Of the 73 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 42 acres would be a permanent loss and 31 acres would be a temporary loss of habitat. Activities that would impact modeled nesting habitat consist of tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, barge unloading facilities, and temporary work areas. Most of the permanent loss of nesting habitat would occur where Intakes 2, 3, and 5 impact the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees. Some nesting habitat would be lost as a result of construction of a permanent access road from the new forebay west to a reusable tunnel material disposal area and where the realigned SR 160 would cross Snodgrass Slough. Permanent losses would also occur along Lambert Road where permanent utility lines would be installed and from the construction of an operable barrier at the confluence of Old River and the San Joaquin River. Temporary losses of nesting habitat would result from the construction of a barge unloading facility west of the intermediate forebay in Snodgrass Slough and where temporary work areas surround intake sites. The riparian habitat in these areas is also composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. Impacts from water conveyance facilities would occur in the central Delta in CZs 3–6, and CZ 8. Habitat loss from water conveyance facilities activities would have the potential to displace individuals, if present, and remove the functions and value of potentially suitable habitat. There are no occurrences of nesting cormorants, herons, or egrets that overlap with the construction footprint of water conveyance facilities; however, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize impacts on cormorants, herons and egrets if they were to nest in the vicinity of construction activities. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 5 acres of nesting habitat for cormorants, herons and egrets. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated. Depending on the extent and value of remaining habitat, this could reduce use of these habitats by these species.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb cormorant, heron, and egret nests if they were present near work sites. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in Alternative 4A-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of cormorant, heron, and egret habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available habitat for these species and are expected to result in overall improvements to and maintenance of habitat values. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below (AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP. *AMM18 Swainson's Hawk* and updated versions of *AMM2 Construction Best Management Practices and Monitoring* and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material and Dredged Material* are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

- Permanent and temporary habitat losses from the above environmental commitments would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described in *AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure for established rookeries. *AMM18 Swainson's Hawk* contains actions described below to reduce the effect of temporal loss of mature riparian habitat, including the transplanting of mature trees.

- *Construction Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect use of the surrounding habitat by cormorants, herons or egrets. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- The primary impact of concern regarding double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron is the loss of existing known nest trees, and other large trees associated with known nest sites. Because these species are highly traditional in their use of rookeries, the establishment of new nest sites is unpredictable. To avoid adverse effects on these species, existing known nest sites would have to be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects on cormorants, herons, and egrets.
- Injury and Direct Mortality: If birds were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 and Mitigation Measure BIO-117 would be available to address these effects on cormorants, herons, and egrets.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Based on modeled habitat, the study area supports approximately 17,966 acres of modeled nesting habitat for cormorants, herons, and egrets. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 78 acres of potential breeding habitat (<1% of the potential breeding habitat in the study area).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat. Using these ratios would indicate that 78 acres of nesting habitat should be restored/ created and 78 acres should be protected to mitigate the losses of cormorant, heron, and egret nesting habitat.

The 251 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by cormorants, herons, and egrets. This time lag between the removal and restoration of nesting habitat could have a substantial impact on white-tailed kite in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active cormorant, heron, and egret nests within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the Alternative 4A reserve system for every tree 20 feet or taller anticipated to be removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the Alternative 4A reserve system in areas that support high-value foraging habitat in clumps of at least three trees each at appropriate sites within or adjacent to conserved cultivated lands, or they could be incorporated as a component of the riparian restoration (Environmental Commitment 7).

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of cormorant, heron, and egret nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that meets the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM7, AMM10, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 and Mitigation Measure BIO-117 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of cormorant, heron, and egret habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on cormorant, heron, and egret habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle VFR1, and by AMM1–AMM6, AMM10, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 and Mitigation Measure BIO-117 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Cooper's hawk and osprey. Therefore, with the implementation of Mitigation Measure BIO-75 and Mitigation Measure BIO-117, Alternative 4A would have a less-than-significant impact on Cooper's hawk and osprey under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries); therefore, DWR will avoid all direct and indirect impacts on rookeries.

Impact BIO-118: Effects Associated with Electrical Transmission Facilities on Cormorants, Herons and Egrets

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons and egrets. New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Waterbirds have a higher susceptibility to collisions than passerines, raptors, and other birds. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new transmission lines constructed as a result of the project would be fitted with flight diverters which would reduce bird strike risk of cormorants, herons, and egrets.

NEPA Effects**:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of cormorants, herons, and egrets by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on cormorants, herons, and egrets.

CEQA Conclusion**:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of cormorants, herons, and egrets by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on cormorants, herons, and egrets.

Impact BIO-119: Indirect Effects of the Project on Cormorants, Herons and Egrets

Indirect construction- and operation-related effects: Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect cormorants, herons, or egrets. If cormorants, herons or egrets were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting cormorants, herons or egrets. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect cormorants, herons or egrets in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including cormorants, herons or egrets. Future operational impacts under water conveyance facilities were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability resulting from proposed flows. Subsequently, a regression model was used to estimate fish-tissue concentrations under these future operational conditions (evaluated starting operations or ESO). Results indicated that changes in total mercury levels in water and fish tissues due to ESO were insignificant (see Draft BDCP Appendix 5.D, *Contaminants*, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community restoration could indirectly affect cormorants, herons or egrets, via uptake in lower tropic levels (as described in the Appendix 5.D, *Contaminants*, of the Draft BDCP).

Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management,* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including cormorants, herons, and egrets. Marsh (tidal and nontidal) restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 4, Environmental Commitment 5) would lead to adverse effects on cormorants, herons, and egrets.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on cormorants, herons, and egrets from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce cormorant, heron, and egret use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect cormorant, heron, and egret use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. Tidal habitat restoration could result in increased exposure of cormorants, herons, and egrets to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration could result in increased exposure of cormorants, herons or egrets to methylmercury through the ingestion of fish in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on the species.

CEQA Conclusion: Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would be less than significant with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, and AMM1–AMM7. The implementation of tidal natural communities restoration could result in increased exposure of cormorants, herons or egrets to methylmercury, through the ingestion of fish in tidally restored areas. This would be a significant impact. However, it is unknown what concentrations of methylmercury are harmful to these species. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on cormorants, herons, and egrets. Tidal habitat restoration could result in increased exposure of cormorants, herons, and egrets to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

With AMM1–AMM7, AMM27, and Environmental Commitment 12 in place, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of cormorants, herons, and egrets. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on cormorants, herons, and egrets.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries), therefore all direct and indirect impacts on rookeries must be avoided.

Impact BIO-120: Periodic Effects of Inundation on Cormorants, Herons and Egrets as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on cormorants, herons, and egrets.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Short-Eared Owl and Northern Harrier

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on short-eared owl and northern harrier. Modeled habitat for short-eared owl and northern harrier include tidal brackish and freshwater emergent wetland, nontidal freshwater perennial emergent wetland, managed wetland, other natural seasonal wetland, grassland, alkali seasonal wetland, vernal pool complex, and selected cultivated lands.

Alternative 4A would result in both temporary and permanent losses of modeled habitat for short-eared owl and northern harrier as indicated in Table 12-4A-45. Full implementation of Alternative 4A would include the following environmental commitments and Resource Restoration and Performance Principles which would benefit short-eared owl and northern harrier.

- Restore or create 37 acres of tidal wetlands in the north Delta (Environmental Commitment 4).
- Restore or create 22 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the central Delta (Resource Restoration and Performance Principle CBR1).
- Protect 119 acres of nontidal wetlands and create 832 acres of nontidal wetlands (Environmental Commitment 3 and Environmental Commitment 10).
- Protect 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3). The following Swainson's hawk Resource Restoration and Performance Principles would be implemented as part of these acres:
  - Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in patch sizes of a minimum of 40 acres (Resource Restoration and Performance Principle SH1).
  - Protect Swainson's hawk foraging habitat above 1 foot above mean sea level with at least 50% in very high-value habitat (see Table 12-4A-35 for a definition habitat value) (Resource Restoration and Performance Principle SH2).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species, AMM1–AMM7, *AMM27 Selenium Management* and Mitigation Measure BIO-75, impacts on short-eared owl and northern harrier would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-45. Changes in Short-Eared Owl and Northern Harrier Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting and Foraging	2,152	683
Total Impacts Water Conveyance Facilities		**2,152**	**683**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting and Foraging	2,212	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,212**	**0**
TOTAL IMPACTS		**4,364**	**683**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-121: Loss or Conversion of Habitat for and Direct Mortality of Short-Eared Owl and Northern Harrier

Alternative 4A would result in the combined permanent and temporary loss of up to 5,047 acres of modeled habitat for short-eared owl and northern harrier (of which 4,364 acres would be a permanent loss and 683 acres would be a temporary loss of habitat, Table 12-4A-45). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate short-eared owl and northern harrier modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,835 acres of modeled short-eared owl and northern harrier habitat (2,152 acres of permanent loss, 683 acres of temporary loss) from CZs 3–6 and CZ 8. Activities that would impact modeled habitat include tunnel, forebay, and intake construction, permanent and temporary access roads, construction of transmission lines, and temporary work areas. The majority of habitat removed would consist of grassland and alfalfa fields. There are no CNDDB or DHCCP surveys records of occurrences of nesting short-eared owl that overlap with the construction footprint of water conveyance facilities. However, there are two DHCCP occurrences of northern harrier that overlap with the footprint of a shaft associated with the pumps at Clifton Court Forebay and a permanent transmission line north of the forebay. Two DHCCP occurrences also overlap with the temporary impact footprint from geotechnical explorations. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize impacts on short-eared owl and northern harrier if they were to nest in the vicinity of construction activities. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal restoration actions through Environmental Commitment 4 would restore an estimated 59 acres of tidal natural communities. These restored wetland areas could provide suitable nesting habitat for short-eared owl and northern harrier. Consequently, although existing nesting habitat for short-eared owl and northern harrier would be removed, restoration of wetland habitats is expected to benefit marsh associated ground nesting birds by increasing the value of their nesting habitat.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of short-eared owl and northern harrier foraging habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for foraging short-eared owl and northern harrier but would not permanently reduce foraging habitat for either species.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of short-eared owl and northern harrier foraging habitat. Some portion of nontidal marsh restoration would be expected to provide habitat for both species.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values.

- Habitat management- and enhancement-related activities could short-eared owl and northern harrier nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to minimize these adverse effects.
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect short-eared owl and northern harrier use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and Mitigation Measure BIO-75 as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged short-eared owl and northern harrier if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to minimize these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

The study area supports approximately 406,784 acres of modeled nesting and foraging habitat for short-eared owl and northern harrier. Alternative 4A would result in the permanent loss of and temporary effects on 5,047 acres of modeled habitat for short-eared owl and northern harrier (<1% of the modeled habitat in the study area). Of the 5,047 acres of modeled habitat impacted, 77 acres consist of wetlands.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by water conveyance facilities would be 1:1 protection of non-wetland habitats and 1:1 protection and 1:1 restoration of wetland habitat. Using these typical ratios would indicate that 4,970 acres of grassland and cultivated lands should be protected, 77 acres of wetlands should be restored or created, and 77 acres of wetlands should be protected to compensate for the losses of short-eared owl and northern harrier habitat.

Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields in addition to tidal and nontidal wetlands. A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected through Alternative 4A. Within these acres of grassland and cultivated lands protection, project proponents would commit to conserving 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat (Resource Restoration and Performance Principle SH1), which would total 6,805 acres. These acres of cultivated lands and grasslands would be located above 1 foot above mean sea level and at least 50% of these lands would be in very high-value production for the Swainson's hawk (alfalfa) (Resource Restoration and Performance Principle SH2).

In addition, 59 acres of tidal freshwater emergent wetland would be restored or created and 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created in the Delta. The restored and protected acres described above would provide suitable nesting and foraging habitat for these species. Environmental Commitment 3, Environmental Commitment 4, and Environmental Commitment 10 would occur in the same timeframe as the construction and early restoration losses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

For the project to avoid adverse effects on individuals, preconstruction surveys would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of short-eared owl and northern harrier nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principles CBR1, SH1, and SH2, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of short-eared owl and northern harrier habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on short-eared owl and northern harrier habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management and enhancement associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles CBR1, SH1, and SH2, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of short-eared owl and northern harrier. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on short-eared owl and northern harrier under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-122: Effects on Short-Eared Owl and Northern Harrier Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that short-eared owl and northern harrier could be subject to power line strikes, which could result in injury or mortality of these species. Short-eared owl and northern harrier would be at low risk of bird strike mortality based on their keen eyesight and largely ground-based foraging behavior (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). The existing network of transmission lines in the project area currently poses the same small risk for these species, and any incremental risk associated with the new power line corridors would also be expected to be low. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. With the implementation of *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters which would further reduce any bird strike risk of short-eared owl and northern harrier.

NEPA Effects: The construction and presence of new transmission lines would not result in an adverse effect on short-eared owl or northern harrier because the risk of bird strike is considered to be low for both species based on their keen eyesight and behavioral characteristics. New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60%, which would further reduce any potential for powerline collisions. Therefore, the construction and operation of transmission lines under Alternative 4A would not result in an adverse effect on short-eared owl or northern harrier.

CEQA Conclusion: The construction and presence of new transmission lines would not result in a significant impact on short-eared owl or northern harrier because the risk of bird strike is considered to be low for both species based on their keen eyesight and behavioral characteristics. New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. All new transmission lines constructed as a result of the project would be fitted with bird diverters (*AMM20 Greater Sandhill Crane*), which have been shown to reduce avian mortality by 60%, which would further reduce any potential for powerline collisions. Therefore, the construction and operation of transmission lines under Alternative 4A would result in a less-than-significant impact on short-eared owl or northern harrier.

Impact BIO-123: Indirect Effects of the Project on Short-Eared Owl and Northern Harrier

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect short-eared owl and northern harrier use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect short-eared owl or northern harrier. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring and would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. A detailed review of the methylmercury issues associated with implementation of Alternative 4A are contained in Appendix D which includes an overview of the Alternative 4A-related mechanisms that could result in increased mercury in the food web, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase. Increased methylmercury associated with natural community restoration could indirectly affect short-eared owl and northern harrier, via uptake in lower tropic levels (as described in Appendix 5.D, *Contaminants*, of the Draft BDCP).

Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management,* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. Environmental Commitment 12 will be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.

Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 4, Environmental Commitment 5) would lead to adverse effects on short-eared owl and northern harrier.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on short-eared owl and northern harrier from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Indirect effects on short-eared owl and northern harrier as a result of constructing the water conveyance facilities could have adverse effects on these species in the absence of environmental commitments and AMMs. However, the implementation of AMM1–AMM7 would help to reduce this effect. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would also be available to address the adverse indirect effects of construction on active nests. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Increased methylmercury associated with natural community restoration could indirectly affect short-eared owl and northern harrier, via uptake in lower tropic levels (as described in Appendix 5.D, *Contaminants*, of the Draft BDCP). However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on short-eared owl and northern harrier.

***CEQA Conclusion*:** Indirect effects of noise and visual disturbance, in addition to the potential for hazardous spills or increased dust on short-eared owl and northern harrier and their habitat as a result of Alternative 4A implementation would represent a substantial adverse effect in the absence of environmental commitments and AMMs. This impact would be significant. The incorporation of AMM1–AMM7 into the Alternative 4A and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level. The implementation of tidal natural communities restoration could result in increased exposure of short-eared owl and northern harrier to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on short-eared owl and northern harrier.

Indirect effects of Alternative 4A implementation would represent an adverse effect on short-eared owl and northern harrier in the absence of other environmental commitments. This would be a significant impact. With AMM1–AMM7 and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on short-eared owl and northern harrier.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-124: Periodic Effects of Inundation on Short-Eared Owl and Northern Harrier as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on short-eared owl and northern harrier.

NEPA Effects**:** No effect.

CEQA Conclusion**:** No impact.

Redhead and Tule Greater White-Fronted Goose

Impacts, relevant protection and restoration actions, and mitigation requirements under CEQA are discussed for these species in Section 4.3.4.8, *General Terrestrial Biology Effects*, of the RDEIR/SDEIS under Impacts BIO-178 through BIO-183. Further details of the methods of analysis for waterfowl and shorebirds can be found in the *BDCP Waterfowl and Shorebird Effects Analysis* (Ducks Unlimited 2013).

Mountain Plover

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on mountain plover. Mountain plover does not breed in California, but winters in the study area. Modeled habitat for mountain plover include grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Alternative 4A would result in both temporary and permanent losses of modeled habitat for mountain plover as indicated in Table 12-4A-46. Full implementation of Alternative 4A would include the following environmental commitments which could benefit the mountain plover.

- Protect 1,060 acres of grassland (Environmental Commitment 3).
- Protect 11,870 acres of cultivated lands (Environmental Commitment 3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to AMM1-AMM7, management activities that would enhance these natural communities for the species, impacts on mountain plover would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-46. Changes in Mountain Plover Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Wintering	1,967	503
Total Impacts Water Conveyance Facilities		**1,967**	**503**
Environmental Commitments 4, 6–7, 9–11[a]	Wintering	2,212	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,212**	**0**
TOTAL IMPACTS		**4,179**	**503**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-125: Loss or Conversion of Habitat for and Direct Mortality of Mountain Plover

Alternative 4A would result in the combined permanent and temporary loss of up to 4,682 acres of modeled wintering habitat for mountain plover (4,179 acres of permanent loss and 503 of temporary loss, Table 12-4A-46). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate mountain plover modeled wintering habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,470 acres of modeled mountain plover habitat (1,967 acres of permanent loss, 503 acres of temporary loss). Impacts would occur from the construction of Intakes 2, 3, and 5 and associated temporary work areas and access roads in CZ 4 between Clarksburg and Courtland; the rerouting of SR 160; construction of the intermediate forebay; and from an reusable tunnel material storage area on Bouldin Island. The construction of the permanent and temporary transmission line corridors through CZs 4–6 and 9 would also remove suitable habitat for the species. Approximately 796 acres would be affected as a result of the placement of an reusable tunnel material area west of the Clifton Court Forebay in CZ 8. In addition, permanent habitat loss would result from the construction of the new forebay south of the existing Clifton court Forebay in CZ 8. There are no CNDDB occurrences of mountain plover that intersect with the water conveyance facilities footprint. However, the study area does overlap with the wintering range for the species. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.
- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 59 acres of modeled mountain plover habitat. The majority of the acres lost would consist of cultivated lands in the West Delta ROA.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of mountain plover wintering habitat.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for mountain plover but would not permanently reduce foraging habitat for the species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of mountain plover wintering habitat.
- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of mountain plover habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities would be expected to have minor adverse effects on available mountain plover habitat. Management of grasslands and cultivated lands for mountain plover such as grazing or mowing would make habitat temporarily unavailable for the species but would ultimately make the habitat more suitable for mountain plover. Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.
- *Water Conveyance Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect mountain plover use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of mountain plover because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 4,682 acres of modeled mountain plover wintering habitat. These effects would result from the construction of the water conveyance facilities and implementing other environmental commitments (*Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 9,364 acres should be protected to compensate for the losses of mountain plover wintering habitat. Project proponents would commit to protect 1,060 acres of grassland and 11,870 acres of cultivated lands, which could provide suitable wintering habitat for mountain plover. *Environmental Commitment 11 Natural Communities Enhancement and Management* would be implemented to ensure that sufficient acres of grassland and cultivated lands were managed to provide suitable habitat for mountain plover and other species with similar habitat requirements (e.g., minimal vegetation, heavily grazed, high invertebrate productivity).

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS

NEPA Effects: The loss of mountain plover wintering habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. AMM1–AMM7 would be in place during all project activities. Considering these commitments, losses and conversions of mountain plover habitat under Alternative 4A would not be adverse.

CEQA Conclusion: The effects on mountain plover wintering habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 11. AMM1–AMM7 would be in place during all project activities. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of mountain plover. Therefore, Alternative 4A would have a less-than-significant impact on mountain plover under CEQA.

Impact BIO-126: Effects on Mountain Plover Associated with Electrical Transmission Facilities

Mountain plovers congregate in flocks during the winter and travel between grasslands and cultivated lands that provide foraging habitat for the species. This flocking behavior puts them at risk of collisions with powerlines. However, plovers exhibit low wing loading and high aspect-ratio wings and as a result can maneuver relatively quickly around an obstacle such as a transmission line. Their wing structure and design allows for rapid flight and quick, evasive actions. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. Plovers are primarily visual foragers and therefore, the risk for collision would be further reduced by *AMM20 Greater Sandhill Crane*, which would require the installation of bird flight diverters on all new transmission lines in the study area.

***NEPA Effects*:** New transmission lines are not expected to have an adverse effect on mountain plover because the probability of bird-powerline strikes is highly unlikely due to their flight behaviors. The implementation of *AMM20 Greater Sandhill Crane* which would require the installation of bird flight diverters on all new transmission lines, which would further reduce any potential for mortality. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on mountain plover.

***CEQA Conclusion*:** New transmission lines would have a less-than-significant impact on mountain plover because the probability of bird-powerline strikes is highly unlikely due to their flight behaviors. The implementation of *AMM20 Greater Sandhill Crane* which would require the installation of bird flight diverters on all new transmission lines, which would further reduce any potential for mortality. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on mountain plover.

Impact BIO-127: Indirect Effects of the Project on Mountain Plover

Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for mountain plover. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect mountain plover. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to mountain plover wintering habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

***NEPA Effects*:** Indirect effects on mountain plover as a result of Alternative 4A implementation could have adverse effects on the species through the modification of habitat. With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 4A implementation would not have an adverse effect mountain plover.

CEQA Conclusion: Indirect effects on mountain plover as a result of Alternative 4A implementation could have a significant impact on the species from modification of habitat. With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 4A implementation would have a less-than-significant impact on mountain plover.

Impact BIO-128: Periodic Effects of Inundation on Mountain Plover as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on mountain plover.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Black Tern

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on black tern. Modeled nesting habitat for black tern in the study area is currently limited to rice in CZ 2.

Alternative 4A would not result in effects on modeled habitat for black tern as indicated in Table 12-4A-47. There is no modeled habitat for the species in the water conveyance facilities footprint and proposed areas of tidal restoration under Alternative 4A.

Table 12-4A-47. Changes in Black Tern Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	0	0
Total Impacts Water Conveyance Facilities		**0**	**0**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**0**	**0**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-129a: Loss or Conversion of Habitat for and Direct Mortality of Black Tern

No habitat would be lost or converted and there would be no direct mortality of black tern under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Conservation Zone 2, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Impact BIO-129b: Indirect Effects of the Project on Black Tern

No indirect effects on black tern were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Conservation Zone 2, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Impact BIO-129c: Periodic Effects of Inundation on Black Tern Nesting Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on black tern habitat under Alternative 4A.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

California Horned Lark and Grasshopper Sparrow

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on California horned lark and grasshopper sparrow. The primary impact of concern for grasshopper sparrow and California horned lark would be the loss of breeding habitat in the project area, which includes grassland vernal pool complex, and alkali seasonal wetland natural communities and selected cultivated lands including grain and hay crops and pasture. Alternative 4A would result in both temporary and permanent losses of modeled breeding habitat for California horned lark and grasshopper sparrow as indicated in Table 12-4A-48. Full implementation of Alternative 4A would include the following environmental commitments which could benefit the California horned lark and the grasshopper sparrow.

- Protect 1,060 acres of grassland (Environmental Commitment 3).
- Protect 11,870 acres of cultivated lands (Environmental Commitment 3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on California horned lark and grasshopper sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-48. Changes in California Horned Lark and Grasshopper Sparrow Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Breeding	1,967	503
Total Impacts Water Conveyance Facilities		**1,967**	**503**
Environmental Commitments 4, 6–7, 9–11[a]	Breeding	2,212	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,212**	**0**
TOTAL IMPACTS		**4,179**	**503**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-130: Loss or Conversion of Habitat for and Direct Mortality of California Horned Lark and Grasshopper Sparrow

Alternative 4A would result in the combined permanent and temporary loss of up to 4,682 acres of modeled nesting habitat for California horned lark and grasshopper sparrow (of which 4,179 acres would be a permanent loss and 503 acres would be a temporary loss of habitat, Table 12-4A-48). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate California horned lark and grasshopper sparrow modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,470 acres of modeled California horned lark and grasshopper sparrow habitat (1,967 acres of permanent loss, 503 acres of temporary loss). Impacts would result from the construction of Intakes 2, 3, and 5 and associated temporary work areas and access roads in CZ 4 between Clarksburg and Courtland; the rerouting of SR 160; construction of the intermediate forebay; and from an reusable tunnel material storage area on Bouldin Island. The construction of the permanent and temporary transmission line corridors through CZs 4–6 and 9 would also remove suitable foraging habitat for the species. Approximately 796 acres would be affected as the result of the placement of an reusable tunnel material area west of the Clifton Court Forebay in CZ 8. In addition, permanent habitat loss would result from the construction of the new forebay south of the existing Clifton court Forebay in CZ 8. Grasshopper sparrows were detected in DHCCP surveys south of Byron Highway in CZ 8 (1 occurrence) and east of Intakes 2 and 3 (6 occurrences), in the Stone Lakes NWR. However, the water conveyance facilities footprint does not overlap with any grasshopper sparrow or California horned lark occurrences. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address adverse effects on nesting California horned larks or grasshopper sparrows. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 59 acres of modeled California horned lark and grasshopper sparrow habitat. The majority of the acres lost would consist of cultivated lands in the West Delta ROA.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of California horned lark and grasshopper sparrow habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for California horned lark and grasshopper sparrow during restoration, but would not permanently reduce habitat availability for either species.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of California horned lark and grasshopper sparrow habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation (mechanical or grazing) and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values for California horned lark and grasshopper sparrow. Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered*

Activities and Associated Federal Actions). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.

- Habitat management- and enhancement-related activities could disturb California horned lark and grasshopper sparrow nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect California horned lark and grasshopper sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and Mitigation Measure BIO-75 as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged California horned lark and grasshopper sparrow if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 4,682 acres of modeled California horned lark and grasshopper sparrow habitat. These effects would result from the construction of the water conveyance facilities and implementing other environmental commitments (*Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 9,364 acres should be protected to compensate for the losses of California horned lark and grasshopper sparrow habitat. Project proponents would commit to protect 1,060 acres of grassland and 11,870 acres of cultivated lands, which could provide suitable habitat for California horned lark and grasshopper sparrow. *Environmental Commitment 11 Natural Communities Enhancement and Management* would be implemented to ensure that sufficient acres of grassland and cultivated lands were managed to provide suitable habitat for mountain plover and other species with similar habitat requirements (e.g., minimal vegetation, heavily grazed, high invertebrate productivity).

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and*

Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects**:** The loss of California horned lark and grasshopper sparrow habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. AMM1–AMM7 would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of California horned lark and grasshopper sparrow under Alternative 4A would not be adverse.

CEQA Conclusion**:** The effects on California horned lark and grasshopper sparrow habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3 and Environmental Commitment 11. AMM1–AMM7 would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of California horned lark and grasshopper sparrow. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on California horned lark and grasshopper sparrow under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-131: Effects on California Horned Lark and Grasshopper Sparrow and Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. *AMM20 Greater Sandhill Crane* would minimize the risk of bird strikes by installing flight-diverters on new and selected existing powerlines.

NEPA Effects**:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the implementation of *AMM20 Greater Sandhill Crane*, the effect of new transmission lines on California horned lark and grasshopper sparrow would not be adverse.

CEQA Conclusion**:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the incorporation of *AMM20 Greater Sandhill Crane*, new transmission lines would have a less-than-significant impact on grasshopper sparrow and California horned lark.

Impact BIO-132: Indirect Effects of the Project on California Horned Lark and Grasshopper Sparrow

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect California horned lark and grasshopper sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect California horned lark or grasshopper sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills. The inadvertent discharge of sediment or excessive dust adjacent to California horned lark and grasshopper sparrow nesting habitat could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

***NEPA Effects*:** Indirect effects on California horned lark and grasshopper sparrow as a result of Alternative 4A implementation could have adverse effects on these species through the modification of habitat and potential for direct mortality. California horned lark and grasshopper sparrow are not covered species under the Alternative 4A, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75 *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

***CEQA Conclusion*:** Indirect effects on California horned lark and grasshopper sparrow as a result of Alternative 4A implementation could have a significant impact on these species. The incorporation of AMM1–AMM7 into the Alternative 4A and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-133: Periodic Effects of Inundation on California Horned Lark and Grasshopper Sparrow as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on California horned lark or grasshopper sparrow.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Least Bittern and White-Faced Ibis

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on least bittern and white-faced ibis. Modeled breeding habitat for least bittern and white-faced ibis includes tidal freshwater, nontidal freshwater emergent wetlands, managed wetlands, and other natural seasonal wetlands in CZ 2, 4, and 11. Alternative 4A would result in both temporary and permanent losses of modeled habitat for least bittern and white-faced ibis as indicated in Table 12-4A-49. Full implementation of Alternative 4A would include the following environmental commitments and Resource Restoration and Performance Principles that would also benefit least bittern and white-faced ibis.

- Restore or create 22 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the central Delta (Environmental Commitment 4 and Resource Restoration and Performance Principle CBR1).
- Protect 119 acres of nontidal wetlands and create 832 acres of nontidal wetlands (Environmental Commitments 3 and 10).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species (including Environmental Commitment 12 Methylmercury Management) and implementation of AMM1–AMM7, *AMM27 Selenium Management*, *AMM37 Recreation*, and Mitigation Measure BIO-75, impacts on least bittern and white-faced ibis would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-49. Changes in Least Bittern and White-Faced Ibis Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	1	5
Total Impacts Water Conveyance Facilities		**1**	**5**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	5	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**5**	**0**
TOTAL IMPACTS		**6**	**5**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-134: Loss or Conversion of Habitat for and Direct Mortality of Least Bittern and White-Faced Ibis

Alternative 4A would result in the combined permanent and temporary loss of up to 11 acres of modeled habitat for least bittern and white-faced ibis (6acres of permanent loss and 5 of temporary loss, Table 12-4A-49). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate least bittern and white-faced ibis habitat. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 5 acres of modeled least bittern and white-faced ibis habitat (1 acre of permanent loss, 5 acres of temporary loss) from CZ 4. Permanent impacts on habitat would result from an reusable tunnel material storage site north of Twin Cities Road and east of the intermediate forebay. Temporary impacts would result from the construction of two temporary transmission lines, one extending east along Lambert Road from the Lambert Road Vent Shaft, and one extending south from the Lambert Road Vent Shaft to the intermediate forebay. The construction footprint for water conveyance facilities does not overlap with any occurrences of least bittern or white-faced ibis. However, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize effects on least bittern and white-faced ibis if they were to nest in the vicinity of the construction footprint. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 5 acres of modeled least bittern and white-faced ibis habitat.

- Environmental Commitment 11 Natural Communities Enhancement and Management: A variety of habitat management actions included in Environmental Commitment 11 Natural Communities Enhancement and Management that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of least bittern and white-faced ibis habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available least bittern and white-faced ibis habitat. The implementation of *AMM37 Recreation* would address potential disturbance on least bittern and white-faced ibis by requiring that trails avoid access to marshes and requiring signage for boaters to slow down when passing sensitive marsh habitats.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least bittern and white-faced ibis use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to further reduce effects.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of least bittern and white-faced ibis because adults and fledged young would be expected to avoid contact with construction and other equipment. However, if either species were to nest in the construction area, equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Construction-related activities could also flush least bittern adults from nests and lead to collision with man-made objects (Sterling 2008). Mitigation Measure BIO-75 would require preconstruction surveys in and adjacent to work areas and, if nests were present, nodisturbance buffers would be implemented.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would result in the permanent loss of and temporary effects on 11 acres (6 acres of permanent loss, 5 acres of temporary loss) of least bittern and white-faced ibis habitat.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of least bittern and white-faced ibis habitat. Using these ratios would indicate that 11 acres of habitat should be restored and 11 acres of habitat should be protected to compensate for the losses of least bittern and white-faced ibis habitat.

Alternative 4A includes the following conservation commitments: 22 acres of tidal freshwater emergent wetland would be restored or created in the central Delta (Resource Restoration and Performance Principle CBR1) and 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created. These would be implemented as part of Environmental Commitment 4, and Environmental Commitment 10 and would be more than sufficient to compensate for impacts on least bittern and white-faced ibis habitat.

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.*

If least bittern or white-faced ibis were to nest in or adjacent to work areas, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address this potentially adverse effect.

- ***NEPA Effects*:** The loss of least bittern and white-faced ibis nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7 and *AMM37 Recreation*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of least bittern and white-faced ibis habitat under Alternative 4A would not be adverse.

***CEQA Conclusion*:**

- The effects on least bittern and white-faced ibis habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 4, Environmental

Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7 and *AMM37 Recreation*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of least bittern and white-faced ibis. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on least bittern and white-faced ibis under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-135: Effects on Least Bittern and White-Faced Ibis Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Waterbirds have a higher susceptibility to collisions than passerines, raptors, and other birds. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species (see Draft BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Powerlines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. All new project transmission lines would be fitted with flight diverters which would reduce bird strike risk of least bittern and white-faced ibis.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of least bittern and white-faced ibis by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on least bittern and white-faced ibis.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. Bitterns and ibises have a high wing loading/low aspect ratio which limits their maneuverability and make them more vulnerable to collisions rather than more agile species. The implementation of *AMM20 Greater Sandhill Crane* would require the installation of bird flight diverters on all new transmission lines, which could reduce bird strike risk of least bittern and white-faced ibis by 60%. With the installation of bird flight diverters, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on least bittern and white-faced ibis.

Impact BIO-136: Indirect Effects of the Project on Least Bittern and White-Faced Ibis

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect least bittern and white-faced ibis use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-44 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect least bittern or white-faced ibis. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could adversely affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring and would ensure that measures were in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. A detailed review of the methylmercury issues associated with implementation of the Alternative 4A are contained in Appendix D, *Substantive BDCP Revisions.* The review includes an overview of the Alternative 4A-related mechanisms that could result in increased mercury in the food web, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase. Increased methylmercury associated with natural community restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower tropic levels (as described in Appendix 5.D, *Contaminants*, of the Draft BDCP).

Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability

- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including least bittern and white-faced ibis. Marsh (tidal and nontidal) restoration has the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium. Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS, and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 4 and Environmental Commitment 5) would lead to adverse effects on least bittern and white-faced ibis.

Because of the uncertainty that exists with respect to the location of tidal restoration activities, there could be a substantial effect on least bittern and white-faced ibis from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Indirect effects on least bittern and white-faced ibis as a result of constructing the water conveyance facilities could have adverse effects on these species in the absence of environmental commitments and AMMs. However, the implementation of AMM1–AMM7 would help to reduce this effect. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would also be available to address the adverse indirect effects of construction on active nests. Tidal habitat restoration could result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Increased methylmercury associated with natural community restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower tropic levels (as described in Appendix 5.D, *Contaminants*, of the Draft BDCP). However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on least bittern and white-faced ibis.

CEQA Conclusion: Indirect effects of noise and visual disturbance, in addition to the potential for hazardous spills or increased dust on least bittern and white-faced ibis and their habitat as a result of Alternative 4A implementation, would represent a substantial adverse effect in the absence of other environmental commitments and AMMs. This impact would be significant. The incorporation of AMM1–AMM7 into the Alternative 4A and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level. Tidal habitat restoration could result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration could result in increased exposure of least bittern and white-faced ibis to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on least bittern and white-faced ibis.

Indirect effects of Alternative 4A implementation would represent an adverse effect on least bittern and white-faced ibis in the absence of other environmental commitments. This would be a significant impact. With AMM 1–AMM7, *AMM27 Selenium Management*, and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modification and would not substantially reduce the number or restrict the range of either species. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on least bittern and white-faced ibis.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-137: Periodic Effects of Inundation on Least Bittern and White-Faced Ibis as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on least bittern or white-faced ibis.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Loggerhead Shrike

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on loggerhead shrike. Modeled habitat for loggerhead shrike includes both high-value and low-value modeled habitat. High-value habitat includes grassland, vernal pool complex and alkali seasonal wetland natural communities in addition to cultivated lands, including pasture and grain and hay crops. Breeding shrikes require shrubs and tall trees for perching and nest placement, and are generally associated with riparian edge grasslands (Humple 2008) or cultivated lands with associated trees and shrubs. Loggerhead shrike modeled habitat is overestimated as it does not differentiate between lands with or without associated nesting vegetation. Low-value habitat includes row crops such as truck and berry crops and field crops which are not considered to be valuable habitat for the species but were included in the model as they may provide foraging opportunities.

Alternative 4A would result in both temporary and permanent losses of modeled habitat for loggerhead shrike as indicated in Table 12-4A-50. Full implementation of Alternative 4A would include the following environmental commitments and Resource Restoration and Performance Principles which would benefit loggerhead shrike.

- Protect 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3). The following Swainson's hawk Resource Restoration and Performance Principles would be implemented as part of these acres.
    - Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in patch sizes of a minimum of 40 acres (Resource Restoration and Performance Principle SH1).
    - Protect Swainson's hawk foraging habitat above 1 foot above mean sea level with at least 50% in very high-value habitat (see Table 12-4A-35 for a definition habitat value) production (Resource Restoration and Performance Principle SH2).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors,

water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs (Resource Restoration and Performance Principle VFR1).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7, and Mitigation Measure BIO-75, impacts on loggerhead shrike would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-50. Changes in Loggerhead Shrike Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	High-value	1,967	503
	Low-value	1,379	610
Total Impacts Water Conveyance Facilities		**3,346**	**1,113**
Environmental Commitments 4, 6–7, 9–11[a]	High-value	2,212	0
	Low-value	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,212**	**0**
Total High-value		**4,179**	**503**
Total Low-value		**1,379**	**610**
TOTAL IMPACTS		**6,061**	**1,113**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-138: Loss or Conversion of Modeled Habitat for and Direct Mortality of Loggerhead Shrike

Alternative 4A would result in the combined permanent and temporary loss of up to 6,671 acres of modeled habitat for loggerhead shrike (of which 4,682 acres is of high-value and 1,989 acres is of low value, Table 12-4A-50). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate loggerhead shrike modeled habitat. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 2,470 acres of high-value loggerhead shrike habitat (1,967 acres of permanent loss, 503 acres of temporary loss). In addition, 1,989 acres of low-value habitat would be removed (1,379 acres of permanent loss, 610 acres of temporary loss). Impacts would occur from the construction of Intakes 2, 3, and 5 and associated temporary work areas and access roads in CZ 4 between Clarksburg and Courtland; the rerouting of SR 160; construction of the intermediate forebay; and from a an reusable tunnel material storage area on Bouldin Island. The construction of the permanent and temporary transmission line corridors through CZs 4–6 and 9 would also remove suitable foraging habitat for the species. Approximately 796 acres would be affected by the placement of and reusable tunnel material area west of the Clifton Court Forebay in CZ 8. In addition, permanent habitat loss would result from the construction of the new forebay south of the existing Clifton court Forebay in CZ 8. Temporarily affected areas (grassland, cultivated lands, and associated shrubs or trees) would be restored within 1 year following completion of construction activities as described *in AMM10 Restoration of Temporarily Affected Natural Communities*.

  Loggerhead shrikes nest in high abundance in shrubs associated with the grasslands to the south and to the west of Clifton Court Forebay. Shrikes were detected using this area at a much higher rate than other grasslands and areas in the Delta during DHCCP surveys (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, of the Draft EIR/EIS). Impacts from water conveyance facilities that overlap with recorded loggerhead shrike nest occurrences (from CNDDB and DHCCP surveys) include the construction of the new forebay (5 occurrences), the reusable tunnel material storage area north-west of the existing forebay (2 occurrences), permanent transmission line south of Clifton Court Road and west of the existing Clifton Court Forebay (1 occurrence), a permanent transmission line that extends along the northern extent of the reusable tunnel material storage areas west of the existing forebay (1 occurrence). Mitigation Measure BIO-75 *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address adverse effects on nesting loggerhead shrikes. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 59 acres of high-value loggerhead shrike habitat.

- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of high-value loggerhead shrike habitat.

- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for loggerhead shrike but would not permanently reduce foraging habitat for the species.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of high-value loggerhead shrike habitat.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values. Fences (e.g., barbed wire) installed as part of Environmental Commitment 11, in or adjacent to protected grasslands and cultivated lands could benefit loggerhead shrike by providing hunting perches and impalement opportunities. Environmental Commitment 11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.

Habitat management- and enhancement-related activities could disturb loggerhead shrike nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests if shrubs and trees in grasslands or cultivated lands were removed, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities could result in ongoing but periodic disturbances that could affect loggerhead shrike use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and Mitigation Measure BIO-75 as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged loggerhead shrike if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these potential effects.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A as a whole would result in the permanent loss of and temporary effects on 4,682 acres of high-value loggerhead shrike habitat and 1,989 acres of low-value loggerhead shrike habitat. These effects would result from the construction of the water conveyance facilities and implementing other environmental commitments (*Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Communities Restoration, Environmental Commitment 8 Grassland Natural Communities Restoration*, and *Environmental Commitment 10 Nontidal Marsh Restoration*). The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 protection of high-value habitat. Using this ratio would indicate that 9,364 acres should be protected to compensate for the loss of high-value habitat. The loss of low-value habitat would not require mitigation because a large proportion of the low-value habitat would result from the conversion and enhancement to high-value habitats.

In addition, temporary impacts on cultivated lands would be restored relatively quickly after completion of construction.

A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected through Alternative 4A. As part of these acres of protection, project proponents would commit to conserving 1 acre of Swainson's hawk foraging habitat for every acre of lost foraging habitat, which would total 6,805 acres and would be located above 1 foot above mean sea level (Resource Restoration and Performance Principle SH1). At least 50% of protected Swainson's hawk foraging habitat would be in very high-value production (Resource Restoration and Performance Principle SH2) (alfalfa) which would also provide suitable high-value habitat for loggerhead shrike. Alternative 4A also contains Resource Restoration and Performance Principle CL1 to maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides which provide nesting habitat for loggerhead shrike. These Resource Restoration and Performance Principles would be associated with Environmental Commitment 3 and would occur in the same timeframe as the construction and early restoration losses and would benefit loggerhead shrike.

Alternative 4A also includes conservation commitments through *Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create 251 acres and protect 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. *AMM18 Swainson's Hawk* includes a measure to plant large mature trees, including transplanting trees scheduled for removal. Trees would be planted in areas that support high-value Swainson's hawk foraging habitat within or adjacent to conserved cultivated lands, or as a component of the riparian restoration (Environmental Commitment 7) where they are in close proximity to suitable foraging habitat. Locating tree plantings and riparian restoration adjacent to Swainson's hawk foraging habitat would also provide suitable nesting habitat for loggerhead shrike.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and loggerhead shrike habitat adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Preconstruction surveys for loggerhead shrike would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of loggerhead shrike habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11. These conservation actions would be guided by Resource Restoration and Performance Principles SH1, SH2, CL1, and VFR1, and by AMM1–AMM6, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of loggerhead shrike habitat under Alternative 4A would not be adverse.

CEQA Conclusion**:** The effects on loggerhead shrike habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 7, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principles SH1, SH2, CL1, and VFR1, and by AMM1–AMM6, AMM1–AMM6, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM18 Swainson's Hawk*, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of loggerhead shrike. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on loggerhead shrike under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-139: Effects on Loggerhead Shrike Associated with Electrical Transmission Facilities

Loggerhead shrike's small, relatively maneuverable body; its lack of flocking behavior, and its diurnal foraging behavior, contribute to a low risk of collision with the proposed transmission lines. Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters which would substantially reduce any potential for mortality of loggerhead shrike individuals from powerline collisions.

NEPA Effects**:** Loggerhead shrike's small, relatively maneuverable body; it's lack of flocking behavior, and it's diurnal foraging behavior, contribute to a low risk of collision with the proposed transmission lines In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new transmission lines, which would substantially reduce the risk of bird strike for loggerhead shrike from the project. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on loggerhead shrike.

CEQA Conclusion**:** Loggerhead shrike's small, relatively maneuverable body; it's lack of flocking behavior, and it's diurnal foraging behavior, contribute to a low risk of collision with the proposed transmission lines In addition, *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new transmission lines, which would substantially reduce the risk of bird strike for loggerhead shrike from the project. Therefore, the construction and operation of new transmission lines under Alternative 4A would result in a less-than-significant impact on loggerhead shrike.

Impact BIO-140: Indirect Effects of the Project on Loggerhead Shrike

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect loggerhead shrike use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect loggerhead shrike. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Indirect effects from construction of the new forebay in CZ 8 could result in substantial effects on active loggerhead shrike nests. DHCCP surveys in 2009 detected 10 nest sites south-west of the Clifton Court Forebay (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, of the Draft EIR/EIS) and the large expanses of grassland in CZ 8 provide high-value nesting habitat for the species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills. The inadvertent discharge of sediment or excessive dust adjacent to loggerhead shrike nesting habitat could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on loggerhead shrike as a result of Alternative 4A implementation could have adverse effects on these species through the modification of habitat and potential for direct mortality. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. The loggerhead shrike is not a covered species under Alternative 4A, and the potential for mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

CEQA Conclusion: Indirect effects on loggerhead shrike as a result of Alternative 4A implementation could have a significant impact on these species. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. The incorporation of AMM1–AMM7 into Alternative 4A and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-141: Periodic Effects of Inundation on Loggerhead Shrike as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on loggerhead shrike.

NEPA Effects**:** No effect.

CEQA Conclusion**:** No impact.

Song Sparrow "Modesto" Population

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on Modesto song sparrow. The Modesto song sparrow is common and ubiquitous throughout the project area, excluding CZ 11, and modeled habitat for the species includes managed wetlands, tidal freshwater emergent, nontidal freshwater emergent, and valley/foothill riparian vegetation communities.

Alternative 4A would result in both temporary and permanent removal of Modesto song sparrow habitat in the quantities indicated in Table 12-4A-51. However, project activities are expected to have little impact on the population. Full implementation of Alternative 4A would include the following environmental commitments and Resource Restoration and Performance Principles which would benefit Modesto song sparrow.

- Restore or create 251 acres of valley/foothill riparian natural community (Environmental Commitment 7).
- Protect 103 acres of existing valley/foothill riparian natural community (Environmental Commitment 3).
- Restore or create 37 acres of tidal wetlands in the north Delta (Environmental Commitment 4).
- Restore or create 22 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the central Delta (Resource Restoration and Performance Principle CBR1).
- Protect 119 acres of nontidal wetlands and create 832 acres of nontidal wetlands (Environmental Commitments 3 and 10).

As explained below, with the restoration or protection of these amounts of habitat, with AMM1–AMM7 and *AMM10 Restoration of Temporarily Affected Natural Communities* in place, and with the implementation of Mitigation Measure BIO-75, impacts on Modesto song sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-51. Changes in Modesto Song Sparrow Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	68	81
Total Impacts Water Conveyance Facilities		**68**	**81**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	5	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**5**	**0**
TOTAL IMPACTS		**73**	**81**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-142: Loss or Conversion of Habitat for and Direct Mortality of Modesto Song Sparrow

Alternative 4A would result in the combined permanent and temporary loss of up to 154 acres of modeled habitat for Modesto song sparrow (73 acres of permanent loss and 81 acres of temporary loss, Table 12-4A-51). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate Modesto song sparrow modeled habitat. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities as described *in AMM10 Restoration of Temporarily Affected Natural Communities*. Although the effects are considered temporary, the restored riparian habitat would require a period of time for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. Each of these individual activities is described below.

- *Water Facilities Construction:* Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 149 acres of modeled Modesto song sparrow habitat (68 acres of permanent loss, 81 acres of temporary loss) from CZs 3–6 and CZ 8. The water conveyance facilities construction footprint overlaps with 77 Modesto song sparrow occurrences and the species is ubiquitous throughout the Delta. The reusable tunnel material storage areas throughout the central Delta overlap with 24 occurrences, shaft locations along the tunnel alignment overlap with 9 occurrences, the permanent transmission line overlaps with 6 occurrences, and 1 occurrence overlaps with the construction of the new forebay in CZ 8. In addition, areas temporarily affected overlap with species occurrences, including the construction of a transmission line (1 occurrence) and geotechnical exploration zones along the tunnel alignment (17 occurrences). Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address adverse effects on nesting Modesto song sparrows. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Construction of the water conveyance facilities and the resultant impacts would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would result in the conversion of an estimated 5 acres of Modesto song sparrow riparian habitat.

- *Environmental Commitment 6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 4.6 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs. Some of the restored riparian habitat in the channel margin would be expected to support nesting habitat for Modesto song sparrow.

- *Environmental Commitment 11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values.

  Habitat management- and enhancement-related activities could affect Modesto song sparrow nests. If the individuals were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects.

- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Modesto song sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Modesto song sparrow if they were present in the project area, because they would be expected to avoid contact with construction and other equipment. If the species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects.

The following paragraphs summarize the combined effects discussed above and describe environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 154 acres of modeled habitat (73 permanent, 81 temporary) for Modesto song sparrow in the study area. These effects would result from the construction of the water conveyance facilities and implementing other environmental commitments (*Environmental Commitment 4 Tidal Natural Communities Restoration*).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these ratios would indicate that 154 acres of suitable habitat should be restored/created and 154 acres should be protected to compensate for the losses of 154 acres of Modesto song sparrow habitat. Habitat that would be restored or protected to benefit Modesto song sparrow would include valley/foothill riparian and tidal and nontidal wetlands.

Alternative 4A includes conservation commitments through *Environmental Commitment 4 Tidal Natural Communities Restoration, Environmental Commitment 7 Riparian Natural Community Restoration* and *Environmental Commitment 3 Natural Communities Protection and Restoration* to restore or create 251 acres and protect 103 acres of valley/foothill riparian woodland. Riparian areas would be restored, maintained, and enhanced to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. In addition, 59 acres of tidal wetlands would be restored or created (37 acres in the north Delta and 22 acres in the central Delta), 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created.

The project also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.*

If Modesto song sparrow were to nest in or adjacent to work areas, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address this potentially adverse effect.

***NEPA Effects*:** The loss of Modesto song sparrow nesting habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of Modesto song sparrow habitat under Alternative 4A would not be adverse.

***CEQA Conclusion*:** The effects on Modesto song sparrow habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 7, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM6, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Modesto song sparrow. Therefore, with the implementation of Mitigation

Measure BIO-75, Alternative 4A would have a less-than-significant impact on Modesto song sparrow under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-143: Effects on Modesto Song Sparrow Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Modesto song sparrow. Existing lines currently pose this risk for Modesto song sparrow and the incremental increased risk from the construction of new transmission lines is not expected to adversely affect the population.

NEPA Effects: The incremental increased risk of bird-powerline strikes from the construction of new transmission lines would not adversely affect the Modesto song sparrow population.

CEQA Conclusion: The incremental increased risk of bird-powerline strikes from the construction of new transmission lines would have a less-than-significant impact on the Modesto song sparrow population.

Impact BIO-144: Indirect Effects of the Project on Modesto Song Sparrow

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect Modesto song sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (see Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS). However, there are no available data to determine the extent to which these noise levels could affect Modesto song sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 including *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to Modesto song sparrow could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community restoration could indirectly affect Modesto song sparrow, via uptake in lower tropic levels (as described in Appendix 5.D, *Contaminants*, of the Draft BDCP).

The potential mobilization or creation of methylmercury within the project area varies with site-specific conditions and would need to be assessed at the project level. Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. If a project is identified where there is a high potential for methylmercury production that could not be fully addressed through restoration design and adaptive management, alternate restoration areas would be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Modesto song sparrow use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could adversely affect Modesto song sparrow use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, in addition to AMM1–AMM7, would be available to address this adverse effect. The implementation of tidal natural communities restoration could result in increased exposure of Modesto song sparrow to methylmercury in tidally restored areas. However, it is currently unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Modesto song sparrow.

***CEQA Conclusion*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Modesto song sparrow use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Modesto song sparrow use of the surrounding habitat. Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would have a less-than-significant impact on Modesto song sparrow with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. The implementation of tidal natural communities restoration could result in increased exposure of Modesto song sparrow to methylmercury in tidally restored areas. This would be a significant impact. However, it is currently unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on Modesto song sparrow.

With AMM1–AMM7 and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, the indirect effects of Alternative 4A implementation would not substantially reduce the number or restrict the range of Modesto song sparrow. Therefore, with the implementation of Mitigation Measure BIO-75, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on Modesto song sparrow.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-145: Periodic Effects of Inundation on Modesto Song Sparrow as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on Modesto song sparrow.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Bank Swallow

This section describes the effects of Alternative 4A, including construction and implementation of environmental commitments, on bank swallow. Bank swallows nest in colonies along rivers, streams, or other water and require fine textured sandy soils in vertical banks to create their burrows. There is little suitable habitat for bank swallow in the study area because most of the erodible banks have been stabilized with of levee revetment. The placement of rock revetment prevents the lateral migration of rivers, removing the natural river process that creates vertical banks through erosion (Bank Swallow Technical Advisory Committee 2013, Stillwater Sciences 2007). An estimated 70-90% of the bank swallow population in California nests along the Sacramento and Feather Rivers (Bank Swallow Technical Advisory Committee 2013) upstream of the study area. However, there are three CNDDB records of bank swallow colonies in the study area: two in CZ 2 north of Fremont Weir, and one in CZ 5 on Brannan Island, just west of Twitchell Island.

The closest natural community to represent modeled habitat for bank swallow is valley foothill riparian. Although there are impacts to the valley foothill riparian natural community along the northeast corner of Clifton Court Forebay, at the intermediate forebay, and on Bouldin Island, it is highly unlikely that the habitat in these locations is suitable for bank swallow (alluvial soils that form steep, eroded banks that have not been stabilized with levee revetment). Reusable tunnel material areas are not expected to be colonized by nesting bank swallows, as it is unlikely that the substrate would provide suitable nesting habitat for the species. However, if reusable tunnel material areas were to become suitable for swallows over time, Mitigation Measure BIO-146 *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would avoid impacts on nesting bank swallows by requiring surveys to be conducted prior to the removal of reusable tunnel material. Alternative 4A would not result in the direct loss of modeled habitat for bank swallow. However, indirect effects of noise and visual disturbance from *Environmental Commitment 4 Tidal Natural Communities Restoration* could impact bank swallow colonies if they were present near work areas. In addition, there is uncertainty with respect to how water flows upstream of the study area would affect bank swallow habitat.

As explained below, impacts on bank swallow under Alternative 4A would not be adverse for NEPA purposes and would be less than significant for CEQA purposes with the implementation of mitigation measures to monitor colonies and address the uncertainty of upstream operations on the species.

Table 12-4A-52. Changes in Bank Swallow Modeled Habitat Associated with Alternative 4A (acres)[a]

		Permanent		Temporary		Periodic[d]	
Project Component	Habitat Type	NT	LLT[c]	NT	LLT[c]	Yolo	Floodplain
Water Conveyance Facilities	Nesting	0	0	0	0	NA	NA
Total Impacts Water Conveyance Facilities		**0**	**0**	**0**	**0**	**NA**	**NA**
Environmental Commitments[b]	Nesting	0	0	0	0	0	0
Total Impacts Environmental Commitments		**0**	**0**	**0**	**0**	**0**	**0**
TOTAL IMPACTS		**0**	**0**	**0**	**0**	**0**	**0**

[a] See Appendix 12E, *Detailed Accounting of Direct Effects of Alternatives on Natural Communities and Covered Species*, of this RDEIR/SDEIS, for a detailed breakdown of environmental commitments' effects over the project's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable environmental commitments.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the implementation of Alternative 4A and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-146: Indirect Effects of Implementation of Alternative 4A on Bank Swallow

Noise and visual disturbances during restoration activities from *Environmental Commitment 4 Tidal Natural Communities Restoration* including operation of earthmoving equipment and human activities at work sites, could result in temporary disturbances that cause bank swallow to abandon active nest burrows adjacent to construction areas. Bank swallow colonies with occupied burrows have been recorded in CZ 5 and construction-related disturbances could result in an adverse effect on individuals. Various activities related to *Environmental Commitment 11 Natural Communities Enhancement and Management* could also have indirect impacts on bank swallow.

***NEPA Effects*:** Construction activities associated with habitat restoration could adversely affect bank swallow colonies in the absence of other measures. Noise and visual disturbances could result in adverse effects on bank swallows including abandonment of nests if active colonies were present within 500 feet of work areas. Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would be available to address this effect.

CEQA Conclusion: Construction activities associated with habitat restoration could represent an adverse effect on bank swallow colonies as a result of modification of habitat and potential mortality of special status species in the absence of other measures. This impact would be significant. Noise and visual disturbances could result in significant impacts on bank swallows if active colonies were present within 500 feet of work areas. Implementation of Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized

To the extent practicable, project proponents will not conduct restoration activities during the bank swallow nesting season (April 1 through August 31). If construction activities cannot be avoided during nesting season, a qualified biologist will conduct preconstruction surveys to determine if active bank swallow nesting colonies are present within 500 feet of work areas. If no active nesting colonies are present, no further mitigation is required. Reusable tunnel material areas are not expected to be colonized by nesting bank swallows, as it is unlikely that the substrate would provide suitable nesting habitat for the species. However, reusable tunnel material sites could become suitable for swallows over time. Surveys of reusable tunnel material areas that have been present for at least 1 year, allowing the substrate to stabilize, will be conducted prior to the removal of reusable tunnel material.

If active colonies are detected, project proponents will establish a nondisturbance buffer (determined in coordination with CDFW and the Bank Swallow Technical Advisory Committee) around the colony during the breeding season. In addition, a qualified biologist will monitor any active colony within 500 feet of construction to ensure that construction activities do not affect nest success.

Impact BIO-147: Effects of Upstream Reservoir and Water Conveyance Facilities Operations on Bank Swallow

Bank swallows are a riparian species that have evolved to deal with a dynamic system that changes with annual variation in variables such as rainfall, or late snowpack runoff. The primary threat to the species is loss of nesting habitat from the placement of rock revetment for levee stabilization. Because of this limited available habitat, and the reduction of natural river process, the species is highly sensitive to 1) reductions in winter flows which are necessary to erode banks for habitat creation, and 2) high flows during the breading season. The potential impacts of changes in upstream flows during the breeding season on bank swallows are the flooding of active burrows and destruction of burrows from increased bank sloughing. Bank swallows arrive in California and begin to excavate their burrows in March, and the peak egg-laying occurs during April and May (Bank Swallow Technical Advisory Committee 2013). Therefore, increases in flows after the March when the swallows have nested and laid eggs in the burrows could result in the loss of nests. On the Sacramento River, breeding season flows between 14,000 and 30,000 cfs have been associated with localized bank collapses that resulted in partial or complete colony failure (Stillwater Sciences 2007).

The CALSIM II modeling results of mean monthly flow were analyzed for three flow gauge stations on the Sacramento River (Sacramento River at Keswick, Sacramento River upstream of Red Bluff, Sacramento River at Verona) and two flow gauge stations on the Feather River (Feather River high-flow channel at Thermalito Dam, and Feather River at the confluence with the Sacramento River). Flows were estimated for wet years, above normal years, below normal years, dry years, and critical years. An average also was estimated (see Section 5.3.1, *Methods for Analysis*, in the Draft EIR/EIS for a description of the model).

On the Sacramento River at the Keswick and Red Bluff gauges, mean monthly flows under Alternative 4A could increase between April and August in below normal, dry, and critical years based on modeling assumptions and output (see Table 1 in Section 11C.4.1.1 and Table 3 in Section 11C.4.1.2 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*, of the Draft EIR/EIS). The increased flows could lead to inundation of active colonies. However, model outputs indicate that flows under Existing Conditions and the predicted flows in the late long-term without the project (NAA) also show increases in flows during the breeding season (April through August) in these water year types. Similar trends are shown for the Feather River (see Table 15 in Section 11C.4.1.8 and Table 17 in Section 11C.4.1.9 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*, of the Draft EIR/EIS). In addition, at the Verona flow gauge on the Sacramento River in average water years (see Table 7 in Section 11C.4.1.4 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*, of the Draft EIR/EIS) flows are predicted to be greater than 14,000 cfs during the breeding season (April through August,) which could lead to bank collapse. However, flows of this height are recorded under Existing Conditions at this flow gage and are also predicted for the late long-term without the project (NAA).

***NEPA Effects*:** High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternative 4A would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. Soil type, high winter flows, and low spring flows all contribute to successful nesting of bank swallow, and even moderate changes in seasonal flows could have an adverse effect on breeding success for the species. Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would be available to address the uncertainty of potential adverse effects of upstream operations on bank swallow.

***CEQA Conclusion*:** High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternative 4A would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. There are many variables that dictate suitable habitat for the species that cannot be clearly quantified, and seasonal changes in flow could increase or decrease suitable habitat for bank swallow depending on soil type and location of current colonies. Implementation of Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would address this potential significant impact and further determine if additional mitigation is required for bank swallow.

Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area

To address the uncertainty of the impact of upstream spring flows on existing bank swallow habitat, DWR will monitor existing colonies upstream of the study area and collect habitat suitability data including soil type, number of active burrows per colony, and height of average burrows. DWR will quantify the magnitude of spring flows that would result in potential mortality of active colonies. In addition, to determine the degree to which reduced winter flows are contributing to habitat loss, DWR will quantify the winter flows required for river meander to create suitable habitat through lateral channel migration and bank resurfacing. If impacts of upstream flows on bank swallow are identified, replacement habitat will be established at a minimum of 2:1 for the length of bank habitat affected. Replacement habitat will consist of removing bank revetment to create habitat for bank swallow at a location subject to CDFW approval (Bank Swallow Technical Advisory Committee 2013).

Yellow-Headed Blackbird

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of environmental commitments, on yellow-headed blackbird. The habitat model used to assess impacts on yellow-headed blackbird includes nesting habitat and foraging habitat. Modeled nesting habitat includes tidal freshwater emergent wetland, other natural seasonal wetland, nontidal freshwater perennial emergent wetland, and managed wetland. These natural communities support aquatic insects which are important prey items for yellow-headed blackbird young (Beedy 2008). Modeled foraging habitat for yellow-headed blackbird consists of cultivated lands and noncultivated land cover types known to support abundant insect populations, including corn, pasture, and feedlots.

Alternative 4A would result in both temporary and permanent losses of yellow-headed blackbird modeled habitat as indicated in Table 12-4A-53. Full implementation of Alternative 4A would include the following environmental commitments and Resource Restoration and Performance Principles which would also benefit yellow-headed blackbird.

- Restore or create 37 acres of tidal wetlands in the north Delta (Environmental Commitment 4).
- Restore or create 22 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the central Delta (Environmental Commitment 4 and Resource Restoration and Performance Principle CBR1)
- Protect 119 acres of nontidal wetlands and create 832 acres of nontidal wetlands (Environmental Commitments 3 and 10).
- Protect 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance habitats for the species and implementation of AMM1–AMM7, *AMM27 Selenium Management*, Environmental Commitment 12, and Mitigation Measure BIO-75, impacts on yellow-headed blackbird would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-53. Changes in Yellow-Headed Blackbird Modeled Habitat Associated with Alternative 4A

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Nesting	27	51

Total Impacts Water Conveyance Facilities		**1,609**	**450**
Environmental Commitments 4, 6–7, 9–11[a]	Nesting	0	0
	Foraging	2,212	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**2,212**	**0**
Total Nesting		**27**	**51**
Total Foraging		**3,794**	**399**
TOTAL IMPACTS		**3,821**	**450**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-148: Loss of Habitat for and Direct Mortality of Yellow-Headed Blackbird

Alternative 4A would result in the combined permanent and temporary loss of up to 4,271 acres of modeled habitat (78 acres of nesting habitat and 4,193 acres of foraging habitat) for yellow-headed blackbird (Table 12-4A-53). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of reusable tunnel material areas, and tidal habitat restoration (Environmental Commitment 4), riparian restoration, (Environmental Commitment 7), grassland restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10). Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other physical facilities could degrade or eliminate yellow-headed blackbird suitable habitat. Each of these individual activities is described below.

- *Water Facilities Construction*: Construction of Alternative 4A water conveyance facilities would result in the combined permanent and temporary loss of up to 78 acres of yellow-headed blackbird nesting habitat (27 acres of permanent loss and 51 acres of temporary loss). In addition, 1,981 acres of foraging habitat would be removed (1,582 acres of permanent loss, 399 acres of temporary loss). Activities that would impact suitable yellow-headed blackbird habitat consist of tunnel, forebay, and intake construction, temporary access roads, and construction of transmission lines. The largest losses of foraging habitat would occur from loss of corn. There are no occurrences of yellow-headed blackbird that overlap with the construction footprint for water conveyance facilities. However, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to address adverse effects on nesting yellow-headed blackbirds. Impacts from water conveyance facilities would occur in the central Delta in CZs 3–6, and CZ 8. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Impacts from water conveyance facilities would occur within the first 10–14 years of Alternative 4A implementation.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Site preparation and inundation from Environmental Commitment 4 would permanently remove or convert an estimated 59 acres of foraging habitat.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of yellow-headed blackbird foraging habitat.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands. These acres may be temporarily unavailable for yellow-headed blackbird but would not permanently reduce foraging habitat for the species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of yellow-headed blackbird foraging habitat. Resulting nontidal marsh creation could benefit yellow-headed blackbird by creating breeding habitat that also supports aquatic insects for foraging.
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb yellow-headed blackbird nests if they were present near work sites. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of yellow-headed blackbird habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, would be expected to have minor effects on available yellow-headed blackbird habitat. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below (AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP. and updated versions of *AMM2 Construction Best Management Practices and Monitoring* and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material and Dredged Material* are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Environmental Commitment 11 would also include the construction of recreational-related facilities, including trails, interpretive signs, and picnic tables (see Draft BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.
- *Water Facilities Operations and Maintenance*: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged yellow-headed blackbird if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. If yellow-headed blackbird were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75,

Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address these adverse effects on yellow-headed blackbird.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments, Resource Restoration and Performance Principles, and AMMs that offset or avoid these effects. NEPA and CEQA conclusions are provided at the end of the section.

Alternative 4A would remove 4,271 acres (78 acres of nesting habitat and 4,193 acres of foraging habitat) of yellow-headed blackbird nesting habitat in the study area. These effects would result from the construction of the water conveyance facilities (78 acres of nesting habitat, 1,981 acres of foraging habitat), and implementing other environmental commitments (*Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 7 Riparian Natural Community Restoration*, *Environmental Commitment 8 Grassland Natural Community Restoration*, *Environmental Commitment 10 Nontidal Marsh Restoration*`,2,212 acres of foraging habitat).Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by water conveyance facilities would be 1:1 for restoration/creation and 1:1 protection of nesting habitat, and 1:1 protection of foraging habitat. Using these ratios would indicate that 78 acres of nesting habitat should be restored/created and 78 acres should be protected to compensate for the water conveyance facilities losses of 78 acres of yellow-headed blackbird nesting habitat. In addition, 4,193 acres of foraging habitat should be protected to compensate for the losses of yellow-headed blackbird foraging habitat.

Project proponents would commit to creating or restoring 59 acres of tidal wetlands (37 acres in the north Delta and 22 acres in the central Delta), creating 832 acres of nontidal wetlands, and protecting 119 acres of nontidal wetlands. These acres of restoration and protection would be more than sufficient to compensate for impacts on 78 acres of yellow-headed blackbird nesting habitat. Alternative 4A would also protect 1,060 acres of grassland and 11,870 acres of cultivated lands, which would provide suitable foraging habitat for yellow-headed blackbird.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

For the project to avoid adversely affecting individuals, preconstruction surveys for avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of yellow-headed blackbird nesting and foraging habitat from Alternative 4A would not be adverse under NEPA because project proponents have committed to avoiding and minimizing effects and to restoring and protecting an acreage that exceeds the typical mitigation ratios described above. This habitat protection, restoration, management, and enhancement would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, losses and conversions of yellow-headed blackbird habitat under Alternative 4A would not be adverse.

***CEQA Conclusion*:** The effects on yellow-headed blackbird habitat from Alternative 4A would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of environmental commitments and AMMs. However, project proponents have committed to habitat protection, restoration, management, and enhancement associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 10, and Environmental Commitment 11. These conservation activities would be guided by Resource Restoration and Performance Principle CBR1, and by AMM1–AMM7, which would be in place during all project activities. In addition, Mitigation Measure BIO-75 would be available to address potential impacts on nesting individuals. Considering these commitments, Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of yellow-headed blackbird. Therefore, with the implementation of Mitigation Measure BIO-75, Alternative 4A would have a less-than-significant impact on yellow-headed blackbird under CEQA.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-149: Effects on Yellow-Headed Blackbird Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbirds. Yellow-headed blackbirds are colonial and have the potential to collide with the proposed transmission lines when migrating in large flocks. However, similar to tricolored blackbird behavior, daily flights associated with foraging likely occur in smaller flocks at heights that are lower than the transmission lines (BDCP Attachment 5.J-2, *Memorandum: Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Marking transmission lines with flight diverters that make the lines more visible to birds has been shown to dramatically reduce the incidence of bird mortality (Brown and Drewien 1995). For example, Yee (2008) estimated that marking devices in the Central Valley could reduce avian mortality by 60%. As described in *AMM20 Greater Sandhill Crane*, all new project transmission lines would be fitted with flight diverters which reduce the potential for yellow-headed blackbird collision with transmission lines.

Transmission line poles and towers also provide perching substrate for raptors, which are predators on yellow-headed blackbird. Although there is potential for transmission lines to result in increased perching opportunities for raptors and result in increased predation pressure on yellow-headed blackbirds, the existing network of transmission lines in the study area currently poses this risk for yellow-headed blackbirds, and any incremental risk associated with the new transmission line corridors would not be expected to affect the study area population. Therefore, it is assumed that the increase in predation risk on yellow-headed blackbird from an increase in raptor perching opportunities is minimal.

***NEPA Effects*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on yellow-headed blackbird. The increase in predation risk on yellow-headed blackbird from an increase in raptor perching opportunities is considered minimal. Therefore, the construction and operation of new transmission lines under Alternative 4A would not result in an adverse effect on yellow-headed blackbird.

CEQA Conclusion**:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. *AMM20 Greater Sandhill Crane* contains the commitment to place bird strike diverters on all new powerlines, which would reduce the potential impact of the construction of new transmission lines on yellow-headed blackbird. The increase in predation risk on yellow-headed blackbird from an increase in raptor perching opportunities is considered minimal. The construction and operation of new transmission lines under Alternative 4A would not substantially reduce the number or restrict the range of the species and would therefore result in a less-than-significant impact on yellow-headed blackbird.

Impact BIO-150: Indirect Effects of the Project on Yellow-Headed Blackbird

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-headed blackbird use of suitable habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 500 to 5,250 feet from the edge of construction activities (Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 5J.D-4 in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SEIS), although there are no available data to determine the extent to which these noise levels could affect yellow-headed blackbird. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect the species in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to yellow-headed blackbird habitat could also have a negative effect on the species. Where nests are located above open water, impacts of contamination, dust, and sediment in water could impact fledglings directly, or affect aquatic insect prey, which is important for feeding young. AMM1–AMM7 would minimize the likelihood of spills from occurring and ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including yellow-headed blackbird. Marsh (tidal and nontidal) restoration has the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of mercury. Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. A detailed review of the methylmercury issues associated with implementation of Alternative 4A are contained in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS. The review includes an overview of the project-related mechanisms that could result in increased mercury in the food web, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase. Increased methylmercury associated with natural community restoration could indirectly affect yellow-headed blackbird, via uptake in lower tropic levels (as described in Appendix 5.D, *Contaminants*, of the Draft BDCP).

Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, *Environmental Commitment 12 Methylmercury Management* is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. Environmental Commitment 12 would be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment would include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce yellow-headed blackbird use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7.

The implementation of tidal natural communities restoration could result in increased exposure of yellow-headed blackbird to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12, which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on yellow-headed blackbird.

***CEQA Conclusion*:** In the absence of AMMs, noise and visual disturbance, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 4A would represent an adverse effect. This impact would be significant. The implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7, would reduce this impact to a less-than-significant level.

The implementation of tidal natural communities restoration could result in increased exposure of yellow-headed blackbird to methylmercury in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on yellow-headed blackbird.

Indirect effects of Alternative 4A implementation would represent an adverse effect on yellow-headed blackbird in the absence of other environmental commitments. This would be a significant impact. With AMM1–AMM7 and Environmental Commitment 12 in place, and with the implementation of Mitigation Measure BIO-75, indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, indirect effects of Alternative 4A implementation would have a less-than-significant impact on yellow-headed blackbird.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-151: Periodic Effects of Inundation of Yellow-Headed Blackbird Nesting Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic inundation effects on yellow-headed blackbird.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Riparian Brush Rabbit

The habitat model used to assess effects on the riparian brush rabbit consists of 38 vegetation associations within the valley/foothill riparian natural community and adjacent grasslands. The vegetation associations were selected based on a review of understory and overstory composition from Hickson and Keeler-Wolf (2007) and species habitat requirements.

Just until recently, the only known naturally occurring populations of riparian brush rabbits were confined to Caswell Memorial State Park (MSP), a 258-acre park supporting riparian oak woodland on the Stanislaus River immediately southeast of the study area, and in the south Delta southwest of Lathrop, which is within the study area (Williams and Basey 1986; Williams et al. 2002) (Figure 12-46). On October 11, 2012 a single female riparian brush rabbit was captured near Durham Ferry Road in riparian habitat along the San Joaquin River between Caswell MSP and Lathrop (Bradbury pers. comm.). This is only the 2nd naturally occurring population documented outside of Caswell MSP. Factors considered in assessing the value of adversely affected habitat for riparian brush rabbit, to the extent information was available, included size and degree of isolation of habitat patches, proximity to recorded species occurrences, and adjacency to conserved lands.

Alternative 4A would result in both temporary and permanent losses of riparian brush rabbit modeled habitat as indicated in Table 12-4A-54. Alternative 4A would include the following environmental commitments and associated Resource Restoration and Performance Principles to benefit the riparian brush rabbit.

- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Resource Restoration and Performance Principle L1).
- Of the 103 acres of protected valley/foothill riparian natural community, protect and maintain 19 acres of early- to mid-successional riparian habitat that meets the ecological requirements of the riparian brush rabbit and that is within or adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat (Environmental Commitment 3 and Resource Restoration and Performance Principle RBR1).
- Of the 251 acres of restored valley/foothill riparian natural community, restore and maintain 19 acres of early- to mid-successional riparian habitat that meets the ecological requirements of the riparian brush rabbit and that is within or adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat (Environmental Commitment 7 and Resource Restoration and Performance Principle RBR2).
- Create and maintain high-water refugia in the 19 acres of restored riparian brush rabbit habitat and the 19 acres of protected riparian brush rabbit habitat, through the retention, construction and/or restoration of high-ground habitat on mounds, berms, or levees, so that refugia are no further apart than 66 feet (Resource Restoration and Performance Principle RBR3).
- In protected riparian areas that are occupied by riparian brush rabbit, monitor for and control nonnative predators that are known to prey on riparian brush rabbit (Resource Restoration and Performance Principle RBR4).
- Of the 1,060 acres of grasslands protected, protect 227 acres of grasslands on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit (Resource Restoration and Performance Principle RBR5).

As explained below, with the restoration and protection of these amounts of habitat, in addition to the AMMs to reduce potential effects, impacts on riparian brush rabbit would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-54. Changes in Riparian Brush Rabbit Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Riparian	15	4
	Grassland	170	57
Total Impacts Water Conveyance Facilities		**185**	**61**
Environmental Commitments 4, 6–7, 9–11[a]	Riparian	0	0
	Grassland	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**185**	**61**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-152: Loss or Conversion of Habitat for and Direct Mortality of Riparian Brush Rabbit

Alternative 4A would result in the permanent and temporary loss of up to 19 acres of riparian habitat and 227 acres of associated grassland habitat for the riparian brush rabbit in the study area

(Table 12-4A-54). Environmental commitments that would result in these losses are conveyance facilities construction and geotechnical investigation. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Development of Alternative 4A water conveyance facilities would result in the permanent removal of approximately 15 acres of riparian habitat and 170 acres of associated grassland habitat and in the temporary removal of 4 acre of riparian habitat and 57 acres of grassland habitat for riparian brush rabbit in CZ 8 (Table 12-4A-54). There are no riparian brush rabbit occurrences in the water conveyance facilities construction footprint. The riparian habitat that would be removed is of low value for the riparian brush rabbit as it consists of several small, isolated patches surrounded by agricultural lands northeast of Clifton Court Forebay. The associated grasslands are also of low value for the species: They consist of long, linear strips that abut riparian habitat, but extend several miles from the riparian habitat and, therefore, provide few if any opportunities for adjacent cover. Trapping efforts conducted for the riparian brush rabbit in this area were negative (see Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*, in the Draft BDCP). Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Protection of 227 acres of grassland and 19 acres of riparian habitat, as well as restoration of 19 acres of riparian habitat would benefit riparian brush rabbit (Table 12-4A-54). A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values in protected habitats may result in localized ground disturbances that could temporarily remove small amounts of riparian brush rabbit habitat. Enhancement and management actions in riparian brush rabbit habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities are expected to have minor adverse effects on available riparian brush rabbit habitat and are expected to result in overall improvements to and maintenance of riparian brush rabbit habitat values over time. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below.

  Passive recreation in the reserve system could result in disturbance of individual riparian brush rabbits foraging in the ecotone between riparian and adjacent open habitats. However, *AMM37 Recreation* limits trail development adjacent to riparian corridors within the range of the riparian brush rabbit. With this minimization measure in place, recreation related effects on the riparian brush rabbit are expected to be minimal.

- Operations and maintenance: Ongoing maintenance of project facilities are not expected to adversely affect the riparian brush rabbit because the species is not expected to occur in the vicinity of proposed facilities.

- Injury and direct mortality: Water conveyance facility construction is not is not likely to result in injury or mortality of individual riparian brush rabbit because the species is not likely to be present in the areas that would be affected by this activity, based on live trapping results (see Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*, in the

Draft BDCP). Valley foothill/riparian natural communities restoration would not result in injury or mortality of the riparian brush rabbit because restoration projects would be designed to avoid occupied riparian brush rabbit habitat and, if that is not possible, rabbits would be trapped and relocated as described in AMM25 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS).

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and AMMs that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

There are 6,012 acres of modeled riparian brush rabbit habitat in the study area, consisting of 2,909 acres of riparian habitat and 3,103 acres of associated grassland habitat. Alternative 4A would result in permanent and temporary effects combined on 19 acres of modeled riparian habitat (less than 1% of the habitat in the study area) and 227 acres of modeled grassland habitat (less than 1% of habitat in the study area) for riparian brush rabbit in CZ 6, CZ 7, and CZ 8.

These effects would result from the construction of the water conveyance facilities. The habitat would be lost in the valley/foothill riparian and grassland natural communities. Most of the loss of riparian brush rabbit habitat would be in an area unlikely to be occupied by the species in CZ 8. Habitat loss in CZ 7, in areas known or likely to be occupied, would also occur. Riparian restoration would be phased to minimize temporal habitat loss. Alternative 4A includes a commitment to protect 227 acres of grassland and 19 acres of riparian habitat, and to restore 19 acres of riparian habitat for riparian brush rabbit. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian brush rabbit habitat. The conserved habitat would also provide more specific ecological requirements of riparian brush rabbit, including large patches of dense riparian brush; ecotonal edges that transition from brush species to grasses and forbs, scaffolding plants to support vines that grow above flood levels; a tree canopy that is open, if present; and high-ground refugia from flooding.

The project would also protect grasslands adjacent to suitable riparian vegetation in areas outside the floodplain levees. These grasslands are expected to provide additional foraging opportunities for the riparian brush rabbit and upland refugia during flood events. Grasslands on the landward side of levees adjacent to restored floodplain will be restored or protected as needed to provide flood refugia and foraging habitat for riparian brush rabbit.

Additionally, nonnative predators that are known to prey on riparian brush rabbit (e.g., feral dogs and cats) would be monitored in protected and restored riparian and grassland areas that are occupied by riparian brush rabbit and controlled as needed (Environmental Commitment 11).

Typical NEPA and CEQA project-level mitigation ratios for loss of riparian and grassland habitats affected by water conveyance facilities would be 1:1 for restoration and protection of the valley/foothill riparian natural community, and 1:1 for protection of grassland for riparian brush rabbit. Using these ratios would indicate that 19 acres of riparian habitat should be restored, 19 acres of riparian habitat should protected, and 227 acres of grassland should be protected for riparian brush rabbit to mitigate near-term losses.

The project also contains commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and*

Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, AMM10 Restoration of Temporarily Affected Natural Communities, AMM25 Riparian Woodrat and Riparian Brush Rabbit, and AMM37 Recreation. These AMMs contain elements that avoid or minimize the risk of project activities affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and updated versions of AMM2, AMM6, and AMM37 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The loss of riparian brush rabbit habitat and potential mortality under Alternative 4A would not be an adverse effect because there is little likelihood of riparian brush rabbits being present and because the project proponents have committed to protecting and restoring the acreage required to meet the typical mitigation ratios described above. This habitat protection, restoration, and enhancement would be guided by species-specific Resource Restoration and Performance Principles L1 and RBR1-RBR5, and by AMM1–AMM6, AMM10, AMM25, and AMM37, which would be in place throughout the period of construction and operations. Considering these commitments, the effects of Alternative 4A as a whole on riparian brush rabbit would not be an adverse effect.

CEQA Conclusion: Considering Alternative 4A's commitment to the protection, restoration, and management of riparian brush rabbit habitat, Resource Restoration and Performance Principles L1 and RBR1-RBR5, and with the implementation of AMM1–AMM7, AMM10, AMM25, and AMM37, the loss of habitat or direct mortality of riparian brush rabbit as a result of implementing Alternative 4A would not represent a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat and potential mortality under this alternative would have a less-than-significant impact on riparian brush rabbit under CEQA.

Impact BIO-153: Indirect Effects of Alternative 4A on Riparian Brush Rabbit

Noise and visual disturbance adjacent to construction activities could indirectly affect the use of modeled riparian brush rabbit riparian habitat and of associated grassland habitat in the study area. These construction activities would include water conveyance, geotechnical investigation, and restoration activities. Water conveyance facilities construction would potentially affect acres of adjacent riparian habitat and of associated grassland habitat: this construction would occur in CZ 8 where there is suitable habitat for the species but surveys by ESRP did not indicate the species is present in this area; therefore, the potential for adverse noise and visual effects from conveyance facility construction would be minimal. The use of mechanical equipment during construction might cause the accidental release of petroleum or other contaminants that would affect the riparian brush rabbit in adjacent habitat, if the species is present.

NEPA Effects: Implementation of AMM1–AMM7, AMM10, AMM25, and AMM37, as part of implementing Alternative 4A would avoid the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications or result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Therefore, indirect effects of Alternative 4A would not have an adverse effect on riparian brush rabbit.

CEQA Conclusion: Indirect effects from operations and maintenance as well as construction-related noise and visual disturbances could affect riparian brush rabbit in riparian and grassland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could affect riparian brush rabbit. The inadvertent discharge of sediment or excessive dust adjacent to riparian brush rabbit habitat could also have a negative effect on the species. With implementation of AMM1–AMM7, AMM10, AMM25, and AMM37 as part of Alternative 4A, the project would avoid and minimize the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Indirect effects of Alternative 4A would have a less-than-significant impact on riparian brush rabbit.

Impact BIO-154: Periodic Effects of Inundation of Riparian Brush Rabbit Habitat as a Result of Implementation of Alternative 4A

No Alternative 4A components would result in periodic effects on riparian brush rabbit.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Riparian Woodrat

The habitat model used to assess effects for the riparian woodrat consists of selected plant alliances from the valley/foothill riparian natural community, geographically constrained to the south Delta portion of the study area in CZ 7, south of State Route 4 and Old River Pipeline along the Stanislaus, San Joaquin, Old, and Middle Rivers. Valley/foothill riparian areas along smaller drainages (Paradise Cut, Tom Paine Slough), and some larger streams in the northern portion of CZ 7 were excluded from the riparian woodrat habitat model due to a lack of trees or riparian corridors that were too narrow. Factors considered in assessing the value of affected habitat for the riparian woodrat, to the extent that information is available, include habitat patch size and connectivity.

The riparian woodrat is not known to occur in the study area. The only verified extant population of riparian woodrats rangewide is 2 miles east of the southern end of the study area in Caswell Memorial State Park along the Stanislaus River (Williams 1986:1–112; Williams 1993). Riparian woodrat may occur in small patches of valley oak riparian forest along the San Joaquin River from the southern tip of the study area north to approximately the Interstate 5 overcrossing near Lathrop (Figure 12-47).

Alternative 4A would not result in losses of riparian woodrat modeled habitat as indicated in Table 12-4A-55. There is no modeled habitat for the species in either the water conveyance facilities or Environmental Commitment 4 (tidal restoration) footprint.

Table 12-4A-55. Changes in Riparian Woodrat Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11	0	0
TOTAL IMPACTS	**0**	**0**

Impact BIO-155: Loss or Conversion of Habitat for and Direct Mortality of Riparian Woodrat

No habitat would be lost or converted and there would be no direct mortality of riparian woodrat under Alternative 4A.

NEPA Effects**:** No effect.

CEQA Conclusion: No Impact.

Impact BIO-156: Indirect Effects of Alternative 4A on Riparian Woodrat

There would be no indirect effects on riparian woodrat from Alternative 4A.

NEPA Effects**:** No effect.

CEQA Conclusion: No Impact.

Impact BIO-157: Periodic Effects of Inundation of Riparian Woodrat Habitat as a Result of Implementation of Alternative 4A

There would be no periodic inundation effects on riparian woodrat from Alternative 4A.

NEPA Effects**:** No effect.

CEQA Conclusion: No Impact.

Salt Marsh Harvest Mouse

The habitat model used to assess effects for the salt marsh harvest mouse includes six habitat types: primary tidal marsh habitat, secondary tidal marsh habitat (low marsh), secondary upland habitat adjacent to tidal marsh habitat, primary habitat within managed wetlands, secondary habitat within managed wetlands (dominated by plants characteristic of low marsh), and upland habitats within managed wetland boundaries. The tidal and managed wetland habitats were discriminated recognizing that regardless of habitat value, managed wetlands are at high risk of catastrophic flooding and have lower long-term conservation value than tidal wetlands.

Alternative 4A would not result in effects on modeled salt marsh harvest mouse habitat as indicated Table 12-4A-56. There is no modeled habitat for the species in the water conveyance facilities footprint and tidal restoration under Alternative 4A would not take place in Suisun Marsh, which is the extent of known salt marsh harvest mouse habitat in the study area.

Table 12-4A-56. Changes in Salt Marsh Harvest Mouse Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	0	0
TOTAL IMPACTS	**0**	**0**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-158: Loss or Conversion of Habitat for and Direct Mortality of Salt Marsh Harvest Mouse

No habitat would be lost or converted and there would be no direct mortality of salt marsh harvest mouse under Alternative 4A. As noted above, water conveyance facilities and Environmental

Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

CEQA Conclusion: No impact.

Impact BIO-159: Indirect Effects of Alternative 4A on Salt Marsh Harvest Mouse

No indirect effects on salt marsh harvest mouse were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

***CEQA Conclusion*:** No impact.

Suisun Shrew

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the environmental commitments, on the Suisun shrew. Primary Suisun shrew habitat consists of all *Salicornia*-dominated natural seasonal wetlands and certain *Scirpus* and *Typha* communities found within Suisun Marsh only. Low marsh dominated by *Schoenoplectus acutus* and *S. californicus* and upland transitional zones within 150 feet of the tidal wetland edge were classified separately as secondary habitat because they are used seasonally (Hays and Lidicker 2000). All managed wetlands were excluded from the habitat model.

Alternative 4A would not result in effects on modeled Suisun shrew habitat as indicated in Table 12-4A-57. There is no modeled habitat for the species in the water conveyance facilities footprint and tidal restoration under Alternative 4A would not take place in Suisun Marsh.

Table 12-4A-57. Changes in Suisun Shrew Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Permanent	Temporary
Total Impacts Water Conveyance Facilities	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]	0	0
TOTAL IMPACTS	**0**	**0**
[a] See discussion below for a description of applicable environmental commitments.		

Impact BIO-160: Loss or Conversion of Habitat for and Direct Mortality of Suisun Shrew

No habitat would be lost or converted and there would be no direct mortality of Suisun shrew under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

CEQA Conclusion: No Impact.

Impact BIO-161: Indirect Effects of Alternative 4A on Suisun Shrew

No indirect effects on Suisun shrew were identified under Alternative 4A. As noted above, water conveyance facilities and Environmental Commitment 4 activities would not be implemented within or adjacent to Suisun Marsh, which is the only portion of the study area where the species is known to occur.

***NEPA Effects*:** No effect.

CEQA Conclusion: No impact.

San Joaquin Kit Fox and American Badger

Within the study area, the modeled habitat for the San Joaquin kit fox and potential habitat for the American badger is restricted to 5,327 acres of grassland habitat west of Clifton Court Forebay along the study area's southwestern edge, in CZ 7–CZ 10. The study area represents the extreme northeastern corner of the San Joaquin kit fox's range in California, which extends westward and southward from the study area border. The northern range of the San Joaquin kit fox (including the study area) was most likely marginal habitat historically and has been further degraded due to development pressures, habitat loss, and fragmentation (Clark et al. 2007). CNDDB (California Department of Fish and Wildlife 2013) reports twelve occurrences of San Joaquin kit foxes along the extreme western edge of the project area within CZ 8, south of Brentwood (Figure 12-49). However, Clark et al. (2007) provide evidence that a number of CNDDB occurrences in the northern portion of the species' range may be coyote pups misidentified as San Joaquin kit foxes. Smith et al. (2006) suggest that the northern range may possibly be a population sink for the San Joaquin kit fox. There are five American badger records in the study area (California Department of Fish and Wildlife 2013). Two are from 1938 and no longer extant. The remaining three are all located in CZ 8, west of Clifton Court Forebay.

Alternative 4A would result in both temporary and permanent losses of San Joaquin kit and American badger habitat (Table 12-4A-58). Grassland restoration, and protection and management of natural communities could affect modeled San Joaquin San Joaquin kit fox habitat and potential American badger habitat. Alternative 4A would include the following environmental commitments and associated Resource Restoration and Performance Principles to benefit the San Joaquin kit fox which would also benefit American badger which uses similar habitat (see Chapter 3, *Conservation Strategy*, of the Draft BDCP). The conservation strategy for the San Joaquin kit fox involves protecting and enhancing habitat in the northern extent of the species' range to increase the likelihood that San Joaquin kit fox may reside and breed in the project area; and providing connectivity to habitat outside the project area.

- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the project area (Resource Restoration and Performance Principle L2).
- Protect 647 acres of grassland in the Byron Hills area (Environmental Commitment 3 and Resource Restoration and Performance Principle G10).

- Protect 150 acres and restore 34 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills including associated grasslands (Environmental Commitments 3 and 9, and Resource Restoration and Performance Principle VP/AW1).
- Increase burrow availability for burrow-dependent species in grasslands including grasslands surrounding restored and protected vernal pool and alkali seasonal wetland complexes (Resource Restoration and Performance Principle VP/AW6).
- Increase prey abundance and accessibility, especially small mammals and insects, for grassland-foraging species in grasslands and within restored and protected vernal pool and alkali seasonal wetland complex (Resource Restoration and Performance Principle VP/AW7).

As explained below, with the restoration and protection of these amounts of habitat, in addition to the AMMs to reduce potential effects, impacts on San Joaquin kit fox and American badger would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-58. Changes in San Joaquin Kit Fox Modeled Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Grassland	267	56
Total Impacts Water Conveyance Facilities		**267**	**56**
Environmental Commitments 4, 6–7, 9–11[a]	Grassland	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**267**	**56**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-162: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Kit Fox and American Badger

Alternative 4A conveyance facilities construction would result in the permanent and temporary loss combined of 323 acres of grassland habitat for the San Joaquin kit fox in the study area (Table 12-4A-58). Because American badger uses grasslands for denning and foraging and may occupy the same range as the San Joaquin kit fox in the project area, effects are anticipated to be the same as those described for San Joaquin kit fox. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual activity discussions.

- *Water Facilities and Operation*: Construction of the conveyance facilities would result in the permanent loss of approximately 267 acres and the temporary loss of 56 acres of modeled San Joaquin kit fox and American badger habitat. This habitat is located in areas of naturalized grassland in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay, in CZ 8. There are 3 San Joaquin kit fox and no American badger occurrences that overlap with the water conveyance facilities footprint.
- Environmental Commitment 11 Natural Communities Enhancement and Management: Protection of 647 acres of grassland would benefit San Joaquin kit fox and American badger

individuals present in the area. A variety of habitat management actions included in Environmental Commitment 11 that are designed to enhance wildlife values on protected lands may result in localized ground disturbances that could temporarily remove small amounts of San Joaquin kit fox and American badger habitat near Clifton Court Forebay, in CZ 8. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor effects on available habitat and are expected to result in overall improvements to and maintenance of San Joaquin kit fox and badger habitat values. However, management activities could result in injury or mortality of San Joaquin kit fox or American badger if individuals were present in work sites or if dens were located in the vicinity of habitat management work sites. *AMM24 San Joaquin Kit Fox* and Mitigation Measure BIO-162: *Conduct Preconstruction Survey for American Badger* would be implemented to ensure that San Joaquin kit fox and American badger dens are avoided. AMM24 is described in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP.

Passive recreation in the reserve system could also result in disturbance of San Joaquin kit foxes and American badger at their den sites. Natal and pupping dens would be particularly vulnerable to human disturbance. Additionally, disease could be transmitted from domestic dogs that enter the reserve system with recreational users. However, *AMM37 Recreation* and Mitigation Measure BIO-162 would prohibit construction of new trails within 250 feet of active San Joaquin kit fox and American badger dens. Existing trails would be closed within 250 feet of active natal/pupping dens until young have vacated, and within 50 feet of other active dens. No dogs would be allowed on reserve units with active San Joaquin kit fox or American badger populations. Rodent control would be prohibited even on grazed or equestrian access areas with San Joaquin kit fox and American badger populations to improve rodent prey availability. AMM37 measures to protect San Joaquin kit fox would also benefit American badger if present. With these restrictions, recreation-related effects on San Joaquin kit fox and American badger are expected to be minimal.

- Operations and maintenance: Ongoing maintenance of project facilities would be expected to have little if any adverse effect on San Joaquin kit fox or American badger. Postconstruction operations and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect either species' use of the surrounding habitat near Clifton Court Forebay, in CZ 8. Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of AMM1–AMM6, AMM10, and AMM24 and with preconstruction surveys for the American badger, as required by Mitigation Measure BIO-162, Conduct Preconstruction Survey for American Badger.

- Injury and direct mortality: Construction vehicle activity may cause injury to or mortality of either species. If San Joaquin kit fox or American badger reside where activities take place (most likely in the vicinity of Clifton Court Forebay, in CZ 8), the operation of equipment for land clearing, construction, operations and maintenance, and restoration, enhancement, and management activities could result in injury to or mortality of either species. Measures would be implemented to avoid and minimize injury to or mortality of these species as described in AMM1–AMM6, AMM10, AMM24, and AMM37 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS) and Mitigation Measure BIO-162.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments and associated Resource Restoration and Performance Principles that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

There are 5,327 acres of modeled San Joaquin kit fox habitat in the study area. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 323 acres of associated grassland habitat for San Joaquin kit fox and potential habitat for American badger, representing 6% of the modeled habitat. These effects would result from construction of the water conveyance facilities.

With full implementation of Alternative 4A, at least 647 acres of grassland would be protected in CZ 8, where the San Joaquin kit fox and American badger are most likely to occur in the study area. In addition, San Joaquin kit fox and American badger would benefit from the protection of 150 acres and restoration of 34 acres of existing vernal pool/alkali seasonal wetlands complexes in the greater Byron Hills. Because San Joaquin kit fox home ranges are large (varying from approximately 1 to 12 square miles; see Appendix 2.A, *Covered Species Accounts*, of the Draft BDCP), habitat connectivity is key to the conservation of the species. Grasslands would be acquired for protection in locations that provide connectivity to existing protected breeding habitats in CZ 8 and to other adjoining San Joaquin kit fox and American badger habitat within and adjacent to the project area. Connectivity to occupied habitat adjacent to the project area would help ensure the movement of San Joaquin kit foxes and American badger, if present, to larger habitat patches outside of the project area in Contra Costa County. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (see Appendix 2.A, *Covered Species Accounts*, of the Draft BDCP). This area connects to more than 620 acres of existing habitat that was protected under the East Contra Costa County HCP/NCCP.

Grasslands in CZ 8 would also be managed and enhanced to increase prey availability and to increase mammal burrows, which could benefit the San Joaquin kit fox and American badger by increasing potential den sites, which are a limiting factor for the San Joaquin kit fox in the northern portion of its range. These management and enhancement actions are expected to benefit the San Joaquin kit fox as well as the American badger by increasing the habitat value of the protected grasslands.

CZ 8 supports 74% of the modeled San Joaquin kit fox grassland habitat in the study area, and the remainder of habitat consists of fragmented, isolated patches that are unlikely to support this species. The project's commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 and to maintain connectivity with the remainder of the satellite population in Contra Costa County would sufficiently offset the impacts resulting from water conveyance facilities construction.

Typical NEPA and CEQA project-level mitigation ratio for the natural community that would be affected would be 2:1 for protection of grassland. Using this ratio would indicate that 646 acres of grassland should be protected for San Joaquin kit fox and American badger to mitigate near-term losses.

Alternative 4A also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged*

Material, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM24 San Joaquin Kit Fox*, and *AMM37 Recreation.* These AMMs contain elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and updated versions of AMM2, AMM6, and AMM37 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS. Remaining effects would be addressed by implementation of Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger.

NEPA Effects: In the absence of the proposed environmental commitments, the effects on San Joaquin kit fox and American badger habitat from Alternative 4A would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, VP/AW1, VP/AW6, VP/AW7, and G10 and guided by AMM1–AMM6, AMM10, AMM24, and AMM37, which would be in place throughout the construction period and operations, and with implementation of Mitigation Measure BIO-162, the effects of Alternative 4A as a whole on San Joaquin kit fox and American badger would not be an adverse effect.

CEQA Conclusion: In the absence of the proposed environmental commitments, the effects on San Joaquin kit fox and American badger habitat from Alternative 4A would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement guided by Resource Restoration and Performance Principles L2, VP/AW1, VP/AW6, VP/AW7, and G10, and guided by AMM1–AMM6, AMM10, AMM24, and AMM37, which would be in place throughout the time period of construction and operations, and with implementation of Mitigation Measure BIO-162, the impact of Alternative 4A as a whole on San Joaquin kit fox and American badger would be less than significant.

Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger

A qualified biologist provided by DWR will survey for American badger concurrent with the preconstruction survey for San Joaquin kit fox and burrowing owl. If badgers are detected, the biologist will passively relocate badgers out of the work area prior to construction if feasible. If an active den is detected within the work area, DWR will establish a suitable buffer distance and avoid the den until the qualified biologist determines the den is no longer active. Dens that are determined to be inactive by the qualified biologist will be collapsed by hand to prevent occupation of the den between the time of the survey and construction activities. In addition, the construction of new trails within 50 feet of active American badger dens would be prohibited. Existing trails would be closed within 250 feet of active natal/pupping dens until young have vacated, and within 50 feet of other active dens. No dogs would be allowed on reserve units with active American badger populations. Rodent control would be prohibited on areas with American badger populations to ensure rodent prey availability.

Impact BIO-163: Indirect Effects of Alternative 4A on San Joaquin Kit Fox and American Badger

Noise and visual disturbances outside the project footprint but within 250 feet of construction activities could temporarily affect modeled San Joaquin kit fox habitat and potential American badger. Water conveyance facilities operations and maintenance activities would include vegetation and weed control, rodent control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. Because operations and maintenance are covered activities rodent control would be prohibited in areas with San Joaquin kit fox or American badger populations to ensure rodent prey availability. While maintenance activities are not expected to remove San Joaquin kit fox and badger habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual foxes and badgers, if present. Given the remote likelihood of active San Joaquin kit fox or badger dens in the vicinity of the conveyance facility, the potential for this effect is small and would further be minimized with the implementation of seasonal no-disturbance buffers around occupied dens, if any, and other measures as described in AMM1–AMM6, AMM10, AMM24, AMM37, and Mitigation Measure BIO-162.

NEPA Effects**:** Implementation of AMM1–AMM6, AMM10, AMM24, and AMM37and Mitigation Measure BIO-162 *Conduct Preconstruction Survey for American Badger*, would avoid the potential for substantial adverse effects on San Joaquin kit fox or American badger, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin kit fox or American badger, or restrict either species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on San Joaquin kit fox or American badger.

CEQA Conclusion**:** Indirect effects from environmental commitment operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin kit fox and American badger. With implementation of AMM1–AMM6, AMM10, AMM24, and AMM37 as part of Alternative 4A construction, operation, and maintenance, the project would avoid the potential for significant adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of either species. In addition, Mitigation Measure BIO-162 as described above, would further reduce of the potential for indirect effects of Alternative 4A on American badger to a less-than-significant level.

Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger

Please see Mitigation Measure BIO-162 under Impact BIO-162.

San Joaquin Pocket Mouse

Habitat for San Joaquin pocket mouse consists of the grassland natural community throughout the study area. The species requires friable soils for burrowing. Alternative 4A would result in both temporary and permanent losses of San Joaquin pocket mouse habitat as indicated in Table 12-4A-59. Alternative 4A would also include the following environmental commitments and associated Resource Restoration and Performance Principles that would likely benefit San Joaquin pocket mouse.

- Protect 1,060 acres of grasslands (Environmental Commitment 3).
- Restore 1,070 acres of grasslands (Environmental Commitment 8).
- Sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states (Resource Restoration and Performance Principle G3).

As explained below, with protection and management of this amounts of habitat, Alternative 4A's impacts on San Joaquin pocket mouse would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-59. Changes in San Joaquin Pocket Mouse Habitat Associated with Alternative 4A (acres)

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Grassland	506	151
Total Impacts Water Conveyance Facilities		**506**	**151**
Environmental Commitments 4, 6–7, 9–11[a]	Grassland	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**0**	**0**
TOTAL IMPACTS		**506**	**151**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-164: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Pocket Mouse

Alternative 4A would result in the combined permanent and temporary loss of up to 657 acres of habitat for San Joaquin pocket mouse, of which 506 acres would be a permanent loss and 151 acres would be a temporary loss of habitat (Table 12-4A-59). Project measures that would result in these losses are water conveyance facilities and transmission line construction, and establishment and use of RTM areas, and *Environmental Commitment 4 Tidal Natural Communities Restoration*. The majority of habitat loss would result from water conveyance facilities. Habitat enhancement and management activities (Environmental Commitment 11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities could degrade or eliminate San Joaquin pocket mouse habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the combined permanent and temporary loss of up to 657 acres of potential San Joaquin pocket mouse habitat (506 acres of permanent loss, 151 acres of temporary loss) in CZ 3–CZ 6 and CZ 8. The majority of grassland that would be removed would be in CZ 8, from the modifications to Clifton Court Forebay. Refer to the Terrestrial Biology Mapbook in Appendix A of this RDEIR/SDEIS for a detailed view of Alternative 4A construction locations. Construction of the forebay would affect the area where there is a record of San Joaquin pocket mouse (California Department of Fish and Game 2012).
- *Environmental Commitment 11 Natural Communities Enhancement and Management:* The creation of recreational trails and recreational staging areas would result in the disturbance of grasslands and minor losses in habitat. The protection of 1,060 acres of grassland for covered species is expected to benefit San Joaquin pocket mouse by protecting existing habitats from potential loss or degradation that otherwise could occur with future changes in existing land use. Habitat management and enhancement-related activities could cause disturbance or direct mortality to San Joaquin pocket mouse if they are present near work areas.

- A variety of habitat management actions included in *Environmental Commitment 11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of San Joaquin pocket mouse habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on habitat and would be expected to result in overall improvements to and maintenance of habitat values. Noise and visual disturbance from management-related equipment operation could temporarily displace individuals or alter the behavior of the species if adjacent to work areas. Alternative 4A enhancement and management actions designed for western burrowing owl would also be expected to benefit San Joaquin pocket mouse.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect San Joaquin pocket mouse use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and environmental commitments as described below.
- Injury and Direct Mortality: Construction could result in direct mortality of San Joaquin pocket mouse if present in construction areas.

The following paragraphs summarize the combined effects discussed above and describe other environmental commitments that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

The habitat model indicates that the study area supports approximately 78,047 acres of potential habitat for San Joaquin pocket mouse. Alternative 4A as a whole would result in the permanent loss of and temporary effects on 657 acres of grasslands that could be suitable for San Joaquin pocket mouse (1% of the habitat in the study area). These effects would result from the construction of the water conveyance facilities. Alternative 4A includes a commitment to protect 1,060 acres of grassland (Environmental Commitment 3) and restore 1,070 acres of grassland (Environmental Commitment 8). Alternative 4A's commitment to sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes would protect a diversity of habitats that San Joaquin pocket mouse could use. All protected habitat would be managed under *Environmental Commitment 11 Natural Communities Enhancement and Management*.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by the project would be 2:1 protection of grassland habitat. Using these typical ratios would indicate that 1,314 acres of grassland natural communities should be protected to mitigate the loss of 657 acres of grassland.

The project also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containments and Countermeasure Plan, and AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and*

Minimization Measures, of the Draft BDCP and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

***NEPA Effects*:** In the absence of the environmental commitments, the effects on San Joaquin pocket mouse habitat and potential mortality of a special-status species resulting from Alternative 4A would represent an adverse effect. However, project proponents have committed to habitat protection and management associated with Environmental Commitment 3 and Environmental Commitment 11. This habitat protection and management would be guided by Resource Restoration and Performance Principle G3, and by AMM1–AMM6 and AMM10, which would be in place during construction. Considering these commitments, losses of San Joaquin pocket mouse and potential mortality under Alternative 4A would not be an adverse effect.

***CEQA Conclusion*:** Considering Alternative 4A's commitment to the protection and management of grasslands and with the implementation of Resource Restoration and Performance Principle G3 and AMM1–AMM6 and AMM10, the loss of habitat or direct mortality through implementation of Alternative 4A would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of San Joaquin pocket mouse. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on San Joaquin pocket mouse under CEQA.

Impact BIO-165: Indirect Effects of Alternative 4A on San Joaquin Pocket Mouse

Construction activities associated with water conveyance facilities, environmental commitments, and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on San Joaquin kit pocket mouse and its habitat. These potential effects would be minimized and avoided through AMM1–AMM6, and AMM10, which would be in effect throughout the construction phase.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove pocket mouse habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual pocket mice, if present.

***NEPA Effects*:** Implementation of the AMMs listed above would avoid the potential for substantial adverse effects on San Joaquin pocket mouse, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin pocket mouse, or restrict the species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on San Joaquin pocket mouse.

***CEQA Conclusion*:** Indirect effects from environmental commitment operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin pocket mouse. With implementation of AMM1–AMM6, and AMM10, as part of Alternative 4A construction, operation, and maintenance, Alternative 4A would avoid the potential for adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of the species. Therefore, the indirect effects under this alternative would have a less-than-significant impact on San Joaquin pocket mouse under CEQA.

Special-Status Bat Species

Special-status bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as tunnels, buildings, and bridges. Various roost strategies could include night roosts, maternity roosts, migration stopover, or hibernation. The habitat types used to assess effects for special-status bats roosting habitat includes valley/foothill riparian natural community, developed lands and landscaped trees, including eucalyptus, palms and orchards. Potential foraging habitat includes all riparian habitat types, cultivated lands, developed lands, grasslands, and wetlands.

There is potential for at least thirteen different bat species to be present in the study area (Figure 12-51), including four California species of special concern and nine species ranked from low to moderate priority by the Western Bat Working Group (see Draft EIR/EIS Appendix 12A, *Special-Status Species with Potential to Occur in the Study Area*, Table 12A-2). In 2009, DHCCP conducted a large-scale effort that involved habitat assessments, bridge surveys, and passive acoustic monitoring surveys for bats (see Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*, in the Draft EIR/EIS for details on methods and results, and Table 12A-2 in Appendix 12A). The majority of the parcels assessed during field surveys contained bat foraging and roosting features and were considered highly suitable habitat. At the time of the 2009 field surveys, DWR biologists initially identified 145 bridges in their survey area. Eleven of the 145 bridges were not accessible and thirteen were determined to not be suitable for bats. Evidence of bat presence was observed at six of the bridges and bat sign (guano, urine staining, odor, or vocalizations) was observed at 26 of the bridges. Biologists observed Mexican free-tailed bats at four of the bridges and unidentified species at the remaining two bridges. One of these bridges, over the Yolo Causeway, was used by approximately 10,000 Mexican free-tailed bats, indicating a maternity roost. A second roost site of about 50 individuals was observed under a bridge in eastern Solano County.

The remaining 89 bridges contained structural features that were considered conducive to maternity, solitary, day and/or night roosting. Night roosts may have crevices and cracks but more often have box beams or other less protected roosting spots where bats rest temporarily while feeding. Day roosts are commonly found in bridges with expansion joints, crevices, or cracks where bats are protected from predators and weather. Seventeen bridges in the survey area had no potential for roosting because they lacked surface features from which bats could hang and offered no protection from weather or predators.

Alternative 4A would result in both temporary and permanent losses of foraging and roosting habitat for special-status bats as indicated in Table 12-4A-60. Protection and restoration for special-status bat species focuses on habitats and does not include manmade structures such as bridges. Alternative 4A would include the following conservation and Resource Restoration and Performance Principles to benefit special-status bats.

- Protect 13,302 acres and restore 2,246 acres of high-value natural communities. This objective involves protecting and restoring a variety of habitat types described below that would also benefit special-status bats (see Table 4.1-3 in Section 4.1.2, *Description of Alternative 4A*, in the RDEIR/SDEIS).
    - Protect 1,060 acres and restore 1,070 acres of grassland (Environmental Commitments 3 and Environmental Commitment 8).
    - Protect 11,870 acres of cultivated lands (Environmental Commitment 3).

- Restore 34 acres and protect 150 acres of vernal pool/alkali seasonal wetland complex (Environmental Commitment 3 and Environmental Commitment 9).
- Protect 119 acres and restore up to 832 acres of nontidal marsh (Environmental Commitment 3 and Environmental Commitment 10).
- Protect 6 acres of ponds (Resource Restoration and Performance Principle G2).
- Restore 59 acres of tidal natural communities (Environmental Commitment 4).
- Restore 251 acres and protect 103 acres of valley/foothill riparian natural community (Environmental Commitment 3 and Environmental Commitment 7).

As explained below, with the restoration and protection of these amounts of habitat, in addition to mitigation measures to reduce potential effects, impacts on special-status bats would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-4A-60. Changes in Special-Status Bat Roosting and Foraging Habitat Associated with Alternative 4A

Project Component	Habitat Type	Permanent	Temporary
Water Conveyance Facilities	Roosting	194	61
	Foraging	4,744	3,731
Total Impacts Water Conveyance Facilities		**4,938**	**3,792**
Environmental Commitments 4, 6–7, 9–11[a]	Roosting	5	0
	Foraging	0	0
Total Impacts Environmental Commitments 4, 6–7, 9–11[a]		**5**	**0**
TOTAL IMPACTS		**4,943**	**3,792**

[a] See discussion below for a description of applicable environmental commitments.

Impact BIO-166: Loss or Conversion of Habitat for and Direct Mortality of Special-Status Bats

Alternative 4A would result in the permanent and temporary loss combined of up to 260 acres of roosting habitat and 8,475 acres of foraging habitat for special-status bats from water conveyance facilities construction and from tidal restoration (Environmental Commitment 4). Foraging habitat effects for water conveyance facilities and Environmental Commitment 4 were not considered adverse as they reflect a conversion from one foraging habitat type (mostly cultivated lands) to another foraging habitat (wetlands). Habitat enhancement and management activities (Environmental Commitment 11) could result in local adverse effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other project facilities could affect special-status bat roosting habitat. A summary of combined impacts and NEPA effects and a CEQA conclusion follows the individual activity discussions.

- *Water Facilities and Operation*: Construction of Alternative 4A conveyance facilities would result in the permanent loss of approximately 194 acres of roosting habitat and 4,744 acres of foraging habitat in the study area. Development of the water conveyance facilities would also result in the temporary removal of up to 61 acres of roosting habitat and up to 3,731 acres of foraging habitat for special-status bats in the study area (Table 12-4A-60). DWR identified two bridges with potential night roosting habitat in the forebay embankment area and tunnel muck area that could be permanently affected by construction for water conveyance facilities. Additional roosting habitat affected by construction and operations includes valley/foothill riparian natural community, developed lands and landscaped trees, including eucalyptus, palms and orchards.

- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would result in the loss of approximately 5 acres of roosting habitat. The roosting habitat that would be removed consists of relatively small and isolated patches along canals and irrigation ditches surrounded by cultivated lands in the Union Island and Roberts Island areas, and several small patches along the San Joaquin River. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, requires that tidal natural communities restoration avoid effects on roosting special-status bats.

- *Environmental Commitment 11 Natural Communities Enhancement and Management*: Implementation of Alternative 4A would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats. The majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands. Restored foraging habitats primarily would replace agricultural lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Noise and visual disturbances during implementation of riparian habitat management actions could result in temporary disturbances that, if bat roost sites are present, could cause temporary abandonment of roosts. This effect would be minimized with implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*.

- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on special-status bats. Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect special-status bat use of the surrounding habitat in the Cache Slough area, and the north and south Delta (CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8). Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of the mitigation measures described below.

- Injury and direct mortality: In addition, to habitat loss and conversion, construction activities, such as grading, the movement of construction vehicles or heavy equipment, and the installation of water conveyance facilities components and new transmission lines, may result in the direct mortality, injury, or harassment of roosting special-status bats. Construction activities related to the environmental commitments could have similar affects. Preconstruction surveys would be conducted and if roosting or maternity sites are detected, seasonal restrictions would be placed while bats are present, as described below in the mitigation measures.

The following paragraphs summarize the combined effects discussed above and describe other Alternative 4A activities that offset or avoid these effects. NEPA effects and CEQA conclusions are also included.

Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat resulting from water conveyance facilities and Environmental Commitment 4.

Alternative 4A would permanently or temporarily affect 260 acres of roosting habitat for special-status bats in the near-term as a result of implementing water conveyance facilities (255 acres roosting habitat) and Environmental Commitment 4 (5 acres roosting habitat). Most of the roosting habitat losses would occur in valley/foothill riparian habitat.

Alternative 4A would restore up to 251 acres and protect 103 acres of valley/foothill riparian roosting habitat and 15,194 acres of additional foraging habitat in natural communities and developed lands. Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats.

Implementation of Alternative 4A would result in an overall benefit to special-status bats within the study area through protection and restoration of approximately 15,548 acres of their foraging and roosting habitats. The target for total protected and restored acreage is based on the sum of all natural community acreage targets. Achieving this is intended to protect and restore natural communities, species-specific habitat elements, and species diversity on a landscape-scale. Achieving this is also intended to conserve representative natural and seminatural landscapes in order to maintain the ecological integrity of large habitat blocks, including desired ecosystem function, and biological diversity.

Should any of the special-status bat species be detected roosting in the study area, construction of water conveyance facilities and restoration activities would have an adverse effect on roosting special-status bats. Noise and visual disturbances and the potential for injury or mortality of individuals associated within implementation of the restoration activities on active roosts would be minimized with implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*. Environmental commitments would sufficiently offset the adverse effects resulting from late long-term effects from water conveyance facilities and Environmental Commitment 4.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected for roosting habitat would be 1:1 for restoration and protection of the valley/foothill riparian natural community. Using these ratios would indicate that 260 acres of riparian habitat should be restored and 260 acres of riparian habitat should be protected.

The project also contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM10 Restoration of Temporarily Affected Natural Communities.* These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: The losses of roosting habitat for special-status bats associated with implementing Alternative 4A are not expected to result in substantial adverse effects on special-status bats, either directly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of special-status bats because the project proponents have committed to protecting the acreage required to meet the typical mitigation ratios described above. The losses of roosting habitat for special-status bats, in the absence of the environmental commitments, would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection and restoration associated with the environmental commitments, Resource Restoration and Performance Principle G2, the implementation of AMM1–AMM6, and AMM10, and with implementation of Mitigation Measure BIO-166, the effects of Alternative 4A as a whole on special-status bats would not be adverse.

CEQA Conclusion: The permanent loss of roosting habitat from Alternative 4A would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure there is no significant impact under CEQA on roosting special-status bats, either directly or through habitat modifications and no substantial reduction in numbers or a restriction in the range of special-status bats. The project also contains commitments to implement Resource Restoration and Performance Principle G2 and AMM1–6 and AMM10. These AMMs include elements that avoid or minimize the risk of project activities affecting habitat and species adjacent to work areas and storage sites. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and updated versions of AMM2 and AMM6 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

The following measure was designed to avoid and minimize adverse effects on special-status bats. However, baseline data are not available or are limited on how bats use the study area, and on individual numbers of bats and how they vary seasonally. Therefore, it is difficult to determine if there would be a substantial reduction in species numbers. Bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as buildings and bridges. Daily and seasonal variations in habitat use are common. To obtain the highest likelihood of detection, preconstruction bat surveys will be conducted by DWR and will include these components.

- Identification of potential roosting habitat within project area.
- Daytime search for bats and bat sign in and around identified habitat.
- Evening emergence surveys at potential day-roost sites, using night-vision goggles and/or active full-spectrum acoustic monitoring where species identification is sought.
- Passive full-spectrum acoustic monitoring and analysis to detect bat use of the area from dusk to dawn over multiple nights.
- Additional on-site night surveys as needed following passive acoustic detection of special status bats to determine nature of bat use of the structure in question (e.g., use of structure as night roost between foraging bouts).

- Qualified biologists will have knowledge of the natural history of the species that could occur in the study area and experience using full-spectrum acoustic equipment. During surveys, biologists will avoid unnecessary disturbance of occupied roosts.

Preconstruction Bridges and Other Structure Surveys

Before work begins on the bridge/structure, qualified biologists will conduct a daytime search for bat sign and evening emergence surveys to determine if the bridge/structure is being used as a roost. Biologists conducting daytime surveys would listen for audible bat calls and would use naked eye, binoculars, and a high-powered spotlight to inspect expansion joints, weep holes, and other bridge features that could house bats. Bridge surfaces and the ground around the bridge/structure would be surveyed for bat sign, such as guano, staining, and prey remains.

Evening emergence surveys will consist of at least one biologist stationed on each side of the bridge/structure watching for emerging bats from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Night-vision goggles and/or full-spectrum acoustic detectors shall be used during emergence surveys to assist in species identification. All emergence surveys would be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted).

Additionally, passive monitoring with full-spectrum bat detectors will be used to assist in determining species present. A minimum of four nights of acoustic monitoring surveys will be conducted within the season that the construction would be taking place. If site security allows, detectors should be set to record bat calls for the duration of each night. To the extent possible, all monitoring will be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted). The biologists will analyze the bat call data using appropriate software and prepare a report with the results of the surveys. If acoustic data suggest that bats may be using the bridge/structure as a night roost, biologists will conduct a night survey from 1–2 hours past sunset up to 6 hours past sunset to determine if the bridge is serving as a colonial night roost.

If suitable roost structures would be removed, additional surveys may be required to determine how the structure is used by bats, whether it is as a night roost, maternity roosts, migration stopover, or for hibernation.

Preconstruction Tree Surveys

If tree removal or trimming is necessary, qualified biologists will examine trees to be removed or trimmed for suitable bat roosting habitat. High-value habitat features (large tree cavities, basal hollows, loose or peeling bark, larger snags, palm trees with intact thatch, etc.) will be identified and the area around these features searched for bats and bat sign (guano, culled insect parts, staining, etc.). Riparian woodland, orchards, and stands of mature broadleaf trees should be considered potential habitat for solitary foliage roosting bat species.

If bat sign is detected, biologists will conduct evening visual emergence survey of the source habitat feature, from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Methodology should follow that described above for the bridge emergence survey.

Additionally, if suitable tree roosting habitat is present, acoustic monitoring with a bat detector will be used to assist in determining species present. These surveys would be conducted in coordination with the acoustic monitoring conducted for the bridge/structure.

Protective Measures for Bats using Bridges/Structures and Trees

Avoidance and minimization measures may be necessary if it is determined that bats are using the bridge/structure or trees as roost sites and/or sensitive bats species are detected during acoustic monitoring. Appropriate measures will be determined in coordination with CDFW and may include measures listed below.

- Disturbance of the bridge will be avoided between April 15 and September 15 (the maternity period) to avoid impacts on reproductively active females and dependent young.
- Installation of exclusion devices from March 1 through April 14 or September 15 through October 30 to preclude bats from occupying the bridge during construction. Exclusionary devices will only be installed by or under the supervision of an experienced bat biologist.
- Tree removal will be avoided between April 15 and September 15 (the maternity period) to avoid impacts on pregnant females and active maternity roosts (whether colonial or solitary).
- All tree removal will be conducted between September 15 and October 30, which corresponds to a time period when bats would not likely have entered winter hibernation and would not be caring for flightless young. If weather conditions remain conducive to regular bat activity beyond October 30th, later tree removal may be considered in consultation with CDFW.
- Trees will be removed in pieces, rather than felling the entire tree.
- If a maternity roost is located, whether solitary or colonial, that roost will remain undisturbed with a buffer as determined in consultation with CDFW until September 15 or until a qualified biologist has determined the roost is no longer active.
- If a non-maternity roost is found, that roost will be avoided and an appropriate buffer established in consultation with CDFW. Every effort should be made to avoid the roost, as methods to evict bats from trees are largely untested. However, if the roost cannot be avoided, eviction would be attempted and procedures designed in consultation with CDFW to reduce the likelihood of mortality of evicted bats. In all cases:
    - Eviction will not occur before September 15th and will match the timeframe for tree removal approved by CDFW.
    - Qualified biologists will carry out or oversee the eviction tasks and monitor the tree trimming/removal.
    - Eviction will take place late in the day or in the evening to reduce the likelihood of evicted bats falling prey to diurnal predators.
    - Eviction will take place during weather and temperature conditions conducive to bat activity.
    - Special-status bat roosts would not be disturbed.

  Eviction procedures may include but are not limited to:

- Pre-eviction surveys to obtain data to inform the eviction approach and subsequent mitigation requirements. Relevant data may include the species, sex, reproductive status and/or number of bats using the roost, and roost conditions themselves such as temperature and dimensions. Surveys may include visual emergence, night vision, acoustic, and/or capture.
- Structural changes may be made to the roost, performed without harming bats, such that the conditions in the roost are undesirable to roosting bats and the bats leave on their own (e.g., open additional portals so that temperature, wind, light and precipitation regime in the roost change).
- Noninjurious harassment at the roost site to encourage bats to leave on their own, such as ultrasound deterrents or other sensory irritants.

- Prior to removal/trimming, after other eviction efforts have been attempted, any confirmed roost tree would be shaken, repeatedly struck with a heavy implement such as an axe and several minutes should pass before felling trees or trimming limbs to allow bats time to arouse and leave the tree. The biologists should search downed vegetation for dead and injured bats. The presence of dead or injured bats would be reported to CDFW.

Compensatory mitigation at a 1:1 ratio for the loss of roosting habitat would be accomplished by the restoration of 251 acres and protection of 103 acres of valley/foothill riparian habitat. Compensation may include the construction and installation of suitable replacement roosting habitat onsite as described below. Depending on the species and type of roost lost, various roost replacement habitats have met with some success (e.g., bat houses, "bat bark," planting cottonwood trees, leaving palm thatch in place rather than trimming). The creation of natural habitat onsite is generally preferable to artificial.

Artificial roosts are often unsuccessful, and care must be taken to determine as closely as possible the conditions in the natural roost to be replaced. Even with such care, artificial habitat may fail. Several artificial roosts have been highly successful in replacing bridge roost habitat when incorporated into new bridge designs. "Bat bark" has been successfully used by Arizona Department of Game and Fish to create artificial crevice-roosting bat habitat mounted on pine trees (Mering and Chambers 2012: 765). Bat houses have at best an inconsistent track record but information is mounting on how to create successful houses. There is no single protocol or recipe for bat-house success. Careful study of the roost requirements of the species in question; the particular conditions at the lost roost site including temperature, orientation of the openings, airflow, internal dimensions and structures (cavity vs. crevice, etc.) should increase the chances of designing a successful replacement.

Restoring riparian woodland with plantings shows signs of success in Colorado. Western red bat activity has been positively correlated with increased vegetation and tree growth, canopy complexity and restoration acreage at cottonwood-willow restoration sites along the Lower Colorado River (Broderick 2012: 39). These complex woodland areas would ultimately provide a wider range of bat species with preferred roost types, including both foliage-roosting and crevice-/cavity-roosting bats.

Impact BIO-167: Indirect Effects of Alternative 4A on Special-Status Bats

Construction activities associated with water conveyance facilities, restoration activities, and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on special-status bats and their roosting habitat.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove special-status bat habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in disturbances to roosting bats, if present. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, is available to address these adverse effects.

Increased exposure to methylmercury associated with tidal natural communities restoration would potentially indirectly affect special-status bat species. *Environmental Commitment 12 Methylmercury Management* describes the process by which tidal natural communities restoration may increase methyl mercury levels in wetlands in the study area. Mercury has been found in high concentrations in some bat species, such as the Indiana bat. Many bat species forage heavily on aquatic insects, which might result in rapid bioaccumulation (Evers et al. 2012). Measures described in *Environmental Commitment 12 Methylmercury Management* are expected to reduce the effects of methylmercury on special-status bat species resulting from tidal natural communities restoration.

***NEPA Effects*:** Implementation of the Mitigation Measure BIO-166 for special-status bats would avoid the potential for substantial adverse effects on roosting special-status bats, either indirectly or through habitat modifications. This mitigation measure and *Environmental Commitment 12 Methylmercury Management* would also avoid and minimize effects that could substantially reduce the number of special-status bats, or restrict species' range. Therefore, the indirect effects of Alternative 4A would not have an adverse effect on special-status bats.

***CEQA Conclusion*:** Indirect effects from environmental commitments, operations and maintenance as well as construction-related noise and visual disturbances could have a significant impact on special-status bat species, either indirectly or through habitat modifications. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, and *Environmental Commitment 12 Methylmercury Management* would reduce this impact to a less-than-significant level by reducing the likelihood for impacts to occur to roosting bats and would ensure Alternative 4A would not result in a substantial reduction in numbers or a restriction in the range of species.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

See Mitigation Measure BIO-166 under Impact BIO-166.

Impact BIO-168: Periodic Effects of Inundation of Special-Status Bat Habitat as a Result of Implementation of Alternative 4A

There would be no periodic effects of inundation on special-status bats or their habitat.

***NEPA Effects*:** No effects.

***CEQA Conclusion*:** No impacts.

4.3.1.1 Plant Species

Vernal Pool Species

Seventeen special-status plant species occur in vernal pools in the study area (Tables 12-2 and 12-3, summarized in Table 12-4A-61). The vernal pool habitat model used for the impact analysis on vernal pool species was developed for the BDCP and was based on vegetation types and associations from various data sets. The model was used to create maps showing the distribution of vernal pool habitat in the study area according to three habitat types in which these species are known to occur, including vernal pool complex, degraded vernal pool complex, and alkali seasonal wetland habitat. Vernal pool complex habitat consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Degraded vernal pool complex habitat consists of habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. Because wetlands in the degraded vernal pool complex are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. A small amount of alkali seasonal wetland habitat was included in the model because alkaline vernal pools are also present in some areas mapped as alkali seasonal wetland.

Because each of the vernal pool species addressed in this EIR/EIS have specific microhabitat affinities, and because vernal pool habitat within the study area is highly heterogeneous with respect to habitat parameters such as soil type and pool depth, the vernal pool habitat model greatly overestimates the extent of habitat in the study area occupied by each species. However, the vernal pool habitat model is likely to encompass all or most of the potential area within which special-status vernal pool plant species would occur. Therefore, it is not likely to underestimate the extent of occupied habitat or to underestimate the effects of Alternative 4A.

Full implementation of Alternative 4A and compliance with Resource Restoration and Performance Principle VPS1 would include the following conservation commitment to benefit special-status vernal pool plant species

- Protect at least two currently unprotected occurrences of alkali milk-vetch in the Altamont Hills or Jepson Prairie core recovery areas (Resource Restoration and Performance Principle VPS1).

The construction activities proposed under Alternative 4A could have impacts on special-status vernal pool plant species. Modeled habitat is within the proposed footprint for the Alternative 4A water conveyance facilities. One known occurrence of a special-status plant species is within the proposed footprint for the Alternative 4A water conveyance facilities. Table 12-4A-61 summarizes the acreage of modeled vernal pool habitat in the study area and the number of occurrences of each special-status vernal pool species in the study area.

Table 12-4A-61. Summary of Impacts on Vernal Pool Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Vernal pool complex	9,557	23	—	—	Habitat loss from construction of the water conveyance facilities
Degraded vernal pool complex	2,576	7	—	—	Habitat loss from construction of the water conveyance facilities
Alkali Seasonal Wetland	188	2	—	—	Habitat loss from construction of the water conveyance facilities
Total	12,321	32	—	—	Habitat loss from construction of the water conveyance facilities and tidal wetland restoration
Species					
Alkali milk-vetch	—	—	16	1	Population loss from construction of the water conveyance facilities
Dwarf downingia	—	—	12	0	None
Boggs Lake hedge-hyssop	—	—	1	0	None
Legenere	—	—	8	0	None
Heckard’s peppergrass	—	—	4[a]	0	None
Ferris’ milk-vetch	—	—	6	0	None
Vernal pool smallscale	—	—	2	0	None
Hogwallow starfish	—	—	0	0	None
Ferris’ goldfields	—	—	4	0	None

Delta woolly marbles	—	—	3	0	None
Saline clover	—	—	9	0	None
Solano grass	—	—	1	0	None

[a] One additional occurrence is in alkali seasonal wetlands.

Impact BIO-169: Effects on Habitat and Populations of Vernal Pool Plants

Under Alternative 4A, construction of the water conveyance facilities would affect habitat for special-status vernal pool species and one occurrence of a special-status vernal pool species.

- *Water Facilities and Operations*: Thirty acres of modeled vernal pool habitat, 19.4 acres of critical habitat for Contra Costa goldfields, and one known occurrence of the 17 vernal pool species are within the proposed footprint for the Alternative 4A water conveyance facilities. One occurrence of alkali milk-vetch in CZ 8 would be crossed by an electric transmission line. Under Alternative 4A, construction and operation of the water conveyance facilities could affect undiscovered occurrences of the seventeen special-status plant species.

- The east-west transmission line would not affect four special-status vernal pool species that occur in the study area. One occurrence each of dwarf downingia, legenere, Heckard's peppergrass, and Boggs Lake hedge-hyssop are within the east-west transmission line study area. However, the transmission line would not cross any of the occurrences.
- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A proposes to benefit special-status vernal pool plants by protecting 67 acres of vernal pool complex. The protected vernal pool habitat would be managed and enhanced to sustain populations of native vernal pool species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration would not affect special-status vernal pool plant species. No known occurrences of special-status vernal pool species would be affected by tidal restoration.
- *Environmental Commitment 6 Channel Margin Enhancement*: No vernal pool habitat or occurrences of special-status vernal pool plant species are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status vernal pool species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No vernal pool habitat or occurrences of special-status vernal pool plant species are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on special-status vernal pool species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: If, through unforeseen circumstances, construction of the water conveyance facilities results in the net loss of vernal pool habitat, environmental commitments would be implemented to compensate for that loss. Because vernal pool complex restoration would focus on habitat that had been cleared and leveled but maintained an intact duripan or claypan, the likelihood of affecting any special-status vernal pool plant species would be low. However, vernal pool restoration could adversely affect remnant populations of special-status vernal pool species or affect vernal pool habitat adjacent to the restoration areas.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid vernal pool habitat and would have no impacts on special-status vernal pool plant species.
- *Avoidance and Minimization Measures*: Effects on special-status vernal pool plant species potentially resulting from implementation of Alternative 4A would be avoided or minimized though *AMM11 Covered Plant Species*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM12 Vernal Pool Crustaceans, and AMM30 Transmission Line Design and Alignment Guidelines.* AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools. In addition, AMM11 specifies that individual projects be designed to avoid critical habitat for listed plant and wildlife vernal pool species. AMM12 limits the direct removal of vernal pool crustacean habitat to no more than 10 wetted acres and the indirect effect to no more than 20 wetted acres. AMM12 also requires that that tidal natural communities restoration or other ground-disturbing covered activities in Conservation Zones 1 and 11 will not result in the adverse modification of primary constituent elements of critical

habitat for vernal pool fairy shrimp, conservancy fairy shrimp, and vernal pool tadpole shrimp. These protections would also apply to critical habitat for Contra Costa goldfields, where it overlaps with critical habitat for these vernal pool crustaceans. AMM30 specifies that the alignment of proposed transmission lines will be designed to avoid sensitive terrestrial and aquatic habitats when siting poles and towers, to the maximum extent feasible. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM11 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

In addition, Environmental Commitment 3 includes Resource Restoration and Performance Principle VPS1 to protect two occurrences of alkali milk-vetch.

In summary, no adverse effects on special-status vernal pool plants would be expected from implementing Alternative 4A. Construction of the water conveyance facilities could affect one species, alkali milk-vetch, although adverse effects on this species would be avoided or minimized though implementation of AMM11 and AMM30. No other known occurrences of special-status vernal pool species would be affected under Alternative 4A. Beneficial effects on special-status vernal pool plants could occur by protecting 67 acres of vernal pool complex and by protecting occurrences of alkali milk-vetch.

The GIS analysis estimated that up to 32 acres of vernal pool habitat could be adversely affected by construction activities. However, the actual effect on habitat for special-status vernal pool plant species is expected to be much less than the estimated impact because Alternative 4A limits the total loss of wetted vernal pool habitat resulting from specific projects to 10 acres (approximately 67 acres of vernal pool complex) (AMM12). At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat for special-status vernal pool plants. This would be consistent with typical NEPA and CEQA project-level mitigation ratios for vernal pool impacts.

***NEPA Effects*:** The loss of modeled habitat for vernal pool plant species would be minimized by AMM12 and offset through the environmental commitments, and effects of constructing the water conveyance facilities on one occurrence of alkali milk-vetch would be avoided through AMM30. Therefore, Alternative 4A would not result in adverse effects on federally-listed vernal pool plant species.

***CEQA Conclusion*:** Because loss of modeled habitat for vernal pool plant species would be offset through restoration, and because impacts on occurrences of special-status vernal pool plant species would be avoided, implementation of Alternative 4A would not result in a reduction in the range or numbers of 17 special-status vernal pool plant species in the study area. Therefore, impacts on special-status vernal pool plant species would be less than significant. No mitigation is required.

Alkali Seasonal Wetland Species

Eight special-status plant species occur in alkali seasonal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-4A-62). Alkali seasonal wetland habitat was modeled separately for four plant species occurring in seasonal alkali wetlands. Because this analysis relies on the data developed for the BDCP, models were only available for species covered under the BDCP. Habitat models were not developed for the four alkali seasonal wetland species not proposed for coverage under the BDCP.

The San Joaquin spearscale habitat model approximated the distribution of suitable San Joaquin spearscale habitat in the study area according to the species' preferred habitat types, intersected with soil series and slope position. Historical and current records of San Joaquin spearscale in the study area indicate that its current distribution is limited to alkaline soil areas with shallow basin or swale microtopography along the western border of the study area. The vegetation cover of the alkaline soils is typically a combination of alkaline soil-adapted species and annual grasses, including annual ryegrass and Mediterranean barley. Habitat types used for the model included alkali seasonal wetlands, vernal pool complex, and grasslands. Soil series used in the model consisted of either clays or clay loams with alkaline horizons. San Joaquin spearscale typically occurs in swales or in level terrain but occasionally occurs on the lower slopes adjacent to streams or swales or where seeps are present. Because some of the soil series with which San Joaquin spearscale is associated can occur on hillsides, slope was used to limit the extent of the model to the toe of the slope where these soils occur by excluding areas with slope greater than 1%. Land uses that are incompatible with the species' habitat requirements, such as modeled habitat polygons falling on leveled or developed lands, were removed from the model.

Modeled habitat for brittlescale was mapped as hydrologic features such as stream corridors and playa pools located on alluvium associated with the Montezuma Block along the western boundary of the study area or on alluvium associated with tertiary formations located along the southwest boundary of the study area. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15.2 meters) on either side of their centerlines to capture the estimated maximum extent of alluvium deposits in proximity to the streams. Mapped habitat that was occupied by urban or intensive agricultural uses was removed from the model.

The habitat model for heartscale was based on the species distribution in the study area (Solano and Yolo Counties) and on the soil types and plant communities within which it occurs. Potential habitat was determined by intersecting the GIS coverage for three parameters: 1) Yolo and Solano County boundaries; 2) Solano, Pescadero, and Willows soils; and 3) grassland, alkali seasonal wetland, and vernal pool complex natural communities. The model excluded areas that have been developed or cultivated, i.e., where the topography, soils, and hydrology have been substantially altered.

Delta button-celery habitat was modeled as alkali seasonal wetland complex, vernal pool complex, other natural seasonal wetland, and grassland occurring on Brentwood, Grangerville, Marcuse, Solano, and Vernalis soil map units within the San Joaquin Basin (i.e., south of the mainstem San Joaquin River). For this species, land cover north of the Discovery Bay area where intensive agriculture was classified as annual grassland were manually deleted from the area of predicted habitat. Additionally, other areas of potential habitat that have been developed were also manually deleted.

Full implementation of Alternative 4A and compliance with Resource Restoration and Performance Principle ASWS1 would include environmental commitments to benefit special-status alkali seasonal wetland species.

- Protect two currently unprotected occurrences of San Joaquin spearscale in Conservation Zones 1, 8, or 11 (Resource Restoration and Performance Principle ASWS1).

Modeled habitat for Delta button-celery would be adversely affected by construction of the Alternative 4A water conveyance facilities. One population of crownscale also would be adversely affected by construction of the water conveyance facilities. No adverse effects on palmate-bracted bird's-beak or recurved larkspur would be expected. Table 12-4A-62 summarizes the acreage of modeled alkali seasonal wetland habitat in the study area and the number of occurrences of each special-status alkali seasonal wetland plant species in the study area.

Table 12-4A-62. Summary of Impacts on Seasonal Alkali Wetland Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
San Joaquin spearscale modeled habitat	14,933	78	—	—	Habitat loss from construction of water conveyance facilities
Brittlescale modeled habitat	451	0	—	—	
Heartscale modeled habitat	6,528	0	—	—	
Delta button-celery modeled habitat	3,361[a]	108	—	—	Habitat loss from construction of water conveyance facilities
Alkali seasonal wetlands	3,723	2	—	—	Habitat loss from construction of water conveyance facilities
Species					
San Joaquin spearscale	—	—	19	1	Population loss from construction of water conveyance facilities
Brittlescale	—	—	8	0	None
Heartscale	—	—	3	0	None
Delta button-celery	—	—	1[b]	0	None
Heckard's peppergrass	—	—	1[c]	0	
Crownscale	—	—	17	1	Population loss from construction of water conveyance facilities
Palmate-bracted bird's-beak	—	—	1	0	None
Recurved larkspur	—	—	4	0	None

[a] A portion of this acreage consists of riparian habitat.
[b] A second occurrence in study area is in riparian habitat.
[c] Four additional occurrences of Heckard's peppergrass are associated with vernal pools.

Impact BIO-170: Effects on Habitat and Populations of Alkali Seasonal Wetland Plants

Alternative 4A would have adverse effects on modeled habitat for San Joaquin spearscale and Delta button-celery. It would also have adverse effects on occurrences of San Joaquin spearscale and crownscale. Under Alternative 4A, construction of the Byron Tract Forebay would permanently remove 78 acres of modeled habitat for San Joaquin spearscale and 108 acres of modeled habitat for Delta button-celery. This could be an adverse effect, depending on whether or not the affected modeled habitat is actually occupied by the species. Modeled habitat is assumed to encompass all potential habitat for a species and may therefore overestimate the area actually occupied. One known occurrence of San Joaquin spearscale near the forebay would be affected by facilities construction. Delta button-celery is not known to occur in CZ 8; the nearest known occurrence, in CZ 9, would not be affected. Construction of the water conveyance facilities would permanently remove about 1.5 acre of habitat occupied by crownscale at the Byron Tract Forebay. All or most of the occurrence would be directly affected. Construction of the water conveyance facilities would not affect brittlescale, heartscale, Heckard's peppergrass, palmate-bracted bird's-beak, or recurved larkspur.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A would benefit alkali seasonal wetland plants by including alkali seasonal wetland in vernal pool complex habitat that would be protected and restored. The protected alkali seasonal wetland habitat would be managed and enhanced to sustain populations of native plant species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: No tidal habitat restoration would be implemented in habitat for special-status plant species. Therefore, tidal habitat restoration would not affect special-status alkali seasonal wetland species.
- *Environmental Commitment 6 Channel Margin Enhancement*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plant species are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status alkali seasonal wetland species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plant species are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on special-status alkali seasonal wetland species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Although some vernal pools are alkaline, alkali seasonal wetlands in the study area consist of alkali grassland, alkali meadow, or iodine bush scrub. Therefore, vernal pool restoration would avoid alkali seasonal wetland habitat and would have no impacts on special-status alkali seasonal wetland plants. In addition, the environmental commitments would compensate for the loss of alkali seasonal wetlands resulting from other environmental commitments by restoring vernal pool complex that includes alkali seasonal wetlands to achieve no net loss of this habitat.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid alkali seasonal wetland habitat and would have no impacts on special-status alkali seasonal wetland plant species.

Avoidance and Minimization Measures: Effects on special-status alkali seasonal wetland plants potentially resulting from implementation of the water conveyance facilities would be avoided or minimized through *AMM2 Construction Best Management Practices and Monitoring, AMM11 Covered Plant Species,* and *AMM30 Transmission Line Design and Alignment Guidelines*. Under AMM11, surveys for special-status plant species would be performed during the planning phase of projects, and any impacts on populations of special-status species would be avoided through project design or subsequently minimized though AMM2. In addition, AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools, which would protect those species with modeled habitat that includes vernal pool complex. Occurrences of special-status species in vernal pools near tidal wetlands would not be affected by tidal habitat restoration where critical habitat for vernal pool species is present and would be avoided under AMM11. AMM30 requires that transmission line construction avoid any losses of alkali seasonal wetland complex natural community. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization*

Measures, of the Draft BDCP, and updated versions of AMM2 and AMM11 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

In summary, only one known occurrence of a special-status alkali seasonal wetland species (crownscale) would be affected under Alternative 4A. AMM11 would be implemented to avoid an adverse effect on the San Joaquin spearscale occurrence.

The primary effect of Alternative 4A on special-status alkali seasonal wetland plant species would be the loss of potential (i.e., modeled) habitat for San Joaquin spearscale and Delta button-celery. Approximately 2 acres of this habitat loss would be alkali seasonal wetlands. The actual effect on modeled habitat for alkali seasonal wetland species is expected to be somewhat less than the estimated impact because some of this habitat is composed of vernal pool complex, and the total loss of wetted vernal pool habitat is limited to 10 acres (approximately 67 acres of vernal pool complex) (AMM12). Loss of modeled habitat would be compensated for by restoring or creating vernal pool complex, alkali seasonal wetlands, and grasslands, in proportion to the amount of each habitat removed. At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat composed of vernal pool complex. Loss of modeled habitat composed of grasslands would be compensated for by restoring grassland habitat on a 1:1 basis. These compensation levels would be consistent with typical NEPA and CEQA project-level mitigation ratios for impacts on vernal pools, alkali seasonal wetlands, and grasslands.

Alternative 4A would have a small beneficial effect on special-status alkali seasonal wetland plants by protecting a small amount of alkali seasonal wetland habitat. The environmental commitments also include protecting 2 occurrences of San Joaquin spearscale.

NEPA Effects: Under Alternative 4A, loss of modeled habitat for alkali seasonal wetland plant species would be offset through restoration of grassland, vernal pool, and alkali seasonal wetland habitat (Environmental Commitment 8, Environmental Commitment 9), and impacts on one occurrence of San Joaquin spearscale would be avoided through AMM11. With avoidance and habitat restoration, these effects would not be adverse. The loss of one occurrence of crownscale, a non-listed species, would result in a reduction in the range and numbers of this species and would be an adverse effect. Adverse effects on crownscale could be avoided or offset through implementation of Mitigation Measure BIO-170.

CEQA Conclusion: Because loss of modeled habitat for alkali seasonal wetland plant species would be offset through restoration, and because impacts on occurrences of special-status alkali seasonal wetland species would be avoided, impacts on alkali seasonal wetlands as a result of implementing Alternative 4A would not result in substantially reducing the number or restricting the range of seven special-status alkali seasonal wetland plant species. However, environmental commitments that benefit or protect listed species do not apply to nonlisted species, and loss of the crownscale population at Byron Tract Forebay would be a significant impact. Implementation of Mitigation Measure BIO-170 would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Special-Status Plant Species

DWR will evaluate all projects for their impacts on special-status plant species, avoid or minimize impacts on species that occur on project sites, and compensate for impacts on species. All impacts on federally listed species, diamond-petaled California poppy, or caper-fruited tropidocarpum shall be avoided. Impacts on other special-status plant species shall be avoided to the extent feasible, and any unavoidable impacts shall be compensated for.

- DWR shall conduct surveys for special-status plant species within and adjacent to all project sites. Special-status plant surveys required for project-specific permit compliance will be conducted during the planning phase to allow design of the individual restoration projects to avoid adverse modification of habitat for specified plant species. The purpose of these surveys will be to verify that the locations of special-status species identified in previous record searches or surveys are extant, identify any new special-status plant species occurrences, and cover any portions of the project area not previously surveyed. The extent of mitigation of direct loss of or indirect effects on special-status plant species will be based on these survey results.
- All surveys shall be conducted by qualified biologists using the using *Guidelines for Conducting and Reporting Botanical Inventories for Federally Listed, Proposed and Candidate Plants* (U.S. Fish and Wildlife Service 1996) and *Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities* (California Department of Fish and Game 2009) during the season that special-status plant species would be evident and identifiable, i.e., during their blooming season. Locations of special-status plant species in proposed construction areas will be recorded using a GPS unit and flagged.
- The construction monitoring plan for the protection of special-status fish, wildlife, and plant species, prepared by DWR before implementing an approved project, will provide for construction activity monitoring in areas identified during the planning stages and species/habitat surveys as having special-status plant species.
- Where surveys determine that a special-status plant species is present in or adjacent to a project site, direct and indirect impacts of the project on the species shall be avoided through the establishment of 250-foot activity exclusion zones surrounding the periphery of the occurrences, within which no ground-disturbing activities shall take place, including construction of new facilities, construction staging, or other temporary work areas. Activity exclusion zones for special-status plant species shall be according to a 250-foot buffer surrounding the periphery of each special-status plant species occurrence, the boundaries of which shall be clearly marked with standard orange plastic construction exclusion fencing or its equivalent. The establishment of activity exclusion zones shall not be required if no construction-related disturbances will occur within 250 feet of the occupied habitat site. The size of activity exclusion zones may be reduced through consultation with a qualified biologist and with concurrence from USFWS or CDFW based on project site-specific conditions.
- Where avoidance of impacts on a special-status plant species is infeasible, DWR will compensate for loss of individuals or occupied habitat of a special-status plant species through the acquisition, protection, and subsequent management in perpetuity of other existing occurrences at a 2:1 ratio (occurrences affected:occurrences preserved). DWR will provide detailed information to USFWS and CDFW on the location of the preserved occurrences, quality of the preserved habitat, feasibility of protecting and managing the areas in-perpetuity, responsible parties, and other pertinent information. If suitable occurrences of a special-status plant species are not available for preservation, then the project shall be redesigned to remove features that would result in impacts on that species.

Grassland Species

Twelve special-status plant species occur in grasslands in the study area (Tables 12-2, 12-3, summarized in Table 12-4A-63). The only modeled plant species occurring in grassland is Carquinez goldenbush. Because this analysis relies on the data developed for the BDCP, models were only available for species covered under the BDCP. Habitat models were not developed for the six grassland species not proposed for coverage under the BDCP.

Carquinez goldenbush modeled habitat included hydrological features such as stream corridors on alluvium derived from the Montezuma Formation. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15 meters) on either side in an effort to capture the estimated maximum extent of alluvium deposits in close proximity to the actual rivers/streams.

Of 78,047 acres of grasslands in the study area, Alternative 4A would adversely affect 657 acres under Alternative 4A. No known occurrences of special-status grassland plant species would be affected. Table 12-4A-63 summarizes the acreage of grassland habitat in the study area and the number of occurrences of each special-status grassland species in the study area.

Table 12-4A-63. Summary of Impacts on Grassland Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Carquinez goldenbush modeled habitat	1,346	0	—	—	
Grassland	78,047	657	—	—	Habitat loss from construction of water conveyance facilities
Species					
Carquinez goldenbush	—	—	10	0	None
Big tarplant	—	—	5	0	None
Round-leaved filaree	—	—	2	0	None
Pappose tarplant	—	—	7	0	None
Parry's rough tarplant	—	—	5	0	None
Small-flowered morning-glory	—	—	0	0	None
Diamond-petaled poppy	—	—	1	0	None
Stinkbells	—	—	1	0	None
Fragrant fritillary	—	—	4	0	None
Gairdner's yampah	—	—	0	0	None
Streamside daisy[a]	—	—	1	0	None
Caper-fruited tropidocarpum	—	—	8	0	None

[a] This species actually occurs in upland woodland, a habitat that has not been mapped or quantified for analysis of Alternative 4A.

Impact BIO-171: Effects on Habitat and Populations of Grassland Plants

Alternative 4A would have no expected effects on known occurrences of special-status plant species that occur in grasslands. However, the loss of 657 acres of grassland would have the potential to affect undocumented populations of special-status grassland species.

No modeled habitat for Carquinez goldenbush and no known occurrences of the 12 special-status grassland plant species are within the proposed footprint for the Alternative 4A water conveyance facilities. About 657 acres of grassland habitat would be affected by construction of the water conveyance facilities. However, this grassland habitat consists of small patches of herbaceous ruderal vegetation along levees that do not provide habitat for special-status grassland species. Therefore, under Alternative 4A, construction and operation of the water conveyance facilities would not affect the 12 special-status grassland species.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A would preserve 1,060 acres of grassland habitat. Protection of grassland habitat may also protect undiscovered occurrences of special-status plant species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration would not affect modeled habitat for Carquinez goldenbush. No other occurrences of special-status grassland plants are within portions of the study area potentially suitable for tidal restoration. Therefore, tidal restoration would have no impacts on known occurrences of special-status grassland plants.
- *Environmental Commitment 6 Channel Margin Enhancement*: No known occurrences of special-status grassland plants are present within areas proposed for channel margin habitat enhancement. Areas mapped as grassland along levees that would be affected by channel margin habitat enhancement are small patches of ruderal vegetation along levees that do not provide habitat for special-status grassland species and are not modeled habitat for Carquinez goldenbush. Therefore, channel margin habitat enhancement would have no impacts on special-status grassland plants.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No modeled habitat for Carquinez goldenbush or known occurrences of special-status grassland plants are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on special-status grassland plant species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Vernal pool complex includes vernal pools as well as the surrounding grassland matrix. Because the habitat to be restored would consist of areas of former vernal pool complex that have been leveled for cultivation, special-status grassland plant species would not be present. Therefore, vernal pool complex restoration would not affect special-status grassland plant species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid grassland habitat and would have no impacts on special-status grassland plant species.
- *Avoidance and Minimization Measures*: Potential effects on undiscovered populations of special-status grassland plants would be avoided or minimized though *AMM11 Covered Plant Species,* and *AMM2 Construction Best Management Practices and Monitoring*. Under AMM11, surveys for special-status plant species would be performed during the planning phase of projects, and any impacts on populations of special-status species would be avoided through project design or

subsequently minimized through AMM2. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM11 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

NEPA Effects: Implementation of Alternative 4A would result in no adverse effects on federally-listed grassland plant species.

CEQA Conclusion: Alternative 4A would have no impacts on special-status grassland species. No mitigation is required.

Valley/Foothill Riparian Species

Four special-status plant species occur in valley/foothill riparian habitat in the study area (Tables 12-2, 12-3, summarized in Table 12-4A-64). Habitat modeling was done for two species, Delta button celery and slough thistle. Because this analysis relies on the data developed for the BDCP, models were only available for species covered under the BDCP. Habitat models were not developed for the two valley/foothill species not proposed for coverage under the BDCP.

The valley/foothill riparian habitat model for Delta button-celery and slough thistle was mapped as all of the study area along the flood plain of the San Joaquin River between the levees from the Mossdale Bridge to Vernalis. Whether or not this modeled habitat is actually occupied by Delta button-celery and slough thistle is unknown; all known occurrences of these species within the area of modeled habitat are believed to be extirpated.

Of 17,966 acres of valley/foothill riparian habitat in the study area, Alternative 4A would affect73 acres, none of which is modeled habitat for Delta button-celery and slough thistle. Table 12-4A-64 summarizes the acreage of modeled habitat for Delta button-celery and slough thistle and the number of occurrences of each special-status riparian species in the study area.

Table 12-4A-64. Summary of Impacts on Valley/Foothill Riparian Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Delta button-celery modeled habitat	3,361[a]	0	—	—	None
Slough thistle modeled habitat	1,834	0	—	—	None
Valley/foothill riparian habitat	17,966	73	—	—	Habitat loss from construction of water conveyance facilities
Species					
Delta button-celery	—	—	1[b]	0	None
Slough thistle	—	—	2	0	None
Northern California black walnut	—	—	1	0	None
Wright's trichocoronis	—	—	1	0	None

[a] A portion of this acreage consists of alkali seasonal wetland
[b] A second occurrence is in alkali seasonal wetland

Impact BIO-172: Effects on Habitat and Populations of Valley/Foothill Riparian Plants

No extant occurrences of Delta button-celery, slough thistle, Northern California black walnut, or Wright's trichocoronis are present in the study area. Therefore, no impacts on special-status valley/foothill riparian plant species are expected. Modeled habitat for Delta button-celery and slough thistle, which may support undocumented occurrences of these species, would not be affected by construction of the water conveyance facilities.

Construction of the water conveyance facilities would remove 73 acres of valley-foothill riparian habitat under Alternative 4A. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian species are within the proposed footprint for the Alternative 4A water conveyance facilities. Therefore, under Alternative 4A, construction and operation of the water conveyance facilities would not affect special-status valley/foothill riparian species.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A would protect 103 acres of existing valley/foothill riparian forest in CZ 7. This action would have no substantial effects on special-status valley/foothill plants because no extant occurrences of special-status valley/foothill plants are present in the study area.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration would inundate 5 acres of valley/foothill riparian habitat. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the portions of the study area potentially suitable for tidal restoration. Therefore, tidal restoration would not affect the special-status valley/foothill riparian plants.
- *Environmental Commitment 6 Channel Margin Habitat Enhancement*: No modeled habitat or occurrences of special-status valley/foothill riparian plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status valley/foothill riparian plant species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No extant occurrences of special-status valley/foothill riparian plant species are present within areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on special-status valley/foothill riparian plant species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No occurrences of special-status valley/foothill riparian plant species are present within areas proposed for vernal pool and alkali seasonal wetland complex restoration. Therefore, vernal pool complex restoration would have no impacts on special-status valley/foothill riparian species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid valley/foothill riparian habitat and would have no impacts on special-status valley/foothill riparian plant species.
- *Avoidance and Minimization Measures*: Effects on Delta button-celery and slough thistle potentially resulting from implementation of Environmental Commitment 5 would be avoided or minimized though *AMM11 Covered Plant Species* and *AMM2 Construction Best Management Practices and Monitoring*. Under AMM11, surveys for special-status plant species would be performed during the planning phase of projects, and any impacts on populations of special-status species would be avoided through project design or subsequently minimized though

AMM2. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM11 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

Because no extant occurrences of special-status valley/foothill riparian plants are known to occur in the study area, Alternative 4A is not expected to adversely affect any special-status valley/foothill riparian plants. Modeled habitat for both Delta button-celery and slough thistle would be affected. Under AMM11, surveys for special-status plants would be performed during the planning phase for floodplain restoration. If Delta button-celery or slough thistle were found to be present in the floodplain restoration area, then the project would be designed to avoid impacts on the populations. Therefore, Alternative 4A would not have an adverse effect on these species.

NEPA Effects: Implementation of Alternative 4A would not have an adverse effect on federally-listed valley/foothill riparian plant species.

CEQA Conclusion: Alternative 4A would have no impact on special-status valley/foothill riparian plant species. No mitigation is required.

Tidal Wetland Species

Eight special-status plant species occur in tidal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-4A-65). Five tidal wetland habitat models were developed for special-status plant species occurring in tidal wetland habitat. Because this analysis relies on the data developed for the BDCP, models were only available for species covered under the BDCP. Habitat models were not developed for the Bolander's water hemlock, which was not proposed for coverage under the BDCP.

Modeled habitat for Mason's lilaeopsis and Delta mudwort was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover type, which was obtained from the BDCP GIS vegetation data layer.

The side-flowering skullcap model mapped the distribution of suitable habitat in the study area according to the species' habitat association with woody riparian habitat. The model selected Delta riparian vegetation types providing the habitat characteristics that side-flowering skullcap seems to require, namely, woody substrate in freshwater tidal areas. The model included vegetation subunits of the BDCP Valley Riparian natural community characterized by California dogwood, white alder, and arroyo willow.

The modeled habitat for soft bird's-beak consisted of pickleweed- and saltgrass-dominated vegetation units located west of the Antioch Bridge. Modeled habitat for these two plant species was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover types. The model used all Tidal Brackish Emergent Wetland polygons that were limited by specific vegetation units that are known to be closely associated with soft bird's-beak habitat.

Habitat for Delta tule pea and Suisun Marsh aster was modeled separately based on the salinity of the water. For the tidal freshwater emergent wetland BDCP land cover type, modeled habitat was mapped as the area within 10 feet (3 meters) of the landward side of the landward boundary, exclusively where this land cover type is adjacent to grassland, vernal pool complex, valley/foothill riparian, or cultivated land habitats cover types. For brackish water areas in and near Suisun Marsh, the model used all tidal brackish emergent wetland polygons within an elevation range of 7 to 10 feet (2 to 3 meters) to capture elevations 1 foot (30 centimeters) below intertidal to 2 feet (60 centimeters) above intertidal.

The modeled habitat for Suisun thistle in and near Suisun Marsh consists of all tidal brackish emergent wetland polygons with the appropriate vegetation. This included vegetation units dominated by saltscale, saltgrass, pickleweed, and broad-leaved peppergrass.

Full implementation of Alternative 4A and compliance with Resource Restoration and Performance Principles TWS1 and TWS2 would include the following environmental commitments to minimize impacts on tidal wetland species.

- No net loss of Mason's lilaeopsis and delta mudwort occurrences within restoration sites (Resource Restoration and Performance Principle TWS1).
- No net loss of Delta tule pea and Suisun Marsh aster occurrences within restoration sites (Resource Restoration and Performance Principle TWS2).

Of 17,357 acres of tidal wetlands in the study area, Alternative 4A would affect 18 acres, including areas that are modeled habitat for Mason's lilaeopsis, Delta mudwort, side-flowering skullcap, Delta tule pea, and Suisun Marsh aster. Known occurrences Mason's lilaeopsis, side-flowering skullcap, and Suisun Marsh aster would be affected. Table 12-4A-65 summarizes the acreage of modeled habitat for special-status tidal wetland species and the number of occurrences of each special-status tidal wetland plant species in the study area.

Table 12-4A-65. Summary of Impacts on Tidal Wetland Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Delta mudwort/ Mason's lilaeopsis modeled habitat	6,081	39	—	—	Habitat loss from construction of water conveyance facilities
Side-flowering skullcap modeled habitat	2,497	9	—	—	Habitat loss from construction of water conveyance facilities
Soft bird's-beak modeled habitat	1,228	0	—	—	None
Delta tule pea/Suisun Marsh aster modeled habitat	5,853	3	—	—	Habitat loss from construction of water conveyance facilities
Suisun thistle modeled habitat	1,281	0	—	—	None
Tidal brackish emergent wetland	8,501	0	—	—	None
Tidal freshwater emergent wetland	8,856	18	—	—	Habitat loss from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Species					
Delta mudwort	—	—	58	0	None
Delta tule pea	—	—	106	0	
Mason's lilaeopsis	—	—	181	8	Occurrences affected by construction of water conveyance facilities
Side-flowering skullcap	—	—	12	1	Occurrence affected by construction of water conveyance facilities
Soft bird's-beak	—	—	13	0	None
Suisun Marsh aster	—	—	164	3	Occurrences affected by construction of water conveyance facilities
Suisun thistle	—	—	4	0	None
Bolander's water hemlock	—	—	8	0	None

Impact BIO-173: Effects on Habitat and Populations of Tidal Wetland Plants

Alternative 4A would have adverse effects on tidal marsh special-status plant species.

The individual effects of each relevant environmental commitment are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual activity discussions.

Water Facilities and Operations: Construction of the Alternative 4A water conveyance facilities would remove 39 acres of modeled habitat for delta mudwort and Mason's lilaeopsis, 9 acres of modeled habitat for side-flowering skullcap, and 3 acres of modeled habitat for Delta tule pea and Suisun Marsh aster. The extent to which modeled habitat is actually occupied by these species is not known; however, eight occurrences of Mason's lilaeopsis, three occurrences of Suisun Marsh aster, and one occurrence of side-flowering skullcap in the study area could be affected by construction impacts. No known occurrences of the other special-status tidal wetland species would be affected by construction of the water conveyance facilities.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: Alternative 4A does not specifically propose to protect any habitat or occurrences of tidal wetland plants nor does it propose active restoration of affected habitat or occurrences.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: Tidal habitat restoration would not affect modeled habitat for Mason's lilaeopsis and Delta mudwort or any occurrences of tidal wetland special-status plant species.
- *Environmental Commitment 6 Channel Margin Enhancement*: Effects of channel margin enhancement were not analyzed. Channel margin enhancement could have adverse effects on tidal wetland plants through direct removal and habitat modification. However, it would compensate for effects on these species by improving the habitat functions of the channel margins as a result of riprap removal and creation of floodplain benches. Side-flowering skullcap would benefit from installation of large woody material, which it appears to colonize.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian habitat restoration is not expected to adversely affect special-status tidal wetland plants. Preparatory work that involves habitat disturbance would occur during implementation of Environmental Commitment 4 and Environmental Commitment 5. Riparian plantings carried out for Environmental Commitment 7 would be placed in floodplain areas, not in tidal wetlands.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: No tidal wetlands or occurrences of special-status tidal wetland plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on special-status tidal wetland plant species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No tidal wetlands or occurrences of special-status tidal wetland plant species are present within areas proposed for vernal pool complex restoration. Therefore, vernal pool complex restoration would have no impacts on special-status tidal wetland plant species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid tidal wetland habitat and would have no impacts on special-status tidal wetland plant species.

Avoidance and Minimization Measures: Effects on special-status tidal wetland plant species potentially resulting from construction of the water conveyance facilities would be avoided or minimized though *AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring,* and *AMM30 Transmission Line Design and Alignment Guidelines*. Under AMM11, surveys for special-status plant species would be performed during the planning phase of projects, and any impacts on populations of special-status species would be avoided through project design or subsequently minimized though AMM2. AMM30, which specifies that the alignment of proposed transmission lines will be designed to avoid sensitive terrestrial and aquatic habitats when siting poles and towers, to the maximum extent feasible, would avoid some impacts on Mason's lilaeopsis and side-flowering skullcap. The AMMs are described in detail in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and updated versions of AMM2 and AMM11 are described in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

In summary, the GIS analysis indicates that Alternative 4A would result in the loss of modeled habitat for five special-status species and result in adverse effects on known occurrences of three of the special-status species occurring in tidal wetlands.

Delta mudwort could lose 39 acres of modeled habitat, but no known occurrences would be affected. Channel margin enhancement (Environmental Commitment 6) and riparian natural community restoration (Environmental Commitment 7) will consider the potential for creating habitat for Delta mudwort; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, natural expansion of populations into the restored habitat may take place

Mason's lilaeopsis could lose 39 acres of modeled habitat), including all or part of eight occurrences. Tidal habitat restoration activities (Environmental Commitment 4) would increase the extent of habitat available for colonization by Mason's lilaeopsis, which could offset this habitat loss. Although active restoration of this species is not proposed, the natural expansion of populations into the restored habitat may take place. The environmental commitments include post-implementation monitoring of affected occurrences and occurrences in reserve lands to confirm that no net loss of occurrences has been achieved.

Both of these species (Delta mudwort, Mason's lilaeopsisr) are widespread in the study area with many occurrences. Habitat modification and loss are the primary stressors that are responsible for their decline and that currently limit their distribution and abundance. Therefore, restoring habitat and improving habitat functions for these species would provide a reasonable expectation that the distribution and abundance of these species would also improve. Because a relatively small amount of modeled habitat would be adversely affected, it is likely that the initial adverse effects of construction activities on these species would be offset and that the overall effect of Alternative 4A on these species would not be adverse.

Side-flowering skullcap could lose one occurrence. Under AMM11, this occurrence would be surveyed for, and because this is a tidal freshwater wetland species, avoidance of the habitat during project construction would be highly likely. No active restoration of this species is proposed, and no post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done. Because impacts on occurrences of side-flowering skullcap would be avoided, the overall effect of Alternative 4A on this species would not be adverse.

***NEPA Effects*:** The loss of modeled and occupied habitat for special-status tidal wetland plants would be offset through tidal habitat restoration (Environmental Commitment 4). Therefore, implementation of Alternative 4A would result in no adverse effects on eight special-status tidal wetland plant species in the study area.

CEQA Conclusion**:** Because loss of occurrences and modeled habitat for special-status tidal habitat plant species would be offset through habitat restoration, impacts on special-status tidal wetland plants as a result of implementing Alternative 4A would not be significant.

Inland Dune Species

Five special-status plant species occur in inland dune habitat in the study area. No habitat models were prepared for inland dune habitat. Table 12-4A-66 summarizes the acreage of inland dune habitat in the study area and the number of occurrences for each special-status inland dune species in the study area.

Table 12-4A-66. Summary of Impacts on Inland Dune Plants under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Inland Dunes	19	0	—	—	None
Species					
Hoover's cryptantha	—	—	1	0	None
Antioch Dunes buckwheat	—	—	1	0	None
Mt. Diablo buckwheat	—	—	1	0	None
Contra Costa wallflower	—	—	3	0	None
Antioch Dunes evening-primrose	—	—	9	0	None

Impact BIO-174: Effects on Habitat and Populations of Inland Dune Plants

Alternative 4A would have no adverse effects on inland dune species (Table 12-4A-66). No construction activities would take place where the species occur. No specific actions to benefit inland dune species are proposed.

NEPA Effects**:** Implementation of Alternative 4A would not affect special-status inland dune species.

CEQA Conclusion**:** Implementation of Alternative 4A would have no impacts on inland dune species. No mitigation is required.

Nontidal Wetland Species

Six special-status plant species occur in nontidal wetlands in the study area. Table 12-4A-67 summarizes the acreage of nontidal wetland habitat in the study area and the number of occurrences of each special-status nontidal wetland species in the study area.

Table 12-4A-67. Summary of Impacts on Nontidal Wetland Plant Species under Alternative 4A

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Nontidal freshwater aquatic	5,567	69	—	—	Loss of habitat from construction of water conveyance facilities
Nontidal freshwater perennial emergent wetland	1,509	8	—	—	Loss of habitat from construction of water conveyance facilities
Species					
Watershield	—	—	3	1	Loss of habitat from construction of water conveyance facilities
Bristly sedge	—	—	18	3	Loss of occurrences from construction of water conveyance facilities
Woolly rose-mallow[a]	—	—	121	14	Loss of occurrences from construction of water conveyance facilities
Eel grass pondweed	—	—	1	0	None
Sanford's arrowhead	—	—	23	1	Loss of occurrences from construction of water conveyance facilities
Marsh skullcap[a]	—	—	1	0	None

[a] Also occurs in valley/foothill riparian habitat.

Impact BIO-175: Effects on Habitat and Populations of Nontidal Wetland Plants

Under Alternative 4A, known occurrences watershield, bristly sedge, woolly rose-mallow, and Sanford's arrowhead would be within the proposed footprint for the water conveyance facilities and could be adversely affected. Alternative 4A would have no adverse effects on eel-grass pondweed or marsh skullcap.

Construction of the Alternative 4A water conveyance facilities would adversely affect four special-status plant species occurring in nontidal wetlands. One of three watershield occurrences in CZ 5 on Bouldin Island could be affected by construction of the water conveyance facilities. This is a historical occurrence that has not been observed since 1893, and it may be extirpated (California Department of Fish and Wildlife 2013). Three occurrences of bristly sedge in CZ 4 and CZ 5, including approximately 1.54 acres of occupied habitat, would be affected by construction of the water conveyance facilities. Fourteen occurrences of woolly rose-mallow would be affected. Six occurrences in CZ 4 could be removed during construction of the intake facilities and disposal of RTM, and four occurrences in CZ 6 and four occurrences in CZ 8 could be affected by construction of other facilities and by geotechnical investigations. Construction of the water conveyance facilities could remove occupied habitat at one occurrence of Sanford's arrowhead in CZ 4. Under Alternative 4A, construction and operation of the water conveyance facilities could affect 77 acres of nontidal wetlands, which could have adverse effects on undiscovered occurrences of the six special-status nontidal wetland plant species.

- *Environmental Commitment 3 Natural Communities Protection and Restoration*: No specific natural communities protection is proposed for nontidal wetlands under Alternative 4A. Therefore, no occurrences of special-status nontidal plants are proposed for protection.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: No habitat or known occurrences of special-status nontidal wetland plants are present within areas proposed for tidal habitat restoration. Therefore, tidal habitat restoration would have no adverse effects on special-status nontidal wetland plants.
- *Environmental Commitment 6 Channel Margin Enhancement*: No known occurrences of special-status nontidal wetland plant species are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on known occurrences of special-status nontidal wetland species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: No known occurrences of special-status nontidal wetland plant species are present within areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on known occurrences of special-status nontidal wetland species.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: No known occurrences of special-status nontidal wetland plant species are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on special-status nontidal wetland species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for vernal pool complex restoration. Therefore, vernal pool complex restoration would have no impacts on special-status nontidal wetland plants.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid existing nontidal marsh and would have no adverse effects on special-status nontidal wetland plants. Alternative 4A may benefit nontidal wetland species by creating 832 acres of nontidal freshwater marsh, including components of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland communities, and by maintaining and enhancing the habitat functions of protected and created nontidal wetland habitats for special-status and other native species. However, no specific actions to benefit special-status species are proposed.

Under Alternative 4A, 119 acres of nontidal marsh would be restored. However, these wetlands would be restored primarily as habitat for giant garter snake. These habitat restoration activities would be unlikely to expand the amount of habitat available to watershield, bristly sedge, woolly rose-mallow, and Sanford's arrowhead, and potential loss of habitat or occurrences resulting from construction activities would not be compensated for. Moreover, because special-status nontidal wetland plant species are not covered under environmental commitments, the species protections afforded to listed species under the AMMs do not apply to these species, and the effects of Alternative 4A on these species would be adverse. Implementation of Mitigation Measure BIO-170, *Avoid, Minimize, or Compensate for Impacts on Special-Status Plant Species*, would reduce these effects.

NEPA Effects: Implementation of Alternative 4A could result in a reduction in the range and numbers of watershield, bristly sedge, woolly rose-mallow, and Sanford's arrowhead, four nontidal wetland species, which would be an adverse effect. Adverse effects on these species could be avoided or offset through implementation of Mitigation Measure BIO-170.

CEQA Conclusion: Under Alternative 4A, construction of the water conveyance facilities could result in a reduction in the range and numbers of watershield, bristly sedge, woolly rose-mallow, and Sanford's arrowhead. These impacts would be significant. Implementation of Mitigation Measure BIO-170 would reduce these impacts to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Special-Status Plant Species

Please see Mitigation Measure BIO-170 under Impact BIO-170.

4.3.1.2 General Terrestrial Biology

Wetlands and Other Waters of the United States

Alternative 4A actions would both permanently and temporarily remove or convert wetlands and open water that are regulated by USACE under Section 404 of the CWA. The 404 regulations and relevant information on mitigating the effects of impact on wetlands and other waters of the United States (waters of the U.S.) are described in Section 12.2.1.1 in Appendix A, *Draft EIR/EIS In-Text Chapter Revisions*, of this RDEIR/SDEIS. The methods used to conduct these analyses are described in Section 12.3.2.4 in Appendix A, *Draft EIR/EIS In-Text Chapter Revisions* of this RDEIR/SDEIS. Waters of the U.S. data used for this analysis is based on a verified wetland delineation from the USACE that was completed in early 2015. The waters of the U.S. were mapped at a finer scale than that which was done for the natural community mapping for the BDCP and therefore the acreages of these two datasets differ when compared to each other. The waters of the U.S. mapping identified numerous agricultural ditches and seasonal wetlands occurring within and associated with cultivated lands, which explains the majority of the difference.

Impact BIO-176: Effects of Constructing Water Conveyance Facilities on Wetlands and Other Waters of the United States

Alternative 4A proposes the construction, maintenance, and operation of water conveyance facilities within, or requiring the unavoidable fill of, waters of the U.S. The estimated fill of jurisdictional waters associated with this alternative is described in Table 12-4A-68 below. Based on the methodology used to conduct this analysis, the losses would occur at intake, tunnel, pipeline, canal, and RTM and borrow/spoil storage sites, transmission corridors, and multiple temporary work areas associated with the construction activity. The permanent waters of the U.S. losses would occur at various locations along the modified pipeline/tunnel alignment. The majority of the loss would occur due to the expansion of Clifton Court Forebay, new transmission lines, construction of Alternative 4A's three intake structures along the eastern bank of the Sacramento River between Clarksburg and Courtland in the north Delta, and at the RTM storage sites associated with tunnel construction at various locations between Lambert Road and Twin Cities Road, on Bouldin Island, and on Byron Tract, adjacent to Clifton Court Forebay.

The temporary effects on waters of the U.S. would also occur mainly at the three intake construction sites along the eastern bank of the Sacramento River, and at barge unloading facilities in the San

Joaquin River, Snodgrass Slough, Potato Slough, Connection Slough, Old River, and West Canal. An additional temporary effect would result from dredging of Clifton Court Forebay.

Table 12-4A-68. Estimated Fill of Waters of the U.S. Associated with the Construction of Water Conveyance Facilities under Alternative 4A

Wetland/Water Type	Permanent Impact	Temporary Impacts Treated as Permanent[a]	Temporary Impact[b]	Total Impact[c]
Agricultural Ditch	45.5	17.4	0	62.9
Alkaline Wetland	20.3	0.1	0	20.4
Clifton Court Forebay	258.0	0	1,931.0	258.0
Conveyance Channel	8.0	2.9	0	10.8
Depression	29.3	7.1	0	36.4
Emergent Wetland	57.2	31.5	0	88.8
Forest	8.3	8.6	0	16.9
Lake	23.2	0	0	23.2
Scrub-Shrub	12.8	5.4	0	18.1
Seasonal Wetland	114.6	25.1	0	139.7
Tidal Channel	19.2	80.7	0	99.9
Vernal Pool	0.3	0	0	0.3
Total	**597**	**179**	**1,931**	**775**

[a] Temporary impacts treated as permanent are temporary impacts expected to last over one year. These impact sites will eventually be restored to pre-project conditions; however, due to the duration of effect, compensatory mitigation will be included for these areas.
[b] Temporary impacts are due to dredging Clifton Court Forebay.
[c] Total does not include temporary impacts on Clifton Court Forebay because these would just be temporary disturbance to open water, which typically do not require compensatory mitigation.

The majority of the impacts on wetlands and waters of U.S. are to wetlands found within cultivated lands (mostly agricultural ditches and seasonal wetlands) and waters associated with Clifton Court Forebay. The impacted seasonal wetlands mapped within the Conveyance Planning Area, as described in Section 12.3.2.4 in Appendix A, *Draft EIR/EIS In-Text Chapter Revisions*, of this RDEIR/SDEIS, all occur in the central Delta within plowed agricultural fields and would be mostly affected by the RTM storage sites and transmission line construction. The effects on Clifton Court Forebay would primarily result from the establishment of new embankments around and across the existing forebay. The forebay would be expanded to the south by an additional 450 acres of storage space resulting in a net gain of open water in the forebay.

Unavoidable impacts on waters of the United States would be offset such that the loss of acreage and functions due to construction activities are fully compensated. Wetland functions are defined as a process or series of processes that take place within a wetland. These include the storage of water, transformation of nutrients, growth of living matter, and diversity of wetland plants, and they have value for the wetland itself, for surrounding ecosystems, and for people. Functions can be grouped broadly as habitat, hydrologic/hydraulic, or water quality. Not all wetlands perform all functions nor do they perform all functions equally well. The location and size of a wetland may determine what functions it will perform. For example, the geographic location may determine its habitat functions, and the location of a wetland within a watershed may determine its hydrologic/hydraulic or water-quality functions. Many factors determine how well a wetland will perform these functions: climatic conditions, quantity and quality of water entering the wetland, and disturbances or alteration within the wetland or the surrounding ecosystem. Wetland disturbances may be the result of natural conditions, such as an extended drought, or human activities, such as land clearing, dredging, or the introduction of nonnative species. Wetlands are among the most productive habitats in the world, providing food, water, and shelter for fish, shellfish, birds, and mammals, and serving as a breeding ground and nursery for numerous species. Many endangered plant and animal species are dependent on wetland habitats for their survival. Hydrologic and hydraulic functions are those related to the quantity of water that enters, is stored in, or leaves a wetland. These functions include such factors as the reduction of flow velocity, the role of wetlands as ground-water recharge or discharge areas, and the influence of wetlands on atmospheric processes. Water-quality functions include the trapping of sediment, pollution control, and the biochemical processes that take place as water enters, is stored in, or leaves a wetland.

The functions of the waters of the U.S. that will be temporarily or permanently impacted by this alternative vary greatly depending primarily on existing land uses and historical levels of disturbance. Generally, agricultural ditches and conveyance channels, which are regularly maintained and often devoid of vegetation, support only minimal hydraulic function (water conveyance), with virtually no water quality or habitat function. With respect to Clifton Court Forebay, the facility is regularly maintained, but supports some hydrologic, hydraulic, and water quality functions (e.g., reduction of velocity, groundwater recharge, and trapping of sediment). Tidal channels affected by this alternative support functions in all three categories, but the level at which these functions perform vary depending on setting, size, and level of disturbance. The alkaline wetlands and vernal pools exist in non-native grasslands and have been subjected to some disturbance due to past land uses. Although these features likely support habitat, water quality, and hydrologic/hydraulic functions, the capacity of these features to perform such functions vary depending on the overall ecological setting and level of disturbance. Functions associated with emergent wetland, forest, and scrub-shrub, depend primarily on the location of these habitat types. Where they exist as in-stream (in-channel islands) or as the thick band of habitat adjacent to a waterway, these features are expected to function at a high level. However, where these habitats exist as thin bands, or where they are situated in agricultural fields, their habitat functions will be considerably lower. All of the wetlands classified as seasonal wetlands occur in agricultural fields. As such, their habitat functions have been greatly compromised, but they retain some water quality and hydrologic/hydraulic function. Like seasonal wetlands, most depressions occur within agricultural areas; however the depressions may support wetland vegetation at their edges. The areas mapped as lake are the dredged borrow ponds created during the construction of Interstate 5. Although relatively small, each lake is likely performing functions from all three categories.

A functional assessment of wetlands proposed for fill will be conducted during the development of the Conceptual Mitigation Plan as part of the Clean Water Act permitting process. The results of this assessment will be compared to the expected functions at the proposed mitigation site(s) such that it can be confirmed that the compensatory mitigation will in fact accomplish full functional replacement of impacted wetlands. All impacted wetlands will be replaced with fully functional compensatory wetland habitat demonstrating high levels of habitat, water quality, and hydrologic/hydraulic function. Since many impacted wetlands will be significantly less than high function, the compensatory mitigation will result in a net increase in wetland function.

-

The proposed project was designed to avoid waters of the U.S, to the maximum extent practicable. Each of the conveyance components has been located in upland areas where it was feasible to do so. Once construction begins, specific measures will be implemented, as described in the AMMs set out in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS (AMM2 and AMM6), to further avoid and minimize effects to waters of the U.S. as well as to special-status species. The AMMs will be implemented at all phases of a project, from siting through design, construction, and on to operations and maintenance. The AMMs that pertain specifically to waters of the United States are AMM1 *Worker Awareness Training,* AMM2 *Construction Best Management Practices and Monitoring*, AMM3 *Stormwater Pollution Prevention Plan*, AMM4 *Erosion and Sediment Control Plan*, AMM5 *Spill Prevention, Containment, and Countermeasure Plan*, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 *Barge Operations Plan*, AMM10 *Restoration of Temporarily Affected Natural Communities*, AMM12 *Vernal Pool Crustaceans*, AMM30 *Transmission Line Design and Alignment Guidelines*, AMM34 *Construction Site Security*, and AMM36 *Notification of Activities in Waterways*.

The implementation of measures to avoid and minimize impacts on habitat for aquatic species and species which utilize aquatic habitats, such as California tiger salamander, giant garter snake, California red legged frog, western pond turtle, riparian woodrat, and riparian brush rabbit, will also result in further avoidance and minimization of effects to waters of the United States.

Aside from wetland habitats that would be created as a result of implementing Environmental Commitment 4–Environmental Commitment 10 described for Alternative 4A, some of which could serve the dual purpose of offsetting effects to species and mitigating impacts on waters of the U.S., more specific mitigation is required to ensure that there is no net loss of wetland functions and values as a result of implementing Alternative 4A pursuant to USACE's and U.S. EPA's Mitigation Rule (see Section 12.2.1.1 in Appendix A, *Draft EIR/EIS In-Text Chapter Revisions*, of this RDEIR/SDEIS). Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the U.S.* would be available to address adverse impacts on waters of the U.S.

NEPA Effects: The permanent and temporary loss of wetlands and waters of the U.S. as a result of constructing Alternative 4A water conveyance facilities would be a substantial effect if not compensated by wetland restoration and protection. This loss would represent a fill of water of the U.S. as defined by Section 404 of the CWA. The project proponents will implement AMMs 1–7, 10, 12, 30, 34, and 36, which would avoid and minimize fill of wetlands and waters and any indirect effects to wetlands and waters. However, specific mitigation would be required to ensure that Alternative 4A does not result in a loss of functions and values of waters of the U.S. and thus that the affect is not adverse. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the U.S.*, would be available to reduce these effects such that they are not adverse.

CEQA Conclusion: The permanent and temporary loss of wetlands and waters of the U.S. as a result of constructing Alternative 4A water conveyance facilities would be a significant impact. Specific mitigation would be required to ensure that Alternative 4A does not result in a loss of functions and values of waters of the U.S. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the U.S.*, would be available to reduce the impact to a less-than-significant level. Additionally, Alternative 4A would restore up to 896 acres of wetlands as part of the proposed project, which would include 59 acres of tidal marsh restoration (Environmental Commitment 4), 5 acres of vernal pool/alkali seasonal wetlands (Environmental Commitment 9; 34 acres of vernal pool complex assuming a wetland density of 15%), and 832 acres of nontidal marsh restoration (Environmental Commitment 10). In addition, Alternative 4A would restore 251 acres of riparian habitat (Environmental Commitment 7), some portion of which may also qualify as forested or scrub-shrub wetland. In addition, 4.6 miles of levees will have channel margin enhancement conducted on them (Environmental Commitment 6), which would include improving channel geometry and restoring riparian, marsh, and mudflat habitats on the water side of levees.

The success in implementing these Environmental Commitments would be assured through effectiveness monitoring, which includes success criteria, and adaptive management as outlined in the *Adaptive Management and Monitoring* sections of the Draft BDCP for tidal marsh restoration (Draft BDCP Section 3.4.4.4), channel margin enhancement (Draft BDCP Section 3.4.6.4), valley/foothill riparian restoration (Draft BDCP Section 3.4.7.4), vernal pool and alkali seasonal wetland complex restoration (Draft BDCP Section 3.4.9.4), and nontidal marsh restoration (Draft BDCP Section 3.4.10.3). All restored areas will be secured in fee-title or through conservation easements.

Alternative 4A would also protect and manage the following natural communities that contain wetlands: 103 acres of valley/foothill riparian, 150 acres of vernal pool complex, and 119 of nontidal marsh. In addition, 1,060 acres of grasslands and 11,870 acres of cultivated lands will be protected and managed, which would likely include areas of seasonal wetlands, ponds, and agricultural ditches.

Alternative 4A also includes the following Resource Restoration and Performance Principles (see Table 4.1-8 in this RDEIR/SDEIS) to further guide the Environmental Commitments that would also contribute to establishing and maintaining the functions and values of restored and protected waters of the U.S.

- Restore or create vernal pool and alkali seasonal wetland complex to achieve no net loss of wetted acres (Resource Restoration and Performance Principle VP/AW2).
- Provide appropriate seasonal flooding characteristics for supporting and sustaining vernal pool and alkali seasonal wetland complex species (Resource Restoration and Performance Principle VP/AW4).
- In grasslands surrounding protected and created vernal pools and alkali seasonal wetlands complex, increase the extent, distribution, and density of native perennial grasses intermingled with other native species, including annual grasses, geophytes, and other forbs (Resource Restoration and Performance Principle VP/AW6).
- Increase the size and connectivity of protected vernal pool and alkali seasonal wetland complex in the greater Byron Hill area (Resource Restoration and Performance Principle VP/AW3).
- Protect up to six acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles (Resource Restoration and Performance Principle G2).
- Maintain and enhance aquatic features in grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for covered amphibian and aquatic reptile species (Resource Restoration and Performance Principle G7).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak

trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Resource Restoration and Performance Principle CL1).

- Create and protect nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, which will include suitable habitat characteristics for western pond turtle (Resource Restoration and Performance Principle WPT1).
- Create aquatic habitat for the giant garter snake will be connected to the protected rice land or equivalent-value habitat (Resource Restoration and Performance Principle GGS1).
- Protect, restore, and/or create rice land or equivalent-value habitat (e.g., perennial wetland) for the giant garter snake in Conservation Zones 4 and/or 5 (Resource Restoration and Performance Principle GGS3).
- Create at least 320 acres of managed wetlands (part of the nontidal wetland restoration acreage) in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands will be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands (Resource Restoration and Performance Principle GSC2).
- Create at least two 90-acre wetland complexes within the Stone Lakes National Wildlife Refuge project boundary. The complexes will be no more than 2 miles apart and will help provide connectivity between the Stone Lakes and Cosumnes River Preserve greater sandhill crane populations. Each complex will consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and will be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes National Wildlife Refuge for greater sandhill crane (Resource Restoration and Performance Principle GSC3).

The project proponents will also implement AMMs 1–7, 10,12, 30, 34, and 36, which would avoid and minimize fill of wetlands and waters and any indirect effects to wetlands and waters. As stated above, specific mitigation would be required to ensure that Alternative 4A does not result in a loss of functions and values of waters of the U.S. Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the U.S.*, would be available to reduce the impact to a less-than-significant level.

Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the U.S.

All mitigation proposed as compensatory mitigation would be subject to specific success criteria, success monitoring, long-term preservation, and long-term maintenance and monitoring pursuant to the requirements of the Mitigation Rule. All compensatory mitigation shall fully replace lost function through the mechanisms discussed below which will result in restoration and/or creation of habitat with at least as much function and value as those of the impacted habitat. In some cases, the mitigation habitat will afford significantly higher function and value than that of impacted habitat.

Compensation ratios are driven by type, condition, and location of replacement habitat as compared to type, condition and location of impacted habitat. Compensatory mitigation usually includes restoration, creation, or rehabilitation of aquatic habitat. The USACE does not typically accept preservation as the only form of mitigation; use of preservation as mitigation typically requires a very high ratio of replacement to impact. It is anticipated that ratios will be a minimum of 1:1, depending on the factors listed above.

Compensatory mitigation will consist of restoration, creation, and/or rehabilitation of aquatic habitat. Typically, impacted habitat will be replaced in-kind, although impacts on some habitat types such as agricultural ditches, conveyance channels, and Clifton Court Forebay, will be mitigated out-of-kind with higher functioning habitat types such as riparian wetland, marsh, and/or seasonal wetland. Compensatory mitigation shall be accomplished by one, or a combination of the following methods:

- Purchase credits for restored/created/rehabilitated habitat at an approved wetland mitigation bank;
- On-site (adjacent to the project footprint) restoration or rehabilitation of wetlands converted to uplands due to past land use activities (such as agriculture) or functionally degraded by such activities;
- On-site (adjacent to the project footprint) creation of aquatic habitat;
- Off-site (within the Delta) restoration or rehabilitation of wetlands converted to uplands due to past land use activities (such as agriculture) or functionally degraded by such activities;
- Off-site (within the Delta) creation of aquatic habitat; and/or
- Payment into the Corps' Fee-in-Lieu program.

Purchase of Credits or Payment into Fee-in-Lieu Program

It is envisioned that purchase of bank credits and/or payment into a fee-in-lieu program will be utilized for habitat types that would be difficult to restore or create within the Delta. Examples are vernal pool habitat, which requires an intact hardpan or other impervious layer and very specific soil types, and alkali seasonal wetland, which requires a specific set of chemical soil parameters. It is anticipated that only a small amount of compensatory mitigation will fall into these categories.

On-Site Restoration, Rehabilitation and/or Creation

Much of the Delta consists of degraded or converted habitat that is more or less functioning as upland. Opportunities will be sought where on-site restoration, rehabilitation, and/or creation could occur immediately adjacent to the project footprint. It is anticipated that some of the compensatory mitigation will fall into this category.

Off-Site Restoration, Rehabilitation and/or Creation

There exists, within the immediate vicinity of the project area, Delta land which has been subject to agricultural practices or other land uses which have degraded or even converted wetlands that existed historically. Sites within the Delta will be evaluated for their restoration, rehabilitation, and/or creation potential. It is anticipated that most of the compensatory mitigation will fall into this category.

Compensatory mitigation will result in no net loss of acreage of Waters of the U.S. and will accomplish full functional replacement of impacted wetlands. All impacted wetlands will be replaced with fully functioning wetland habitat demonstrating high levels of habitat, water quality, and hydrologic/hydraulic function. Since many impacted wetlands are likely to function at significantly less than high levels, the compensatory mitigation will result in a significant net increase in wetland function.

Impact BIO-177: Effects of Implementing Environmental commitments (Environmental Commitment 4 - Environmental Commitment 10) on Wetlands and Other Waters of the United States

The habitat protection and restoration activities associated with Alternative 4A's environmental commitments (Environmental Commitment 4–Environmental Commitment 10) could alter the acreages and functions and values of wetlands and waters of the United States in the study area. Because these environmental commitments have not been defined to the level of site-specific footprints, it is not possible to specifically delineate and quantify these effects on wetlands and waters; however the project would conduct tidal restoration (Environmental Commitment 4), riparian restoration (Environmental Commitment 7), grasslands restoration (Environmental Commitment 8), and nontidal marsh restoration (Environmental Commitment 10) within 2,207 acres of cultivated lands that likely contain agricultural ditches and seasonal wetlands (as was identified during the delineation for the Conveyance Planning Area). In addition, 5 acres of valley/foothill riparian would be affected by tidal restoration (Environmental Commitment 4). The proportion of these areas that actually contain waters and wetlands is expected to be low; however for the purposes of this analysis a conservative estimate of 10% was applied to estimate the amount of wetlands and waters that may be affected within these areas, which would be 221 acres.

Alternative 4A would result in the restoration of 896 acres of wetlands and waters, as well the protection and management of 269 acres of wetland natural communities (vernal pool complex and nontidal marsh) and 13,033 acres of other natural communities that likely contain some degree of wetlands and waters (valley/foothill riparian, grasslands, and cultivated lands). As discussed above, Alternative 4A would also implement AMMs, Resource Restoration and Performance Principles, and adaptive management and monitoring together with these environmental commitments. The Environmental Commitments and associated measures could serve the dual purpose of offsetting effects to species and mitigation impacts on waters of the U.S.; however, more specific mitigation is required to ensure that there is no net loss of wetland functions and values as a result of implementing these Environmental Commitments under Alternative 4A pursuant to USACE's and U.S. EPA's Mitigation Rule. Mitigation Measure BIO-176, Compensatory Mitigation for Fill of Waters of the U.S. would be available to address adverse impacts on waters of the U.S.

NEPA Effects: The implementation of Environmental Commitment 4–Environmental Commitment 10 for Alternative 4A would potentially result in the conversion of wetlands and waters in cultivated lands and along the margins of Delta channels. These wetlands and waters would likely be converted to tidal and nontidal wetlands, including some open water, and possibly grasslands through implementation of Environmental Commitment 4, Environmental Commitment 8, and Environmental Commitment 10. Although, the increase in wetland acreage and wetland functions from these Environmental Commitments could offset the effects on waters of the U.S. occurring in these areas, implementation of Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the U.S.*, would be required to ensure that these effects are not adverse.

***CEQA Conclusion*:** The implementation of Environmental Commitment 4–Environmental Commitment 10 for Alternative 4A would potentially result in the conversion of wetlands and waters in cultivated lands and along the margins of Delta channels. These wetlands and waters would likely be converted to tidal and nontidal wetlands, including some open water, and possibly grasslands through implementation of Environmental Commitment 4, Environmental Commitment 8, and Environmental Commitment 10. Although, the increase in wetland acreage and wetland functions from these Environmental Commitments could offset the effects on waters of the U.S. occurring in these areas, implementation of Mitigation Measure BIO-176, *Compensatory Mitigation for Fill of Waters of the U.S.*, would be required to ensure that the impacts are reduced to a less-than-significant level.

Shorebirds and Waterfowl

This section describes the effects of Alternative 4A, including water conveyance facilities construction and implementation of the environmental commitments, on shorebirds and waterfowl. Managed wetlands, tidal natural communities, and cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands) provide freshwater nesting, feeding, and resting habitat for a large number of Pacific flyway waterfowl and shorebirds.

Alternative 4A would result in both temporary and permanent losses of shorebird and waterfowl habitat. Full implementation of Alternative 4A would also include the following environmental commitments and associated Resource Restoration and Performance Principles that would benefit shorebirds and waterfowl through habitat restoration and protection.

- Restore or create 37 acres of tidal wetlands in the north Delta (Environmental Commitment 4).
- Restore or create 22 acres of *Schoenoplectus* and *Typha*-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the south Delta (Environmental Commitment 10 and Resource Restoration and Performance Principle CBR1).
- Protect 119 acres of nontidal wetlands and create 832 acres of nontidal wetlands (Environmental Commitment 3 and Environmental Commitment 10).
- Protect 1,060 acres of grassland and 11,870 acres of cultivated lands (Environmental Commitment 3).

Impact BIO-178: Loss or Conversion of Habitat for Waterfowl and Shorebirds as a Result of Water Conveyance Facilities Construction

Development of the water conveyance facilities would result in the permanent removal of approximately 22 acres of managed wetland, 3 acres of tidal wetlands, 61 acres of nontidal wetlands, and 3,768 acres of suitable cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands). In addition, 29 acres of managed wetland, 15 acres of tidal wetlands, 15 acres of nontidal wetlands and 1,339 acres of suitable cultivated lands would be temporarily impacted. No rice would be impacted as a result of constructing the water conveyance facilities. These losses of habitat would occur within the first 10–14 years of Alternative 4A implementation in the Delta.

A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected through Alternative 4A. In addition, 59 acres of tidal freshwater emergent wetland would be restored or created and 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created in the Delta. The restored and protected acres described above would provide suitable nesting habitat for these species. These conservation actions would be associated with the aforementioned environmental commitments and would occur in the same timeframe as the construction losses. Construction activities could have an adverse effect on nesting shorebirds or waterfowl if they were present in or adjacent to work areas and could result in destruction of nests or disturbance of nesting and foraging behaviors. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

***NEPA Effects*:** Habitat loss from construction of the Alternative 4A water conveyance facilities would not result in an adverse effect on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected in the near-term timeframe. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be an adverse effect on nesting shorebirds and waterfowl. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

***CEQA Conclusion*:** Habitat loss from construction of the Alternative 4A water conveyance facilities would have a less-than-significant impact on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected in the near-term timeframe. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be a significant impact. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, which would identify birds prior to disturbance and would allow for avoidance measures, would reduce this impact on nesting birds to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-179: Loss or Conversion of Habitat for Wintering Waterfowl as a Result of Implementation of Alternative 4A

The implementation of Environmental Commitments would result in the permanent loss or conversion of 2,212 acres of cultivated lands.

- *Environmental Commitment 4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 54 acres of cultivated lands.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 251 acres of cultivated lands.
- *Environmental Commitment 8 Grassland Natural Community Restoration*: Grassland restoration would convert approximately 1,070 acres of cultivated lands into grasslands.

- *Environmental Commitment 10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent removal of 832 acres of cultivated lands

A total of 1,060 acres of grassland and 11,870 acres of cultivated lands would be protected through Alternative 4A. In addition, 59 acres of tidal freshwater emergent wetland would be restored or created and 119 acres of nontidal wetlands would be protected, and 832 acres of nontidal wetlands would be created in the Delta. Some portion of these wetlands would be expected to provide suitable habitat for wintering waterfowl. The restored and protected acres described above would provide foraging habitat for wintering waterfowl and the acres of cultivated lands protected would provide adequate food sources and resting habitat for waterfowl species. Restoration and protection acres would be associated with Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 8 and Environmental Commitment 10 and would occur in the same timeframe as the construction and early restoration losses. Environmental Commitment 11 would be implemented to guide management of cultivated lands and wetlands for shorebird and waterfowl species.

***NEPA Effects*:** The loss or conversion of 2,212 acres of cultivated lands would not be adverse under NEPA because project proponents have committed to restoring and protecting an acreage that exceeds the typical mitigation ratios for cultivated lands (1:1 protection). This habitat protection and restoration would be guided by Resource Restoration and Performance Principle CBR1 described above and would not be expected to substantially alter food productivity for wintering waterfowl in the Delta. Therefore the implementation of Alternative 4A would not represent an adverse effect on wintering waterfowl.

***CEQA Conclusion*:** The loss or conversion of 2,212 acres of cultivated lands would not represent a substantial impact because project proponents have committed to restoring and protecting an acreage that exceeds the typical mitigation ratios for cultivated lands (1:1 protection). This habitat protection and restoration would be guided by Resource Restoration and Performance Principle CBR1 described above and would not be expected to substantially alter food productivity for wintering waterfowl in the Delta. Therefore the implementation of Alternative 4A would have a less-than-significant impact on wintering waterfowl.

Impact BIO-180: Loss or Conversion of Habitat for Breeding Waterfowl from Implementation of Alternative 4A

Implementation of Environmental Commitments under Alternative 4A would not be expected to reduce managed wetlands in the Delta. Alternative 4A would protect 119 acres and create 832 acres of nontidal marsh. In addition, 59 acres of tidal freshwater wetlands would be restored in the Delta which would be expected to contain water during the breeding period (March through July). Restoration and protection acres would be associated with Environmental Commitment 3, Environmental Commitment 4, and Environmental Commitment 10 and would occur in the same timeframe as the construction and early restoration losses. Environmental Commitment 11 would be implemented to guide management of wetlands for shorebird and waterfowl species.

***NEPA Effects*:** Implementation of environmental commitments under Alternative 4A would not reduce managed wetlands in the Delta, and would create nontidal and tidal wetlands. Therefore, Alternative 4A would not have an adverse effect on breeding waterfowl.

***CEQA Conclusion*:** Implementation of environmental commitments under Alternative 4A would not reduce managed wetlands in the Delta, and would create nontidal and tidal wetland habitat. Therefore, Alternative 4A would have a less-than-significant impact on breeding waterfowl.

Impact BIO-181: Loss or Conversion of Habitat for Shorebirds from the Implementation of Conservation Components

Shorebird use of the study area varies by species and fluctuates both geographically and by habitat type throughout the year. Shallow flooded agricultural fields and wetlands support large numbers of wintering and migrating shorebirds (Shuford et al. 1998), particularly least and western sandpipers, dunlin, greater yellowlegs and long-billed dowitcher. Rice lands of the Sacramento Valley provide important breeding habitat for shorebirds such as American avocet and black-necked stilt (Shuford et al. 2004) and have been designated as a Western Hemisphere Shorebird Reserve Network Site of International Importance (Hickey et al. 2003). Managed wetlands provide suitable foraging and roosting habitat for shorebirds; black-necked stilts, avocets, and yellowlegs use this habitat type almost exclusively. Water depth in all of these habitat types is an important habitat variable as the majority of shorebird species require water depths of approximately 10–20 cm for foraging (Isola et al. 2000, Hickey et al. 2003).

Managed Wetlands

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for managed wetland habitat suitability (Table 1, ICF International 2013): black-necked stilt (*Himantopus mexicanus*), greater yellowlegs (*Tringa melanoleuca*), and long-billed dowitcher (*Limnodromus scolopaceus*). Dunlin (*Calidris alpine*), least sandpiper (*Calidris minutilla*), semipalmated plover (*Charadrius semipalmatus*), and western sandpiper (*Calidris mauri*), had a rank 2 for managed wetland habitat suitability. Black-bellied plover (*Pluvialis squatarola*) and whimbrel (*Numenius phaeopus*) both had rank 3 for managed wetland habitat suitability.

No managed wetlands would be converted or lost from the implementation of Environmental Commitment 4, Environmental Commitment 7, or Environmental Commitment 10. However, 832 acres of nontidal marsh would be created under Environmental Commitment 10.

Cultivated Lands

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for cultivated lands habitat suitability (Table 1, ICF International 2013): killdeer (*Charadrius vociferous*), long-billed curlew, and whimbrel within pasture habitat and sandhill crane was ranked 1 for grain and hay crops. Long-billed dowitcher and killdeer both had a rank 2 for idle crop habitat suitability and black-bellied plover was ranked 2 for pasture habitat. Red-necked phalarope (*Phalaropus lobatus*) and Wilson's phalarope (*Phalaropus tricolor*) were both ranked 2 for grain and hay crops. Long-billed dowitcher, dunlin, least sandpiper, and long-billed curlew were all ranked 3 for rice habitat suitability and killdeer was ranked 3 for field crop habitat suitability.

Within the Delta, 54 acres of cultivated lands would be permanently converted to tidal wetlands as a result of tidal restoration (Environmental Commitment 4), 251 acres would be permanently lost as a result of riparian restoration (Environmental Commitment 7), 1,070 acres would be converted to grassland as a result of grassland restoration (Environmental Commitment 8), and 832 acres would be converted to nontidal wetlands as a result of nontidal marsh restoration (Environmental Commitment 10).

Tidal Wetlands

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for tidal mudflat habitat suitability (Table 6, ICF International 2013): black-bellied plover, dunlin, least sandpiper, marbled godwit (*Limosa fedoa*), semipalmated plover, short-billed dowitcher (*Limnodromus griseus*), western sandpiper, and willet (*Tringa semipalmata*). Long-billed curlew (*Numenius americanus*) and whimbrel both had a rank 2 for tidal mudflat habitat suitability. American avocet (*Recurvirostra americana*) was ranked 3 for tidal mudflat habitat suitability. For tidal brackish emergent wetland/tidal freshwater emergent wetland, willet was ranked 2 and long-billed curlew and whimbrel were both ranked 3 for habitat suitability.

No tidal wetlands would be converted or lost from the implementation of Environmental Commitment 4, Environmental Commitment 7, Environmental Commitment 8, or Environmental Commitment 10. However, 59 acres of tidal wetlands would be created under Environmental Commitment 4.

Nontidal Wetlands

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for nontidal wetland habitat suitability (Table 6, ICF International 2013): red-necked phalarope and Wilson's phalarope for nontidal freshwater perennial emergent wetland and American avocet for alkali seasonal wetland complex. Greater yellowlegs had a rank 2 for vernal pool complex habitat suitability. Red-necked phalarope and western sandpiper were both ranked 3 for alkali seasonal wetland habitat suitability and greater yellowlegs was ranked 3 for nontidal freshwater perennial emergent wetland habitat suitability.

No nontidal wetlands would be converted or lost from the implementation of Environmental Commitment 4, Environmental Commitment 7, or Environmental Commitment 10. However, 832 acres of nontidal wetlands would be created under Environmental Commitment 10.

The protection and restoration of natural communities would also include management and enhancement actions under *Environmental Commitment 11 Natural Communities Enhancement and Management.* The following management activities to benefit shorebirds would be considered for implementation under Environmental Commitment 11 in areas where they would not conflict with other species management.

- Managed wetlands and Nontidal Wetlands:
    - Managed wetlands can be potentially manipulated to provide the optimum water depths for foraging shorebirds and islands for nesting (Hickey et al. 2003).
    - During fall and spring, stagger the timing and location of draining and flooding to optimize the extent of shallow-water habitat; varying depths within the wetland unit helps to create temporal variation in foraging opportunities. During warm, dry springs when wetland units dry quickly, wetland units can be re-supplied with water to extend habitat availability for shorebirds.
    - Provide open, shallow water habitat adjacent to minimally vegetated, shallowly sloped edges for nesting shorebirds between April and July.
    - Provide islands with little to no vegetation to increase the likelihood of shorebird roosting and nesting.

- Create low slopes on islands and levees; gradual angles (10–12:1) are better than steep angles.
- Limit levee maintenance during the nesting season (April through July). However, mowing the center of levees is fine.
- Potentially add material to levees or to islands to encourage nesting for some species.

- Cultivated Lands:
  - Maintaining a mosaic of dry and flooded crop types, and varying water depths will promote a diverse community of waterbirds, including shorebirds, during fall migration and winter (Shuford et al. 2013).
  - To provide wintering habitat for multiple waterbird guilds, including shorebirds, use a combination of flooding practices that include one-time water application and maintenance flooding while also providing unflooded habitat (Strum et al. *in review*).
  - The post-harvest flooding of winter wheat and potato fields in early fall (July- September) can provide substantial benefits to shorebirds at a time of very limited shallow-water habitat on the landscape (Shuford et al. 2013).
  - Stagger the drawdown of flooded rice and other winter-flooded agricultural fields to prolong the availability of flooded habitat (Iglecia et al. 2012). Be aware of soil type because this practice may not be as effective on soils that drain quickly.
  - Remove as much stubble as possible in rice and other agricultural fields after harvest to increase the potential shorebird habitat on intentionally flooded or unflooded fields that may passively gather rain water (Iglecia et al. 2012).
  - Shallowly flood available agricultural fields during July, August, and September to provide early fall migration habitat for shorebirds. Fields should be free of vegetation prior to flooding, have minimal micro-topography (e.g., no large clods), and should remain flooded for up to three week periods (after three weeks, vegetation encroachment reduces habitat value for shorebirds; ICF International 2013).
  - Manage levee habitats to have minimal vegetation but do not spray herbicide directly or drive on levees during the nesting season (April–July, Iglecia et al. 2012).
  - Maintain a minimum top-width of 30 inches for levees, based on increased avocet use of wider levees (Iglecia et al. 2012).
  - When possible, flood fields with nesting habitat (modified levees and islands) in late April to provide nesting habitat for American avocets (Iglecia et al. 2012).
  - Finer grained substrate (clods smaller than a fist) in rice and other agricultural fields may be more appealing for nesting shorebirds (Iglecia et al. 2012).
  - Maintain gently sloping levees and island sides (10–12:1; Iglecia et al. 2012).
  - Islands should be disked along with the rest of the field after harvest to help inhibit vegetation growth (Iglecia et al. 2012).

***NEPA Effects*:** Alternative 4A implementation would result in the conversion of cultivated lands in the Delta to tidal and nontidal wetlands. The result would be a loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While losses of cultivated lands would be incurred, protection, enhancement, and management of 11,870 acres of cultivated lands would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these crop types are being driven by Swainson's hawk, giant garter snake, and greater sandhill crane, they would also benefit shorebirds with the implementation of the management actions outlined in *Environmental Commitment 11 Natural Communities Enhancement and Management*. Habitat conversion would not be expected to result in an adverse effect on shorebird populations in the study area.

CEQA Conclusion: Alternative 4A implementation would result in the conversion of cultivated lands in the Delta to tidal and nontidal wetlands. The result would be a loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While losses of cultivated lands would be incurred, protection, enhancement, and management of 11,870 acres of cultivated lands would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these crop types are being driven by Swainson's hawk, giant garter snake, and greater sandhill crane, they would also benefit shorebirds with the implementation of the management actions outlined in *Environmental Commitment 11 Natural Communities Enhancement and Management*. Habitat conversion would not be expected to adversely affect shorebird populations in the study area. With the protection and restoration of acres in the Delta watershed, in addition to the implementation of the management actions outlined in *Environmental Commitment 11 Natural Communities Enhancement and Management*, habitat conversion would be expected to have a less-than-significant impact on shorebird populations in the study area.

Impact BIO-182: Effects on Shorebirds and Waterfowl Associated with Electrical Transmission Facilities

New transmission lines installed in the study area would increase the risk for bird-power line strikes, which could result in injury or mortality of shorebirds and waterfowl. The existing network of power lines in the study currently poses a risk for shorebirds and waterfowl in the Delta. New transmission lines would increase this risk and have an adverse effect on shorebird and waterfowl species in the absence of other avoidance and minimization measures. The implementation of *AMM20 Greater Sandhill Crane* would reduce potential effects through the installation of flight-diverters on new transmission lines, and selected existing transmission lines in the study area.

NEPA Effects: New transmission lines would increase the risk for shorebird and waterfowl power line strikes which could have a substantial adverse effect as a result of direct mortality. This impact would be significant. With the implementation of *AMM20 Greater Sandhill Crane*, the potential effect of the construction of new transmission lines on shorebird and waterfowl would not be adverse.

CEQA Conclusion: New transmission lines would increase the risk for shorebird and waterfowl power line strikes which could have a substantial adverse effect as a result of direct mortality. This impact would be significant. The implementation of *AMM20 Greater Sandhill Crane* would reduce the potential impact of powerline strikes from the construction of new transmission lines on shorebirds and waterfowl to a less-than-significant level.

Impact BIO-183: Indirect Effects of Plan Implementation on Shorebirds and Waterfowl

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect shorebird and waterfowl use of modeled habitat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect shorebirds and waterfowl or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to shorebirds and waterfowl in the study area could also have a negative effect on these species. AMM1–AMM7 would ensure that measures were in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in shorebird and waterfowl species. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Bioaccumulation of methylmercury varies by species as there are taxonomic differences in rates of detoxification within the liver (Eagles-Smith et al. 2009). Organisms feeding within pelagic-based (algal) food webs have been found to have higher concentrations of methylmercury than those in benthic or epibenthic food webs; this has been attributed to food chain length and dietary segregation (Grimaldo et al. 2009). That is, the pelagic food chain tends to be longer than the benthic food chain, which allows for greater biomagnification of methylmercury in top predators. Also, there is less prey diversity at the top of the pelagic food chain than in the benthic food chain; pelagic top predators eat smaller fish and little else, while benthic top predators consume a variety of organisms, many of which are lower in the food chain than fishes and thus have less potential for methylmercury biomagnification. Shorebirds and waterfowl that forage on invertebrates and bivalves, may therefore have lower concentrations of methylmercury than diving ducks that forage on fish. A detailed review of the methylmercury issues associated with implementation of Alternative 4A are contained in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS. The review includes an overview of the project-related mechanisms that could result in increased mercury in the food web, and how exposure to individual species may occur based on feeding habits and where their habitat overlaps with the areas where mercury bioavailability could increase.

Largemouth bass was used as a surrogate species for analysis and the modeled effects of mercury concentrations from changes in water operations under water conveyance facilities on largemouth bass did not differ substantially from existing conditions (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS); therefore, results also indicate that shorebird and waterfowl mercury tissue concentrations would not measurably increase as a result of water conveyance facilities implementation.

Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, Alternative 4A restoration activities that create newly inundated areas (Environmental Commitment 4 and Environmental Commitment 5) could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). Mercury is generally elevated throughout the Delta, and restoration of the lower potential areas in total may result in generalized, very low level increases of mercury. Given that some species have elevated mercury tissue levels without the project, these low level increases could result in some level of effects. Restoration in Suisun Marsh would convert managed wetlands to tidal wetlands, which would be expected to result in an overall reduction in mercury methylation.

Due to the complex and very site-specific factors that will determine if mercury becomes mobilized into the foodweb, Environmental Commitment 12, is included to provide for site-specific evaluation for each restoration project. On a project-specific basis, where high potential for methylmercury production is identified that restoration design and adaptive management cannot fully address while also meeting restoration objectives, alternate restoration areas will be considered. Environmental Commitment 12 will be implemented in coordination with other similar efforts to address mercury in the Delta, and specifically with the DWR Mercury Monitoring and Analysis Section. This environmental commitment will include the following actions.

- Assess pre-restoration conditions to determine the risk that the project could result in increased mercury methylation and bioavailability
- Define design elements that minimize conditions conducive to generation of methylmercury in restored areas.
- Define adaptive management strategies that can be implemented to monitor and minimize actual postrestoration creation and mobilization of methylmercury.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including shorebird and waterfowl species. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, Alternative 4A restoration activities that create newly inundated areas could increase bioavailability of selenium (see Chapter 3, *Conservation Strategy*, of the Draft BDCP for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, of the Draft EIR/EIS and it was determined that, relative to Existing Conditions and the No Action Alternative, water conveyance facilities would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related environmental commitments (Environmental Commitment 4 and Environmental Commitment 5) would lead to adverse effects on shorebirds and waterfowl species.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on shorebirds and waterfowl from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats, (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of Alternative 4A water conveyance facilities could reduce shorebird and waterfowl use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect shorebird and waterfowl use of the surrounding habitat. AMM1–AMM7 would minimize these effects, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals.

Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects associated with noise and visual disturbances, and increased exposure to selenium from Alternative 4A implementation would not have an adverse effect on shorebirds and waterfowl.

Changes in water operations under water conveyance facilities would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. However, the concentrations of methylmercury that are harmful varies by species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on shorebirds and waterfowl.

CEQA Conclusion: Indirect effects that include noise and visual disturbance, potential hazardous spills, increased dust and sedimentation, and increased methylmercury and selenium exposure as a result of Alternative 4A water conveyance facilities construction and operation and maintenance would represent an adverse effect as a result of habitat modification and potential for direct mortality of shorebirds and waterfowl in the absence of the environmental commitments and AMMs. This would be a significant impact.

AMM1–AMM7, and implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce potential adverse effects of noise, visual disturbance and potential for spills, dust, and sedimentation.

Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Changes in water operations under water conveyance facilities would not be expected to result in increased mercury bioavailability or exposures to Delta foodwebs. Tidal habitat restoration could result in increased exposure of California least tern to methylmercury. There is potential for increased exposure of the foodwebs to methylmercury in these areas, with the level of exposure dependent on the amounts of mercury available in the soils and the biogeochemical conditions. This could result in a significant impact. However, the concentrations of methylmercury that are harmful varies by species, and the potential for increased exposure varies substantially within the study area. Implementation of Environmental Commitment 12 which contains measures to assess the amount of mercury before project development, followed by appropriate design and adaptation management, would minimize the potential for increased methylmercury exposure, and would result in no adverse effect on shorebirds and waterfowl.

Therefore, with AMM1–7, AMM27, and Environmental Commitment 12 in place, in addition to the implementation of Mitigation Measure BIO-75, the indirect effects of Alternative 4A implementation would not result in a substantial adverse effect through habitat modification or potential mortality. Therefore, the indirect effects of Alternative 4A implementation would have a less-than-significant impact on shorebirds and waterfowl.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Common Wildlife and Plants

Common wildlife and plants are widespread, often abundant, species that are not all covered under laws or regulations that address conservation or protection of individual species. Common wildlife do have some level of protection under California Fish and Game Code and most bird species have protections under the Migratory Bird Treaty Act. Examples of common wildlife and plants occurring in the study area are provided within the discussion for each natural community type in Section 12.1.2.2, *Special-Status and Other Natural Communities*, of the Draft EIR/EIS. Impacts on common wildlife and plants would occur through the same mechanisms discussed for natural communities and special-status wildlife and plants for each alternative.

Impact BIO-184: Effects on Habitat and Populations of Common Wildlife and Plants

Effects on habitat of common wildlife and plants, including habitat removal and conversion, are discussed in the analysis of Alternative 4A effects on natural communities (Impacts BIO-1 through BIO-21. In general, effects on habitat of common wildlife and plants would not be adverse. Through the course of implementing the project over a 15-year time period, several natural communities and land cover types would be reduced in size, primarily from construction of the water conveyance facility, but also from restoration of other natural communities. Grassland, managed wetland and cultivated lands would be reduced in acreage, so the common species that occupy these habitats would be affected. However, the losses in acreage and value of these habitats would be offset by protection, restoration, enhancement, and management actions under Alternative 4A, including *Environmental Commitment 3 Natural Communities Protection and Restoration*, *Environmental Commitment 4 Tidal Natural Communities Restoration*, *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 7 Riparian Natural Community Restoration*, *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *Environmental Commitment 10 Nontidal Marsh Restoration*, and *Environmental Commitment 11 Natural Communities Enhancement and Management*. In addition, the AMMs contained in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS would be in place to reduce or eliminate the potential to adversely affect both special-status and common wildlife and plants.

Direct effects on common wildlife and plants from constructing water conveyance facilities and implementing environmental commitments would include construction or inundation-related disturbances that result in injury or mortality of wildlife or plants and the immediate displacement of wildlife. Indirect effects include project-related disturbances to nearby wildlife and plants during construction (e.g., disruption of breeding and foraging behaviors from noise and human activity, habitat degradation from fugitive dust and runoff) and effects occurring later in time (e.g., collisions of birds with transmission lines, habitat fragmentation, vegetation management). Indirect effects could result both from construction and from operations and maintenance (e.g., ground disturbances could result in the spread and establishment of invasive plants).

NEPA Effects: The direct and indirect effects associated with implementing the environmental commitments of Alternative 4A would not be adverse because the environmental commitments and AMMs also expand and protect natural communities, avoid or minimize effects on special-status species, prevent the introduction and spread of invasive species, and enhance natural communities. These actions would result in avoiding and minimizing effects on common wildlife and plants as well.

CEQA Conclusion: Construction and operation of the water conveyance facilities and habitat restoration activities would have impacts on common wildlife and plants in the study area through habitat loss and through direct or indirect loss or injury of individuals. The loss of habitat would not be substantial, because habitat restoration would increase the amount and extent of habitat available for use by most common wildlife and plant species. Environmental commitments to avoid or minimize effects on special-status species, and to enhance natural communities also would result in avoiding and minimizing effects on common wildlife and plants. Consequently, implementation of Alternative 4A is not expected to cause any populations of common wildlife or plants to drop below self-sustaining levels, and this impact would be less than significant. No mitigation would be required.

Wildlife Corridors

Essential Connectivity Areas (ECAs) are lands likely to be important to wildlife movement between large, mostly natural areas at the state wide level. The ECAs form a functional network of wildlands that are considered important to the continued support of California's diverse natural communities. Four general areas were identified within the study area that contain ECAs (Figure 12-2). The BDCP also identified important landscape linkages in the Plan Area to guide reserve design, which can also be seen on Figure 12-2.

Impact BIO-185: Effects of Alternative 4A on Wildlife Corridors

Alternative 4A water conveyance facilities would cross two of the ECAs identified during the analysis, the Stone Lake-Yolo Bypass ECA and the Mandeville Island-Staten Island ECA.

The construction of Intakes 2 and 3, the rerouting of Hwy 160, temporary tunnel work areas, and RTM areas j would occur within the Stone Lake-Yolo Bypass ECA. These activities would result in the permanent loss of narrow strips of riparian vegetation along the Sacramento River and the permanent and temporary loss of cultivated lands. Alternative 4A would not substantially increase impediments to movement of any nonavian wildlife that could move from Stone Lakes to Yolo Bypass because the Sacramento River and Sacramento River Deep Water Ship Channel already create a barrier to dispersal for nonavian species. However, the conversion of riparian and cultivated lands and the presence of the intakes would locally constrict the north-south movement of nonavian terrestrial species in the area between the Sacramento River and the Southern Pacific Dredger Cut west of Stone Lakes, as well as the east-west movement between Stone Lakes and the east bank of the Sacramento River. No records of wildlife species were identified within these construction footprints, though there are several records for Swainson's hawk in the vicinity. Though there would be losses in Swainson's hawk foraging habitat and potential nesting habitat in these areas, these loses would not substantially impede the movements of Swainson's hawks in the area. The loss in habitat is addressed in the Swainson's hawk effects analysis.

The addition of temporary transmission lines within the Stone Lake-Yolo Bypass ECA, which would be in place for approximately 7 years, could adversely affect birds during periods of low visibility. Sandhill cranes that are known to roost at Stones Lakes could particularly be adversely affected by the addition of the north-south running transmission line to the west of Stone Lakes and by the east-west transmission line between Stone Lakes and the Cosumnes Preserve; however this line would generally parallel an existing transmission line. Because the proposed east-west transmission line parallels an existing line and would only be in place for approximately 7 years it would not likely create a barrier to the future movement of cranes in this area (see impact discussions for greater and lesser sandhill cranes).

The Alternative 4A conveyance facilities would also pass through the Mandeville Island-Staten Island ECA, which also has several know roost locations for greater sandhill crane. Within this ECA, Alternative 4A would result in the construction of a large RTM disposal area on Bouldin Island, permanent access roads on Bouldin and Mandeville Islands, and temporary transmission lines across most of the ECA. As discussed above, the temporary transmission lines could adversely affect the movement of cranes and other bird species during periods of low visibility. The RTM disposal area may create a physical barrier to movement for some species and could make this area unusable as wildlife habitat for close to 10 years during the tunnel construction. The access roads are mostly located on existing dirt and paved roads and would therefore not create any new physical barriers but could temporarily increase road mortality during periods of construction. The conveyance alignment at this location would be within the tunnel and thus not create a barrier to wildlife movement.

Alternative 4A conveyance facilities would create some localized disruption in wildlife movement and the temporary and permanent transmission lines would create additional barriers to movement for avian species during periods of low visibility. However, overall the Alternative 4A alignment would not create substantial barriers to movement between ECAs because the majority of the alignment consists of a tunnel that would be beneath riparian corridors, which are the most likely dispersal routes for terrestrial animals in the majority of the study area, and because the large surface impacts (the intakes) are in areas that already have barriers to movement for nonavian terrestrial species (Sacramento River and Sacramento River Deep Water Ship Channel).

Restoration activities may occur in some of the ECAs. These activities would generally improve the movement of wildlife within and outside of the study area. In addition, the preservation of restored lands (Environmental Commitment 3) and the enhancement and management of these areas (Environmental Commitment 11) would improve and maintain wildlife corridors within the study area.

NEPA Effects: Alternative 4A conveyance facilities would create local barriers to dispersal but overall the restoration activities would improve opportunities for wildlife dispersal within the study area and between areas outside of the study area and therefore overall Alternative 4A would not adversely affect wildlife corridors.

CEQA Conclusion: Alternative 4A conveyance facilities would create local barriers to dispersal and create barriers to safe movement of avian species during periods of low visibility but overall the restoration activities would improve opportunities for wildlife dispersal within the study area and between areas outside of the study area and therefore overall Alternative 4A would result in less-than-significant impacts on wildlife corridors.

Invasive Plant Species

The invasive plant species that primarily affect each natural community in the study area, which include water hyacinth, perennial pepperweed, giant reed, and Brazilian waterweed, are discussed in Section 12.1.4, *Invasive and Noxious Plant Species*, of the Draft EIR/EIS. Invasive species compete with native species for resources and can alter natural communities by altering fire regimes, hydrology (e.g., sedimentation and erosion), light availability, nutrient cycling, and soil chemistry but also have the potential to harm human health and the economy by adversely affecting natural ecosystems, water delivery, flood protection systems, recreation, agricultural lands, and developed areas (Randall and Hoshovsky 2000). The construction and restoration activities associated with Alternative 4A could result in the introduction or spread of invasive plant species by creating temporary ground disturbance that provides opportunities for colonization by invasive plants in the study area.

The primary mechanisms for the introduction of invasive plants as the result of implementation of Alternative 4A are listed here.

- Grading, excavation, grubbing, and placement of fill material.
- Breaching, modification, or removal of existing levees and construction of new levees.
- Modification, demolition, and removal of existing infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure).
- Maintenance of infrastructure.
- Removal of existing vegetation and planting/seeding of vegetation.
- Maintaining vegetation and vegetation structure (e.g., grazing, mowing, burning, trimming).
- Dredging waterways.

Clearing operations and the movement of vehicles, equipment, and construction materials in the study area would facilitate the introduction and spread of invasive plants by bringing in or moving seeds and other propagules. These effects would result from four activities.

- Spreading chipped vegetative material from clearing operations over topsoil after earthwork operations are complete.
- Importing, distributing, storing, or disposing of fill, RTM, borrow, spoil, or dredge material.
- Traffic from construction vehicles (e.g., water and cement trucks) and personal vehicles of construction staff.
- Transport of construction materials and equipment within the study area and to/from the study area.

Table 12-4A-69 lists the acreages of temporary disturbance in each natural community in the study area that would result from implementation of Alternative 4A.

Table 12-4A-69. Summary of Temporary Disturbance in Natural Communities under Alternative 4A

Natural Community	Temporary Impacts (acres)
Tidal perennial aquatic	2,098
Tidal brackish emergent wetland	0
Tidal freshwater emergent wetland	15
Valley foothill riparian	31
Grassland	151
Inland dune scrub	0
Alkali seasonal wetland complex	0
Vernal pool complex	3
Other natural seasonal wetland	0
Nontidal freshwater perennial emergent wetland	6
Nontidal perennial aquatic	10
Managed wetlands	29
Cultivated lands	1,309
Total	**3,652**

Impact BIO-186: Adverse Effects on Natural Communities Resulting from the Introduction and Spread of Invasive Plant Species

Alternative 4A would have adverse effects on natural communities as a result of the introduction and spread of invasive plant species through implementation of water conveyance facilities, Environmental Commitment 3, Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, Environmental Commitment 9, Environmental Commitment 10 and AMM6. No adverse effects are expected from implementation of other project-related environmental commitments.

- *Water Facilities and Operations*: Construction of the Alternative 4A water conveyance facilities would result in the temporary disturbance of 3,652 acres that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 3 Natural Communities Protection and Restoration*: The restoration activities in the natural communities located in planned conservation areas would result in the temporary disturbance of restoration areas that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 4 Tidal Natural Communities Restoration*: The activities associated with the restoration of tidal perennial aquatic, tidal mudflat, tidal freshwater emergent wetland, and tidal brackish emergent wetland in ROAs would result in the temporary disturbance of tidal areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by designing restoration projects to minimize the establishment of nonnative submerged aquatic vegetation, and early restoration projects would be monitored to assess the response of nonnative species to restoration designs and local environmental conditions. If indicated by monitoring results, the project proponents would implement invasive plant control measures in restored natural communities to help ensure the establishment of native marsh plain plant species. Additionally, the project proponents would actively remove submerged and floating aquatic vegetation in subtidal portions of tidal natural community restoration sites.
- *Environmental Commitment 6 Channel Margin Enhancement*: The temporary effects of channel margin enhancement were not estimated because specific locations for this activity and their areal extent have not been developed. Channel margin enhancement (Sacramento River between Freeport and Walnut Grove, San Joaquin River between Vernalis and Mossdale, Steamboat and Sutter Sloughs, and salmonid migration channels in the interior Delta) would result in the temporary disturbance of channel areas that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 7 Riparian Natural Community Restoration*: The restoration of valley/foothill riparian habitat would result in the temporary disturbance of riparian areas that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: The restoration of vernal pool and alkali seasonal wetland complexes, primarily in CZ 8, would result in the temporary disturbance of grassland areas that would provide opportunities for colonization by invasive plant species.
- *Environmental Commitment 10 Nontidal Marsh Restoration*: Nontidal marsh restoration, which would take place through conversion of agricultural lands primarily in CZ 4, would result in the temporary disturbance of fallow agricultural areas that would provide opportunities for

colonization by invasive plant species. These adverse effects would be reduced by monitoring the development of marsh vegetation to determine if nonnative vegetation needs to be controlled to facilitate the establishment of native marsh vegetation or if restoration success could be improved with supplemental plantings of native species. If indicated by monitoring, nonnative vegetation control measures and supplemental plantings would be implemented.

- *Avoidance and Minimization Measures*: *AMM6 Spoils, Reusable Tunnel Material, and Dredged Material Disposal Plan* would have adverse effects if spoils, RTM, dredged material, or chipped vegetative materials containing viable invasive plant propagules are used as topsoil in uninfested areas.

The adverse effects that would result from the introduction and spread of invasive plants through colonization of temporarily disturbed areas would be minimized by implementation of Environmental Commitment 11, AMM4, AMM10, and AMM11.

Environmental Commitment 11 Natural Communities Enhancement and Management would reduce these adverse effects by implementing invasive plant control within the Alternative 4A restoration areas to reduce competition on native species, thereby improving conditions for special-status species, ecosystem function, and native biodiversity. The invasive plant control efforts would target new infestations that are relatively easy to control or the most ecologically damaging nonnative plants for which effective suppression techniques are available. In aquatic and emergent wetland communities, Brazilian waterweed, perennial pepperweed, barbgrass, and rabbitsfoot grass would be controlled (and tidal mudflats would be maintained). In riparian areas, invasive plant control would focus on reducing or eliminating species such as Himalayan blackberry, giant reed, and perennial pepperweed. In grassland areas, techniques such as grazing and prescribed burning may be used to decrease the cover of invasive plant species.

Implementation of AMM4, AMM10, and AMM11 would also reduce the adverse effects that could result from construction activities. The AMMs provide methods to minimize ground disturbance, guidance for developing restoration and monitoring plans for temporary construction effects, and measures to minimize the introduction and spread of invasive plants. AMM4 would involve the preparation and implementation of an erosion and sediment control plan that would control erosion and sedimentation and restore soils and vegetation in affected areas. The restoration and monitoring plans for implementation of AMM10 would involve methods for stockpiling, storing, and restoring topsoil, revegetating disturbed areas, monitoring and maintenance schedules, adaptive management strategies, reporting requirements, and success criteria. AMM10 would also include planting native species appropriate for the natural community being restored, with the exception of some borrow sites in cultivated lands that would be restored as grasslands.

AMM11 specifies that the project proponent would retain a qualified botanist or weed scientist prior to clearing operations to determine if affected areas contain invasive plants. If areas to be cleared do contain invasive plants, then chipped vegetation material from those areas would not be used for erosion control but would be disposed ~~of~~ to minimize the spread of invasive plant propagules (e.g., burning, composting). During construction of the water conveyance facilities and construction activities associated with the environmental commitments, construction vehicles and construction machinery would be cleaned prior to entering construction sites that are in or adjacent natural communities other than cultivated lands and prior to entering any Alternative 4A restoration sites or conservation lands other than cultivated lands. Vehicles working in or travelling off paved roads through areas with infestations of invasive plant species would be cleaned before travelling to other parts of the study area. Cleaning stations would be established at the perimeter of Alternative 4A activities along construction routes as well as at the entrance to reserve system lands. Biological monitoring would include locating and mapping locations of invasive plant species within the construction areas during the construction phase and the restoration phase. Infestations of invasive plant species would be targeted for control or eradication as part of the restoration and revegetation of temporarily disturbed construction areas.

***NEPA Effects*:** The implementation of AMM4, AMM10, and AMM11, and Environmental Commitment 11 would reduce the potential for the introduction and spread of invasive plants and avoid or minimize the potential effects on natural communities and special-status species; therefore, these effects would not be adverse.

***CEQA Conclusion*:** Under Alternative 4A, impacts on natural communities from the introduction or spread of invasive plants as a result of implementing Alternative 4A would not result in the long-term degradation of a sensitive natural community due to substantial alteration of site conditions and would, therefore, be considered less than significant. No mitigation would be required.

Compatibility with Plans and Policies

Impact BIO-187: Compatibility of the Proposed Water Conveyance Facilities and Other Environmental Commitments with Federal, State, or Local Laws, Plans, Policies, or Executive Orders Addressing Terrestrial Biological Resources in the Study Area

Constructing the water conveyance facilities and implementing associated environmental commitments for Alternative 4A have the potential for being incompatible with plans and policies related to managing and protecting terrestrial biological resources of the study area. A number of laws, plans, policies, programs, and executive orders that are relevant to actions in the study area provide guidance for terrestrial biological resource issues as overviewed in Section 12.2, *Regulatory Setting*, of the Draft EIR/EIS. This overview of plan and policy compatibility evaluates whether Alternative 4A would be compatible or incompatible with such enactments, rather than whether impacts would be adverse or not adverse, or significant or less than significant. If the incompatibility relates to an applicable plan, policy, or executive order adopted to avoid or mitigate terrestrial biological resource effects, then an incompatibility might be indicative of a related significant or adverse effect under CEQA and NEPA, respectively. Such physical effects of Alternative 4A on terrestrial biological resources are addressed in the impacts on natural communities and species. The following is a summary of compatibility evaluations related to terrestrial biological resources for laws, plans, policies, and executive orders relevant to the project.

Federal and State Legislation

- The federal Clean Water Act, Endangered Species Act, Fish and Wildlife Coordination Act, Migratory Bird Treaty Act, Rivers and Harbors Act and Marine Mammal Protection Act all contain legal guidance that either directly or indirectly promotes or stipulates the protection and conservation of terrestrial biological resources in the process of undertaking activities that involve federal decisionmaking. The goals and objectives contained in Alternative 4A that provide the major guidance for implementing the various project elements of Alternative 4A are all designed to promote the long-term viability of the natural communities, special-status species, and common species that inhabit the study area. While some of the environmental commitments of the alternative involve permanent and temporary loss of natural communities and associated habitats during facilities construction and expansion of certain natural communities, the long-term implementation of the project would provide for the long-term viability and expansion of the habitats and special-status species populations in the study area. Alternative 4A environmental commitments would be compatible with the policies and directives for terrestrial biological resources contained in these federal laws.

- The California Endangered Species Act, California Native Plant Protection Act, Porter-Cologne Water Quality Control Act, and Natural Communities Conservation Planning Act are state laws that have relevance to the management and protection of terrestrial biological resources in the study area. Each of these laws promotes consideration of wildlife and native vegetation either through comprehensive planning or through regulation of activities that may have an adverse effect on the terrestrial and aquatic natural resources of the state. Alternative 4A contains goals and objectives that have been developed to promote the species protection and natural resource conservation that are directed by these state laws. Alternative 4A environmental commitments would be compatible with the policies and directives contained in these laws.
- The *Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992* (*Delta Protection Act*) and the *Sacramento-San Joaquin Delta Reform Act*, which updated the Delta Protection Act, promote the maintenance and protection of natural resources and the protection of agricultural land uses in the Delta's primary zone through the goals and policies contained in the 2009 updated Land Use and Resources Management Plan (LURMP). While nothing in the LURMP is binding on state agencies that are project proponents, the LURMP does promote restoration and enhancement of habitats for the terrestrial and aquatic species of the Delta on public land. The project's goals and objectives would be compatible with these LURMP goals (Delta Protection Commission 2010).
- The *Suisun Marsh Preservation Act* of 1974 was designed to protect the Suisun Marsh for long-term use as wildlife habitat, with a goal of preserving and enhancing the quality and diversity of the Marsh's aquatic and wildlife habitats. Alternative 4A would not affect Suisun Marsh; therefore, it would be compatible with the intent of the Suisun Marsh Preservation Act.

Plans, Programs, and Policies

- *The Delta Plan*, which was developed by the Delta Stewardship Council in compliance with the 2009 Sacramento-San Joaquin Delta Reform Act, is mandated to achieve two co-equal goals: provide for a more reliable water supply for California and protect, restore, and enhance the Delta ecosystem. The co-equal goals are to be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place. The project is intended to contain water management and environmental commitments consistent with the Delta Plan. The Delta Stewardship Council will determine whether the project is compatible with the goals and objectives of the Delta Plan prior to its approval. The compatibility of the project with the Delta Plan is considered in detail in Section 13.2.2.2, *The Delta Plan*, of the Draft EIR/EIS.
- *California Wetlands Conservation Policy*, which was adopted by Executive Order in 1993, promotes a long-term gain in the quantity, quality and permanence of wetlands acreages and values in California. The project's environmental commitments that provide for an expansion of wetland acreage and quality in the Delta are compatible with the intent of the California Wetlands Conservation Policy.
- *The North American Waterfowl Management Plan* (*NAWMP*) and *Central Valley Joint Venture* (*CVJV*) strive to maintain and expand wetlands and uplands for waterfowl and shorebirds in the major basins of California's Central Valley. The NAWMP is a management plan jointly approved

by the United States and Canada in 1986. It contains general guidance from the principal wildlife management agencies of the two countries for sustaining abundant waterfowl populations by conserving landscapes through self-directed partnerships (joint ventures) that are guided by sound science. The CVJV is the joint venture established for overseeing NAWMP implementation in the Central Valley. The CVJV is made up of 21 conservation organizations, state and federal government agencies, and one corporation that have formed a partnership to improve the habitat conditions for breeding and nonbreeding waterfowl, breeding and nonbreeding shorebirds, waterbirds, and riparian-dependent songbirds in the Central Valley. The CVJV's 2006 Implementation Plan (Central Valley Joint Venture 2006) establishes conservation objectives and priorities for these bird groups within the basins of the Central Valley. The project study area includes all or portions of three Implementation Plan basins— the Delta, Yolo and Suisun basins. The 2006 Implementation Plan contains basin-specific objectives for wetland restoration, protection of existing wetland habitats, wetland enhancement, adequate power and water supplies for wetland management, agricultural land enhancement, farmland easements that maintain waterfowl food resources on agricultural land, and farmland easements that buffer existing wetlands from urban and residential growth.

Implementation of the Alternative 4A environmental commitments would result in reductions in cultivated land and managed wetland acreage in the Delta only; however, increases in tidal and nontidal wetlands in this basin would be another result. The project also contains a significant commitment to long-term protection of agricultural land (over 9,000 acres) for waterfowl, shorebirds and other sensitive wildlife species. The sum of these actions would be consistent with the objectives of the Implementation Plan.

- Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan, Cosumnes River Preserve Management Plan, Brannan Island and Franks Tract State Recreation Areas General Plan, and the Lower Sherman Island Wildlife Area Land Management Plan are primarily designed to preserve and enhance the natural resource and recreation qualities of these areas. Implementing Alternative 4A, especially construction of water conveyance facilities, and land modification associated with Environmental Commitment 4 restoration activities, could create temporary disruptions to the terrestrial biological resource management activities in these management areas. The ultimate goals of aquatic and terrestrial habitat enhancement and restoration contained in the project would be compatible with the long-term management goals of these areas. Proposed restoration areas in the Delta would be designed to be compatible with and to complement the current management direction for these areas and would be required to adapt restoration proposals to meet current policy established for managing these areas.
- *Suisun Marsh Preservation Agreement* and *Suisun Marsh Plan* are the most recent efforts by the state and federal agencies responsible for Suisun Marsh (the Marsh) to maintain its long-term viability as managed wetlands and wildlife habitat, consistent with the Suisun Marsh Preservation Act. Alternative 4A would not directly or indirectly affect the Suisun Marsh and its natural habitats; therefore, it would be consistent with the Plan's management goals.
- *California Aquatic Invasive Species Management Plan* does not address terrestrial invasive species. Implementation of the project's habitat management objectives affect terrestrial species that utilize study area aquatic habitats. These effects are positive in that the project's objectives are to control and remove invasive aquatic species that are detrimental to native aquatic and terrestrial species. Implementation of project's environmental commitments would be undertaken with the goal of avoiding any further spread of aquatic invasive species. Alternative

4A would, therefore, be compatible with the objectives of the California Aquatic Invasive Species Management Plan.

- *Habitat Conservation Plans and Natural Community Conservation Plans* are the subject of a detailed analysis in Section 12.3.3.18, *Effects on Other Conservation Plans*, in the Draft EIR/EIS. The analysis considers the compatibility of the alternatives with all HCPs and NCCPs that share planning area with the study area. The Alternative 4A study area overlaps geographically with six conservation plans. The water conveyance facilities construction actions would still overlap with the South Sacramento, San Joaquin, East Contra Costa and East Alameda County planning areas, but there would be little effect on implementation of the HCP/NCCPs for these areas. The environmental commitments associated with Alternative 4A would remove relatively small acreages of primarily cultivated land in all six of the overlapping plan areas (Yolo, Solano, South Sacramento, East Contra Costa, East Alameda and San Joaquin County HCP/NCCPs). The consistency analysis below indicates that the degree to which the competition for conservation lands would impact the conservation goals of other plans is limited. Alternative 4A would have much less risk from competition for conservation lands. In most cases, because of the flexibility for acquisition targets incorporated into Alternative 4A and other plans, the potential conflict would be manageable, and significant conflicts with the implementation of overlapping plans could be avoided. In certain cases, especially pertaining to similar restoration objectives, perceived conflicts may also represent opportunities for collaboration to jointly achieve similar conservation goals. Because implementing Alternative 4A would not result in a conflict with the provisions of an adopted HCP, NCCP or other approved local, regional or state habitat conservation plan, there would be a less-than-significant impact.

Executive Orders

- *Executive Order 11990: Protection of Wetlands* requires all federal agencies to consider wetland protection in their policies and actions. The project proposes to protect, enhance and expand the wetlands of the study area, and, therefore, would be compatible with Executive Order 11990.

- *Executive Order 13112: Invasive Species* directs federal agencies to prevent and control the introduction and spread of invasive species in a cost-effective and environmentally sound manner. Alternative 4A construction and restoration actions have the potential to both introduce and spread invasive species in the study area. Implementation of AMM11 described in this in Appendix D, *Substantive BDCP Revisions* of this RDEIR/SDEIS could make Alternative 4A implementation compatible with Executive Order 13112.

- *Executive Order 113443: Facilitation of Hunting Heritage and Wildlife Conservation* directs federal agencies whose activities affect public land management, outdoor recreation, and wildlife management to facilitate the expansion and enhancement of hunting opportunities, and the management of game species and their habitat. Alternative 4A environmental commitments that involve conversion of cultivated land and managed wetland to tidal and nontidal wetlands and other natural communities would conflict with the hunting expansion and enhancement aspects of this executive order. Refer to Chapter 15, *Recreation*, of the Draft EIR/EIS for a detailed analysis of the effects of alternatives on hunting opportunities. The habitat protection and expansion environmental commitments of Alternative 4A would be compatible with the executive order's goal of facilitating the management of habitats for some game species.

NEPA Effects: The potential plan and policy incompatibilities of implementing Alternative 4A identified in the analysis above indicate the potential for a physical consequence to the environment.

The primary physical consequence of concern is the conversion of cultivated land and managed wetland to natural wetland and riparian habitat in the study area. The physical effects are discussed in the Shorebirds and Waterfowl analysis above, and no additional NEPA effects determination is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Section 13.2, *Regulatory Setting*, of the Draft EIR/EIS for a further discussion of the responsibilities of state and federal agencies to comply with local regulations, and a discussion of the relationship between plan and policy consistency and physical consequences to the environment.

CEQA Conclusion: The potential plan and policy incompatibilities of implementing Alternative 4A identified in the analysis above indicate the potential for a physical consequence to the environment. The primary physical consequence of concern is the conversion of cultivated land and managed wetland to natural wetland and riparian habitat in the study area. The physical effects are discussed in the Shorebirds and Waterfowl analysis above, and no additional CEQA conclusion is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Section 13.2, *Regulatory Setting*, of the Draft EIR/EIS for a further discussion of the responsibilities of state and federal agencies to comply with local regulations, and a discussion of the relationship between plan and policy consistency and physical consequences to the environment.

4.3.9 Land Use

Impact LU-1: Incompatibility with Applicable Land Use Designations, Goals, and Policies as a Result of Constructing the Proposed Water Conveyance Facility

NEPA Effects: Incompatibility with land use regulations stemming from the construction of water conveyance structures under Alternative 4A would be identical to those described for Alternative 4.

Like Alternative 4, Alternative 4A would place temporary and permanent structures on lands designated for other uses by the general plans of Sacramento, San Joaquin, Contra Costa, and Alameda Counties. As described in Table 13-11 in Chapter 13, *Land Use*, of the Draft EIR/EIS, this would include 15 acres in Alameda County; almost 4,302 acres in Contra Costa County; 2,112 acres in Sacramento County; and 2,815 acres in San Joaquin County. The construction of the water conveyance facilities would require land use activities that would be incompatible with land use designations, goals and policies ascribed to the study area and for the purposes of reducing environmental impacts. To the extent that constructing Alternative 4A would result in incompatibilities with land use designations, goals and policies designed to avoid or reduce environmental effects, these potential incompatibilities are described in Chapter 13, *Land Use*, Section 13.3.3.9, Impact LU-1 in Appendix A of this RDEIR/SDEIS. As discussed in Section 13.3.2, *Determination of Effects*, of the Draft EIR/EIS, to the extent that alternatives are incompatible with such land use designations, goals, and policies, any related environmental effects are discussed in other chapters.

CEQA Conclusion: These incompatibilities indicate the potential for a physical consequence to the environment. As discussed in Section 13.3.2, *Determination of Effects*, of the Draft EIR/EIS, the physical effects they suggest are discussed in other chapters throughout this document. The relationship between plans, policies, and regulations and impacts on the physical environment is discussed in Section 13.3.1, *Methods for Analysis*, of the Draft EIR/EIS.

Impact LU-2: Conflicts with Existing Land Uses as a Result of Constructing the Proposed Water Conveyance Facility

NEPA Effects: Effects related to conflicts with existing land uses under Alternative 4A would be identical to those described for Alternative 4. As for Alternative 4, construction and operation of physical facilities for water conveyance would create temporary or permanent conflicts with existing land uses (including displacement of existing structures and residences) because of the construction of permanent features of the facility. As described in Table 13-12 of Chapter 13, *Land Use*, 85 structures would be displaced, including 19 residential, 7 recreational, 50 storage/support, and 9 other structures (such as power/utility structures and bridges). Indirect impacts would primarily happen as a result of incompatibility with adjacent land uses or the loss or increased difficultly of access to parcels. Table 13-12 in Appendix A of this RDEIR/SDEIS, summarizes the estimated number of structures affected across structure type and alternative and Mapbook Figure M13-4 in the Mapbook Volume of the Draft EIR/EIS shows the distribution of these effects across the Modified Pipeline/Tunnel conveyance alignment.

The removal of a substantial number of existing permanent structures as a result of constructing the water conveyance facility would be considered a direct, adverse socioeconomic effect of this alternative under NEPA. When required, the project proponents would provide compensation to property owners for losses due to implementation of the alternative, which would reduce the severity of economic effects related to this physical impact, but would not reduce the severity of the physical impact itself. Project conflicts with existing public structures under Alternative 4A are addressed in Section 4.3.16, *Public Services and Utilities*, of this RDEIR/SDEIS; potential adverse effects on the environment related to the potential release of hazardous materials contained in structures to be demolished are addressed in 4.3.20, *Hazards and Hazardous Materials*, of this RDEIR/SDEIS; and potential adverse effects on traditional cultural properties are addressed in Section 4.3.14, *Cultural Resources*, of this RDEIR/SDEIS.

CEQA Conclusion: Construction of the proposed water conveyance facility would necessitate the removal of a substantial number of existing permanent structures. The removal of existing structures is not, in itself, considered a significant environmental impact, though removal might entail economic impacts. Significant environmental impacts would only result if the structures qualified as "historical resources" or the removal of structures led to significant physical effects on certain other resources. As discussed in Section 13.3.2, *Determination of Effects*, of the Draft EIR/EIS, such effects are discussed in other sections throughout the document. Project conflicts with existing public structures under Alternative 4A are addressed in Section 4.3.16, *Public Services and Utilities*, of this RDEIR/SDEIS; potential impacts on the public and environment related to the potential release of hazardous materials contained in structures to be demolished are addressed in Section 4.3.20, *Hazards and Hazardous Materials*, of this RDEIR/SDEIS; and potential impacts on "historical resources" (including qualifying structures) and traditional cultural properties are addressed in Section 4.3.14, *Cultural Resources*, of this RDEIR/SDEIS. Where applicable, project proponents will provide compensation to property owners for losses due to implementation of Alternative 4A. This compensation would not constitute mitigation for any related physical impact; however, it would reduce the severity of economic effects.

Impact LU-3: Create Physical Structures Adjacent to and through a Portion of an Existing Community as a Result of Constructing the Proposed Water Conveyance Facility

NEPA Effects: Effects related to any potential division of an existing community as a result of the construction of water conveyance facilities under Alternative 4A would be identical to those described for Alternative 4. Construction of permanent facilities and associated work areas would be located around the community of Hood. A tunnel carrying water south from Intakes 2 and 3 to the intermediate forebay would be placed under the community. The tunnel would be constructed below the surface and would not interfere with the existing community; therefore, the alignment would not create a physical structure adjacent to or through the existing community. A temporary power line would be constructed around the northern, eastern, and southern sections of the community, which would provide power to the intake work areas during construction. Additionally, a temporary work area associated with construction of the conveyance facilities would be built adjacent to Hood on the southern side of the community, and would serve as a staging area during the construction phase. It would consist of facilities such as parking areas, offices, and construction equipment storage. Construction and the long-term placement of Intakes 3 and 5, although not adjacent to Hood, would be built about one-quarter mile north and one-half mile south of Hood, respectively, and would substantially alter the lands to the north and south of the community. While permanent physical structures adjacent to or through Hood are not anticipated to result from this alternative, activities associated with their construction could make it difficult to travel within and around Hood in certain areas for a limited period of time. Mitigation Measures TRANS-1a and TRANS-1b are available to address this effect. Additionally, the lasting placement of the intake facilities would represent physical structures that would substantially alter the setting of the community's surroundings, constituting an adverse effect.

CEQA Conclusion: During the construction of the tunnels between Intakes 3 and 5 and the intermediate forebay, construction activities would occur to the north and south of the community of Hood, and a proposed temporary power line would cross through portions of the community. Even though access to and from the community would be maintained over the long-term, the nearby construction of the temporary work area would substantially alter the setting of the community in the near term. Similarly, the nearby construction of Intakes 3 and 5, although not adjacent to Hood, would create permanent physical structures approximately one-quarter mile north and one-half mile south of Hood that would substantially alter the community's surroundings. These structures would therefore result in a significant and unavoidable impact. Implementation of Mitigation Measures TRANS-1a and TRANS-1b would reduce the severity of this impact by supporting continued access to and from the community on transportation routes; however, permanent structures in the community's vicinity would remain, and the impact would be significant and unavoidable.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Chapter 19, *Transportation*, under Impact TRANS-1 in the discussion of Alternative 4 in the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1b in Chapter 19, *Transportation*, under Impact TRANS-1 in the discussion of Alternative 4 in the Draft EIR/EIS.

Impact LU-4: Incompatibility with Applicable Land Use Designations, Goals, and Policies as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Effects of Alternative 4A related to incompatibility with applicable land use designations, goals, and policies resulting from implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar in mechanism to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 4A would protect and restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, and 6-10, as compared with 83,800 acres under Alternative 4. Up to 4.6 miles of channel margin habitat would be enhanced under Alternative 4A with Environmental Commitment 6 (compared with 20 miles under Alternative 4). Similarly, Environmental Commitments 11, 12, 15, and 16 would be implemented only at limited locations. Conservation Measures 2, 5, 13, 14, and 17–21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 4A would likely be substantially smaller than those associated with Alternative 4. Because Alternative 4A doesn't include those Conservation Measures, the BDCP will be treated as a covered activity under the Delta Plan. The consistency between this alternative and the Delta Plan is discussed in detail in Appendix G of this RDEIR/SDEIS.

Because the locations for the implementation of these environmental commitments are unknown at this time, there is some uncertainty about whether new land uses related to these environmental commitments would be incompatible with existing land use designations, goals, and policies.

However, the restoration associated with these environmental commitments would be consistent with open space, and would generally be compatible with the study area, which predominantly consists of agriculture and open space. Most activities would be anticipated to take place on land designated for agriculture, open space, natural preserve and recreation; therefore, local designations, goals, and policies related to preservation of those attributes would likely be compatible with the restoration actions that would take place under these environmental commitments. Additionally, actions would be limited compared to other BDCP alternatives, and actions would be dispersed across the study area. Specific impacts to agriculture or wildlife habitat are evaluated in Chapter 13, *Agricultural Resources*, and 11, *Terrestrial Resources*. Therefore, implementation of this alternative is not anticipated to result in substantial incompatibilities with local land use regulations. Impacts would not be adverse.

CEQA Conclusion: Because specific locations for the implementation of many of these land-intensive actions are unknown at this point, there is some uncertainty about whether new land uses related to these environmental commitments would be incompatible with existing land uses. However, the restoration associated with these environmental commitments would be consistent with open space, and would generally be compatible with the study area, which is a predominantly agricultural area. Specific impacts to agriculture or wildlife habitat are evaluated in Chapter 13, *Agricultural Resources*, and 11, *Terrestrial Resources*. Therefore, implementation of this alternative is not anticipated to result in substantial incompatibilities with local land use regulations. Impacts would be less than significant because environmental commitment actions would be largely consistent with open space and agricultural uses, actions would be limited compared to other BDCP alternatives, and actions would be dispersed across the study area. No mitigation is required.

Impact LU-5: Conflicts with Existing Land Uses as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Effects related to conflicts with existing land uses under Alternative 4A would be similar in mechanism to those described for Alternative 4, but to a substantially smaller magnitude based on the conservation activities proposed under Alternative 4A (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS and under Impact LU-4, above). While the location of each restoration and/or enhancement action is not known at this time, it is possible that implementing these measures may result in temporary (e.g., construction activities that may conflict with land designated as open space) or permanent (e.g., displacement of existing residents and removal of existing structures) physical conflicts with existing land uses in or immediately adjacent to the study area.

Because the locations for the implementation of these environmental commitments are unknown at this time, there is some uncertainty about whether new land uses related to these environmental commitments would be incompatible with existing land uses. However, the restoration associated with these environmental commitments would be consistent with open space, and would generally be compatible with land uses within and adjacent to the study area, which predominantly consists of agriculture and open space. Most activities would be anticipated to take place on land designated for agriculture, open space, natural preserve and recreation; therefore, land uses related to preservation of those attributes would likely be compatible with the restoration actions that would take place under these environmental commitments. Additionally, actions would be limited compared to other BDCP alternatives, and actions would be dispersed across the study area. Specific impacts to agriculture or wildlife habitat are evaluated in Chapter 13, *Agricultural Resources*, and 11, *Terrestrial Resources*. Therefore, implementation of this alternative is not anticipated to result in substantial incompatibilities with local land use regulations. Impacts would not be adverse.

CEQA Conclusion: Because specific locations and types of restoration to be implemented are unknown at this point, there is some uncertainty about whether new land uses related to these environmental commitments would conflict with existing land uses or result in the permanent conversion of land uses. However, the restoration associated with these environmental commitments would be consistent with open space, and would generally be compatible with the study area, which is a predominantly agricultural area. Specific impacts to agriculture or wildlife habitat are evaluated in Chapters 13, *Agricultural Resources*, and 11, *Terrestrial Resources*. Therefore, implementation of this alternative is not anticipated to conflict with existing land uses. Impacts would be less than significant because environmental commitment actions would be largely consistent with open space and agricultural uses, actions would be limited compared to other BDCP alternatives, and actions would be dispersed across the study area. No mitigation is required.

Impact LU-6: Create Physical Structures Adjacent to and through a Portion of an Existing Community as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and16

NEPA Effects: Effects related to the physical division of an existing community under Alternative 4A would be similar in mechanism to those described for Alternative 4, but to a substantially smaller magnitude based on the conservation activities proposed under Alternative 4A (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS and under Impact LU-4, above). Because the locations for the implementation of these habitat restoration and enhancement activities are unknown at this point, a conclusion about this alternative's potential to divide an existing community cannot be made; however, because, large-scale restoration actions that take place in areas suitable for open space, resource conservation, and habitat are not likely to create permanent physical divisions in existing communities, this impact is not anticipated to be adverse.

CEQA Conclusion: Because the locations for the implementation of habitat restoration and enhancement activities are unknown at this point, a conclusion about this alternative's potential to divide an existing community cannot be made; however, because, large-scale restoration actions that take place in areas suitable for open space, resource conservation, and habitat are not likely to create permanent physical divisions in existing communities, this impact is anticipated to be less than significant.

4.3.10 Agricultural Resources

Impact AG-1: Temporary Conversion, Short-Term Conversion, and Permanent Conversion of Important Farmland or of Land Subject to Williamson Act Contracts or in Farmland Security Zones as a Result of Constructing the Proposed Water Conveyance Facility

NEPA Effects: The temporary and short-term conversion and permanent conversion of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones to nonagricultural uses would be identical to those described under Alternative 4 (as described in Chapter 14, *Agricultural Resources,* Section 14.3.3.9 in Appendix A of this RDEIR/SDEIS) and would constitute an adverse effect on the physical environment. Alternative 4A would result in the temporary or short-term conversion of approximately 1,495 acres of Important Farmland and 1,132 acres of land subject to Williamson Act contracts to other uses. Permanent features associated with this alternative could convert approximately 3,909 acres of Important Farmland and 2,035 acres of land subject to Williamson Act contracts to other uses. Mapbook Figure M14-7 in the Mapbook Volume of the Draft EIR/EIS shows all of the construction features (including temporary work areas) associated with this proposed water conveyance facility alignment along with Important Farmland. Disposal and reuse of RTM (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), along with Mitigation Measure AG-1, would be available to reduce these effects.

CEQA Conclusion: Construction of physical structures associated with the water conveyance facility proposed under this alternative would occupy Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones, directly precluding agricultural use for the duration of construction. Temporary and short-term construction of facilities would convert approximately 1,495 acres of Important Farmland and 1,132 acres of land subject to Williamson Act contracts or in Farmland Security Zones to other uses. Physical structures would also permanently convert approximately 3,909 acres of Important Farmland and 2,035 acres of land subject to Williamson Act contracts or in Farmland Security Zones to other uses. As described above and in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, it is anticipated that the RTM and dredged material would be removed from RTM storage areas (which represent a substantial portion of the permanent impact areas) and reused, as appropriate, as bulking material for levee maintenance, as fill material for habitat restoration projects, or other beneficial means of reuse identified for the material. Because these activities would convert a substantial amount of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones to nonagricultural uses, however, they are considered significant impacts on the environment. Implementation of Mitigation Measure AG-1 would reduce these impacts by implementing activities such as siting project footprints to encourage continued agricultural production; relocating or replacing agricultural infrastructure in support of continued agricultural activities; engaging counties, owners/operators, and other stakeholders in developing optional agricultural stewardship approaches; and/or preserving agricultural land through offsite easements or other agricultural land conservation interests. However, these impacts remain significant and unavoidable after implementation of this measure for the same reasons provided under Alternative 4. For further discussion of potential incompatibilities with land use designations, see Section 4.3.9, *Land Use*, in this RDEIR/SDEIS.

Mitigation Measure AG-1: Develop an Agricultural Lands Stewardship Plan (ALSP) to Maintain Agricultural Productivity and Mitigate for Loss of Important Farmland and Land Subject to Williamson Act Contracts or in Farmland Security Zones

Please see Mitigation Measure AG-1 under Impact AG-1 in the discussion of Alternative 4 in the Draft EIR/EIS.

Impact AG-2: Other Effects on Agriculture as a Result of Constructing and Operating the Proposed Water Conveyance Facility

Effects associated with construction and operation of the water conveyance facility under this alternative would be identical to those described under Alternative 4 in terms of effects related to seepage from the operation of forebays and from disruption of drainage and irrigation facilities during construction of water conveyance facilities. The conveyance alignment constructed under this alternative would cross or interfere with approximately 43 miles of agricultural delivery canals and drainage ditches. These activities could create indirect but adverse effects on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation in localized areas adjacent to forebays and through disruption of drainage and irrigation facilities.

Under Alternative 4A, Operational Scenarios H3 and H4, the operation of new physical facilities combined with hydrodynamic effects of habitat restoration activities could indirectly affect agriculture by causing changes to the quality of irrigation water in parts of the study area. Relative to Existing Conditions, Alternative 4A would result in an increase in the number of days the Bay-Delta WQCP EC objectives would be exceeded in the Sacramento River at Emmaton, and in the San Joaquin River at San Andreas Landing (Table EC-1 in Appendix B of this RDEIR/SDEIS). The percent of days the Emmaton EC objective would be exceeded for the entire period modeled (1976–1991) would increase from 6% under Existing Conditions to 17–18% and the percent of days out of compliance would increase from 11% under Existing Conditions to 26–28%, depending on the operations scenario. The percent of days the San Andreas Landing EC objective would be exceeded would increase from 1% to 2% under Operational Scenario H3, and would decrease to 0% under Operational Scenario H4. The percent of days out of compliance with the EC objective for San Andreas Landing would increase from 1% to 4% for Operational Scenario H3, and would decrease to 0% under Operational Scenario H4.

As discussed in Section 4.3.4, *Water Quality*, of this RDEIR/SDEIS, sensitivity analyses suggest that many of these modeled exceedances are a result of modeling artifacts or a result of operating rules used by the CALSIM II model under extreme hydrologic and operational conditions where there is not enough water supply to meet all requirements. In these cases, CALSIM II uses a series of operating rules to reach a solution that is a simplified version of the very complex decision processes that SWP and CVP operators would use in actual extreme conditions. Thus, it is unlikely that the Emmaton objective would actually be violated due to dead pool conditions, as suggested by modeling results. In the case of San Andreas Landing, the small number of modeled exceedances not attributable to modeling artifacts would be small in magnitude, last only a few days, and could be addressed with real time operations of the SWP and CVP (see Chapter 8, *Water Quality,* Section 8.3.1.1, in Appendix A of this RDEIR/SDEIS for a description of real time operations of the SWP and CVP). However, the results at Emmaton indicate that water supply could be either under greater stress or under stress earlier in the year, and EC levels at Emmaton and in the western Delta may increase as a result, leading to EC degradation and increased possibility of adverse effects on agricultural beneficial uses.

Average EC levels at the western and southern Delta compliance locations would decrease, except at Emmaton during the drought period, from 3–38% for the entire period modeled (1976–1991) and 3–32% during the drought period modeled (1987–1991) (Tables EC-8A and EC-8B in Appendix B of this RDEIR/SDEIS). At Emmaton, there would be an increase in average EC for the drought period of 4–5%, and a decrease of 5–7% for the entire period modeled. There would be increases in average EC at two interior Delta locations: the S. Fork Mokelumne River at Terminous average EC would increase 5% for the entire period modeled and 4% during the drought period modeled; and San Joaquin River at San Andreas Landing average EC would decrease 6% for the entire period modeled, but increase 1–3% during the drought period modeled. The geographic extent and magnitude of EC increases relative to Existing Conditions would be smaller than those described for Alternative 4 in Chapter 8, *Water Quality*, Section 8.3.3.9 in Appendix A of this RDEIR/SDEIS.

Relative to the No Action Alternative (ELT), the percent of days exceeding EC objectives or percent of days out of compliance would increase at the Sacramento River at Emmaton, San Joaquin River at San Andreas Landing, and Old River near Middle River and at Tracy Bridge (Table EC-1 in Appendix B of this RDEIR/SDEIS). The increase in percent of days exceeding the EC objective would be 5% or less at these locations, depending on the operational scenario (i.e., H3 or H4). The increase in percent of days out of compliance would be 7% or less at these locations, depending on the operational scenario.

In general, the changes in frequency of exceedances of EC objectives relative to the No Action Alternative (ELT) would be similar to those discussed above relative to Existing Conditions, and thus the conclusions of the sensitivity analyses discussed above extend to the comparison to the No Action Alternative (ELT). For the entire period and drought period modeled, average EC levels would increase at interior and southern Delta locations: the average EC increase would be 5% for the S. Fork Mokelumne River at Terminous and 1% or less in Old River at Middle River and Tracy Bridge (Tables EC-8A and EC-8B in Appendix B of this RDEIR/SDEIS). The geographic extent and magnitude of EC increases relative to the No Action Alternative (ELT) would be smaller than those described for Alternative 4 in Chapter 8, *Water Quality*, Section 8.3.3.9, in Appendix A of this RDEIR/SDEIS.

NEPA Effects: Considered together, construction and operation of the water conveyance facility under this alternative could create indirect but adverse effects on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation in localized areas and disruption of drainage and irrigation facilities. Water quality modeling results indicate that it is unlikely that there would be increased frequency of exceedance of agricultural EC objectives in the western, interior, or southern Delta. However, there could be increased long-term and drought period average EC levels during the summer months in the Sacramento River at Emmaton under Alternative 4A relative to the No Action Alternative, which could adversely affect agricultural beneficial uses. Implementation of Mitigation Measures AG-1, GW-1, GW-5, and WQ-11 (including Mitigation Measure WQ-11a) will reduce the severity of these adverse effects.

CEQA Conclusion: Water conveyance facility construction and operation could create a significant impact on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation in localized areas and disruption of drainage and irrigation facilities. Water quality modeling results indicate that average EC levels at Emmaton would increase by up to 5% relative to Existing Conditions during the summer months of the drought period, and more generally in dry and critical water year types. The increases during the drought period could cause substantial degradation of water quality and thereby impact the agricultural beneficial uses in the western Delta. The western Delta is CWA Section 303(d) listed for elevated EC and the increased EC degradation that could occur in the western Delta could make beneficial use impairment measurably worse. The comparison to Existing Conditions reflects changes in EC due to both Alternative 4A operations and climate change/sea level rise.

Implementation of Mitigation Measures AG-1, GW-1, GW-5, and WQ-11 (including Mitigation Measure WQ-11a) will reduce the severity of these impacts by implementing activities such as siting project footprints to encourage continued agricultural production; monitoring changes in groundwater levels during construction; offsetting water supply losses attributable to construction dewatering activities; monitoring seepage effects; relocating or replacing agricultural infrastructure in support of continued agricultural activities; engaging counties, owners/operators, and other stakeholders in developing optional agricultural stewardship approaches; and/or preserving agricultural land through offsite easements or other agricultural land conservation interests. Implementation of Mitigation Measure WQ-11 (including Mitigation Measure WQ-11a) would be expected to reduce the water quality effects on agricultural resources to a less-than-significant level. However, the impact related to conversion of Important Farmland would remain significant and unavoidable after implementation of these measures for the same reasons provided under Alternative 4.

Mitigation Measure AG-1: Develop an Agricultural Lands Stewardship Plan (ALSP) to Maintain Agricultural Productivity and Mitigate for Loss of Important Farmland and Land Subject to Williamson Act Contracts or in Farmland Security Zones

Please see Mitigation Measure AG-1 under Impact AG-1 in the discussion of Alternative 4 in Chapter 14, *Agricultural Resources*, of the Draft EIR/EIS.

Mitigation Measure GW-1: Maintain Water Supplies in Areas Affected by Construction Dewatering

Please see Mitigation Measure GW-1 under Impact GW-1 in the discussion of Alternative 1A in Chapter 7, *Groundwater*, of the Draft EIR/EIS.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A in Chapter 7, *Groundwater*, of the Draft EIR/EIS.

Mitigation Measure WQ-11: Avoid, Minimize, or Offset, as Feasible, Reduced Water Quality Conditions

Please see Mitigation Measure WQ-11 under Impact WQ-11 in the discussion of Alternative 1A in Chapter 8, *Water Quality*, of the Draft EIR/EIS. (Mitigation Measure WQ-11b does not apply to Alternative 4A).

Mitigation Measure WQ-11a: Adaptively Manage Diversions at the North and South Delta Intakes to Reduce or Eliminate Water Quality Degradation in Western Delta

Please see Mitigation Measure WQ-11a under Impact WQ-11 in the discussion of Alternative 4A in Section 4.3.4, *Water Quality*, of this RDEIR/SDEIS.

Impact AG-3: Temporary Conversion, Short-Term Conversion, and Permanent Conversion of Important Farmland or of Land Subject to Williamson Act Contracts or in Farmland Security Zones as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

Effects of Alternative 4A related to the conversion of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones associated with these environmental commitment activities would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 4A would restore up to approximately 15,548 acres of habitat under Environmental Commitments 3, 4, 6–10 as compared with 83,800 acres under Alternative 4. Channel margin enhancement would be implemented on up to 4.6 levee miles compared to 20 miles under Alternative 4. Similarly, Environmental Commitments 11, 12, 15, and 16 would be implemented only at limited locations. Installation of nonphysical fish barriers at Georgiana Slough may require conversion of a small area of Important Farmland for potential construction of an access road and/or storage facility. Conservation Measures 2, 5, 13, 20, and 21 would not be implemented as part of this alternative. Considered together, the magnitude of effects under Alternative 4A would likely be substantially smaller than those associated with Alternative 4.

NEPA Effects: Because locations have not been selected for many of these habitat restoration and enhancement activities, the precise extent of this effect is unknown. However, based on the large proportion of land in the Conservation Zones designated as Important Farmland and/or subject to Williamson Act contracts or in Farmland Security Zones, it is anticipated that a substantial area of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones would be directly converted to habitat purposes under this alternative, resulting in an adverse effect on the environment. While conflicts with or cancellation of Williamson Act contracts would not—by itself—constitute an adverse effect on the quality of the human environment, the related conversion of the underlying agricultural resource would result in such an effect. Mitigation Measure AG-1 would be available to lessen the severity of these potential effects. Also, under the provisions of Government Code §51223, it may be feasible to rescind Williamson Act contracts for agricultural use, and enter into open space contracts under the Williamson Act, or open space easements pursuant to the Open Space Easement Act. To the extent this mechanism is used, it would eliminate the Williamson Act conflicts otherwise resulting from changes from agriculture to restoration and mitigation uses. For further discussion of potential incompatibilities with land use policies, see Section 4.3.9, *Land Use*, of this RDEIR/SDEIS.

CEQA Conclusion: This alternative would restore up to 1,400 acres under environmental commitments geared toward the restoration of various natural communities. Additionally, up to 4.6 linear miles of channel margin habitat would be enhanced. Implementation of restoration activities and other conservation actions could result in conversion of a substantial amount of Important Farmland and conflict with land subject to Williamson Act contracts or in Farmland Security Zones, resulting in a significant impact on agricultural resources in the study area. Implementation of Mitigation Measure AG-1 will reduce the severity of these impacts by implementing activities such as siting features to encourage continued agricultural production; relocating or replacing agricultural infrastructure in support of continued agricultural activities; engaging counties, owners/operators, and other stakeholders in developing optional agricultural stewardship approaches; and/or preserving agricultural land through offsite easements or other agricultural land conservation interests. However, these impacts remain significant and unavoidable after implementation of this measure for the same reasons provided under Alternative 4.

Mitigation Measure AG-1: Develop an Agricultural Lands Stewardship Plan (ALSP) to Maintain Agricultural Productivity and Mitigate for Loss of Important Farmland and Land Subject to Williamson Act Contracts or in Farmland Security Zones

Please see Mitigation Measure AG-1 under Impact AG-1 in the discussion of Alternative 4 in Chapter 14, *Agricultural Resources*, of the Draft EIR/EIS.

Impact AG-4: Other Effects on Agriculture as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

Effects of Alternative 4A related to the conversion of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones associated with these environmental commitment activities would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction,* of this RDEIR/SDEIS, Alternative 4A would restore up to approximately 15,548 acres of habitat as compared with 83,800 acres under Alternative 4. Channel margin enhancement would be implemented on up to 4.6 levee miles compared to 20 miles under Alternative 4. Similarly, Environmental Commitments 11, 12, 15, and 16 would be implemented only at limited locations. Conservation Measures 2, 5, 13, 20, and 21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 4A would likely be substantially smaller than those associated with Alternative 4, and effects on agricultural activities related to increased frequency of floodplain inundation would not occur.

Increased frequency of inundation associated with proposed tidal habitat restoration and channel margin habitat enhancement would result in increased groundwater recharge, which could result in groundwater level rises and soil saturation on adjacent lands, as described under Chapter 7, *Groundwater*, Impact GW-6, in Appendix A of this RDEIR/SDEIS. These conditions could limit agricultural production in certain areas. Conversely, in areas where the project results in a larger vertical distance between the water table and crop roots, plants with shallow roots may not be able to extract enough water to maintain optimal growth without modifying irrigation or drainage infrastructure. While the geographic incidence and potential severity of these effects are unknown and would depend on existing localized groundwater levels in the vicinity of sites chosen for restoration, they would be anticipated to create an adverse effect on agricultural resources if they were to substantially restrict agricultural uses.

As discussed in Section 4.3.4, *Water Quality*, under Impact WQ-12 in this RDEIR/SDEIS, implementation of these conservation actions would not introduce new sources of EC into the study area. Therefore, as they relate to salinity of irrigation water, these measures would not be anticipated to restrict agricultural uses within the study area. Implementation of tidal wetland restoration would increase the exchange of tidal water in restoration areas; however, consideration of this measure and its potential effects on electrical conductivity in the Delta has been incorporated in the assessment of water conveyance facility operations under Impact AG-2.

Construction activities and the permanent footprints associated with land acquired for habitat restoration or enhancement could directly or indirectly disrupt existing agricultural irrigation and drainage facilities throughout the study area. Where irrigation or drainage infrastructure is disconnected from the farmland it serves, agricultural uses could be substantially restricted. However, the location and severity of this effect would depend on site-specific conditions.

Restoration implemented under Alternative 4A could result in substantial changes in land use patterns in parts of the study area, which could indirectly affect some farmlands by causing changes to the microclimates surrounding sensitive agricultural crops. For example, large areas of tidal habitat could create a localized climate that would be less supportive of yields of certain crops adjacent to the areas. However, this effect is speculative and its potential severity would depend on site-specific conditions.

The project proponents would acquire and protect up to approximately 10,100 acres of cultivated lands and manage them for specific habitat values corollary to agricultural use for species including Swainson's hawk, giant garter snake, greater sandhill crane, white-tailed kite, and tricolored blackbird. While acquisition of these lands would protect agricultural uses on the majority of these lands, specific management actions implemented could reduce crop yields, restrict crop choices, and convert small portions of cultivated lands to nonagricultural uses, as described under Alternative 4. Overall, these effects would not be anticipated to result in the substantial restriction of agricultural uses.

NEPA Effects: Implementation of conservation actions under this alternative could create indirect but adverse effects on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation and seepage or disruption of drainage and irrigation facilities. Further evaluation of these effects would depend on additional information relating to the location of these activities and other detailed information. However, implementation of Mitigation Measures AG-1 and GW-5 will reduce the severity of these adverse effects.

CEQA Conclusion: Implementation of conservation actions under this alternative could create a significant impact on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation and seepage or disruption of drainage and irrigation facilities. Further evaluation of these effects would depend on additional information relating to the location of these activities and other detailed information. Implementation of Mitigation Measures AG-1 and GW-5 will reduce the severity of these impacts by implementing activities such as siting features to encourage continued agricultural production; monitoring seepage effects; relocating or replacing agricultural infrastructure in support of continued agricultural activities; engaging counties, owners/operators, and other stakeholders in developing optional agricultural stewardship approaches; and/or preserving agricultural land through offsite easements or other agricultural land conservation interests. However, these impacts remain significant and unavoidable after implementation of these measures for the same reasons provided under Alternative 4.

Mitigation Measure AG-1: Develop an Agricultural Lands Stewardship Plan (ALSP) to Maintain Agricultural Productivity and Mitigate for Loss of Important Farmland and Land Subject to Williamson Act Contracts or in Farmland Security Zones

Please see Mitigation Measure AG-1 under Impact AG-1 in the discussion of Alternative 4 in Chapter 14, *Agricultural Resources*, of the Draft EIR/EIS.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A in Chapter 7, *Groundwater*, of the Draft EIR/EIS.

4.3.11 Recreation

Impact REC-1: Permanent Displacement of Existing Well-Established Public Use or Private Commercial Recreation Facility Available for Public Access as a Result of the Location of Proposed Water Conveyance Facilities

NEPA Effects: The extent of the permanent displacement of public use or private commercial recreation areas located within the Delta occurring under Alternative 4A would be the same as described for Alternative 4, as described in Chapter 15, *Recreation,* Section 15.3.3.9 in Appendix A of this RDEIR/SDEIS. The recreation areas that could be adversely affected are the Cosumnes River Preserve and Clifton Court Forebay. Recreation could be disrupted at the Cosumnes River Preserve by placing an RTM area to the north of the preserve, constructing an east-west permanent transmission line adjacent to the northern boundary of the preserve, and locating permanent tunnel shafts on the preserve. Modifications made to Clifton Court Forebay would disrupt recreation activities occurring on and near the forebay's south embankment. Other potential impacts along the alignment of the water conveyance facility include disruption of use of portions of Staten Island and use of DWR ponds currently used for water ski instruction and hound racing. As described in detail under Alternative 4, construction of the water conveyance facilities under Alternative 4A would not result in an adverse effect on public use or private commercial recreation facilities because none of these facilities would be permanently displaced.

CEQA Conclusion: The extent of permanent displacement of public use or private commercial recreation areas under Alternative 4A would be the same as discussed for Alternative 4 because the type and alignment of the water conveyance facilities are identical between the two alternatives. This includes placing permanent facilities on or disrupting access to the Cosumnes River Preserve, including public access to portions of Staten Island. Similarly, recreation use of the Clifton Court Forebay embankments would be disrupted during construction. Specifically, public access to the forebay's south embankment, which supports fishing and hunting, would be disrupted during construction. Alternative 4A would not result in the permanent displacement of well-established public use or private commercial recreation facilities available for public access. The impact on these facilities would be less than significant and no mitigation is required.

Impact REC-2: Result in Long-Term Reduction of Recreation Opportunities and Experiences as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: The extent of the long-term reduction of recreation experiences within the Delta as a result of construction the water conveyance facilities under Alternative 4A would be the same as described for Alternative 4. Two recreation sites, Clifton Court Forebay and Cosumnes River Preserve, are within the construction footprint and six recreation sites or areas (Stone Lakes National Wildlife Refuge, Clarksburg Boat Launch, Wimpy's Marina, Delta Meadows, Bullfrog Landing Marina, and Lazy M Marina) are within the 1,200- to 1,400-foot indirect impact area. Potential indirect effects on recreation include loss of access, construction noise, and changes in the visual character of the area surrounding the recreation sites.

As discussed in detail under Alternative 4, impacts on recreation occurring within the Stone Lakes NWR would be attributable to noise and changes in visual character as a result of temporary work areas, RTM storage, geotechnical exploration, construction of Intakes 2 and 3, and construction of the temporary transmission lines. Recreation activities that could be adversely affected include wildlife and environmental education.

The Clarksburg Boat Launch is on the west bank of the Sacramento River across the river from the site of Intake 3. Although access to the boat launch would be maintained during the construction period, noise generated during construction and geotechnical testing could adversely affect use of the public access areas near the boat launch for fishing or other activities.

As discussed under Alternative 4, impacts on recreation opportunities occurring within the Cosumnes River Preserve would include disruption of wildlife viewing and docent-guided tours. Although no recreation opportunities would be permanently displaced, recreation opportunities occurring within portions of the preserve could be adversely affected during construction as result of the introduction of noise, light, and temporary facilities such as access roads, safe haven work sites, and tunnel shaft with temporary work areas.

Wimpy's Marina is a private boating facility located on the south fork of the Mokelumne River southeast of Walnut Grove. Geotechnical exploration would occur along the tunnel corridor for approximately 2.5 years and would introduce noise that would adversely affect recreation occurring at the marina.

As discussed in detail under Alternative 4, recreation occurring at Delta Meadows could be affected by geotechnical testing and construction and operation of the intermediate forebay and spillway. These features would generate noise and introduce visual disturbances to the recreation site.

Recreation occurring at the Bullfrog Landing Marina on Middle River could be affected by noise and visual disturbance as a result of constructing the water conveyance across Bacon Island. This would include impacts from constructing a temporary access road on the island as well as a temporary safe haven work area. Anglers on the river between the marina and the construction area would also experience noise and visual disturbances during construction.

On-water recreation opportunities not associated with formal recreation sites could be affected by the introduction of noise and light during the construction period. The quality of recreation opportunities in the vicinity of construction sites may be adversely affected by noise and changes in visual character.

As discussed in detail under Alternative 4, recreation opportunities, including fishing and hunting, could be adversely affected by expanding Clifton Court Forebay. Recreation would be adversely affected because access to the forebay would not be allowed during construction.

Construction of Alternative 4A intakes and water conveyance facilities would result in disruption to recreational opportunities. Indirect effects on recreation experiences may occur as a result of impaired access, construction noise, or negative visual effects. Overall, construction and geotechnical exploration may occur year-round and last from 2.5 to 13.5 years at individual construction sites near recreation sites or areas and in-river construction would be primarily limited to June 1 through October 31 each year, which would result in a long-term reduction of recreational opportunities or experiences. Mitigation measures (REC-2, BIO-75, AES-1a, AES-1b, AES-1c, AES-1d, AES-1e, AES-1f, AES-1g, AES-4a, AES-4b, AES-4c, TRANS-1a, TRANS-1b, TRANS-1c, NOI-1a, and NOI-1b) are available to address adverse effects on recreation resulting from introduction of noise and light and the loss of access. However, due to the length of time that construction would occur and the dispersed effects across the Delta, the direct and indirect effects related to temporary disruption of existing recreational activities at facilities within the impact area would be adverse.

CEQA Conclusion: Construction of the Alternative 4A intakes and related water conveyance facilities would result in permanent and long-term (i.e., lasting over 2 years) impacts on well-established recreational opportunities and experiences in the study area because of access, noise, and visual setting disruptions that could result in loss of public use. These impacts would occur year-round. The mitigation measures described below, in combination with environmental commitments, would reduce some construction-related impacts by compensating for effects on wildlife habitat and species; minimizing the extent of changes to the visual setting, including nighttime light sources; manage construction-related traffic; and implementing noise reduction and complaint tracking measures. However, the level of impact would not be reduced to a less-than-significant level because it is not certain the mitigation would reduce the level of these impacts to less than significant in all the instances occurring within the entire study area. Therefore, these impacts are considered significant and unavoidable.

Mitigation Measure REC-2: Provide Alternative Bank Fishing Access Sites

Please see Mitigation Measure REC-2 under Impact REC-2 in the discussion of Alternative 4 in Chapter 15, *Recreation* of the Draft EIR/EIS.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

Please see Mitigation Measure BIO-75 under Impact BIO-75 in the discussion of Alternative 4 in Chapter 12, *Biological Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please see Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources* of the Draft EIR/EIS.

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Please see Mitigation Measure AES-1b under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please see to Mitigation Measure AES-1c under Impact AES-1in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Please see to Mitigation Measure AES-1d under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please see Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Please see Mitigation Measure AES-1f under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Please see Mitigation Measure AES-1g under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4a: Limit Construction to Daylight Hours within 0.25 Mile of Residents

Please see Mitigation Measure AES-4a under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4b: Minimize Fugitive Light from Portable Sources Used for Construction

Please see Mitigation Measure AES-4b under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4c: Install Visual Barriers along Access Routes, Where Necessary, to Prevent Light Spill from Truck Headlights toward Residences

Please see Mitigation Measure AES-4c under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please see Mitigation Measure TRANS-1a under TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please see Mitigation Measure TRANS-1b under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please see Mitigation Measure TRANS-1c under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Please see Mitigation Measure NOI-1a under Impact NOI-1 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Please see Mitigation Measure NOI-1b under Impact NOI-1 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Impact REC-3: Result in Long-Term Reduction of Recreational Navigation Opportunities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: The extent of the long-term reduction in recreational navigation opportunities as a result of constructing the proposed water conveyance facilities under Alternative 4A would be identical to Alternative 4. Construction activities associated with constructing the three intakes on the Sacramento River, siphons near Clifton Court Forebay, Head of Old River barrier and operating barges and constructing temporary barge unloading facilities at Snodgrass Slough, Potato Slough, San Joaquin River, Middle River, Connection Slough, Old River, and the West Canal would disrupt boat passage and navigation at and near these sites. Although implementing Mitigation Measure TRANS-1a and helping to fund measures to reduce aquatic weeds would reduce impacts on recreational navigation, these effects would remain adverse because of the long duration of construction which would continually reduce recreation opportunities and distract from experiences occurring near construction activity.

CEQA Conclusion: Impacts on recreational navigation during construction of the water conveyance facilities under Alternative 4A would be identical to those described under Alternative 4. Impeding boat passage and navigation and resulting impacts on recreation would occur during construction of the intakes, temporary barge unloading facilities, and siphons. Although Mitigation Measure TRANS-1a would reduce impacts on navigation associated with barge unloading facilities and participating in the aquatic weed reduction program would help address impacts on navigation, the impact of constructing the water conveyance facilities would be considered significant and unavoidable.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please see Mitigation Measure TRANS-1a under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact REC-4: Result in Long-Term Reduction of Recreational Fishing Opportunities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: The extent of changes in sport fishing opportunities occurring within the study area under Alternative 4A would be the same as Alternative 4. Constructing water intakes, siphons, and operable barrier and placement and use of barge unloading facilities during tunnel/pipeline construction would result in temporary water quality effects (e.g., turbidity, accidental spills, disturbance of contaminated sediments); elevated underwater noise (associated with pile driving and other construction activities); fish exposure to stranding and direct physical injury; and temporary exclusion or degradation of spawning and rearing habitats. Expanding Clifton Court Forebay would restrict access to bank fishing sites during the construction period. Although fish populations likely would not be affected to the degree that the abundance of sport fish would be substantially reduced, construction conditions would introduce noise and visual disturbances that would affect the recreation experience for anglers.

Although construction would occur for more than 2 years and cause a long-term reduction in fishing opportunities at one recreational site, construction of the proposed water conveyance facilities would not affect most fishing opportunities throughout the Delta. Additionally, mitigation measures are available to enhance and ensure access to nearby fishing sites and to address noise and visual disturbances.

Construction of the water conveyance facilities would not result in a long-term adverse effect on fishing opportunities because the effects would be limited to construction sites and would not limit fishing opportunities occurring in other parts of the Delta. Mitigation Measures REC-2, NOI-1a, NOI-1b, AES-1a, AES-1b AES-1c AES-1d, AES-1e, AES-1f, and AES-1g would help reduce or avoid impacts on recreational fishing occurring at construction sites.

CEQA Conclusion: The impact on recreational fishing opportunities as a result of constructing the water conveyance facilities under Alternative 4A would be the same as Alternative 4. The combined impact on recreational fishing opportunities would be considered significant. Implementing mitigation measures REC-2, NOI-1a, NOI-1b, AES-1a, AES-1b AES-1c AES-1d, AES-1e, AES-1f, and AES-1g would reduce the impact on recreational fishing to a less-than-significant level by providing alternate fishing sites, reducing noise generated during construction activities, and limiting changes in the visual character of recreational fishing sites.

Mitigation Measure REC-2: Provide Alternative Bank Fishing Access Sites

Please see Mitigation Measure REC-2 under Impact REC-2 in the discussion of Alternative 4 in Chapter 15, *Recreation*, of the Draft EIR/EIS.

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Please see Mitigation Measure NOI-1a under Impact NOI-1 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Please see Mitigation Measure NOI-1b under, Alternative 1A in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please see Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Please see Mitigation Measure AES-1b under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please see Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Please see Mitigation Measure AES-1d under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please see Mitigation Measure AES-1e under AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Please see Mitigation Measure AES-1f under AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Please see Mitigation Measure AES-1g under AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Impact REC-5: Result in Long-Term Reduction of Recreational Fishing Opportunities as a Result of the Operation of the Proposed Water Conveyance Facilities

NEPA Effects: The effects of operating the water conveyance facilities on recreational fishing opportunities under Alternative 4A would be the same as described under Alternative 4, because the same conveyance facilities would be built under Alternative 4A as under Alternative 4 and the operational scenarios analyzed under Alternative 4 cover the range of operational scenarios under Alternative 4A. Operation of Alternative 4A may result in changes in entrainment, spawning, rearing, and migration. However, effects on fish species that are popular for recreational fishing are not of a nature/level that will adversely affect recreational fishing. While there are some significant impacts on specific non-listed species, as discussed in Section 4.3.7, *Fish and Aquatic Resources*, of this RDEIR/SDEIS they are typically limited to specific rivers and not the population of that species as a whole. The effect is not adverse because it would not result in a substantial long-term reduction in recreational fishing opportunities.

CEQA Conclusion: The potential impact on covered and non-covered sport fish species from operation of Alternative 4A would be considered less than significant because any impacts on fish and, as a result, impacts on recreational fishing, are anticipated to be isolated to certain areas and would not affect the abundance of popular sport fish.

Impact REC-6: Cause a Change in Reservoir or Lake Elevations Resulting in Substantial Reductions in Water-Based Recreation Opportunities and Experiences at North- and South-of-Delta Reservoirs

NEPA Effects: The methodology for assessing effects on recreation at major upstream storage reservoirs for Alternative 4A is the same as applied to Alternative 4 with the exception that Alternative 4A includes only Operational Scenarios H3 and H4. The results of this assessment are shown in Tables 4.3.11-1 and 4.3.11-2 below.

Existing Conditions (CEQA Baseline) Compared to Alternative 4A ELT (2025)

Under Alternative 4A Operational Scenarios H3 and H4 recreation thresholds would be exceeded more frequently at Trinity, Shasta, Oroville, Folsom, and San Luis Reservoirs relative to Existing Conditions. These changes represent a greater than 10% increase in the frequency the recreation thresholds are exceeded under Operational Scenario H3 and H4 at Trinity, Shasta, Oroville, Folsom, and San Luis Reservoirs, compared to Existing Conditions. However, as discussed in Section 15.3.1, *Methods for Analysis*, of the Draft EIR/EIS these changes in SWP/CVP reservoir elevations are primarily attributable to change in demand and other external factors such as sea level rise and climate change. It is not possible to specifically define the exact extent of the changes due to implementation of the action alternative using these model simulation results. Thus, the precise contributions of the external factors to the total differences between Existing Conditions and Alternative 4A Operational Scenarios H3 and H4 cannot be isolated in this comparison. Please refer to the comparison of the No Action Alternative (ELT) to Alternative 4A for a discussion of the potential effects on end-of-September reservoir and lake elevations attributable to operation of Alternative 4A.

Existing Conditions (CEQA Baseline) Compared to Alternative 4A LLT (2060)

Under Alternative 4A Operational Scenarios H3 and H4 recreation thresholds would be exceeded more frequently at Trinity, Shasta, Oroville, Folsom, New Melones, and San Luis Reservoirs relative to Existing Conditions. These changes represent a greater than 10% increase in the frequency the recreation thresholds are exceeded under Operational Scenario H3 at Trinity, Shasta, Oroville, Folsom, and San Luis Reservoirs and under Operational Scenario H4 at Trinity, Shasta, Oroville, Folsom, New Melones, and San Luis Reservoirs. However, as discussed in Section 15.3.1, *Methods for Analysis*, of the Draft EIR/EIS these changes in SWP/CVP reservoir elevations are primarily attributable to change in demand and other external factors such as sea level rise and climate change. It is not possible to specifically define the exact extent of the changes due to implementation of the action alternative using these model simulation results. Thus, the precise contributions of the external factors to the total differences between Existing Conditions and Alternative 4A Operational Scenarios H3 and H4 cannot be isolated in this comparison.

No Action Alternative (ELT) Compared to Alternative 4A

The comparison of Alternative 4A to the No Action Alternative (ELT) condition most closely represents changes in reservoir elevations that may occur as a result of operation of Alternative 4A because both conditions external factors such as change in demand and sea level rise and climate change (see Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS). As shown in Table 4.3.11-1 and Table 4.3.11-2, below, Alternative 4A Operational Scenarios H3 and H4 would result in changes in the frequency with which the end-of-September reservoir levels at Trinity, Shasta, Oroville, Folsom, New Melones, and San Luis Reservoirs would fall below levels identified as important water-dependent recreation thresholds. The CALSIM II modeling results indicate that reservoir levels under Alternative 4A operations would either not change or would fall below the individual reservoir recreation thresholds less frequently than under No Action Alternative (ELT) conditions at Trinity, Shasta, Oroville, and New Melones Reservoirs. Operation of Alternative 4A would not adversely affect water-dependent or water-enhanced recreation at these reservoirs. Overall, these conditions represent improved recreation conditions under operation of Alternative 4A because there would be slightly fewer years in which end-of-September reservoir levels would fall below the recreation thresholds thus indicating better boating opportunities, when compared to No Action Alternative (ELT) conditions.

The modeling result for Folsom Reservoir indicates there could be up to 3 and 2 additional years under Alternative 4A Operational Scenarios H3 and H4, respectively, during which the reservoir level would fall below the reservoir's boating threshold at the end of September. The incremental change would not exceed the 10% increase in the frequency threshold that would indicate an adverse impact on recreation occurring at the reservoir.

The modeling results for San Luis Reservoir indicate there could be up to 23 and 45 additional years under Alternative 4A Operational Scenarios H3 and H4, respectively, during which the reservoir level would fall below the reservoir boating threshold at the end of September relative to the No Action Alternative (ELT) condition. This is a greater than 10% change and would be considered a substantial reduction in recreational boating opportunities at San Luis Reservoir. Shoreline fishing would still be possible, and other recreation activities at the reservoir—picnicking, biking, hiking, and fishing—would be available. The reduction in surface elevations at San Luis Reservoir under Operational Scenarios H3 and H4 would result in an adverse impact on recreation occurring at the reservoir by restricting access by boaters. Mitigation Measure REC-6 would be available to address this effect.

CEQA Conclusion: This impact on water-dependent and water-enhanced recreation opportunities at north- and south-of-Delta reservoirs would be less than significant because, with the exception of San Luis Reservoir, the CALSIM II modeling results indicate that reservoir levels attributable to Alternative 4A operations would either slightly decrease (Folsom Reservoir) or would fall below the individual reservoir thresholds less frequently than under No Action Alternative (ELT). These changes in reservoir and lake elevations would result in a less-than-significant impact on recreation opportunities and experiences at Trinity, Shasta, Oroville, Folsom, and New Melones Reservoirs. At Trinity, Shasta, Oroville, and Folsom Reservoirs, because there would be fewer years in which the reservoir or lake levels fall below the recreation threshold relative to No Action Alternative (ELT) conditions, these effects would be considered beneficial to recreation opportunities and experiences. At Trinity, Shasta, Oroville, Folsom, New Melones, and San Luis Reservoirs, there would be more years in which the reservoir or lake levels fall below the recreation threshold at Late Long Term relative to Existing Conditions. However, as discussed in Section 15.3.1, *Methods for Analysis*, of the Draft EIR/EIS these changes in SWP/CVP reservoir elevations are primarily attributable to change in demand and other external factors such as sea level rise and climate change. It is not possible to specifically define the exact extent of the changes due to implementation of the action alternative using these model simulation results. Operation of Alternative 4A would not substantially affect water-dependent or water-enhanced recreation at these reservoirs. At San Luis Reservoir, the reduction in reservoir access by boaters under Operational Scenarios H3 and H4 would be significant because it is a greater than 10% change and could result in a significant impact on recreation. Mitigation Measure REC-6 would reduce this impact to less than significant.

Mitigation Measure REC-6: Provide a Temporary Alternative Boat Launch to Ensure Access to San Luis Reservoir

Consistent with applicable recreation management plans, DWR and Reclamation will work with DPR to establish a boat ramp extension at or near the Basalt boat launch or other alternative boat ramp site at San Luis Reservoir to maintain reservoir access in years when access becomes unavailable.

Table 4.3.11-1. Summary of Years with Reduced SWP and CVP Reservoir Recreation Opportunities (End-of September Elevations below Recreation Thresholds) for Alternative 4A

	Recreation Threshold[a]								
	Trinity Lake			Shasta Lake			Lake Oroville		
	<2,270 ft Elevation			<967 ft Elevation			<700 ft Elevation		
Scenario	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative (ELT) (CEQA/ NEPA)	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative (ELT) (CEQA/ NEPA)	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative (ELT) (CEQA/ NEPA)
Existing Condition (CEQA)	21			17			17		
No Action Alternative (ELT)	32	11		22	5		26	9	
Alternative 4A (ELT)									
Operational Scenario H3	29	8	-3	22	5	0	21	4	-5
Operational Scenario H4	29	8	-3	20	3	-2	24	7	-2
Alternative 4A (LLT)									
Operational Scenario H3	41	20		28	11		29	12	
Operational Scenario H4	40	18		24	7		35	18	

[a] Recreation thresholds selected for the analysis represent the reservoir surface water elevation at which recreation opportunities become diminished due to restricted access to boat ramps, exposure of previously submerged islands or shoals that affect boater safety, and shoreline degradation.

[b] The number of years out of the 82 simulated when the September end-of-month elevation is less than the recreation elevation threshold for the selected project alternative scenario. An elevation less than the recreation threshold indicates occurrences during which recreation opportunities may be diminished (see note a, above).

[c] The change values are the number of years of the simulated conditions that the selected alternative differs from the comparison condition (i.e., the Existing Condition or No Action Alternative ELT). A positive change would indicate more years with reduced recreation opportunities.

Table 4.3.11-2. Summary of Years with Reduced SWP and CVP Reservoir Recreation Opportunities (End-of September Elevations below Recreation Thresholds) for Alternative 4A

	Recreation Threshold[a]								
	Folsom Lake <405 ft Elevation			New Melones Lake <900 ft Elevation			San Luis Reservoir <360 ft Elevation		
Scenario	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action ELT (CEQA/ NEPA)	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action ELT (CEQA/ NEPA)	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action ELT (CEQA/ NEPA)
Existing Condition (CEQA)	22			9			3		
No Action (ELT)	33	11		8	-1		9	6	
Alternative 4A (ELT)									
Scenario H3	36	14	3	8	-1	0	32	29	23
Scenario H4	35	13	2	9	0	1	54	51	45
Alternative 4A (LLT)									
Operational Scenario H3	44	22		13	4		37	34	
Operational Scenario H4	47	25		12	3		55	52	

[a] Recreation thresholds selected for the analysis represent the reservoir surface water elevation at which recreation opportunities become diminished due to restricted access to boat ramps, exposure of previously submerged islands or shoals that affect boater safety, and shoreline degradation.

[b] The number of years out of the 82 simulated when the September end-of-month elevation is less than the recreation elevation threshold for the selected project alternative scenario. An elevation less than the recreation threshold indicates occurrences during which recreation opportunities may be diminished (see note a, above).

[c] The change values are the number of years of the simulated conditions that the selected alternative differs from the comparison condition (i.e., the Existing Condition or No Action ELT). A positive change indicates more years with reduced recreation opportunities relative to the comparison condition. A negative change indicates fewer years with reduced recreation opportunities relative to the comparison condition.

Impact REC-7: Result in Long-Term Reduction in Water-Based Recreation Opportunities as a Result of Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: The effects of maintaining the water conveyance facilities on water-based recreation under Alternative 4A would be the same as described under Alternative 4. These potential effects would occur as a result of regular maintenance activities of the intakes. The effect on boating is not considered adverse because the boat passage around the intakes would be maintained and disruption of boat access in the immediate vicinity of the intakes would be short-term.

CEQA Conclusion: Effects on recreation resulting from the maintenance of intake facilities would be short-term and intermittent and would not result in significant impacts on boat passage, navigation, or water-based recreation within the vicinity of the intakes.

Impact REC-8: Result in Long-Term Reduction in Land-Based Recreation Opportunities as a Result of Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: The effects of maintaining the water conveyance facilities on land-based recreation under Alternative 4A would be the same as described under Alternative 4. Maintenance activities would be short-term and intermittent, occur within the immediate vicinity of water conveyance facility, and are not expected to generate noise that would distract from adjacent recreation opportunities. Therefore, there would be no effects on recreation opportunities as a result of maintenance of the proposed water conveyance facilities.

CEQA Conclusion: Maintenance of conveyance facilities would be short-term and intermittent and would not result in any changes to land-based recreational opportunities. Therefore, there would be no impact and no mitigation would be required.

Impact REC-9: Result in Long-Term Reduction in Fishing Opportunities as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementing conservation and stressor reduction components as part of Alternative 4A would result in effects on fishing opportunities similar to those described for Alternative 4. The magnitude of the effects occurring under Alternative 4A would be much less than under Alternative 4 because the total acreage that would be affected by the conservation and stressor reduction actions (Environmental Commitments 3, 4, 6–12, 15, and16) occurring in the Plan Area would be much less than the conservation measures proposed under Alternative 4. Construction, operation, and maintenance of the conservation and stressor reduction components could have affects that would be similar in nature to those discussed above for construction, operation, and maintenance of proposed water conveyance facilities. Although similar in nature, the potential intensity of any effects would likely be substantially lower because the nature of the activities associated with implementing the conservation and stressor reduction components would be much less when compared to Alternative 4. In addition, the conservation and stressor reduction components would be expected to result in long-term benefits to aquatic species.

During the implementation stage, construction activity associated with the conservation and stressor reduction components could result in adverse effects on recreation by temporarily or permanently limiting access to fishing sites and disturbing fish habitat. The impact on fishing opportunities as the conservation and stressor reduction components are constructed would not be considered adverse because the actions would be small and localized. In the long term, the impact on fishing opportunities would be considered beneficial because the conservation and stressor reduction measures could benefit aquatic habitat and fish abundance. Therefore, overall, there would not be an adverse impact to fishing opportunities in the long-term.

CEQA Conclusion: Conservation and stressor reduction components would be expected to improve fishing opportunities within the Plan Area. The adverse and beneficial impacts would be similar to those described under Alternative 4, however the extent of those impacts would be much less because the restoration actions occurring under Alternative 4A would include much less acreage and a smaller geographic scope than the conservation measures described under Alternative 4. The impact on fishing opportunities as the conservation and stressor reduction components are constructed would be considered less than significant because the actions would be small and localized. In the long term, the impact on fishing opportunities would be considered beneficial because the conservation and stressor reduction measures could benefit aquatic habitat and fish abundance.

Impact REC-10: Result in Long-Term Reduction in Boating-Related Recreation Opportunities as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementing conservation and stressor reduction components as part of Alternative 4A would result in effects on boating-related recreation similar to the effects discussed under Alternative 4 for implementing conservation measures. However, the extent of the effects on boating under Alternative 4A would be much less because the total acreage that would be affected by the conservation and stressor reduction actions occurring in the Plan Area would be much less when compared to Alternative 4. Restoration of channel margin enhancement, riparian natural community, and nontidal marsh could provide increased boating opportunities within the study area.

CEQA Conclusion: Channel modification and other activities associated with implementation of some of the conservation and stressor reduction components may limit some opportunities for boating and boating-related recreation by reducing the extent of navigable water available to boaters. However, overall the conservation and stressor reduction components would also lead to an enhanced boating experience by expanding the extent of waterways available to boaters. Overall, these measures would not be anticipated to result in a long-term reduction in boating-related recreation activities; therefore, this impact is considered less than significant.

Impact REC-11: Result in Long-Term Reduction in Upland Recreational Opportunities as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and16

NEPA Effects: Implementing conservation and stressor reduction components as part of Alternative 4A would result in effects on upland recreational opportunities similar to Alternative 4. However, the extent of these effects occurring under Alternative 4A would be much less than under Alternative 4 because the total acreage that would be affected by the conservation and stressor reduction actions occurring in the Plan Area would be much less. The actions could benefit the same types of recreation opportunities (e.g., hunting, hiking, walking, wildlife viewing, botanical viewing, nature photography, picnicking, and sightseeing) as described for Alternative 4, however the recreational benefits accruing from these actions would be much less because of the smaller acreage that would be restored. Conversely, the conservation and stressor reduction actions could adversely affected established recreation activities that would no longer be possible or compatible with restoration. These potential adverse effects would be would be similar to those described under Alternative 4, however the effects are expected to be much less because of the smaller total acreage that would be restored.

Implementing the conservation and stressor reduction components could result in an adverse effect on recreation opportunities by reducing the extent of upland recreation sites and activities available to hiking, nature photography, or other similar activity. However, implementation of the measures would also restore or enhance new potential sites for upland recreation thereby potentially improving the quality of recreational opportunities. Therefore, overall, there would not be an adverse impact.

CEQA Conclusion: Similar to Alternative 4, site preparation and earthwork activities occurring under Alternative 4A required to implement the conservation and stressor reduction components could temporarily limit or disrupt opportunities for upland recreational. These impacts on upland recreational opportunities would be considered less than significant because—similar to Alternative 4—environmental commitments incorporated into the project would require the project proponents to consult with CDFW to expand wildlife viewing, angling, and hunting opportunities as an element of the conservation and stressor reduction components. These components would not be anticipated to result in a substantial long-term disruption of upland recreational activities; thus, this impact is considered less than significant.

Impact REC-12: Compatibility of the Proposed Water Conveyance Facilities and Other Environmental Commitments with Federal, State, or Local Plans, Policies, or Regulations Addressing Recreation Resources

NEPA Effects: Similar to Alternative 4A, constructing the water conveyance facilities and implementing the conservation and stressor reduction components under Alternative 4A could result in incompatibilities with plans and policies that address recreation. A number of plans and policies that coincide with the study area provide guidance for recreation resource issues are overviewed in Chapter 15, *Recreation*, Section 15.2, *Regulatory Setting*, of the Draft EIR/EIS. This overview of plan and policy compatibility evaluates whether Alternative 4A is compatible or incompatible with such enactments, rather than whether impacts are adverse or not adverse or significant or less than significant. If the incompatibility relates to an applicable plan, policy, or regulation adopted to avoid or mitigate recreation effects, then an incompatibility might be indicative of a related significant or adverse effect under CEQA and NEPA, respectively. Such physical effects of Alternative 4A on recreation resources are addressed in Impacts REC-1 through REC-11, and in other sections, such as Section 4.3.19, *Noise*, and Section 4.3.13, *Aesthetics and Visual Resources*, of this RDEIR/SDEIS. A summary of the compatibility evaluations related to recreation resources for plans and policies is contained in the analysis of Alternative 4 and is applicable to Alternative 4A. Generally the evaluation found that implementing Alternative 4A would not be compatible with some provisions of The Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992 and some policies of the Sacramento, San Joaquin, Contra Costa, and Alameda Counties general plans that address recreation.

CEQA Conclusion: The incompatibilities identified in the analysis indicate the potential for a physical consequence to the environment. The physical effects are discussed in Alternative 4A, impacts REC-1 through REC-11, and no additional CEQA conclusion is required related to the compatibility of the alternative with relevant plans and polices.

4.3.12 Socioeconomics

Impact ECON-1: Temporary Effects on Regional Economics and Employment in the Delta Region during Construction of the Proposed Water Conveyance Facilities

The regional economic effects on employment and income in the Delta region during construction of Alternative 4A would be identical to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are identical. Under Alternative 4A, direct construction employment is anticipated to vary over the 14-year construction period with an estimated 66 full time equivalent (FTE) jobs in the first year and 486 FTE jobs in the final year of the construction period. Construction employment is estimated to peak at 2,278 FTE jobs in year 9. Total employment (direct, indirect, and induced) would peak in year 12, at 8,673 FTE jobs.

The footprint of conveyance and related facilities such as roads and utilities would remove some existing agricultural land from production, so the effects on employment and income would be negative. Direct agricultural employment would be reduced by an estimated 16 FTE jobs, while total employment (direct, indirect, and induced) associated with agricultural employment would fall by 57 FTE jobs. Based on the crop production values changes described in Impact ECON-6 for construction effects, the direct agricultural job losses would more likely be concentrated in the vegetable, truck, orchard, and vineyard crop sectors, which are relatively labor intensive, than in the grain, field, and forage crop sectors, where more jobs are mechanized. Mapbook Figures M14-7 and M14-8 in the Mapbook Volume of the Draft EIR/EIS display areas of Important Farmland and lands under Williamson Act contracts that could be converted to other uses due to the construction of water conveyance facilities for the Modified Pipeline/Tunnel alignment.

The Alternative 4A construction footprint would not result in the abandonment of any active producing natural gas wells in the study area, as described in Section 4.3.22, *Minerals*, Impact MIN-1 in this RDEIR/SDEIS. Therefore, this alternative would not be anticipated to result in the loss of employment or labor income associated with monitoring and maintaining these wells.

NEPA Effects: Because construction of water conveyance facilities would result in an increase in construction-related employment and labor income, this would be considered a beneficial effect. However, these activities would also be anticipated to result in a decrease in agricultural-related employment and labor income, which would be considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: Construction of the proposed water conveyance facilities would temporarily increase total employment and income in the Delta region. The change would result from expenditures on construction, increasing employment, and from changes in agricultural production, decreasing employment. Changes in recreational expenditures and natural gas well operations could also affect regional employment and income, but these have not been quantified. The total change in employment and income is not, in itself, considered an environmental impact. Significant environmental impacts within the meaning of CEQA would only result if the changes in regional economics cause reasonably foreseeable physical impacts. Such environmental effects are discussed in other sections throughout this RDEIR/SDEIS. Removal of agricultural land from production is addressed under Impacts AG-1 and AG-2 in Section 4.3.10, *Agricultural Resources*, of this RDEIR/SDEIS; changes in recreation related activities are addressed under Impacts REC-1 through REC-4 in Section 4.3.11, *Recreation*, of this RDEIR/SDEIS; abandonment of natural gas wells is addressed under Impact MIN-1 in Section 4.3.22, *Mineral Resources*, of this RDEIR/SDEIS. When required, DWR would provide compensation to property owners for economic losses due to implementation of the alternative. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts are discussed under Impact AG-1 in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, in Appendix A of this RDEIR/SDEIS.

Impact ECON-2: Effects on Population and Housing in the Delta Region during Construction of the Proposed Water Conveyance Facilities

Effects on population and housing in the Delta region during construction of Alternative 4A would be identical to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are identical.

Construction of conveyance facilities would require an estimated peak of 2,278 workers in year 9 of the assumed 14-year construction period. It is anticipated that many of these new jobs would be filled from within the existing five-county labor force; however, it is anticipated that some specialized workers may be recruited from outside the five-county region and would relocate to the area. An estimated 30%of workers could come from out of the Delta region, suggesting that approximately 690 workers could relocate to the Delta region at the peak of the construction period. However, this additional population would constitute a minor increase in the total 2025 projected regional population of 4.6 million and be distributed throughout the region. Changes in demand for public services resulting from any increase in population are addressed under Impacts UT-1 through UT-6 in Section 4.3.16, *Public Services and Utilities*, of this RDEIR/SDEIS.

Changes in housing demand are based on changes in supply resulting from displacement during facilities construction and changes in housing demand resulting from employment associated with construction of conveyance facilities. As described under Impact LU-2 in Section 4.3.9, *Land Use,* of this RDEIR/SDEIS, construction of water conveyance facilities under Alternative 4 would conflict with approximately 19 residential structures. The physical footprints of the three intake facilities, along with associated work areas, are anticipated to create the largest disruption to structures, conflicting with 12 of these residences.

The construction workforce would most likely commute daily to the work sites from within the five-county region; however, if needed, there are about 53,000 housing units available to accommodate workers who may choose to commute on a workweek basis or who may choose to temporarily relocate to the region for the duration of the construction period, including the estimated 690 workers who may temporarily relocate to the Delta region from out of the region. In addition to the available housing units, there are recreational vehicle parks and hotels and motels within the five-county region to accommodate any construction workers. As a result, and as discussed in more detail in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, of this RDEIR/SDEIS, construction of the proposed conveyance facilities is not expected to substantially increase the demand for housing within the five-county region.

NEPA Effects: Within specific local communities, there could be localized effects on housing. However, given the availability of housing within the five-county region, predicting where this impact might fall would be speculative. In addition, new residents would likely be dispersed across the region, thereby not creating a burden on any one community. Because these activities would not result in permanent concentrated, substantial increases in population or new housing, they would not be considered to have an adverse effect.

CEQA Conclusion: Construction of the proposed water conveyance facilities would result in minor population increases in the Delta region with adequate housing supply to accommodate the change in population. Therefore, the minor increase in demand for housing is not anticipated to lead to reasonably foreseeable adverse physical changes constituting a significant impact on the environment.

Impact ECON-3: Changes in Community Character as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to changes in community character in the Delta region during construction of Alternative 4A would be identical to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are identical.

Throughout the five-county Delta region, population and employment would expand as a result of the construction of water conveyance facilities, as discussed under Impacts ECON-1 and ECON-2. Agricultural contributions to the character and culture of the Delta would be likely to decline commensurate with the projected decline in agricultural-related acreage, employment, and production. This could result in the closure of agriculture-dependent businesses or those catering to agricultural workers, particularly in areas where conversion of agricultural land would be most concentrated, including near the intakes in the vicinity of Clarksburg and Hood and the expanded Clifton Court Forebay east of Byron. Similar effects on community character could result from anticipated changes to recreation in the study area. However, social influences associated with the construction industry would grow during the multi-year construction period for water conveyance structures under Alternative 4A.

Legacy communities in the Delta, which are those identified as containing distinct historical and cultural character, include Locke, Bethel Island, Clarksburg, Courtland, Freeport, Hood, Isleton, Knightsen, Rio Vista, Ryde, and Walnut Grove. These communities provide support services and limited workforce housing for the area's agricultural industry. Some housing is also provided to retirees and workers commuting to nearby urban areas including Sacramento. Construction activities associated with water conveyance facilities would be anticipated to result in changes to the rural qualities of these communities during the construction period (characterized by predominantly agricultural land uses, relatively low population densities, and low levels of associated noise and vehicular traffic), particularly for those communities in proximity to water conveyance structures, including Clarksburg, Hood, and Walnut Grove. Effects associated with construction activities could also result in changes to community cohesion if they were to restrict mobility, reduce opportunities for maintaining face-to-face relationships, or disrupt the functions of community organizations or community gathering places (such as schools, libraries, places of worship, and recreational facilities). Under Alternative 4A, several gathering places that lie in the vicinity of construction areas could be indirectly affected by noise and traffic associated with construction activities, including Delta High School, the Clarksburg Library, Clarksburg Community Church, Resurrection Life Community Church, Citizen Land Alliance, Discovery Bay Chamber of

Commerce, Courtland Fire Department, and several marinas or other recreational facilities (see Chapter 15, *Recreation*, Table 15-15 in the Draft EIR/EIS).

Under Alternative 4A, additional regional employment and income could create net positive effects on the character of Delta communities. In addition to potential demographic effects associated with changes in employment, however, property values may decline in areas that become less desirable in which to live, work, shop, or participate in recreational activities. For instance, negative visual- or noise-related effects on residential property could lead to localized abandonment of buildings. While water conveyance construction could result in beneficial effects relating to the economic welfare of a community, adverse social effects could also arise as a result of declining economic stability in communities closest to construction effects and in those most heavily influenced by agricultural and recreational activities. Implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation, would reduce adverse effects (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

CEQA Conclusion: Construction of water conveyance facilities under Alternative 4A could affect community character in the Delta region. However, because these impacts are social in nature, rather than physical, they are not considered impacts under CEQA. To the extent that changes to community character would lead to reasonably forseeable physical impacts involving population growth, such impacts are described under Impact ECON-2 and in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, of this RDEIR/SDEIS. Furthermore, notable decreases in population or employment, even if limited to specific areas, sectors, or the vacancy of individual buildings, could result in alteration of community character stemming from a lack of maintenance, upkeep, and general investment. However, implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation, would reduce the extent of these effects such that a significant impact would not occur (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Specifically, these include commitments to develop and implement erosion and sediment control plans, develop and implement hazardous materials management plans, provide notification of maintenance activities in waterways, develop and implement a noise abatement plan, develop and implement a fire prevention and control plan, and prepare and implement mosquito management plans.

Impact ECON-4: Changes in Local Government Fiscal Conditions as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to changes in local government fiscal conditions during construction of Alternative 4A would be identical to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are identical. Under Alternative 4A, publicly-owned water conveyance facilities would be constructed on land of which some is currently held by private owners. Property tax and assessment revenue generated by lands that would be transferred from private to is estimated to total $7.3 million over the construction period. Typically, decreases in revenue could potentially result in the loss of a substantial share of some agencies' tax bases and particularly for smaller districts affected by a project. However, California Water Code (Section 85089 subdivision 9b) specifies that the entities constructing and operating a new Delta conveyance facility will fully mitigate for the loss of property tax revenues or assessments levied by local governments or special districts. This Water Code requirement will ensure that tax revenues forgone as a result of transferring land from private to public ownership will be fully offset. In addition, as discussed under Impact ECON-1, construction of the water conveyance facilities would be anticipated to result in a net temporary increase of income and employment in the Delta region. This would also create an indirect beneficial effect through increased sales tax revenue for local government entities that rely on sales taxes.

CEQA Conclusion: Under Alternative 4A, construction of water conveyance facilities would result in the removal of a portion of the property tax base for various local government entities in the Delta region. Over the construction period, property tax and assessment revenue generated by these properties is estimated at $7.3 million. These potential losses would be offset by the provisions in the California Water Code that require entities constructing and operating new Delta conveyance facilities to fully mitigate for the loss of property tax or assessments levied by local governments or special districts. It is anticipated that the Water Code requirement will ensure that forgone tax revenues will be fully offset. In addition, CEQA does not require a discussion of socioeconomic effects except where they would result in reasonably foreseeable physical changes. The potential for a physical change to the environment as a result of changes in tax revenues would be avoided by offsetting the potential losses in tax revenues.

Impact ECON-5: Effects on Recreational Economics as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects on recreational economics under Alternative 4A would be identical to those described for Alternative 4 in Chapter 16, Socioeconomics, Section 16.3.3.9, in Appendix A, because the water conveyance facilities proposed under these alternatives are identical. As described and defined under Impacts REC-1 through REC-4 in Section 4.3.11, *Recreation*, of this RDEIR/SDEIS, construction of water conveyance facilities under Alternative 4A would include elements that would be permanently located in two existing recreation areas. Additionally, substantial disruption of other recreational activities considered temporary and permanent would occur in certain areas during the construction period. Were it to occur, a decline in visits to Delta recreational sites as a result of facility construction would be expected to reduce recreation-related spending, creating an adverse effect throughout the Delta region. Additionally, if construction activities shift the relative popularity of different recreational sites, implementation of Alternative 4A may carry localized beneficial or adverse effects.

Access would be maintained to all existing recreational facilities, including marinas, throughout construction. As part of Mitigation Measure REC-2, project proponents would enhance nearby fishing access sites and would incorporate public recreational access into design of the intakes along the Sacramento River. Implementation of this measure along with separate, non-environmental commitments as set forth in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS relating to the enhancement of recreational access and control of aquatic weeds in the Delta would reduce these effects. Environmental commitments would also be implemented to reduce some of the effects of construction activities on the recreational experience. Similarly, mitigation measures proposed throughout other sections of this document, and listed under Impact REC-2 in Section 4.3.11, *Recreation*, of this RDEIR/SDEIS would also contribute to reducing construction effects on recreational experiences in the study area.

Construction of water conveyance structures would be anticipated to result in a lower-quality recreational experience in a number of localized areas throughout the Delta, despite the implementation of environmental commitments. With a decrease in recreational quality, particularly for boating and fishing (two of the most popular activities in the Delta), the number of visits would be anticipated to decline, at least in areas close to construction activities. Under this alternative, recreational uses at Clifton Court Forebay and in small areas of the Cosumnes River Preserve on Staten Island would be directly affected by construction activities. Six other recreational sites or areas would experience periods of construction-related effects, including noise, access, visual disturbances, or a combination of these effects. As described under Impact REC-2 in Section 4.3.11, *Recreation*, of this RDEIR/SDEIS, these include Clarksburg Boat Launch (fishing access), Stone Lakes NWR, Wimpy's Marina, Delta Meadows River Park, Bullfrog Landing Marina, and Lazy M Marina. Overall, the multi-year schedule and geographic scale of construction activities and the anticipated decline in recreational spending would be considered an adverse effect. The commitments and mitigation measures cited above would contribute to the reduction of this effect.

CEQA Conclusion: Construction of the proposed water conveyance facilities under Alternative 4A could affect recreational revenue in the Delta region if construction activities result in fewer visits to the area. Fewer visits would be anticipated to result in decreased economic activity related to recreational activities. This section considers only the economic effects of recreational changes brought about by construction of the proposed water conveyance facilities. Potential physical changes to the environment relating to recreational resources are described and evaluated under Impacts REC-1 through REC-4 in Section 4.3.11, *Recreation*, in this RDEIR/SDEIS.

Impact ECON-6: Effects on Agricultural Economics in the Delta Region during Construction of the Proposed Water Conveyance Facilities

Effects on agricultural economics related to construction of Alternative 4A would be identical to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are identical.

Construction of conveyance facilities would convert land from existing agricultural uses to project-related construction uses, and agricultural land could also be affected by changes in water quality and other conditions that would affect crop productivity. These direct effects on agricultural land are described under Impacts AG-1 and AG-2 in Section 4.3.10, *Agricultural Resources,* in this RDEIR/SDEIS. Total value of irrigated crop production in the Delta would decline on average by $5.3 million per year during the construction period, with total irrigated crop acreage declining by about 4,700 acres. Other effects related to production costs, travel time, and loss of investments in production facilities and standing orchards and vineyards would also occur as a result of facilities construction.

NEPA Effects: Because construction of the proposed water conveyance facilities would lead to reductions in crop acreage and in the value of agricultural production in the Delta region, this is considered an adverse effect. Mitigation Measure AG-1, described under Impact AG-1 in Chapter 14, *Agricultural Resources*, Section 14.3.3.2 in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: Construction of the proposed water conveyance facilities would reduce the total value of agricultural production in the Delta region. The removal of agricultural land from production is addressed under Impacts AG-1 and AG-2 in Section 4.3.10, *Agricultural Resources,* in this RDEIR/SDEIS. The reduction in the value of agricultural production is not considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause reasonably forseeable physical impacts. Such physical effects are discussed in other chapters throughout this RDEIR/SDEIS. When required, DWR would provide compensation to property owners for economic losses due to implementation of the alternative.

While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts are discussed under Impact AG-1 in Chapter 14, *Agricultural Resources*, Section 14.3.3.2 in Appendix A of this RDEIR/SDEIS.

Impact ECON-7: Permanent Regional Economic and Employment Effects in the Delta Region during Operation and Maintenance of the Proposed Water Conveyance Facilities

While the specific criteria guiding operations of water conveyance facilities under Alternative 4A would differ somewhat from those under Alternative 4, for the purposes of socioeconomic analysis, it is assumed that operation and maintenance effects under Alternative 4A would be essentially identical to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives are identical and, in the context of the regional economy, operational outcomes related to water supply, water quality, recreation, or fisheries would be similar between the two alternatives. Ongoing operation and maintenance of facilities would result in increased expenditures. The increased project operation and maintenance expenditures are expected to result in a permanent increase in regional employment and income, including an estimated 129 direct and 183 total (direct, indirect, and induced) FTE jobs.

The operation and maintenance of conveyance and related facilities such as roads and utilities would result in the permanent removal of agricultural land from production following construction, and the effects on employment and income would be negative, including the loss of an estimated 11 agricultural and 39 total (direct, indirect, and induced) FTE jobs. Based on the permanent crop production value changes described in Impact ECON-12, the agricultural job losses would more likely be concentrated in the vegetable, truck, orchard, and vineyard crop sectors, which are relatively labor intensive, than in the grain, field, and forage crop sectors, where more jobs are mechanized. Mapbook Figures M14-7 and M14-8 in the Mapbook Volume of the Draft EIR/EIS display areas of Important Farmland and lands under Williamson Act contracts that could be converted to other uses due to the construction of water conveyance facilities for the Modified Pipeline/Tunnel alignment.

NEPA Effects: Because continued operation and maintenance of water conveyance facilities would result in an increase in operations-related employment and labor income, this would be considered a beneficial effect. However, the long-term footprint of facilities would lead to a continued decline in agricultural-related employment and labor income, which would be considered an adverse effect. Mitigation Measure AG-1, described under Impact AG-1 in Chapter 14, *Agricultural Resources*, Section 14.3.3.2 in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: Operation and maintenance of the proposed water conveyance facilities would increase total employment and income in the Delta region. The net change would result from expenditures on operation and maintenance and from changes in agricultural production. The total change in income and employment is not, in itself, considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause reasonably forseeable physical impacts. Such physical effects are discussed in other chapters throughout this RDEIR/SDEIS. Removal of agricultural land from production is addressed under Impacts AG-1 and AG-2 in Section 4.3.10, *Agricultural Resources*, of this RDEIR/SDEIS; and changes in recreation related activities are addressed under Impacts REC-5 through REC-8 in Section 4.3.11, *Recreation* in this RDEIR/SDEIS. When required, DWR would provide compensation to landowners as a result of acquiring lands for the proposed conveyance facilities. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts are discussed under Impact AG-1 in Chapter 14, *Agricultural Resources*, Section 14.3.3.2 in Appendix A of this RDEIR/SDEIS.

Impact ECON-8: Permanent Effects on Population and Housing in the Delta Region during Operation and Maintenance of the Proposed Water Conveyance Facilities

While the specific criteria guiding operations of water conveyance facilities under Alternative 4A would differ somewhat from those under Alternative 4, for the purposes of socioeconomic analysis, it is assumed that operation and maintenance effects under Alternative 4A would be identical to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives are identical. Operations and maintenance of conveyance facilities would require approximately 130 permanent new workers. Given the nature of those operation and maintenance jobs, the existing water conveyance facilities already in the five-county region, the large workforce in the region, and the large water agencies with headquarters in that region, it is anticipated that most of these new jobs would be filled from within the existing five-county labor force; however, it is anticipated that some workers with specialized skills may be recruited from outside the five-county region and would relocate to the area. This additional population would constitute a minor increase in the total 2025 projected regional population of 4.6 million and be distributed throughout the region. Changes in demand for public services resulting from any increase in population are addressed under Impact UT-7 in Section 4.3.16, *Public Services and Utilities* in this RDEIR/SDEIS. It is anticipated that most of the operational workforce would be drawn from within the five-county region. Consequently, operation of the conveyance facilities would not result in impacts on housing.

NEPA Effects: Because these activities would not result in concentrated, substantial increases in population or new housing, they would not be considered to have an adverse effect.

CEQA Conclusion: Operation and maintenance of the proposed water conveyance facilities would result in minor population increases in the Delta region with adequate housing supply to accommodate the change in population and therefore significant impacts on the physical environment are not anticipated.

Impact ECON-9: Changes in Community Character during Operation and Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: While the specific criteria guiding operations of water conveyance facilities under Alternative 4A would differ somewhat from those under Alternative 4, for the purposes of socioeconomic effects, it is assumed that operation and maintenance effects under Alternative 4A would be essentially identical to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives are identical and, in the context of community character, operational outcomes related to water supply, water quality, recreation, or fisheries would be similar between the two alternatives. Throughout the five-county Delta region, population and employment could slightly expand as a result of continued operation and maintenance of the water conveyance facilities. Agricultural contributions to the character and culture of the Delta would be likely to decline commensurate with the projected decline in agricultural-related employment and production. This could result in the closure of agriculture-dependent businesses or those catering to agricultural employees, particularly in areas where conversion of agricultural land would be most concentrated, including near the intakes in the vicinity of Clarksburg and Hood and near the expanded Clifton Court Forebay. Similar effects could accrue to areas disproportionately dependent on existing recreational activities. However, influences associated with those hired to operate, repair, and maintain water conveyance facilities would grow. To the extent that this anticipated economic shift away from agriculture results in demographic changes in population, employment level, income, age, gender, or race, the study area would be expected to see changes to its character, particularly in those Delta communities most substantially affected by demographic changes based on their size or proximity to water conveyance facilities.

While some of the rural qualities of Delta communities, including relatively low noise and traffic levels, could return to near pre-construction conditions during the operational phase, other effects would be lasting. For instance, the visual appearance of intakes and other permanent features would compromise the predominantly undeveloped and agricultural nature of communities like Clarksburg, Courtland, and Hood, which would be located closest to the permanent water conveyance features. Lasting effects on areas made less desirable in which to live, work, shop, or participate in recreational activities as a result of water conveyance facility operations could lead to localized abandonment of buildings. Such lasting effects could also result in changes to community cohesion if they were to restrict mobility, reduce opportunities for maintaining face-to-face relationships, or disrupt the functions of community organizations or community gathering places (such as schools, libraries, places of worship, and recreational facilities). While ongoing operations could result in beneficial effects relating to the economic welfare of a community, adverse social effects could linger in communities closest to character-changing effects and in those most heavily influenced by agricultural and recreational activities. Implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation would reduce adverse effects (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Specifically, these commitments include notification of maintenance activities in waterways, development and implementation of a noise abatement plan, and preparation and implementation of mosquito management plans.

CEQA Conclusion: Operation and maintenance of water conveyance facilities under Alternative 4A could affect community character in the Delta region. However, because these impacts are social in nature, rather than physical, they are not considered impacts under CEQA. To the extent that changes to community character would lead to reasonably forseeable physical impacts involving population growth, such impacts are described under Impact ECON-8 and in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, in this RDEIR/SDEIS. Furthermore, notable decreases in population or employment, even if limited to specific areas, sectors, or the vacancy of individual buildings, could result in alteration of community character stemming from a lack of maintenance, upkeep, and general investment. However, implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation, would reduce the extent of these effects such that a significant impact would not occur (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Specifically, these include commitments to develop and implement erosion and sediment control plans, develop and implement hazardous materials management plans, provide notification of maintenance activities in waterways, develop and implement a noise abatement plan, develop and implement a fire prevention and control plan, and prepare and implement mosquito management plans.

Impact ECON-10: Changes in Local Government Fiscal Conditions during Operation and Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: Effects on local government fiscal conditions during operation and maintenance of Alternative 4A would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives are identical. While Alternative 4A would not be associated with a 50-year permit term, forgone revenue is estimated to be the same as for Alternative 4 ($44.1 million) over a 50-year period. These decreases in revenue could potentially result in the loss of a substantial share of some agencies' tax bases, particularly for smaller districts affected by Alternative 4A. However, as discussed under Impact ECON-4, California Water Code, requires that entities constructing and operating a new Delta conveyance for offsetting the loss of property tax or assessment revenues. The requirement will ensure that forgone tax revenues resulting from transferring lands for private to public ownership will be fully offset.

CEQA Conclusion: Under Alternative 4A, the ongoing operation and maintenance of water conveyance facilities would reduce t property tax revenue levels for various local government entities in the Delta region. Over a 50-year period, property tax and assessment revenue forgone is estimated at $44.1 million. These potential losses would be offset by the provisions in the Water Code that require entities constructing and operating new Delta conveyance facilities to fully mitigate for the loss of property tax assessments levied by local governments or special districts. It is anticipated that the Water Code requirement will ensure that forgone tax revenues will be fully offset. Furthermore, CEQA does not require a discussion of socioeconomic effects except where they would result in reasonably forseeable physical changes. The potential for physical change to the environment as a result of changes would be avoided by offsetting the losses in tax revenues.

Impact ECON-11: Effects on Recreational Economics during Operation and Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: As discussed under Impacts REC-5 through REC-8 in Section 4.3.11, *Recreation,* in this RDEIR/SDEIS, operation and maintenance activities associated with the proposed water conveyance facilities under Alternative 4A are anticipated to create minor effects on recreational resources. Maintenance of conveyance facilities, including intakes, would result in periodic temporary but not substantial adverse effects on boat passage and water-based recreational activities. As discussed in Impact REC-7 in Chapter 15, *Recreation*, of the Draft EIR/EIS, most intake maintenance, such as painting, cleaning, and repairs, would be done with barges and divers, and could cause a temporary impediment to boat movement in the Sacramento River in the immediate vicinity of the affected intake structure and reduce opportunities for waterskiing, wakeboarding, or tubing in the immediate vicinity of the intake structures. However, boat passage and navigation on the river would still be possible around any barges or other maintenance equipment and these effects would be expected to be short-term (2 years or less). Although water-based recreation (e.g., boating, waterskiing, wakeboarding) may be restricted at and in the vicinity of intakes, many miles of the Sacramento River would still be usable for these activities during periodic maintenance events. Additionally, implementation of the environmental commitment to provide notification of maintenance activities in waterways (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) would reduce these effects. Because effects of facility maintenance would be short-term and intermittent, substantial economic effects are not anticipated to result from operation and maintenance of the facilities.

CEQA Conclusion: Operation and maintenance activities associated with the proposed water conveyance facilities under Alternative 4A are anticipated to create minor effects on recreational resources and therefore, are not expected to substantially reduce economic activity related to recreational activities. This section considers only the economic effects of recreational changes. Potential physical changes to the environment relating to recreational resources are described and evaluated in Impacts REC-5 through REC-8 in Section 4.3.11, *Recreation,* of this RDEIR/SDEIS.

Impact ECON-12: Permanent Effects on Agricultural Economics in the Delta Region during Operation and Maintenance of the Proposed Water Conveyance Facilities

Effects on agricultural economics during operation and maintenance of Alternative 4A would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives are identical and, in the context of the regional agricultural economy, outcomes related to water quality would be similar between the two alternatives.

During operation and maintenance of conveyance facilities existing agricultural land would be in uses that include direct facility footprints and associated permanent roads and utilities. Agricultural land could also be affected by changes in water quality and other conditions that would affect crop productivity. These direct effects on agricultural land are described in Impacts AG-1 and AG-2 in Section 4.3.10, *Agricultural Resources,* in this RDEIR/SDEIS. Total value of irrigated crop production in the Delta region would decline on average by $3.6 million per year during operation and maintenance, with total irrigated crop acreage declining by about 3,400 acres. Other effects related to production costs, travel time, crop yields, and crop selection could also occur during operation and maintenance activities. If operation of the proposed conveyance facilities increases salinity in part of the Delta, crops that are more sensitive to salinity could shift to other lands in the five-county Delta region. See Section 4.3.10, *Agricultural Resources*, Impact AG-2, in this RDEIR/SDEIS for further discussion of effects from changes in salinity.

NEPA Effects: The footprint of water conveyance facilities would result in lasting reductions in crop acreage and in the value of agricultural production in the Delta region; therefore, this is considered an adverse effect. Mitigation Measure AG-1, described under Impact AG-1 in Chapter 14, *Agricultural Resources*, Section 14.3.3.2 in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: During operation and maintenance of the proposed water conveyance facilities the value of agricultural production in the Delta region would be reduced. The permanent removal of agricultural land from production is addressed under Impacts AG-1 and AG-2 in Section 4.3.10, *Agricultural Resources,* of this RDEIR/SDEIS. The reduction in the value of agricultural production is not considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause reasonably forseeable physical impacts. Such effects are discussed in other chapters throughout this RDEIR/SDEIS. When required, DWR would provide compensation to property owners for economic losses due to implementation of the alternative. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical effect. Measures to reduce these impacts are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS.

Impact ECON-13: Effects on the Delta Region's Economy and Employment Due to the Implementation of Environmental Commitments 3, 4, 6–12, 15, and16

In the Delta region, spending on conservation actions would include construction, operation, and maintenance activities that would convert or disturb existing land use. The effects on the economy of the Delta region would be similar in kind, though not in magnitude, to those estimated for Alternative 4. As described under Section 4.1, *Introduction*, Alternative 4A would include substantially less habitat enhancement and restoration. Additionally, under Alternative 4A, Conservation Measures 2, 5, 13, 20, and 21 would not be implemented. In general, changes in regional economic activity (employment and income) would include increases from the construction and operation and maintenance-related activity, declines resulting from agricultural or other land uses converted or impaired, changes in recreation spending that could be positive or negative depending on the specific restoration action, and declines from abandonment of natural gas wells. As discussed in Section 4.3.22, *Minerals*, Impact MIN-5, in this RDEIR/SDEIS, operations of natural gas wells in the Delta region would be affected where wells are located in restoration areas to be inundated. In areas that would be permanently inundated at restoration sites, producing natural gas wells may be abandoned.

NEPA Effects: Because implementation of conservation actions would be anticipated to result in an increase in construction and operation and maintenance-related employment and labor income, this would be considered a beneficial effect. However, implementation of these components would also be anticipated to result in a decrease in agricultural-related and natural gas production-related employment and labor income, which would be considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite. Additionally, measures to reduce impacts on natural gas wells are discussed in Chapter 26, *Mineral Resources*, Section 26.3.3.2, Impact MIN-5, in Appendix A of this RDEIR/SDEIS.

CEQA Conclusion: Implementation of the proposed conservation actions would affect total employment and income in the Delta region. The change in total employment and income in the Delta region is based on expenditures resulting from implementation of the habitat enhancement and restoration activities and any resulting changes in agricultural production, recreation, and natural gas production. The total change in employment and income is not, in itself, considered an environmental impact. Significant environmental impacts within the meaning of CEQA would only result if the changes in regional economics cause reasonably forseeable physical impacts. Such environmental effects are discussed in other chapters throughout this RDEIR/SDEIS. Removal of agricultural land from production is addressed in Section 4.3.10, *Agricultural Resources*, Impacts AG-3 and AG-4; changes in recreation-related activities are addressed in Section 4.3.11, *Recreation,* Impacts REC-9 through REC-11; and abandonment of natural gas wells is addressed in Section 4.3.22, *Minerals*, Impact MIN-5. When required, the project proponents would provide compensation to property owners for economic losses due to implementation of the alternative. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts and impacts on natural gas wells are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, and Chapter 26, *Mineral Resources*, Section 26.3.3.2, Impact MIN-5, in Appendix A of this RDEIR/SDEIS.

Impact ECON-14: Effects on Population and Housing in the Delta Region as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: In the Delta region, implementation of habitat enhancement and restoration activities could increase employment and convert land from existing uses, including possible displacement of residential housing and business establishments. The effects on population and housing in the Delta region would be similar in kind, though substantially smaller in magnitude, to those described for Alternative 4. In general, the changes in population and housing would include increases in population from the construction and operation and maintenance-related activity and declines in residential housing and business establishments as a result of lands converted or impaired. Because these activities would not result in concentrated, substantial increases in population or new housing, they would not be considered to have an adverse effect.

CEQA Conclusion: Implementation of the proposed habitat enhancement and restoration activities could affect total population and housing in the Delta region. The change in total population and housing in the Delta region is based on employment resulting from implementation of the proposed conservation activities. The change in population and housing is expected to be minor relative to the five-county Delta region, and dispersed throughout the region. Therefore, significant impacts on the physical environment are not anticipated to result.

Impact ECON-15: Changes in Community Character as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: As noted under Impacts ECON-13 and ECON-14, conservation activities designed to restore, conserve, or enhance natural habitat would be anticipated to create economic effects similar in kind, if not in magnitude, to those described for Alternative 4, including increases to employment and changes in land use that could trigger the disruption of agricultural and recreational economies. They could also affect the possible displacement of residences and businesses. The effects these activities would create with regard to community character would depend on the nature of each measure along with its specific location, size, and other factors that are not yet defined.

Under Alternative 4A, temporary construction associated with implementation of these measures could lead to demographic changes and resulting effects on the composition and size of Delta communities. Earthwork and site preparation associated with environmental commitments could also detract from the rural qualities of the Delta region; however, their implementation would take place in phases over time, which would limit the extent of effects taking place at any one point in time.

Implementation of these measures could also alter community character over the long term. Conversion of agricultural land to restored habitat would result in the erosion of some economic and social contributions stemming from agriculture in Delta communities. However, in the context of the Delta region, a substantial proportion of land would not be converted. Additionally, restored habitat could support some rural qualities, particularly in terms of visual resources and recreational opportunities. These effects could attract more residents to some areas of the Delta, and could replace some agricultural economic activities with those related to recreation and tourism. To the extent that agricultural facilities and supportive businesses were affected and led to vacancy, alteration of community character could result from these activities. However, protection of cultivated lands would ensure the continuation of agricultural production on up to 10,100 of acres in the Delta. If necessary, implementation of mitigation measures and environmental commitments related to transportation, agriculture, and recreation would be anticipated to reduce these adverse effects (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Specifically, these include commitments to develop and implement erosion and sediment control plans, develop and implement hazardous materials management plans, provide notification of maintenance activities in waterways, develop and implement a noise abatement plan, develop and implement a fire prevention and control plan, and prepare and implement mosquito management plans.

CEQA Conclusion: Implementation of habitat enhancement and restoration activities under Alternative 4A could affect community character within the Delta region. However, because these impacts are social in nature, rather than physical, they are not considered impacts under CEQA. To the extent that changes to community character are related to physical impacts involving population growth, these impacts are described in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, in this RDEIR/SDEIS. Furthermore, notable decreases in population or employment, even if limited to certain areas, sectors, or the vacancy of individual buildings, could result in decay and blight stemming from a lack of maintenance, upkeep, and general investment. However, implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation, would reduce the extent of these effects such that a significant impact would not occur (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIS/SDEIS). Specifically, these include commitments to develop and implement erosion and sediment control plans, develop and implement hazardous materials management plans, provide notification of maintenance activities in waterways, develop and implement a noise abatement plan, develop and implement a fire prevention and control plan, and prepare and implement mosquito management plans.

Impact ECON-16: Changes in Local Government Fiscal Conditions as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

As discussed in relation to construction of water conveyance facilities, habitat restoration and enhancement activities under Alternative 4A would also take place, in part, on land held by private owners and from which local governments derive revenue through property taxes and assessments. In particular, environmental commitments related to protection and restoration of natural communities would require the acquisition of multiple parcels of land.

The loss of a substantial portion of an entity's tax base would represent an adverse effect on an agency, resulting in a decrease in local government's ability to provide public goods and services. Under Alternative 4A, property tax and assessment revenue forgone as a result of environmental commitment implementation is estimated to reach $13.4 million as a result of implementing Environmental Commitments 3, 4, 6-12, and 16. Decreases in revenue could potentially represent a substantial share of individual agency tax bases, particularly for smaller districts affected by large, contiguous areas identified for habitat restoration.

Additionally, installation of non-physical fish barriers at Georgiana Slough may require that land currently on property tax rolls be acquired and eventually removed from the tax base. The fiscal effects stemming from this activity are, however, anticipated to be minor based upon the relatively small areas of land necessary for its implementation.

NEPA Effects: Effects on local government fiscal conditions during operation and maintenance Environmental Commitments 3, 4, 6-12, 15, and 16 is estimated to total $13.4 million. However, as discussed under Impact ECON-4, California Water Code, requires that entities constructing and operating a new Delta conveyance for offsetting the loss of property tax or assessment revenues.

The requirement will ensure that forgone tax revenues resulting from transferring lands for private to public ownership will be fully offset and an adverse impact on local agency tax revenues would be avoided.

CEQA Conclusion: Under Alternative 4A, implementation of habitat enhancement and restoration activities would result in the removal of a portion of the property tax base for various local government entities in the Delta region. Over a 50-year period, property tax and assessment revenue forgone is estimated to reach $13.4 million, compared with annual property tax revenue of more than $934 million in the Delta counties (California State Controller's Office 2012). These potential losses would be offset by the provisions in the Water Code that require entities constructing and operating new Delta conveyance facilities to fully mitigate for the loss of property tax assessments levied by local governments or special districts. It is anticipated that the Water Code requirement will ensure that forgone tax revenues will be fully offset. Furthermore, CEQA does not require a discussion of socioeconomic effects except where they would result in physical changes. The potential for a physical change to the environment attributable to foregone tax revenues would be avoided by offsetting the loss of those revenues.

Impact ECON-17: Effects on Recreational Economics as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementation of habitat enhancement and restoration activities under this alternative would be anticipated to create an adverse effect on recreational resources by limiting access to facilities, restricting boat navigation, and disturbing fish habitat while restoration activities are taking place. These measures may also permanently reduce the extent of upland recreation sites. However, these components could also create beneficial effects by enhancing aquatic habitat and fish abundance, expanding the extent of navigable waterways available to boaters, and improving the quality of existing upland recreation opportunities. Therefore, the potential exists for the creation of adverse and beneficial effects related to recreational economics. Adverse effects would be anticipated to be primarily limited to areas close to restoration areas and during site preparation and earthwork phases. These effects could result in a decline in visits to the Delta and reduction in recreation-related spending, creating an adverse economic effect throughout the Delta. Beneficial recreational effects would generally result during later stages of restoration implementation as environmental conditions supporting recreational activities are enhanced. These effects could improve the quality of recreational experiences, leading to increased economic activities related to recreation, particularly in areas where habitat enhancement or restoration could create new recreational opportunities.

CEQA Conclusion: Site preparation and earthwork activities associated with a number of environmental commitments would limit opportunities for recreational activities where they occur in or near existing recreational areas. Noise, odors, and visual effects of construction activities would also temporarily compromise the quality of recreation in and around these areas, leading to potential economic impacts. However, over time, implementation could improve the quality of existing recreational opportunities, leading to increased economic activity. This section considers only the economic effects of recreational changes brought about by implementation of habitat enhancement and restoration activities. CEQA does not require a discussion of socioeconomic effects except where they would result in reasonably foreseeable physical changes. Potential physical changes to the environment relating to recreational resources are described and evaluated in Section 4.3.11, *Recreation,* Impacts REC-9 through REC-11 in this RDEIR/SDEIS.

Impact ECON-18: Effects on Agricultural Economics in the Delta Region as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Habitat enhancement and restoration activities would convert land from existing agricultural uses. These direct effects on agricultural land are described qualitatively in Section 4.3.10, *Agricultural Resources,* Impacts AG-3 and AG-4 in this RDEIR/SDEIS. Effects on agricultural economics would include effects on crop production and agricultural investments resulting from restoration actions on agricultural lands. The effects would be similar in kind to those described for lands converted due to construction and operation of the conveyance features and facilities. The total acreage and crop mix of agricultural land potentially affected is not specified at this time, but when required, the project proponents would provide compensation to property owners for losses due to implementation of the alternative. Because implementation of habitat enhancement and restoration activities would be anticipated to lead to reductions in crop acreage and in the value of agricultural production in the Delta region, this is considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: Implementation of habitat enhancement and restoration activities would reduce the total value of agricultural production in the Delta region. The permanent removal of agricultural land from production is addressed in Section 4.3.10, *Agricultural Resources,* Impacts AG-3 and AG-4, of this RDEIR/SDEIS. The reduction in the value of agricultural production is not considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause reasonably forseeable physical impacts. Such physical effects are discussed in other chapters throughout this RDEIR/SDEIS. When required, the project proponents would provide compensation to property owners for economic losses due to implementation of the alternative. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS.

Impact ECON-19: Socioeconomic Effects in the South-of-Delta Hydrologic Regions

As described in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, in this RDEIR/SDEIS, the operational components of water conveyance facilities under Alternative 4A could result in a number of effects in areas receiving SWP and CVP water deliveries outside of the Delta. Generally, these effects would be similar to those described for Alternative 4 (Operational Scenarios H3 and H4) in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the incremental change in Delta exports is similar, when compared to the relevant No Action condition.

Under Operational Scenario H3 as considered for Alternative 4A (at the ELT), Delta exports would increase by 11% when compared to the No Action Alternative (ELT), as shown in Table B.1-3 in Appendix B of this RDEIR/SDEIS. Under Operational Scenario H3 as considered for Alternative 4 (LLT), Delta exports would also increase by 11% when compared to the No Action Alternative (LLT), as shown in Table 5-9 in Appendix A of this RDEIR/SDEIS. Under Scenario H4 as considered for Alternative 4A (ELT), Delta exports would decrease by less than 1% when compared to the No Action Alternative (ELT), as shown in Table B.1-3 in Appendix B of this RDEIR/SDEIS. Under Operational Scenario H4 as considered for Alternative 4 (at the late long-term), Delta exports would decrease by 1% when compared to the No Action Alternative (LLT), as shown in Table 5-9 in Appendix A of this RDEIR/SDEIS.

Changes in the amount, cost, or reliability of water deliveries could create socioeconomic effects in the hydrologic regions. To the extent that unreliable or insufficient water supplies currently represent obstacles to agricultural production, Alternative 4A may support more stable agricultural activities by enabling broader crop selection or by reducing risk associated with uncertain water deliveries. As a result of an increase in water supply and supply reliability, farmers may choose to leave fewer acres fallow and/or plant higher-value crops. While the locations and extent of any increases in production would depend on local factors and individual economic decisions, a general increase in production would be anticipated to support growth in seasonal and permanent on-farm employment, along with the potential expansion of employment in industries closely associated with agricultural production. These include food processing, agricultural inputs, and transportation.

In contrast, decreased water deliveries may affect socioeconomics in hydrologic regions through mechanisms similar to those described above; however, the effects would generally be reversed. For example, it is reasonable to expect that reduced or less reliable water deliveries would result in decreased agricultural production and, in turn, a reduction in both direct and indirect agricultural employment. Economic and social patterns tied to predominant agricultural industrial activities and land uses could erode, changing the character of agricultural communities in hydrologic regions. If operation of water conveyance facilities under Alternative 4A reduced M&I deliveries to the extent that it would, in the long run, constrain population growth, its implementation could reinforce a socioeconomic status quo or limit potential economic and employment growth in hydrologic regions. Such changes to agricultural production and population growth with its associated economic activity could also lead to shifts in the character of communities in the hydrologic regions with resultant beneficial or adverse effects.

Generally, these effects (both beneficial and adverse) would be most concentrated in hydrologic regions where agriculture is a primary industry and where agricultural operations depend most heavily on SWP and CVP deliveries.

NEPA Effects: Increases in average annual water deliveries to service areas could induce population growth and new housing to accommodate growth. Such deliveries could also provide support for water-intensive industries. Long-term water supply reliability is an important component in enabling long-term population increases. However, other factors—including natural growth, employment opportunities, local policy, and quality of life—are more likely to determine population growth. Nonetheless, population growth could stimulate economic activity resulting from increased demand for goods and services. This increased demand could create broad economic benefits for regions whose growth is supported by increased deliveries under Alternative 4A.

Social changes, including changes in community character, could also result from an expansion in population or economic activity linked to changes in water deliveries. For example, more stable agricultural production and associated economic activities in areas where agriculture is a predominant industry could strengthen and reinforce existing economic and social patterns and institutions. Increased production could also intensify existing socioeconomic challenges, including seasonal cycles in employment, housing demand, and provision of social services. In areas where population growth would be enabled by increased water supplies or reliability, changes to community character could result from an increased population, including the potential for changes in urban form, environmental factors such as traffic or noise, demographic composition, or the rise of new or broader economic or social opportunities. Again, the nature and extent of such changes would be predominantly influenced by prevailing socioeconomic forces, rather than any specific change associated with implementation of Alternative 4A.

Changes in agricultural production and population growth could also affect local government fiscal conditions. Population growth would be anticipated to result in higher property and sales tax revenue while increased agricultural activity could result in higher sales tax receipts for a local jurisdiction. However, growth would also require expanded public services to meet the needs of a larger population and a larger economic base. Expansion could require additional spending on education, police and fire protection, medical services, and transportation and utility infrastructure. Whether such growth would result in a long-term net benefit or cost would depend on a number of factors including prevailing local service levels and tax rates, as well as the characteristics of the growth.

Changes in water deliveries associated with operation of Alternative 4A could result in beneficial or adverse socioeconomic effects in areas receiving water from the SWP and CVP. In hydrologic regions where water deliveries are predicted to increase when compared with the No Action Alternative, more stable agricultural activities could support employment and economic production associated with agriculture. Where M&I deliveries increase, population growth could lead to general economic growth and support water-intensive industries. Such changes could also lead to shifts in the character of communities in the hydrologic regions with resultant beneficial or adverse effects. Likewise, growth associated with deliveries could require additional expenditures for local governments while also supporting increases in revenue.

CEQA Conclusion: As described above, the operational components of the proposed water conveyance facilities could result in a number of socioeconomic effects in areas receiving SWP and CVP water deliveries outside of the Delta. However, because these impacts are social and economic in nature, rather than physical, they are not considered environmental impacts under CEQA. To the extent that changes in socioeconomic conditions in the hydrologic regions would lead to reasonably forseeable physical impacts, such impacts are described in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, in this RDEIR/SDEIS.

4.3.13 Aesthetics and Visual Resources

Impact AES-1: Substantial Alteration in Existing Visual Quality or Character during Construction of Conveyance Facilities

NEPA Effects: The potential under Alternative 4A to create substantial alteration in visual quality or character during construction of conveyance facilities would be identical to those impacts described under Alternative 4 and would constitute an adverse effect on existing visual character because of the long-term nature of construction, combined with the proximity to sensitive receptors, effects on residences and agricultural buildings, removal of vegetation, and changes to topography through grading. The primary features that would affect the existing visual quality and character under Alternative 4A, once the facility has been constructed, would be Intakes 2, 3, and 5, the intermediate forebay and expanded Clifton Court Forebay, landscape effects from spoil/borrow and RTM areas, the operable barrier, and transmission lines. These changes would be most evident in the northern portion of the study area, which would undergo extensive changes from the permanent establishment of large industrial facilities and the supporting infrastructure along and surrounding the segment of the Sacramento River from Clarksburg to north of Courtland where the intakes would be situated. Mitigation Measures AES-1a through AES-1g are available to address visual effects resulting from construction of Alternative 4A water conveyance facilities.

CEQA Conclusion: Construction of Alternative 4A would substantially alter the existing visual quality and character present in the study area in an identical manner as described for Alternative 4. The long-term nature of construction of the intakes, pipeline/tunnel, work areas, spoil/borrow and RTM areas, shaft sites, barge unloading facilities, and operable barrier; presence and visibility of heavy construction equipment; proximity to sensitive receptors; relocation of residences and agricultural buildings; removal of riparian vegetation and other mature vegetation or landscape plantings; earthmoving and grading that result in changes to topography in areas that are predominantly flat; addition of large-scale industrial structures (intakes and related facilities); remaining presence of large-scale borrow/spoil and RTM area landscape effects; and introduction of tall, steel transmission lines would all contribute to this impact. This impact would be significant because of the substantial visual changes that would result from conveyance facility construction. Mitigation Measures AES-1a through AES-1g would partially reduce impacts, but not to a less-than-significant level because not all of the visual changes could be eliminated and permanent changes would be made to the regional landscape. Thus, Alternative 4A would result in significant and unavoidable impacts on the existing visual quality and character in the study area.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please see Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Please see Mitigation MeasureAES-1b under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please see Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Please see Mitigation Measure AES-1d under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please see Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Please see Mitigation Measure AES-1f under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Please see Mitigation Measure AES-1g under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Impact AES-2: Permanent Effects on a Scenic Vista from Presence of Conveyance Facilities

NEPA Effects: Effects related to scenic vistas under Alternative 4A would be identical to those described for Alternative 4. During construction the introduction of construction equipment and removal of vegetation would alter the scenic elements that contribute to the viewing experience from scenic vistas. The intakes would introduce visually dominant and discordant features in the foreground and middleground views in vistas that would be very noticeable to all viewer groups in areas of low to high landscape sensitivity levels. As described for Alternative 4, the effects of permanent access road effects on scenic vistas would not be adverse. The effects of shaft site pads and access hatches on scenic vistas could be adverse. The large scale of intakes, the visual presence of large-scale borrow/spoil and RTM area landscape effects, and transmission lines may result in adverse effects on scenic vistas (see discussions under Sections 17.3.1.2, *Preparation of Visual Simulations*, and 17.3.1.3, *Analysis of the Alternatives' Impact on Visual Resources*, of the Draft EIR/EIS). Overall, effects on scenic vistas associated with Alternative 4A would be adverse because some elements of the conveyance facilities would permanently change views to scenic vistas. Mitigation Measures AES-1a, AES-1c, and AES-1e are available to address these effects.

CEQA Conclusion: Construction of conveyance facilities under Alternative 4A would have identical effects on scenic vistas as described for Alternative 4. Because proposed permanent access roads generally follow existing rights-of-way, they would have less-than-significant impacts on scenic vistas. The presence of the intake structures and pumping plants, large-scale borrow/spoil and RTM area landscape effects, shaft site pads and access hatches, and transmission lines would result in significant impacts on scenic vistas because construction and operation would result in a reduction in the visual quality in some locations and introduce dominant visual elements that would result in noticeable changes in the visual character of scenic vistas in the study area. Mitigation Measure AES-1a, AES-1c, and AES-1e would partially reduce these impacts but not to a less-than-significant level. Thus, impacts on scenic vistas associated with Alternative 4A would be significant and unavoidable.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please refer to Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please refer to Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please refer to Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Impact AES-3: Permanent Damage to Scenic Resources along a State Scenic Highway from Construction of Conveyance Facilities

NEPA Effects: Effects on state scenic highways under Alternative 4A would be identical to those described for Alternative 4. Intakes 2, 3, and 5, the RTM area north of Intake 2, and the intermediate forebay would be immediately and prominently visible in the foreground from SR 160 and would result in an overall noticeable effect on viewers relative to their current experience of the study area's scenic resources along SR 160 and River Road, where the landscape sensitivity level is high. As described for Alternative 4, the visual elements introduced by the intakes, RTM area north of Intake 2, and intermediate forebay associated with Alternative 4A would conflict with the existing forms, patterns, colors, and textures along River Road and SR 160; would dominate riverfront visible from SR 160; and would alter broad views and the general nature of the visual experience presently available from River Road and SR 160. These changes would reduce the visual quality near intake structure locations and result in noticeable changes in the visual character of scenic vista viewsheds in the study area. This effect would be adverse for the same reasons discussed for Alternative 4. Mitigation Measures AES-1a, AES-1c, and AES-1e are available to address these effects.

CEQA Conclusion: Construction of conveyance facilities under Alternative 4A would have identical effects on scenic highways as described for Alternative 4. Because proposed permanent access roads generally follow existing rights-of-way, they would have less-than-significant impacts on scenic vistas. The presence of the intake structures and pumping plants, RTM area landscape effects, shaft site pads and access hatches, and transmission lines would result in significant impacts on scenic vistas because construction and operation would result in a reduction in the visual quality in some locations and introduce dominant visual elements that would result in noticeable changes in the visual character of scenic vista viewsheds in the study area. Mitigation Measures AES-1a, AES-1c, and AES-1e would partially reduce these impacts but not to a less-than-significant level for the same reasons identified for Alternative 4. Thus, impacts on scenic vistas associated with Alternative 4A would be significant and unavoidable.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please refer to Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please refer to Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please refer to Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Impact AES-4: Creation of a New Source of Light or Glare That Would Adversely Affect Views in the Area as a Result of Construction and Operation of Conveyance Facilities

NEPA Effects: Effects resulting from light and glare under Alternative 4A would be identical to those described for Alternative 4. Intakes 2, 3, and 5 and their associated pumping plants, surge towers, and facilities and the pumping plant at the intermediate forebay would create noticeable effects relating to light and glare (Figures 17-76 through 17-78 in the Draft EIR/EIS). Overall, because the study area currently experiences low levels of light and because there are a larger number of viewers in and around the waterways, intake structures, and forebay that would be affected by these noticeable changes contrasting with the existing rural character, effects associated with new sources of daytime and nighttime light and glare are considered adverse. Mitigation Measures AES-4a through AES-4c are available to address these effects.

CEQA Conclusion: Construction of conveyance facilities under Alternative 4A would have identical effects, related to light and glare, as described for Alternative 4. The impacts associated with light and glare under Alternative 4A are significant because there are a larger number of viewers in and around the waterways, intake structures, and intermediate forebay; project facilities would increase the amount of nighttime lighting in the Delta above existing ambient light levels; and the study area currently experiences low levels of light because there are fewer light/glare producers than are typical in urban areas. Mitigation Measures AES-4a through AES-4c would partially reduce these impacts but not to a less-than-significant level because all instances of light and glare impacts would not be reduced by the available mitigation measures. Thus, the new sources of daytime and nighttime light and glare associated with Alternative 4A would result in significant and unavoidable impacts on public views in the project vicinity.

Mitigation Measure AES-4a: Limit Construction to Daylight Hours within 0.25 Mile of Residents

Please refer to Mitigation Measure AES-4a under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4b: Minimize Fugitive Light from Portable Sources Used for Construction

Please refer to Mitigation Measure AES-4b under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4c: Install Visual Barriers along Access Routes, Where Necessary, to Prevent Light Spill from Truck Headlights toward Residences

Please refer to Mitigation Measure AES-4c under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Impact AES-5: Substantial Alteration in Existing Visual Quality or Character during Operation

NEPA Effects: Effects on the visual environment through operations and maintenance of the water conveyance facilities under Alternative 4A would be identical to those described for Alternative 4. The greatest visual effects resulting from operations would be maintenance of the intakes and dredging the forebays. However, all activities would maintain the visual character of the facilities, once built, and would not act to further change the visual quality or character of the facilities or surrounding visual landscape during operation. These effects on the existing visual quality and character during operation would not be adverse because the activities would not result in further substantial changes to the existing natural viewshed or terrain, alter existing visual quality of the region or eliminate visual resources, or obstruct or permanently reduce visually important features.

CEQA Conclusion: Operation of Alternative 4A would have identical visual quality effects as those described for Alternative 4. Maintenance of the conveyance facilities (i.e., intakes, tunnels, forebays and transmission lines) would be required periodically and would involve painting, cleaning, and repair of structures; dredging at forebays (at approximately 50-year intervals); vegetation removal and care along embankments; tunnel inspection; and vegetation removal within transmission line rights-of-way. These activities could be visible from the water or land by sensitive viewers in proximity to these features. All activities would maintain the visual character of the facilities, once built, and would not act to further change the visual quality or character of the facilities or surrounding visual landscape during operation. Maintenance and operation of Alternative 4A once constructed, would not result in further substantial changes to the existing natural viewshed or terrain, alter existing visual quality of the region or eliminate visual resources, or obstruct or permanently reduce visually important features. Thus, overall, operation and maintenance of Alternative 4A would have a less-than-significant impact on existing visual quality and character in the study area because operations would not change the visual quality of the environment and maintenance activities would be minor and intermittent. No mitigation is required.

Impact AES-6: Substantial Alteration in Existing Visual Quality or Character during Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Effects of Alternative 4A related to the potential for alteration of existing visual quality or character from implementing these environmental commitments would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 4A would restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, 6, 7, 8 and 9–11 as compared with 83,800 acres under Alternative 4. Similarly, Environmental Commitments 11, 12, 15, and 16 would be implemented only at limited locations. Conservation Measures 2, 5, 13, 14, and 17–21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 4A would likely be smaller than those associated with Alternative 4.

NEPA Effects: Effects on the existing visual character, scenic vistas, scenic highways, and light and glare would be similar to those under Alternative 4 because restored/enhanced lands would result in incremental and site-specific changes to the landscape in a similar manner. Because only portions of the restoration environmental commitments and fewer of the other stressor reduction environmental commitments would be implemented under Alternative 4A, it is likely that the visual and aesthetic effects would be less than those presented for Alternative 4. However, these visual and aesthetic impacts are considered to be adverse because site-specific, localized adverse visual effects could occur at the sites of projects implemented under the Alternative 4A environmental commitments. Mitigation Measures AES-1a through AES-1g and Mitigation Measures AES-4a through AES-4c are available to address effects from habitat restoration and enhancement actions.

In addition, Mitigation Measures AES-6a and AES-6b are available to help reduce adverse visual effects. Upon development of site-specific design information and plans, additional mitigation measures may be identified to address action-specific adverse effects. Mitigation Measure AES-6c is also available to help inventory, classify, and protect the unique visual landscape of the Delta.

CEQA Conclusion: Implementation of environmental commitments under Alternative 4A would have similar but less impacts than identified for Alternative 4. Alternative 4A has the potential to affect existing visual quality and character, views of scenic vistas, views from scenic highways, and introduce new sources of light and glare in the study area. These potential impacts are considered to be significant because construction of environmental commitments could potentially change views from public areas, negatively affect sensitive receptors and require multiple year construction at specific locations that are currently unknown.

Implementing mitigation measures AES-1a through AES-1g would partially reduce the impacts of Alternative 4A on aesthetic and visual resources but not to a less-than-significant level because restoration and other actions implemented under this alternative could create considerable changes to the visual character of sensitive receptors that may not be fully mitigated by these mitigation measures. Thus, implementation of environmental commitments under Alternative 4A would result in significant and unavoidable impacts on the existing visual quality and character in the study area.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please refer to Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 1A in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Please refer to Mitigation Measure AES-1b under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please refer to Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Please refer to Mitigation Measure AES-1d under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please refer to Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Please refer to Mitigation Measure AES-1f under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Please refer to Mitigation Measure AES-1g under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4a: Limit Construction to Daylight Hours Within 0.25 Mile of Residents

Please refer to Mitigation Measure AES-4a under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4b: Minimize Fugitive Light from Portable Sources Used for Construction

Please refer to Mitigation Measure AES-4b under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4c: Install Visual Barriers along Access Routes, Where Necessary, to Prevent Light Spill from Truck Headlights toward Residences

Please refer to Mitigation Measure AES-4c under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-6a: Underground New or Relocated Utility Lines Where Feasible

Please refer to Mitigation Measure AES-6a under Impact AES-6 in the discussion of Alternative 1A in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-6b: Develop and Implement an Afterhours Low-Intensity and Lights Off Policy

Please refer to Mitigation Measure AES-6b under Impact AES-6 in the discussion of Alternative 1A in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-6c: Implement a Comprehensive Visual Resources Management Plan for the Delta and Study Area

Please refer to Mitigation Measure AES-6c under Impact AES-6 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Impact AES-7: Compatibility of the Proposed Water Conveyance Facilities and Other Environmental Commitments with Federal, State, or Local Plans, Policies, or Regulations Addressing Aesthetics and Visual Resources

NEPA Effects: Constructing water conveyance facilities and implementing other environmental commitments under Alternative 4A would generally have the same potential for incompatibilities with one or more plans and policies related to preserving the visual quality and character of the Delta as described for Alternative 4. As described for Alternative 4, potential incompatibility with plans and policies could exist related to preserving the visual quality and character of the Delta (i.e., The Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992, Delta Protection Commission Land Use and Resource Management Plan for the Primary Zone of the Delta, Delta Plan, Brannan Island and Franks Tract State Recreation Areas General Plan). In addition, with the exception of Solano County, the alternative may be incompatible with county general plan policies that protect visual resources in the study area.

CEQA Conclusion: The potential incompatibilities with plans and policies listed above indicate the potential for a physical consequence to the environment. The physical effects they suggest are discussed in impacts AES-1 through AES-6, above, and no additional CEQA conclusion is required related to the compatibility of Alternative 4A with relevant plans and policies.

4.3.14 Cultural Resources

Impact CUL-1: Effects on Identified Archaeological Sites Resulting from Construction of Conveyance Facilities

The extent of identified archaeological sites within the area that could be affected by construction of Alternative 4A conveyance facilities are the same as described for Alternative 4. This encompasses the 10 previously recorded archeological sites occurring in the footprint of the conveyance facility. Site descriptions summarizing available information regarding these resources, are provided in Appendix 18B, *Identified Cultural Resources Potentially Affected by BDCP Alternatives*, Section B.1.2, *Archaeological Site Descriptions*, of the Draft EIR/EIS.

The significance of the identified archeological sites are the same as described for Alternative 4. Because many of these resources are large (typically in excess of 30 meters across), they are each likely to contain sufficient integrity to yield artifacts in their original associations in a manner that will convey the significance themes outlined in the Alternative 4 discussion. These resources are likely to qualify as historical resources under CEQA and historic properties under the National Register of Historic Places (NRHP).

The mechanisms that could affect the archeological sites would be identical to those described for Alternative 4. These resources occur within the footprint of both temporary work areas and permanent surface impacts and would be subject to the same types of disturbance described under Alternative 4. Construction of the water conveyance facilities has the potential to materially impair these resources under CEQA and to adversely affect the resources as defined by Section 106 of the National Historic Preservation Act (NHPA).

NEPA Effects: Construction may disturb and damage NRHP and California Register of Historic Resources CRHR-eligible archaeological resources. This effect is considered adverse because the damage may impair the integrity of these resources and thus reduce their ability to convey their significance

CEQA *Conclusion:* Construction of conveyance facilities would affect 10 identified archaeological resources that occur in the footprint of this alternative. DWR identified these resources and found that they are likely to qualify as historical resources under CEQA (see the individual site descriptions in Appendix 18B, *Identified Cultural Resources Potentially Affected by BDCP Alternatives*, Section B.1.2, *Archaeological Site Descriptions*, of the Draft EIR/EIS). This impact would be significant because construction could materially alter or destroy the physical integrity of the resource and/or their potential to yield information useful in archaeological research through excavation and disruption of the spatial associations that contain meaningful information. Identified but currently inaccessible resources may also be significant under other register criteria; indirect effects such as introduction of inconsistent changes to the setting may also diminish the significance of these resources. Mitigation Measure CUL-1 would reduce this impact, by recovering data at affected significant archeological sites and by monitoring and protecting resources during construction. However, this measure would not ensure preservation of the physical integrity of the resources or ensure that all of the scientifically important material would be retrieved because feasible archaeological excavation only typically retrieves a sample of the deposit, and portions of the site containing important information may remain after treatment. The impact on identified archaeological sites is considered significant and unavoidable because construction could damage the remaining portions of the deposit.

Mitigation Measure CUL-1: Prepare a Data Recovery Plan and Perform Data Recovery Excavations on the Affected Portion of the Deposits of Identified and Significant Archaeological Sites

Please see Mitigation Measure CUL-1 under Impact CUL-1 in the discussion of Alternative 4 in Chapter 18, *Cultural Resources*, of the Draft EIR/EIS.

Impact CUL-2: Effects on Archaeological Sites to Be Identified through Future Inventory Efforts

The potential effects of constructing water conveyance facilities on archaeological sites identified through future inventories would be the same as described for Alternative 4. These future impacts could occur because most of the area crossed by the proposed water conveyance facility is not currently legally accessible and as such has not been surveyed for the presence of archaeological sites. As with Alternative 4, Alternative 4A would also require extensive geotechnical testing that could damage or destroy archaeological sites. Although the majority of the footprint of the water conveyance facility has not been surveyed, sensitive resources have been located within and near the portions of the alignment that have been surveyed. For this reason, additional archaeological resources are likely to be found in the portion of the footprint where surveys have not yet been conducted. For the reason enumerated under Alternative 4, these sites are likely to qualify as historical resources or unique archaeological resources under CEQA and historic properties under Section 106 of the NHPA.

The potential effects on historic sites under Alternative 4A would be the same as those disclosed for Alternative 4. In summary, historic sites are likely to be associated with the historic-era themes of settlement, reclamation, agriculture, and flood management in the Delta region and as such contributed to the economic base for developing urban centers. These historic sites are likely to qualify as historical resources or unique archaeological resources under CEQA and historic properties under Section 106 of the NHPA.

Absent mitigation, ground-disturbing construction is likely to physically damage many of these resources by disrupting the spatial associations that convey data useful in research or changing the setting such that the resource no longer contains its significance. These impacts would materially impair these resources within the meaning of CEQA and adversely affect the resources within the meaning of Section 106 of the NHPA. These effects would be adverse.

NEPA Effects: This alternative has the potential to damage previously unidentified archaeological sites. Because these sites may qualify for the NRHP or CRHR, damage to these sites may diminish their integrity. For these reasons this effect would be adverse.

CEQA *Conclusion:* The footprint for this alternative is sensitive for both prehistoric and historic-era resources that cannot be identified at this time because much of the footprint is not legally accessible. Because many of these resources are likely to have data useful in prehistoric and historic archaeological research, as well as the integrity to convey this significance, they are likely to qualify as historical resources or unique archaeological sites under CEQA or historic properties under the Section 106 of the NHPA. Ground-disturbing construction may materially alter the significance of these resources by disrupting the spatial associations that could yield important data, resulting in a significant effect. Mitigation Measure CUL-2 would address the impacts of both prehistoric and historic resources through conducting inventories, evaluating significance, and proposing treatment of archeological and historic resources as well as monitoring during the construction phase. However, this mitigation cannot guarantee that all eligible or significant resources would be preserved in place, or that all important data would be retrieved before construction destroys these resources. The scale of the project, investment into existing designs, and the presence of other important environmental resources such as habitat, natural communities, and wetlands that should be avoided are constraints on the flexibility and feasibility of avoidance. For these reasons this impact is significant and unavoidable.

Mitigation Measure CUL-2: Conduct Inventory, Evaluation, and Treatment of Archaeological Resources

Please see Mitigation Measure CUL-2 under Impact CUL-2 in the discussion of Alternative 4 in Chapter 18, *Cultural Resources*, of the Draft EIR/EIS.

Impact CUL-3: Effects on Archaeological Sites That May Not Be Identified through Inventory Efforts

The potential effects of construction of the water conveyance facilities on archaeological sites that may not be identified during inventory efforts would be the same as described for Alternative 4. The effects on archaeological resources would be the same because the design of the water conveyance facilities and construction methods and duration would be identical for both alternatives. As described for Alternative 4, although surveys will be completed for the water conveyance footprint, such surveys cannot guarantee that all sites will be identified prior to construction.

Ground-disturbing activities occurring under Alternative 4A, including the construction of surface features such as intakes, subterranean tunnel boring operations, and access may disturb and damage these resources before they can be identified and avoided during monitoring efforts required under Mitigation Measure CUL-3. This damage and disturbance may materially impair these resources within the meaning of CEQA or adversely affect the resources within the meaning of Section 106 because this disturbance would impair the ability of these resources to yield data useful in research. While Mitigation Measure CUL-3 would reduce the potential for this impact, it would not guarantee the impact would be avoided entirely. Therefore, this impact would be adverse.

NEPA Effects: Constructing Alternative 4A has the potential to damage previously unidentified archaeological sites that also may not necessarily be identified prior to construction. While cultural resource inventories will be completed once legal access is secured, no inventory can ensure that all resources are identified prior to construction. Because these sites may qualify for the NRHP or CRHR, damage to these sites may diminish their integrity. For these reasons this effect would be adverse.

CEQA *Conclusion:* This impact on archeological resources not identified during inventory efforts would be considered significant for the same reasons described for Alternative 4. Construction has the potential to disturb previously unidentified archaeological sites qualifying as historical resources, historic properties, or unique archaeological resources. Mitigation Measure CUL-3 would reduce but not entirely avoid the potential for this impact, by implementing construction worker training, monitoring, and discovery protocols. This impact would remain significant and unavoidable because archaeological resources may not be identified prior to disturbance.

Mitigation Measure CUL-3: Implement an Archaeological Resources Discovery Plan, Perform Training of Construction Workers, and Conduct Construction Monitoring

Please see Mitigation Measure CUL-3 under Impact CUL-3 in the discussion of Alternative 4 in Chapter 18, *Cultural Resources*, of the Draft EIR/EIS.

Impact CUL-4: Effects on Buried Human Remains Damaged during Construction

Effects on buried human remains during construction occurring under Alternative 4A would be the same as described for Alternative 4. As described in greater detail for Alternative 4, the footprint of the water conveyance facilities is sensitive for buried historic and prehistoric human remains. While inventory and monitoring efforts are prescribed by Mitigation Measures CUL-2 and CUL-3, the large land area subject to disturbance under Alternative 4A make exhaustive sampling to identify all buried and isolated human remains technically and economically infeasible. For these reasons the potential remains that such resources may be damaged or exposed before they can be discovered through inventory or monitoring. This effect would be adverse.

NEPA Effects: Buried human remains may be damaged by constructing Alternative 4A because such remains may occur either in isolation or as part of identified and previously unidentified archaeological resources where construction will occur. This effect would be adverse.

CEQA *Conclusion:* Damage to buried human remains during construction would be considered a significant impact for the same reasons described for Alternative 4. The project area is sensitive for buried human remains and construction of Alternative 4A would likely result in disturbance of these features. Disturbance of human remains, including remains interred outside of cemeteries is considered a significant impact in the State CEQA Guidelines Appendix G checklist. Mitigation Measure CUL-4 would reduce the severity of this impact by following state and federal guidelines, including notifying the county coroner and the Native American Heritage Commission (NAHC), if human remains are discovered during construction. This impact would be considered significant and unavoidable, because mitigation would not guarantee that these features could be discovered and treated in advance of construction and the scale of construction makes it technically and economically infeasible to perform the level of sampling necessary to identify all such resources prior to construction.

Mitigation Measure CUL-4: Follow State and Federal Law Governing Human Remains if Such Resources Are Discovered during Construction

Please see Mitigation Measure CUL-4 under Impact CUL-4 in the discussion of Alternative 4 in Chapter 18, *Cultural Resources*, of the Draft EIR/EIS.

Impact CUL-5: Direct and Indirect Effects on Eligible and Potentially Eligible Historic Architectural/Built-Environment Resources Resulting from Construction Activities

Effects of constructing the water conveyance facilities on built-environment resources under Alternative 4A would be the identical to those described for Alternative 4. As described in greater detail under Alternative 4 and Appendix 18B, *Identified Cultural Resources Potentially Affected by BDCP Alternatives*, of the Draft EIR/EIS, a total of 17 built-environment resources have the potential to be directly or indirectly affected by constructing the water conveyance facilities. These effects would materially impair the resources within the meaning of CEQA and result in adverse effects within the meaning of Section 106 because they would diminish the characteristics that convey the significance of the resources.

NEPA Effects: This alternative would result in direct and indirect effects on NRHP and CRHR eligible built environment resources. These alterations may diminish the integrity of these resources. For these reasons this effect would be adverse.

CEQA *Conclusion:* Alternative 4A would result in the same impacts on identified historic-era built-environment resources that are described for Alternative 4. The impacts on the 17 built-environment resources are considered significant because construction may require demolition or alter the character of the resource to such a degree that each resource may no longer be able to convey its significance. Mitigation Measure CUL-5 would reduce the impact by implementing a built environment treatment plan that includes preparing an HSR, assessing preconstruction conditions, implementing protection measures, and preparing Historic American Buildings Survey (HABS) records for CRHR and NRHP-eligible historic buildings and structures that will be demolished. The impact on historic-era built-environment resources would remain significant and unavoidable because even with mitigation, the scale of the project and the constraints imposed by other environmental resources make avoidance of all significant effects unlikely.

Mitigation Measure CUL-5: Consult with Relevant Parties, Prepare and Implement a Built Environment Treatment Plan

Please see Mitigation Measure CUL-5 under Impact CUL-5 in the discussion of Alternative 4 in Chapter 18, *Cultural Resources*, of the Draft EIR/EIS.

Impact CUL-6: Direct and Indirect Effects on Unidentified and Unevaluated Historic Architectural/Built-Environment Resources Resulting from Construction Activities

Effects of constructing the water conveyance facilities on unidentified and unevaluated historic architectural and built-environment resources under Alternative 4A would be the identical to those described for Alternative 4. As described in detail for Alternative 4, although DWR does not have legal access to the majority of the footprint for the water conveyance, historical documentation suggests numerous additional resources occur in the footprint of the water conveyance facilities that have not been identified or which cannot currently be accessed and evaluated. Construction may result in direct demolition of these resources, damage through vibration, or indirect effects such as changes to the setting.

The resources may exhibit significance under both CEQA (State CEQA Guidelines Section 15064.5[a][3]) and the NRHP (30 CFR 60.4). In addition, because many of the historic-era structures in the Delta region are intact, and retain their rural agricultural setting, many of these resources are likely to have integrity within the meaning of CEQA and the NRHP (14 California Code of Regulations [CCR] Section 4852[c], 30 CFR 60.4). Because many unidentified resources are likely to have significance and integrity, they may qualify as historical resources under CEQA and historic properties under Section 106 of the NHPA.

NEPA Effects: This alternative may result in direct modification or indirect changes to the setting for inaccessible and NRHP and CRHR-eligible resources. These changes may diminish the integrity of these resources. For these reasons, this effect would be adverse.

CEQA *Conclusion:* Alternative 4A would result in the same impacts on unidentified and unevaluated historic architectural and built-environment resources that are described for Alternative 4.

Construction may also result in permanent indirect effects such as changes to the setting. Direct demolition or changes to the setting would be material alterations because they would either remove the resource or alter the resource character, resulting in an inability of the resource to convey its significance. Many of these resources are likely to qualify as historic properties or historical resources under the NHPA and CEQA. Mitigation Measure CUL-6 would reduce these impacts by requiring surveys be conducted on previously inaccessible properties to determine if constructing the water conveyance facilities would adversely affect the properties and if so, the development and implementation of treatment plans. The scale of the project and the constraints imposed by other environmental resources make avoidance of all significant effects unlikely. For these reasons this impact remains significant and unavoidable even with implementation of the following mitigation measure.

Mitigation Measure CUL-6: Conduct a Survey of Inaccessible Properties to Assess Eligibility, Determine if These Properties Will Be Adversely Impacted by the Project, and Develop Treatment to Resolve or Mitigate Adverse Impacts

Please see Mitigation Measure CUL-6 under Impact CUL-6 in the discussion of Alternative 4 in Chapter 18, *Cultural Resources*, of the Draft EIR/EIS.

Impact CUL-7: Effects of Environmental Commitments on Cultural Resources

Implementing conservation and stressor reduction components at part of Alternative 4A would result in impacts on cultural resources similar in kind to those of Alternative 4. The extent of these impacts occurring under Alternative 4A would be much less than under Alternative 4, however, because the total acreage that would be affected by the restoration actions occurring within the Plan Area would be substantially less. The following Environmental Commitments could result in impacts on cultural because they involve ground-disturbing activities:

- *Environmental Commitment 3 Natural Communities Protection and Restoration*
- *Environmental Commitment 4 Tidal Natural Communities Restoration*
- *Environmental Commitment 6 Channel Margin Enhancement*
- *Environmental Commitment 7 Riparian Natural Community Restoration*
- *Environmental Commitment 8 Grassland Natural Community Restoration*
- *Environmental Commitment 9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*
- *Environmental Commitment 10 Nontidal Marsh Restoration*

These environmental commitments would result in effects on cultural resources when ground-disturbing work is performed to construct improvements and enhance or restore natural communities. Similar to Alternative 4, direct effects would occur through demolition or destruction of NRHP-, CRHR-, and/or local registry-eligible prehistoric and historic archaeological sites, unique archaeological sites, traditional cultural places (TCPs), human remains, and built-environment resources. In addition, indirect effects may occur where changes to the setting alter the existing setting in a manner that is inconsistent with the feeling and association of the resource. Because the ability of the resources to convey their significance would be lost this effect would materially alter these resources under CEQA and would be adverse under NEPA. For example, reclaimed agricultural landscapes that are converted to habitat may no longer convey the themes of agriculture and settlement, and thus would be inconsistent with remaining features associated with rural historic landscapes created by reclamation, cultivation, and ranching.

Mitigation Measure CUL-7 below addresses the impact on cultural resources as a result of implementing the conservation and stressor reduction components. Because of the large acreages of land included in all these components, it is unlikely that all effects on NRHP-, CRHR-, and /or local registry-eligible resources and unique archaeological sites could be avoided. Therefore, this impact would be adverse.

NEPA Effects: Implementation of conservation and stressor reduction components would result in ground-disturbing work and introduction of new infrastructure to the Plan Area. These physical modifications may result in direct effects on NRHP and CRHR eligible resources. These changes may therefore reduce the integrity of these resources. For these reasons these effects would be adverse.

CEQA *Conclusion:* Implementing conservation and stressor reduction components would require ground-disturbing activities that could alter the significant characteristics of NRHP, CRHR, and/or local registry-eligible cultural resources, including prehistoric and historic archaeological sites, TCPs, and built-environment resources such as historic architectural structures and rural historic landscapes. The same construction may damage unique archaeological sites. This construction would likely result in materially adverse changes for the following reasons.

- Ground-disturbing construction in archaeological sites disrupts the spatial associations that contain data useful in research, thus diminishing or destroying the basis for the significance of the resource.
- Ground-disturbing construction may either directly demolish or indirectly affect the setting of built-environment resources, resulting in an inability of the resource to convey its significance.
- Ground-disturbing construction may either directly demolish or change the setting of TCPs resulting in an inability of the resource to convey its significance.
- Ground-disturbing construction may inadvertently disturb human remains.

The alteration of a resource that changes the characteristics that convey its significance is a material alteration under CEQA. The inadvertent disturbance of human remains is a significant impact under CEQA under the CEQA Guidelines Appendix G checklist. Because this construction would materially alter these categories of resources and disturb human remains it would result in a significant impact. Mitigation Measure CUL-7 would reduce these impacts by identifying and evaluating resources, avoiding resources where possible, and developing treatment where avoidance is not possible. In addition construction would be monitored. However, because of the acreage that could be disturbed as a result of implementing the components, as well as the multiple constraints associated with other environmental resources that require mitigation or avoidance, it is unlikely that all cultural resources could be avoided. Therefore, this impact remains significant and unavoidable.

Mitigation Measure CUL-7: Conduct Cultural Resource Studies and Adopt Cultural Resource Mitigation Measures for Cultural Resource Impacts Associated with Implementation of Environmental Commitments 3, 4, 6–12, 15, and16

Please see Mitigation Measure CUL-7 under Impact CUL-7 in the discussion of Alternative 4 in Chapter 18, *Cultural Resources*, of the Draft EIR/EIS.

Impact CUL-8: Compatibility of the Proposed Water Conveyance Facilities and Environmental Commitments with Plans and Policies

Similar to Alternative 4, constructing the proposed water conveyance facilities and implementing conservation and stressor reduction components under Alternative 4A could result in the potential for incompatibilities with plans and policies adopted to protect the cultural resources of the Delta. A number of plans and policies that coincide with the study area provide guidance for protection of cultural resources as overviewed in Section 18.2.3, *Regional and Local Plans, Policies, and Regulations*, of the Draft EIR/EIS. The policies include the Alameda County East Area Plan, Contra Costa County General Plan, San Joaquin County General Plan, Sacramento County General Plan, Solano County General Plan, and the Yolo County General Plan. A detailed summary of the policies is provided in the discussion of Alternative 4. Similar to Alternative 4, the construction of the water conveyance facilities and conservation and stressor reduction components under Alternative 4A would be compatible with the cultural resource protection policies indicated in the Alameda County East Area Plan, San Joaquin County General Plan, Yolo County General Plan, and potentially incompatible with the Contra Costa County General Plan, Sacramento County General Plan, and Solano County General Plan. Similar to Alternative 4, restoration actions under Alternative 4A would be compatible with policies that emphasize mitigation and incompatible with policies that emphasize preservation.

As described in Chapter 13, *Land Use*, Section 13.2.3, of the Draft EIR/EIS, state and federal agencies are not subject to local land use regulations. Furthermore, policy incompatibility, by itself is not a physical impact on the environment.

NEPA Effects: Because federal agencies are not regulated by local land use policy, the alternative would not result in a conflict with local land use laws.

CEQA Conclusion: As under Alternative 4, the Plan Area under Alternative 4A is governed by cultural resource management policies adopted by the various counties with jurisdiction in this region. For policies that emphasize preservation or mitigation Alternative 4 will be compatible with these policies because DWR and appropriate federal agencies will implement cultural resource management practices that will identify significant resources, preserve such resources where feasible, and complete mitigation to reduce significant effects where preservation is not feasible. For policies that emphasize preservation, the project is incompatible in some instances because multiple constraints governing the location of proposed facilities makes preservation of all significant cultural resources unlikely. It should be noted that, as described in Chapter 13, *Land Use*, Section 13.2.3, of the Draft EIR/EIS, state and federal agencies are not subject to local land use regulations. Furthermore, policy incompatibility, by itself is not a physical impact on the environment.

4.3.15 Transportation

Impact TRANS-1: Increased Construction Vehicle Trips Resulting in Unacceptable LOS Conditions

NEPA Effects: Traffic volumes generated during construction of Alternative 4A would be identical to those evaluated under Alternative 4. As shown in Table 19-25 in the Draft EIR/EIS, under baseline plus background growth (BPBG) conditions, a total of 23 roadway segments would exceed level of service (LOS) for at least 1 hour during the 6:00 AM to 7:00 PM analysis period. Construction associated with Alternative 4A would cause LOS thresholds to be exceeded for at least 1 hour during the 6:00 AM to 7:00 PM analysis period on a total of 38 roadway segments under baseline plus background growth plus project (BPBGPP) conditions. Alternative 4A would therefore exacerbate an already unacceptable LOS under BPBG conditions on 15 roadway segments (38 minus the 23 that would already be operating at an unacceptable LOS under BPBG conditions). The effect of increased traffic volumes in excess of LOS thresholds would be adverse.

Mitigation Measures TRANS-1a through TRANS-1c are available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement that is identified in any mitigation agreement(s) contemplated by Mitigation Measure TRANS-1c is not fully funded and constructed before the project's contribution to the effect is made, an adverse effect in the form of unacceptable LOS would occur. Therefore, this effect would be adverse. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, effects would not be adverse.

CEQA Conclusion: Construction under Alternative 4A would add hourly traffic volumes to study area roadways that would exceed acceptable LOS thresholds. This would be a significant impact. Mitigation Measures TRANS-1a through TRANS-1c would reduce the severity of this impact, but not to less-than-significant levels. The project proponents cannot ensure that required roadway capacity improvements outlined under TRANS-1c will be fully funded or constructed prior to the project's contribution to the impact. If an improvement identified in the mitigation agreement(s) contemplated by Mitigation Measure TRANS-1c is not fully funded and constructed before the project's contribution to the impact is made, a significant impact in the form of unacceptable LOS would occur. Accordingly, this impact would be significant and unavoidable. If, however, all improvements required to avoid significant impacts prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, impacts would be less than significant.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1b under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1c under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-2: Increased Construction Vehicle Trips Exacerbating Unacceptable Pavement Conditions

NEPA Effects: Traffic volumes generated during construction of Alternative 4A would be identical to those evaluated under Alternative 4. As shown in Table 19-26 in the Draft EIR/EIS, construction of Alternative 4 would deteriorate existing pavement conditions to less than the acceptable pavement condition index (PCI) or similar applicable threshold on a total of 46 roadway segments. Damage to roadway pavement is also expected throughout the study area on various local and state roads, as well as on a few interstates. The effect of roadway damage in excess of PCI thresholds would be adverse.

Mitigation Measures TRANS-2a through TRANS-2c are available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents cannot ensure that the agreements or encroachment permits will be obtained from the relevant transportation agencies. If an agreement or encroachment permit is not obtained, an adverse effect in the form of deficient pavement conditions would occur. Accordingly, this effect could remain adverse. If, however, mitigation agreement(s) or encroachment permit(s) providing for the improvement or replacement of pavement are obtained and any other necessary agreements are completed, adverse effects could be avoided.

CEQA Conclusion: Construction under Alternative 4A would add traffic trips to study area roadways that would exacerbate unacceptable pavement conditions. This would be a significant impact. Mitigation Measures TRANS-2a through TRANS-2c would reduce the severity of this impact, but not necessarily to less-than-significant levels, as the project proponents cannot ensure that the agreements or encroachment permits will be obtained from the relevant transportation agencies. If an agreement or encroachment permit is not obtained, a significant impact in the form of deficient pavement conditions would occur. Accordingly, this impact could be significant and unavoidable. If, however, mitigation agreement(s) or encroachment permit(s) providing for the improvement or replacement of pavement are obtained and any other necessary agreements are completed, impacts would be reduced to less than significant.

Mitigation Measure TRANS-2a: Prohibit Construction Activity on Physically Deficient Roadway Segments

Please refer to Mitigation Measure TRANS-2a under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-2b: Limit Construction Activity on Physically Deficient Roadway Segments

Please refer to Mitigation Measure TRANS-2b under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-2c: Improve Physical Condition of Affected Roadway Segments as Stipulated in Mitigation Agreements or Encroachment Permits

Please refer to Mitigation Measure TRANS-2c under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-3: Increase in Safety Hazards, Including Interference with Emergency Routes during Construction

NEPA Effects: The potential for Alternative 4A to increase safety hazards during construction would be identical to those impacts described under Alternative 4. Increases in heavy construction traffic on local roadways could increase safety hazards, such as conflicts with recreational and commuter traffic and with farming operations. The increase in heavy construction traffic using emergency routes could also interfere with emergency service response times. Minor delays and congestion created by rerouted traffic during the temporary realignment of Byron Highway/South Pacific Railroad could create localized interferences with emergency service response times in the vicinity of Bryon Highway. The effect of increased safety hazards from increased heavy construction traffic on local roadways and emergency routes would be adverse.

Mitigation Measure TRANS-1c is available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the effect is made, an adverse effect in the form of increased safety hazards would occur. Accordingly, this effect would be adverse. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, effects would not be adverse.

CEQA Conclusion: Construction of Alternative 4A would increase the amount of trucks using the transportation system in the study area, which could increase the potential for safety hazards, including conflicts with farming operations, emergency services, and recreational and commuter traffic. Minor delays and congestion created by rerouted traffic during the temporary realignment of Byron Highway/South Pacific Railroad could also create localized interferences with emergency service response times in the vicinity of Bryon Highway. This would be a significant impact.

Mitigation Measure TRANS-1c will reduce the severity of this impact, but not to less-than-significant levels since the project proponents cannot ensure that the improvements will be fully funded or constructed prior to the project's contribution to the impact. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the impact is made, a significant impact in the form of increased safety hazards would occur. If, however, all improvements required to avoid significant impacts prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, impacts would be less than significant.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1c in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-4: Disruption of Marine Traffic during Construction

NEPA Effects: The potential for Alternative 4A to disrupt marine traffic during construction would be identical to those impacts described under Alternative 4. Commercial barges would be used to transport tunnel segments from three concrete precast yards to temporary barge unloading facilities on Bouldin Island and at the Clifton Court Forebay. Tugboats would also be used during intake and forebay construction.

Approximately 5,500 barge trips are projected to carry tunnel segments from existing precast yards to project sites via the Sacramento River and other waterways, averaging approximately 8 trips per day through the segment hauling period (2020 to 2025). This potential effect is not considered adverse because construction of Alternative 4A would not require modification to existing deep water channels, interfere with Port of Stockton navigation, or substantially increase the volume of barge movement within the study area, such that existing marine traffic would be disrupted. Barge routes and landing sites will be selected to maximize continuous waterway access and a minimum waterway width greater than 100 feet. Moreover, Mitigation Measure TRANS-1a would also reduce any potential disruptions as it includes stipulations to notify the commercial and leisure boating community of proposed barge operations in the waterways.

CEQA Conclusion: Construction of Alternative 4A would not require modification to existing deep water channels, interfere with Port of Stockton navigation, or substantially increase the volume of barge movement within the study area such that existing marine traffic would be disrupted (on average, only 8 additional barge trips per day are expected through the segment hauling period). Accordingly, this impact would be less than significant. While no mitigation is required, it is important to note that Mitigation Measure TRANS-1a (implemented to reduce effects from Impact TRANS-1) would reduce any potential disruptions as it includes stipulations to notify the commercial and leisure boating community of proposed barge operations in the waterways.

Impact TRANS-5: Disruption of Rail Traffic during Construction

NEPA Effects: The potential for Alternative 4A to disrupt rail traffic during construction would be identical to those impacts described under Alternative 4. The water conveyance alignment crosses under the existing BNSF/Amtrak San Joaquin line between Bacon Island and Woodward Island and would therefore have no effect on freight service. Similarly, construction of the Clifton Court Forebay would not disrupt UPRR Tracy Subdivision service since the line is currently inactive. However, if the UPRR Tracy Subdivision branch line is reopened, construction activities may adversely affect new service. Mitigation Measure TRANS-1a, which includes stipulations to coordinate with rail providers to develop alternative transportation modes (e.g., trucks or buses) is available to address this effect.

CEQA Conclusion: Construction of Alternative 4A would not physically cross or require modification to an active railroad. However, if the UPRR Tracy Subdivision branch line is reopened, construction activities at the Clifton Court Forebay may affect new service. This would be a significant impact. Mitigation Measure TRANS-1a, which includes stipulations to coordinate with rail providers to develop alternative transportation modes (e.g., trucks or buses) would reduce this impact to less than significant.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-6: Disruption of Transit Service during Construction

NEPA Effects: The potential for Alternative 4A to disrupt transit service during construction would be identical to those impacts described under Alternative 4. Construction activities associated with Alternative 4A would increase LOS below applicable thresholds, as well as exacerbate already unacceptable LOS conditions (refer to Impact TRANS-1). Increased congestion resulting from construction traffic would result in an adverse effect on transit routes and schedules, particularly along the SCT Link/Delta Route and Greyhound bus lines.

Mitigation Measures TRANS-1a through TRANS-1c are available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the effect is made, an adverse effect in the form of disruptions to transit service would occur. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, effects would not be adverse.

CEQA Conclusion: Construction activities associated with Alternative 4A would increase LOS below applicable thresholds, as well as exacerbate already unacceptable LOS conditions. Increased congestion resulting from construction traffic would result in a significant impact on transit routes and schedules, particularly along the SCT Link/Delta Route and Greyhound bus lines. Mitigation Measures TRANS-1a through TRANS-1c are available to reduce this impact, but not necessarily to a level that would not be less than significant, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the effect is made, a significant and unavoidable impact in the form of disruptions to transit service would occur. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the impact is made, impacts would be less than significant.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1b in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1c in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-7: Interference with Bicycle Routes during Construction

NEPA Effects: The potential for Alternative 4A to interfere with bicycle routes during construction would be identical to those impacts described under Alternative 4. Increased traffic and vehicle delays during construction could temporarily disrupt bicycle routes on SR 160/River Road and potentially on SR 12. The effect of disruption to bicycle routes during construction would be adverse. Mitigation Measure TRANS-1a, which requires alternative access routes via detours or bridges be provided to maintain continual circulation for bicyclists, is available to reduce this effect.

CEQA Conclusion: Increased traffic and vehicle delays during construction could temporarily disrupt bicycle routes on SR 160/River Road and potentially on SR 12, resulting in a significant impact. However, Mitigation Measure TRANS-1a would reduce the severity of this impact to less-than-significant levels because project proponents would provide alternate access routes via detours or bridges to maintain continual circulation for local travelers in and around construction zones, including bicycle riders.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-8: Increased Traffic Volumes and Delays during Operations and Maintenance of Conveyance Facilities

NEPA Effects: Traffic volumes generated during long-term operation of Alternative 4A would be identical to those evaluated under Alternative 4. It is estimated that routine operations and yearly maintenance activities would require approximately 40 and 35 employees, respectively. Given the limited number of workers involved and the large number of work sites, it is not anticipated that routine operations and maintenance activities or major inspections would result in substantial increases of traffic volumes or roadway congestion. The impact of increased traffic volumes and delays during project operations would not be adverse.

CEQA Conclusion: Given the limited number of workers involved and the large number of work sites, it is not anticipated that routine operations and maintenance activities or major inspections under Alternative 4A would result in substantial increases of traffic volumes or roadway congestion. The impact of increased traffic volumes and delays during operations would therefore be less than significant. No mitigation is required.

Impact TRANS-9: Permanent Alteration of Transportation Patterns during Operations and Maintenance

NEPA Effects: The potential for Alternative 4A to permanently alter transportation patterns during operations and maintenance would be identical to those impacts described under Alternative 4. Impacts on public roadways would be limited to the intake areas and would not substantially alter traffic patterns. The design and construction of all project components (i.e., conveyances, intakes, and forebays) would provide for on-going continuity of all rail operations following completion of construction. Impediments to boat traffic associated with the intakes would continue for the life of the project, but would not substantially affect boat passage or usage. The effect of permanent alteration of transportation patterns during operations would therefore not be adverse.

CEQA Conclusion: Impacts on public roadways would be limited to the intake areas and would not substantially alter traffic patterns. The design and construction of all project components (i.e., conveyances, intakes, and forebays) would provide for on-going continuity of all rail operations following completion of construction. Impediments to boat traffic associated with the intakes would continue for the life of the project, but would not substantially affect boat passage or usage. Accordingly, the impact of permanent alteration of transportation patterns during operations would be less than significant. No mitigation is required.

Impact TRANS-10: Increased Traffic Volumes during Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Effects of Alternative 4A related to increased traffic volumes during implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar to, but less than, those described for Alternative 4. Habitat restoration and enhancement activities that require personnel or heavy-duty equipment transport would generate traffic on area roadways. Roads and highways in and around Suisun Marsh could experience increases in traffic volumes, resulting in localized congestion and conflicts with local traffic. Maintenance and monitoring of the restoration areas would also generate some vehicle trips. The effect would vary according to the amount of traffic generated by implementation of the specific environmental commitment, the location and timing of the actions called for in the environmental commitment, and the roadway and traffic conditions at the time of implementation.

As described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, the Yolo Bypass Fisheries Enhancement (CM2) would not be completed as a component of Alternative 4A. Similarly, Alternative 4A would only restore up to 1,396 acres of habitat under Environmental Commitments 3, 4, 6, 7, and 9–11 as compared with 83,839 acres under Alternative 4. Therefore, the magnitude of traffic volumes and associated traffic impacts under Alternative 4A would likely be smaller than those associated with Alternative 4. Nevertheless, the effect of increased traffic volumes during construction and maintenance of Environmental Commitments 3, 4, 6–12, 15, and 16 would be adverse.

Mitigation Measures TRANS-1a through TRANS-1c are available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement that is identified in any mitigation agreement(s) contemplated by Mitigation Measure TRANS-1c is not fully funded and constructed before the project's contribution to the effect is made, an adverse effect in the form of unacceptable LOS would occur. Therefore, this effect would be adverse. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, effects would not be adverse.

CEQA Conclusion: Impacts on roadways could result in circulation delays or the inability to maintain adequate vehicular access in or around restoration or enhancement work zones. Roads and highways in and around Suisun Marsh could experience increases in traffic volumes, resulting in localized congestion and conflicts with local traffic. Maintenance and monitoring of the restoration areas would also generate some vehicle trips. The impact of increased traffic volumes during implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be significant. Mitigation Measures TRANS-1a through TRANS-1c would reduce the severity of this impact, but not to less-than-significant levels. The project proponents cannot ensure that the improvements will be fully funded or constructed prior to the project's contribution to the impact. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the impact is made, a significant impact would occur. Therefore, the project's impacts on roadway segment LOS would be conservatively significant and unavoidable. If, however, all improvements required to avoid significant impacts prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, impacts would be less than significant.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1b in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1c in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-11: Compatibility of the Proposed Water Conveyance Facilities and Other Environmental Commitments with Plans and Policies

NEPA Effects: Constructing the water conveyance facilities and implementing the environmental commitments under Alternative 4A would generally have the same potential for incompatibilities with one or more transportation plans and policies as described for Alternative 4. As described for Alternative 4, the project would be constructed with regulations related to transportation and circulation enforced by local (including the local metropolitan planning organizations [MPOs]) and federal agencies (including the Federal Highway Administration [FHWA] and Federal Aviation Administration [FAA]). The project would also be consistent with Public Resources Code Section 21092.4, Delta Protection Act of 1992, and Delta Plan. Accordingly, there would be no adverse effect.

CEQA Conclusion: The potential incompatibilities with plans and policies listed above indicate the potential for a physical consequence to the environment. The physical effects they suggest are discussed in impacts TRANS-1 and TRANS-10, above and no additional CEQA conclusion is required related to the compatibility of Alternative 4A with relevant plans and policies.

Impact TRANS-12: Potential Effects on Navigation From Changes in Surface Water Elevations Caused by Construction of Water Conveyance Facilities

Construction for Intakes 2, 3, and 5 will be accomplished using coffer dams at each location. Coffer dams will isolate each construction area from the Sacramento River and will be used to de-water the construction area. Intakes and screens have been designed and located on-bank to minimize changes to river flow characteristics. Nevertheless, some localized water elevation changes will occur upstream and adjacent to each coffer dam at these intake sites due to facility location within the river. These localized surface elevation changes will not exceed an increase of 0.10 feet at any intake location even at high river flows (when surface elevation changes would be expected to be highest). This represents the highest surface upstream elevation increase after coffer dam removal and during intake operation. Because this maximum increase in elevation is entirely localized, downstream surface elevation changes during intake construction would be insignificant and changes to river depth and width at any location will be insignificant. As a result, boat passage and river use, including Sacramento River tributaries, will not be affected.

As explained in Chapter 6, *Surface Water*, construction of facilities within or adjacent to waterways could change surface water elevations or runoff characteristics. In total, Alternative 4A would result in alterations to drainage patterns, stream courses, and runoff; and potential for slightly increased surface water elevations in the rivers and streams during construction and operations of facilities located within the waterway, as described for Alternative 1A. Construction of the facilities under Alternative 4A would not result in a substantial decrease in surface water elevations on any navigable waterways and therefore would not have an adverse effect on navigation. Although the increase in surface water elevations in rivers and streams under Alternative 4 creates a potential impact regarding flooding (which is considered less-than-significant with implementation of Mitigation Measure SW-4) the changes in surface water elevation would not have any adverse effects on navigation. See Chapter 6, *Surface Water*, for additional information regarding changes to surface water under Alternative 4A.

NEPA Effects: Water surface changes and potential impacts associated with intake construction are not considered adverse to navigation. Water depth and surface elevations will not be substantially effected from construction of the water conveyance facilities (either localized or downstream of the intake structures). Although some construction activities and in-water features (i.e., cofferdams) may cause minor changes in surface water elevations, these effects are highly localized and surface water elevations would not increase by more than .10 feet at any location, even during flood events. These changes would not result in a substantial decrease in surface water elevations on any navigable waterways. Therefore, surface water changes associated with construction of the water conveyance facilities would not cause an adverse impact to navigation.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in surface water elevation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in surface water elevation during construction of the intakes will not have a significant impact on navigation.

Impact TRANS-13: Potential Effects of Navigation from Changes in Surface Elevations Caused by Operation of Intakes

The hydraulic modeling scenario for this analysis included five intakes because that is the maximum number of intakes included under any alternative. The modeling also assumed the highest North Delta diversion capacity allowed under any alternative. Alternatives with fewer intakes and/or lower diversion capacity, such as Alternative 4A (three intakes and 9,000 cfs maximum diversion capacity), would have less effects to surface water elevations. With respect to Alternative 4A, operation of Intakes 2, 3, and 4 may have localized effects on water surface elevation during certain operational regimes and at various river flows. While intake operations and pumping levels are dictated by many factors, Sacramento River diversions are limited during low flows by operational rules. The nature and extent of impacts caused by diversions at an intake are dependent in large part on the location of the intake on the river. To minimize the intake effects on river surface elevations, intakes were designed as on-bank structures and were placed so that river flood and flow characteristic will be minimally altered. Based on hydrologic modelling, even at the lowest river flows (taking into account both seasonal and tidal variations) and at maximum intake operation (full diversions at each of five alternative intakes), estimates are that boat draft depths of at least 16.5 feet will be maintained within the Sacramento River. *Planning and Design of Navigation Locks* United States Army Corps of Engineers, EM 1110-2-2602 (September 30, 1995) pages 3-8. This river depth has occurred historically and has been adequate to support navigation along the Sacramento River. Additionally, under these same intake divisions/river flows, water surface elevations would be lowered by no more than 0.7 feet, which represents a localized and maximum estimate. Surface elevations downstream of the intakes would be affected less, and during higher river flow and lower intake diversions, river depths would be greater than the minimum estimate.

The minimal changes in surface water elevation anticipated under Alternative 4A, even assuming a maximum lowering of 0.7 feet, would not likely expose any currently unexposed natural or man-made features that would affect or impeded. There would be no new snags or obstructions that would impede navigation.

Moreover, even when operating at maximum capacity, the intakes would not alter flows in a way that would affect commercial vessels or recreational watercraft. The intakes are designed to ensure pumping velocities will have minimal impacts to aquatic species. It is unlikely that changes in flow velocity would be perceptible to operators of marine vessels or recreational watercraft and would have no effect on navigation.

Additional information regarding changes to surface water elevations can be found in Chapter 6, *Surface Water*.

NEPA Effects: Water surface changes and potential impacts associated with intake operation are not considered adverse. Water depth and surface elevations will not be significantly effected (either localized or downstream of the intake structures) and will therefore not have an adverse effect on navigation.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in surface water elevation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in surface water elevation during operation of the intakes will not have a significant impact on navigation.

Impact TRANS-14: Potential Effects on Navigation Caused by Sedimentation from Construction of Intakes

Construction for Intakes 2, 3, and 5 will be accomplished using coffer dams at each location. Coffer dams will isolate each construction area from the Sacramento River and will be used to de-water the construction area. Construction of coffer dams would require sheet pile driving that would result in incremental suspension of bed sediments. These effects would be temporary and would not have an effect on navigation. Sheet piles at the edge of the levee embankment would likely change eddy currents locally, but rock slope in the transition zone would limit those currents and potential changes to bed load dynamics. As a result, erosion and sedimentation into the Sacramento River during intake construction would be minimal.

Moreover, potential sedimentation effects will be further minimized by limiting the duration of in-water construction activities and through implementing the environmental commitments described in Appendix 3B, *Environmental Commitments,* including the commitment to *Develop and Implement Erosion and Sediment Control Plans* to control short-term and long-term erosion and sedimentation effects and to restore soils and vegetation in areas affected by construction activities following construction. This commitment is related to Avoidance and Minimization Measure (AMM) 4, *Erosion and Sediment Control Plan*, described in BDCP Appendix 3.C. It is anticipated that multiple erosion and sediment control plans will be prepared for construction activities, each taking into account site-specific conditions such as proximity to surface water, erosion potential, drainage, etc. The plans will include all the necessary state requirements regarding erosion control and will implement BMPs for erosion and sediment control that will be in place for the duration of construction activities.

Implementation of Mitigation Measure SW-4 (Implement Measures to Reduce Runoff and Sedimentation) will further ensure that impacts from sedimentation are minimal.

NEPA Effects: Construction of coffer dams and intake construction would not have an adverse effect on navigation through increased sedimentation and erosion/deposition in the navigable channel.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in sedimentation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in sedimentation during construction of the intakes will not have a significant impact on navigation.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please refer to Mitigation Measure SW-4 in Alternative 1A, Impact SW-4.

Impact TRANS-15: Potential Effects on Navigation Caused by Sedimentation From Construction of Barge Facilities

Under Alternative 4A, five temporary barge landings would be constructed at locations adjacent to construction work areas for the delivery of construction materials. Each of the five proposed barge landings would include in-water and over-water structures, such as piling dolphins, docks, ramps, and possibly conveyors for loading and unloading materials; and vehicles and other machinery. Construction of the five barge landings would involve piles at each landing.

To address potential erosion and sedimentation impacts from barge facility construction associated with Alternative 4A, the project proponents will ensure that a Barge Operations Plan is developed and implemented for facility construction. The requirements for the Barge Operations Plan are described in Draft EIR/EIS Appendix 3B, *Environmental Commitments*. This commitment is related to AMM7, *Barge Operations Plan*, described in BDCP Appendix 3.C. This plan will be developed and submitted by the construction contractors per standard DWR contract specifications. Erosion control measures during construction activities at project locations are provided in Appendix 3B, *Environmental Commitments*, as noted above in the discussion of the intakes. Fleeting facilities will be either docking facilities built through pile and wharves or loaded and unloaded using landward positioned cranes. In either case, through AMM7 and the Environmental Commitments, impacts to sedimentation through construction related activities will be localized and minimal.

Implementation of Mitigation Measure SW-4 (Implement Measures to Reduce Runoff and Sedimentation) will further ensure that impacts from sedimentation are minimal.

NEPA Effects**:** Construction and operation of the barge facilities under Alternative 4A would not have an adverse effect on navigation.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in sedimentation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in sedimentation from the temporary barge facilities will not have a significant impact on navigation.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please refer to Mitigation Measure SW-4 in Alternative 1A, Impact SW-4.

Impact TRANS-16: Potential Effects on Navigation Caused by Sedimentation From Construction of Clifton Court Forebay

Clifton Court Forebay would be dredged and redesigned to provide an area where water flowing from the new north Delta facilities will be isolated from water diverted from south Delta channels. While Clifton Court Forebay is a "navigable water," use of the forebay is limited to maintenance operations and is not open to commercial or recreational navigation.

NEPA Effects: Since Clifton Court Forebay is not open to navigation, there is no effect.

CEQA Conclusion: No impact.

Impact TRANS-17: Potential Effects on Navigation Caused by Sedimentation From Operation of Intakes

Sediment loads are present in the Sacramento River as bed loads or distributed within the water column. The Sacramento River is sediment "starved" for most of the year since upstream reservoirs act as settling basins for suspended sediments. In most cases, sediment load is concentrated on the river bed and this bed load depends on several factors including particle size, particle density and flow velocity. To exclude bed loads from entering intake structures during operation, design criteria for the intakes require that the lowest point of the screen is placed above the river bed in such a way that there is no change in bed sediment erosion/distribution patterns. Additionally, screen locations for this alternative are placed on the outer bends of the river to minimize scour, erosion and sediment loading at those locations. Flow control baffles at intakes would be adjusted to control sedimentation near the screens as needed and air jets at screens are proposed to re-suspend sediments as needed.

Implementation of Mitigation Measure SW-4 (Implement Measures to Reduce Runoff and Sedimentation) will further ensure that impacts from sedimentation are minimal.

NEPA Effects: Operational criteria and design specifications for intake operations will result in no change to water column or bed load sediment dynamics. Erosion and deposition patterns will change little if any during intake operation. As a result, there will be no adverse effect on navigation either near or downstream of the intake locations.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in sedimentation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in sedimentation during operation of the proposed intakes will not have a significant impact on navigation.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please refer to Mitigation Measure SW-4 in Alternative 1A, Impact SW-4.

Impact TRANS-18: Potential Effects on Navigation From Construction and Operations of Head of Old River Barrier

Alternative 4A proposes work at the Head of Old River including the construction of fish and flow control gates as well as a small boat lock to allow recreational boat passage. An analysis of potential impacts of this work on navigation was completed in 2005 by Jones and Stokes (*South Delta Improvements Program Vol I: Environmental Impact Statement/Environmental Impact Report*. Draft. October. (J&S 020533.02.) State Clearinghouse #2002092065. Sacramento, CA.) ("SDIP EIS/EIR"). The SDIP EIS/R analyzed whether the proposed barrier/gates facility and locks would cause a change in south Delta flows or water level, river flows or surface water elevations that would result in substantial changes to existing recreational or commercial boating activity and opportunities.

The changes in access to Delta waterways by boats and other vessels during construction and operation of the gates, during channel dredging activities, and attributable to changes in water levels/depths were addressed. Most of the waterways in the immediate project vicinity are public waterways navigable by recreational craft, including rowboats, large houseboats, and cabin cruisers. These waterways are also navigable by smaller commercial vessels, including towing and salvage vessels, clamshell dredges, dredges for repair and maintenance of levees and channels, and pile-driving vessels. Boat access points in the project area include River's End Marina, located on the south side of the DMC, at the confluence with Old River; Tracy Oasis Marina Resort, located on the east side of Tracy Boulevard and the north side of Old River; and possibly at Heinbockle Harbor, located at Tracy Boulevard, on the south side of Grant Line/Fabian and Bell Canal.

According to a California Department of Parks and Recreation (DPR) survey, minimal boat launching and use occurs in the project area. The channels within the project area are too small to accommodate large commercial vessels, and because the channels are also part of an existing temporary barriers project, larger vessels cannot use these channels when the barriers are in place. A boat lock at the proposed facility would ensure boat access upstream of the gate regardless of gate operations. In this regard, upstream boat access could improve over current conditions. Additionally, from June 16 through September 30, the gates will be open and no boat lock operations will be necessary.

With respect to both recreational and commercial navigation, and based on analysis provided in the SDIP EIS/EIR, boat access impacts during facility construction will be less than significant (p. 5.8-14, 5.8-18, 5.8-21), impacts to navigation caused by water level changes during barrier operation will be less than significant (p. 5.8-15. 5.8-19, 5.8-22), impact to non-recreational boaters due to temporary dredging operation will be less than significant (p. 5.8-16, 5.8-19, 5.8-22), and impacts on recreation as a result of constructing and operating any of the alternatives will not be significant (p. 7.4-1).

Construction of the operable barrier could result in increased sedimentation near the gates. Maintenance dredging around the gate would be necessary to clear out sediment deposits. Dredging around the gates would be conducted using a sealed clamshell dredge. Depending on the rate of sedimentation, maintenance would occur every 3 to 5 years. A formal dredging plan with further details on specific maintenance dredging activities will be developed prior to dredging activities. Guidelines related to dredging activities, including compliance with in-water work windows and turbidity standards are described further in Appendix 3B, *Environmental Commitments*, under *Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material*. These activities would ensure that sedimentation would not result in an adverse impact to navigation.

NEPA Effects: With respect to construction and operations of the Head of Old River Barrier, Alternative 4A would have no adverse effect on either commercial or recreational navigation activities.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, construction and operations of the Head of Old River barrier will not have a significant impact on navigation.

Impact TRANS-19: Potential Cumulative Effects on Navigation from Construction and Operations of Water Conveyance Facilities

As explained above and with respect to the construction and operation of these facilities, Alternative 4A would not result in an adverse effects to navigation due to water level elevation changes or altered sedimentation patterns. It is highly unlikely that other projects would combine with these impacts of the project to result in cumulative effects on navigation. This is because the minimal effects of these elements of the project on navigation are localized and would combine only with probable future projects if the projects were located immediately adjacent to the project components. There are no other reasonably foreseeable projects proposed to be located near or adjacent to the planned Alternative 4A facilities.

NEPA Effects: Alternative 4A in combination with other reasonably foreseeable projects would not have a cumulatively adverse effect on navigation.

CEQA Conclusion**:** Because it does not involve a physical change in the environment, effects to navigation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, Alternative 4A in combination with other reasonably foreseeable projects would not have a cumulatively significant impact on navigation.

4.3.16 Public Services and Utilities

Impact UT-1: Increased Demand on Law Enforcement, Fire Protection, and Emergency Response Services from New Workers in the Plan Area as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to the provision of law enforcement, fire protection, and emergency response services as a result of construction of the proposed water conveyance facilities would be identical to those described for Alternative 4. Increased Public Service Demands Associated with Workers Relocating to the Study Area

Alternative 4A would not result in a permanent increase in population that could tax the ability to provide adequate law enforcement, fire protection services, and medical services, the increase in construction workers anticipated during the construction period of approximately 13.5 years could increase demands for these services during this period. The construction population needed for construction of the water conveyance facilities would primarily come from the existing five-county labor force which is already served by law enforcement agencies and medical/emergency response services (hospitals) in the Plan Area (Tables 20A-1 to 20A-3 in Appendix 20A of the Draft EIR/EIS), and because the minor increase in demand from the worker population that would move into the area to fill specialized jobs (e.g., tunnel construction) would be spread across the large multi-county study area, construction of the alternative is not anticipated to result in an increased demand on law enforcement, fire protection, or medical services. This effect is not considered adverse.

Increased Public Service Demands Associated with Construction Work Areas and Activities

Construction of Alternative 4A would be identical to Alternative 4. Alternative 4A would not increase the demand on law enforcement, fire protection, and emergency response services either due to an increased worker population or due to construction-related hazards, such that it would result in substantial adverse physical effects associated with the provision of, or the need for, new or physically altered governmental facilities. Environmental commitments to lessen the impacts associated with construction property protection and the potential for construction-related accidents associated with hazardous materials spills, contamination, or fires, and reduce potential effects associated with increased service demands from new construction workers in the Plan Area (as discussed in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) would continue to reduce potential effects associated with increased service demands from new construction workers in the project area. Impacts on emergency response times from construction traffic using emergency routes are discussed in Chapter 19, *Transportation*, Impact Trans-3, of the Draft EIR/EIS. Therefore, the effect would not be adverse.

CEQA Conclusion: The potential for impacts on law enforcement and fire services and facilities is not expected to be significant because the estimated increase in population in the Plan Area associated with construction of the alternative during peak construction would be distributed over multiple cities and counties within the Plan Area. Incorporation of environmental commitments (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) would minimize construction-related accidents associated with hazardous materials spills, contamination, and fires, and provide for onsite security at construction sites would minimize potential effects related to the potential for construction-related accidents, and increased demand for public services associated with construction property protection. Environmental commitments would also be incorporated to reduce potential exposure of hazardous materials to the human and natural environment, thereby minimizing the potential demand for fire or emergency services.

Construction of Alternative 4A would not require new or physically altered governmental facilities since it would not cause a marked increase in the worker population in the Plan Area, nor would it increase the potential for construction-related hazards. This impact would be less than significant. No mitigation is required.

Impact UT-2: Displacement of Public Service Facilities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Construction impacts of water facilities under Alternative 4A would be identical to those under Alternative 4. There are no public facilities in the proposed tunnel alignment. Construction of the tunnel facilities is not anticipated to conflict with any public facilities, nor would it require the construction or major alteration of such facilities. Therefore, this effect would not be adverse.

CEQA Conclusion: Construction of the proposed water conveyance facilities under Alternative 4A would not require the construction or major alteration of public service facilities. Therefore, this impact would be less than significant. No mitigation is required.

Impact UT-3: Effects on Public Schools as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Construction of Alternative 4A water conveyance facilities will be identical to Alternative 4 and is not anticipated to result in a substantial increase in demand for public schools in the Plan Area and would not create a need for new or physically altered public schools due to the fact that any increase in the population due to the necessary construction workforce would be temporary and would represent a small incremental increase in the projected regional population. Most of the project construction jobs would be filled by workers from within the existing five-county labor force and any incremental increase in school-age children of construction personnel moving into the area for specialized jobs (e.g., tunnel construction) required by construction of Alternative 4A would likely be distributed through a number of schools within the Plan Area. There would be no adverse effect.

CEQA Conclusion: There would be a significant impact if the proposed action resulted in substantial adverse physical effects associated with the provision of, or the need for, new or physically altered governmental facilities, the construction of which could cause significant environmental effects, for any public services. The majority of construction jobs are expected to be filled by workers from the existing five-county labor force. The incremental increase in school-age children of construction personnel moving into the area for specialized construction jobs (e.g., tunnel construction) would likely be distributed through a number of schools within the Plan Area. This increase in school enrollment would not be substantial enough to exceed the capacity of any individual district, or to warrant construction of a new facility or alteration of an existing facility within the Plan Area. The impact would be less than significant. No mitigation is required.[1]

---

[1] Under California law, the rules governing what constitutes adequate mitigation for impacts on school facilities is governed by legislation. Pursuant to the operative statutes, impacts on schools, with some exceptions, are sufficiently mitigated, as a matter of law, by the payment of school impact fees by residential developers. (See Cal. Gov. Code, §§ 65995[h], 65996[a].)

Impact UT-4: Effects on Water or Wastewater Treatment Services and Facilities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to the need for expanded water or wastewater treatment facilities would be similar to those for Alternative 4. For purposes of this analysis, the amount of water supply required under this alternative would be the same as under Alternative 4. As such, the total potable water supply needed under this alternative is estimated to be 177.8 million gallons (Table 20-3 in the Draft EIR/EIS). It is anticipated that if there are existing water lines in the vicinity of the construction sites, the field office will connect to them. Because construction of this alternative would primarily occur in rural parts of the study area, and is not likely to occur in areas with municipal water service, it is not expected to impact municipal water systems. If there are no existing water lines in the vicinity, then field offices will require construction of a water tank. Water for construction will be provided by available sources to the extent possible; if needed, water may be brought to the construction sites in water trucks. Construction impacts associated with trucks, including water trucks, are addressed in Chapter 19, *Transportation*, Chapter 22, *Air Quality and Greenhouse Gases*, and Chapter 23, *Noise*. As such, this alternative would not likely adversely affect municipal water supplies. Additionally, the potable water demand would be temporary and limited to the construction period.

Tunnel boring for Alternative 4A would create a substantial amount of wastewater as with Alternative 4. As part of the alternative, DWR would implement an environmental commitment (as discussed in Appendix 3B, *Environmental Commitments*) that would dispose of and reuse spoils, reusable tunnel material, and dredged material. Concrete batch plants would also create wastewater, which would be treated onsite at designated concrete batch plant sites. Wastewater generated during construction at field offices and temporary construction facilities will be served by temporary portable facilities (e.g., portable toilets). As discussed in Chapter 8, *Water Quality*, as part of the *Environmental Commitments* (Appendix 3B) for each alternative, DWR will be required to conduct project construction activities in compliance with the State Water Board's *NPDES Stormwater General Permit for Stormwater Discharges Associated with Construction and Land Disturbance Activities* (Order No. 2009-0009-DWQ/NPDES Permit No. CAS000002). This General Construction NPDES Permit requires the development and implementation of a SWPPP that outlines the temporary construction-related BMPs to prevent and minimize erosion, sedimentation, and discharge of other construction-related contaminants, as well as permanent post-construction BMPs to minimize adverse long-term stormwater related–runoff water quality effects.

Considered across the alternative, potable water supply needs are substantial in volume; however, these requirements would need to be met over a construction period of approximately 13.5 years, and would be anticipated to be met with non-municipal water sources without any need for new water supply entitlements. Also similar to Alternative 4, wastewater created as a result of tunnel boring and concrete batching would be provided by temporary facilities and treated onsite. Construction of Alternative 4A would not require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities. This effect would not be adverse.

CEQA Conclusion: Construction of Alternative 4A would not require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities. While construction of Alternative 4A would require 177.8 million gallons of potable water, this supply could be met by non-municipal sources such as non-municipal water wells or water trucks, without any new water supply entitlements. Additional needs for wastewater treatment and potable water could also be served by non-municipal entities. Water for construction activities would be brought to the site in water trucks. Wastewater services for construction crews would be provided by temporary portable facilities. This impact would be less than significant. Mitigation is not required.

Impact UT-5: Effects on Landfills as a Result of Solid Waste Disposal Needs during Construction of the Proposed Water Conveyance Facilities

NEPA Effects: Alternative 4A would create the same amount of solid waste as Alternative 4. Overall, the construction waste that could be generated by implementing Alternative 4A would not result in an adverse effect on the capacity of available landfills because 50% or more of construction waste generated by this alternative would be diverted (in accordance with diversion requirements set forth by the State Agency Model IWMA and BMP 13 [Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS]), and the construction debris and excavated material that would require disposal at a landfill could be accommodated by, and would have a negligible effect, on the remaining permitted capacity of Plan Area landfills. This alternative is not expected to affect the lifespan of area landfills, because over 70% of the remaining permitted capacity is associated with landfills with expected lifespans of between 18 and 70 years—well beyond the expected timeframe for construction of project facilities, when solid waste disposal services would be needed. This effect would not be adverse.

CEQA Conclusion: Based on the capacity of the landfills in the region, and the waste diversion requirements set forth by the State of California, it would be expected that construction of the proposed water conveyance facilities would not cause any exceedance of landfill capacity. RTM resulting from construction of tunnel segments would be treated in designated RTM work areas. Debris from structure demolition, power poles, utility lines, piping, and other materials would be diverted from landfills to the maximum extent feasible at the time of demolition. This alternative is not expected to affect the lifespan of area landfills, because over 70% of the remaining permitted capacity is associated with landfills with expected lifespans of between 18 and 70 years—well beyond the expected timeframe for construction of project facilities, when solid waste disposal services would be needed. Further, implementation of BMP 13 (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) would require development of a project-specific construction debris recycling and diversion program to achieve a documented 50% diversion of construction waste. Construction of Alternative 4A would not create solid waste in excess of the permitted capacity of area landfills, nor would it adversely affect the expected lifespan of these solid waste facilities. Therefore, there would be a less-than-significant impact on solid waste management facilities.

Impact UT-6: Effects on Regional or Local Utilities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Disruption of utility services or relocation of existing facilities would be identical to that described under Alternative 4. This water conveyance alignment, along with its associated physical structures, could interfere with 12 overhead power/electrical transmission lines Figure 24-6 in the Draft EIR/EIS), 6 natural gas pipelines (Table 20-5 and Figure 24-3 in the Draft EIR/EIS), 11 inactive oil or gas wells (Figure 24-5 in the Draft EIR/EIS), the Mokelumne Aqueduct, and 43 miles of agricultural delivery canals and drainage ditches, including approximately 13 miles on Byron Tract, and 7 miles on Bouldin Island. Additionally, active gas wells may need to be plugged and abandoned. Relocation of additional facilities near proposed forebays, RTM, and borrow or spoils areas could also be necessary. The potential damage and disruption to buried and overhead electric transmission lines would be similar for telecommunication infrastructure. Because relocation and disruption of existing utility infrastructure would be required under this alternative and would have the potential to create environmental effects, this effect would be adverse.

Mitigation Measures UT-6a, UT-6b, and UT-6c are available to reduce the severity of this effect. If coordination with all appropriate utility providers and local agencies to integrate with other construction projects and minimize disturbance to communities were successful under Mitigation Measure UT-6b, the effect would not be adverse.

CEQA Conclusion: Under this alternative, most features would avoid disrupting existing facilities by crossing over or under infrastructure. However, construction of facilities would conflict with existing utility facilities in some locations. Regional power transmission lines and one natural gas pipeline would require relocation. Because the relocation and potential disruption of utility infrastructure would be required, this impact would be significant.

Mitigation Measures UT-6a, UT-6b, and UT-6c are available to reduce these impacts through measures that could avoid disruption of utility infrastructure. If coordination with all appropriate utility providers and local agencies to integrate with other construction projects and minimize disturbance to communities were successful under Mitigation Measure UT-6b, the impact would be less-than-significant. However, because coordination with a third party is required in order to carry out this mitigation, a conservative assessment of significant and unavoidable is being made.

Mitigation Measure UT-6a: Verify Locations of Utility Infrastructure

Please see Mitigation Measure UT-6a under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, of the Draft EIR/EIS.

Mitigation Measure UT-6b: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Operational Reliability

Please see Mitigation Measure UT-6b under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, of the Draft EIR/EIS.

Mitigation Measure UT-6c: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Worker and Public Health and Safety

Please see Mitigation Measure UT-6c under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, of the Draft EIR/EIS.

Impact UT-7: Effects on Public Services and Utilities as a Result of Operation and Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: Operation and maintenance activities would require minimal labor. Impacts under Alternative 4A would be identical to that under Alternative 4. Given the limited number of workers involved and the large number of work sites, it is not anticipated that routine operations and maintenance activities or major inspections would result in substantial demand for law enforcement, fire protection, or emergency response services. In addition, operation and maintenance would not place service demand on public schools or libraries. The operation and maintenance of the proposed water conveyance facilities would not result in the need for new or physically altered government facilities as a result of increased need for public services.

Potential effects associated with operation and maintenance of water conveyance facilities would be similar to those described under Alternative 4. Therefore, Alternative 4A would not result in physical effects associated with the provision of new or physically altered government facilities.

Operation and maintenance of Alternative 4A facilities would involve use of water for pressure washing intake screen panels and basic cleaning of building facilities and other equipment. Impacts would be identical to those under Alternative 4. The operation and maintenance of the proposed water conveyance facilities would not result in the need for new water supply entitlements, or require construction of new water or wastewater treatment facilities or expansion of existing facilities.

Similar to Alternative 4, the operation and maintenance activities associated with the proposed water conveyance facilities would not be expected to generate solid waste such that there would be an increase in demand for solid waste management providers in the Plan Area and surrounding communities. Therefore, there would be no or minimal effect on solid waste management facilities.

As with Alternative 4, operation and maintenance of proposed water conveyance facilities under this alternative would require new transmission lines for intakes, pumping plants, operable barriers, boat locks, and gate control structures throughout the various proposed conveyance alignments and construction of project facilities. Points of interconnection would be located identically to Alternative 4.

Operation and maintenance activities associated with the proposed water conveyance facilities would not be expected to result in the disruption or relocation of utilities. Effects associated with energy demands of operation and maintenance of the proposed water conveyance facilities are addressed in Chapter 21, *Energy*, of the Draft EIR/EIS.

Overall, operation and maintenance of the conveyance facilities under Alternative 4A would not result in adverse effects on service demands, water supply and treatment capacity, wastewater and solid waste facilities nor conflict with local and regional utility lines. There would not be an adverse effect.

CEQA Conclusion: Operation and maintenance activities associated with the Alternative 4A proposed water conveyance facilities would not result in the need for the provision of, or the need for, new or physically altered government facilities from the increased need for public services; construction of new water and wastewater treatment facilities or generate a need for new water supply entitlements; generate solid waste in excess of permitted landfill capacity; or result in the disruption or relocation of utilities. The impact on public services and utilities would be less than significant. No mitigation is required.

Impact UT-8: Effects on Public Services and Utilities as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Effects of Alternative 4A related to the potential for effects on public services and utilities from implementing applicable conservation and other stressor reductions would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 4A would restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, 6–10 as compared with 83,900 acres under Alternative 4. Environmental Commitments 11, 12, 15, and 16 would be implemented only at limited locations. Conservation Measures 2, 5, 13, 14, and 17–21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 4A would likely be smaller than those associated with Alternative 4.

Public Services

Potential effects of implementing conservation and other stressor reductions under Alternative 4A on law enforcement, fire protection, and emergency response services would primarily involve demand for services related to construction site security and construction-related accidents. The effect would be similar to that under Alternative 4, but because only portions of the restoration conservation measures and fewer of the other stressor reduction conservation measures would be implemented under Alternative 4A, it is likely that the effects on public services would be less than those presented for Alternative 4. This effect would not be considered adverse with the implementation of environmental commitments to provide onsite private security services at construction areas and environmental commitments that would minimize the potential for construction-related accidents associated with hazardous materials spills, contamination, or fires, as described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS. These environmental commitments would be incorporated into this alternative and would provide for onsite security at construction sites and minimize construction-related accidents associated with hazardous materials spills, contamination, and fires that may result from construction of the conservation components.

Utilities

Water and Wastewater

Implementation of some of the conservation components, in particular those involved with restoration and enhancement of some habitat types, could require a water supply, but would not require city or county treated water sources. Effects would be similar to, but lesser in magnitude than that under Alternative 4, due to the fact that Alternative 4A involves smaller acreage amounts of restoration and conservation. Additionally, some components that would require water supply under Alternative 4 are not a part of Alternative 4A (CM5). Conservation components that could increase need for water supply are restoration of natural tidal communities (Environmental Commitment 4), channel margin (Environmental Commitment 6), riparian (Environmental Commitment 7), vernal pool and alkali seasonal wetland complex (Environmental Commitment 9), and nontidal marsh habitats (Environmental Commitment 10); and maintenance of these habitats. Measures related to the reduction of stressors on covered species that are a part of Alternative 4A would not generally require a treated water supply or generate wastewater. Because the location and construction or operational details (i.e., water consumption and water sources associated with conservation components of these facilities and programs) have not yet been developed, the need for new or expanded water or wastewater treatment facilities is uncertain. However, because the habitat restoration and enhancement activities consist of restoration consistent with open space, the need for new or expanded wastewater treatment facilities is unlikely.

Solid Waste

Implementation of some of the conservation components would result in construction debris and green waste. Implementation of habitat restoration and enhancement proposed under Environmental Commitments 4, 6, 7, and 9–11 would involve restoration, enhancement, and management of various types of habitat. Construction activities could require clearing and grubbing, demolition of existing structures (e.g., roads and utilities), surface water quality protection, dust control, establishment of storage and stockpile areas, temporary utilities and fuel storage, and erosion control. Effects would be similar to, but less in magnitude than that under Alternative 4, due to the fact that Alternative 4A involves smaller acreage amounts of restoration and conservation. The estimated tonnage of construction debris and solid waste that would be generated from construction associated with the proposed conservation components is unknown. However, there is a remaining landfill capacity of over 300 million tons in nearby landfills (Table 20A-6 in Appendix 20A of the Draft EIR/EIS). The disposal of construction debris and excavated material would occur at several different locations depending on the type of material and its origin. Based on the capacity of the landfills in the region, and the waste diversion requirements set forth by the State of California, it is expected that construction and operation of the proposed conservation components would not cause any exceedance of landfill capacity.

Electricity and Natural Gas

Conservation components including habitat restoration and enhancement would, in some cases, involve substantial earthwork and ground disturbance. As discussed above under Impact UT-6, construction could potentially disrupt utility services, and ground disturbance has potential to damage underground utilities. The long-term conversion of existing utility corridors to habitat purposes could require the relocation of utility infrastructure, which could carry environmental effects. Mitigation Measures UT-6a, UT-6b, and UT-6c would be available to reduce the severity of these effects.

Effects would be similar to, but less in magnitude than that under Alternative 4, due to the fact that Alternative 4A involves smaller acreage amounts of restoration and conservation. The locations, construction, and operational details for these and other conservation components have not been identified. Adverse effects due to the construction, operation and maintenance activities associated with the conservation components are not expected to result in the need for new government facilities to provide public services or the need for new or expanded water or wastewater treatment facilities based on increased demand. Environmental commitments would minimize construction-related accidents associated with hazardous materials spills, contamination, and fires that may result from construction of the conservation components. However, there is a potential for the disruption or relocation of utility infrastructure, which has the potential to result in an adverse effect. Further, no substantive adverse effects on solid waste management facilities are anticipated. Because the location and construction and operational details (i.e., water consumption and water sources associated with conservation components) related to these facilities and programs have not yet been developed, the need for new or expanded water or wastewater treatment facilities is uncertain. However, because the habitat restoration and enhancement activities consist of restoration consistent with open space, the need for new or expanded wastewater treatment facilities is unlikely. This effect would be adverse.

CEQA Conclusion: Significant impacts could occur if implementation of the proposed conservation components would result in the need for the provision of, or the need for, new or physically altered government facilities from the increased need for public services; construction of new water and wastewater treatment facilities or generate a need for new water supply entitlements; generate solid waste in excess of permitted landfill capacity; or result in the disruption or relocation of utilities.

Implementation of the proposed conservation components under Alternative 4A is not likely to require alteration or construction of new government facilities due to increased need for public services and utilities. Several measures to reduce stressors on covered species could result in water supply requirements, but are not expected to require substantial increases in demand on municipal water and wastewater treatment services.

Construction and operation activities associated with the proposed conservation measures would result in a less-than-significant impact on solid waste management facilities based on the capacity of the landfills in the region, and the waste diversion requirements set forth by the State of California.

Potential impacts of implementing conservation components on law enforcement, fire protection, and emergency response services within the ROAs would be less-than-significant with the incorporation of environmental commitments into this alternative and would minimize construction-related accidents associated with hazardous materials spills, contamination, and fires that may result from construction of the conservation components (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

The need for new or expanded water facilities and the potential to disrupt utilities in the study area as a result of construction of operation of conservation and other stressor reductions is unknown at this time, nor have construction and operational details been settled upon. However, because the habitat restoration and enhancement activities consist of restoration consistent with open space, the need for new or expanded wastewater treatment facilities is unlikely. While Mitigation Measures UT-6a, UT-6b, and UT-6c could reduce the significance of impacts on utilities; it is uncertain whether these mitigations could reduce this impact in every case. Therefore, this impact would be significant and unavoidable.

Mitigation Measure UT-6a: Verify Locations of Utility Infrastructure

Please see Mitigation Measure UT-6a under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6b: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Operational Reliability

Please see Mitigation Measure UT-6b under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6c: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Worker and Public Health and Safety

Please see Mitigation Measure UT-6c under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

4.3.17 Energy

Impact ENG-1: Wasteful or Inefficient Energy Use for Temporary Construction Activities

NEPA Effects: Total construction energy use (2,132 GWh and 104 million gallons of diesel and gasoline) and the potential for Alternative 4A to result in a wasteful, inefficient or unnecessary consumption of construction energy would be identical to Alternative 4. Construction BMPs would ensure that only high-efficiency equipment is utilized during construction (see Appendix 3B, *Environmental Commitments*, Section 3B.5.3, in Appendix A of this RDEIR/SDEIS) and that construction activity would not result in an adverse effect on energy resources.

CEQA Conclusion: Energy requirements for construction of the water conveyance facilities associated with Alternative 4A would equate to 2,132 GWh during the construction period. Alternative 4A would also consume approximately 104 million gallons of diesel and gasoline. Construction BMPs would ensure that only high-efficiency equipment is utilized during construction and that construction activity would result in a less-than-significant impact on energy resources. No mitigation is required.

Impact ENG-2: Wasteful or Inefficient Energy Use for Pumping and Conveyance

NEPA Effects: Alternative 4A water conveyance operations would be similar to the range of possible operations for the spring and fall Delta outflow requirements that would occur under Alternative 4 Operational Scenario H3 and Alternative 4 Operational Scenario H4. As shown in Table 21-12 in Appendix A of this RDEIR/SDEIS, energy use for north Delta intake pumping and tunnel conveyance would range between 150 GWh per year and 170 GWh per year under ELT conditions. Accordingly, increased energy use at the north Delta would be slightly higher under Alternative 4A (ELT) than estimated for Alternative 4 (energy use under Alternative 4A LLT would be identical to energy use under Alternative 4). While Alternative 4A would still increase energy demand at the north Delta, relative to the No Action Alternative, operation of the water conveyance facility would be managed to maximize efficient energy use, including off-peak pumping and use of gravity. Accordingly, implementation of Alternative 4A would not result in a wasteful or inefficient energy use and there would be no adverse effect.

CEQA Conclusion: Operation of Alternative 4A would require an additional 150 and 170 GWh per year under ELT conditions for north Delta pumping, relative to Existing Conditions. Operation of the water conveyance facility under both scenarios would be managed to maximize efficient energy use, including off-peak pumping and use of gravity. Accordingly, implementation of Alternative 4A would not result in a wasteful or inefficient energy use and this impact would be less than significant. No mitigation is required.

Impact ENG-3: Compatibility of the Proposed Water Conveyance Facilities and Environmental Commitments 3, 4, 6–12, 15, and 16 with Plans and Policies

NEPA Effects: Constructing the water conveyance facilities and implementing the environmental commitments under Alternative 4A would generally have the same potential for incompatibilities with one or more plans and policies related to energy resources as described for Alternative 4. As described for Alternative 4, the project would be constructed and operated in compliance with regulations related to energy resources enforced by Federal Energy Regulatory Commission (FERC) and other federal agencies. The project would not conflict with the Warren-Alquist Act or State CEQA Guidelines, Appendix F, *Energy Conservation.* Accordingly, there would be no adverse effect.

CEQA Conclusion: The potential incompatibilities with plans and policies listed above indicate the potential for a physical consequence to the environment. The physical effects they suggest are discussed in impacts ENG-1 and ENG-2, above and no additional CEQA conclusion is required related to the compatibility of Alternative 4A with relevant plans and policies.

4.3.18 Air Quality and Greenhouse Gases

Impact AQ-1: Generation of Criteria Pollutants in Excess of the SMAQMD Regional Thresholds during Construction of the Proposed Water Conveyance Facility

NEPA Effects: Construction emissions generated by Alternative 4A in the Sacramento Metropolitan Air Quality Management District (SMAQMD) would be identical to those generated by Alternative 4. As shown in Table 22-99 in Appendix A of this RDEIR/SDEIS, nitrogen oxide (NO_X) emissions would exceed SMAQMD's daily threshold for all years between 2018 and 2029, even with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Since NO_X is a precursor to ozone and particulate matter (PM), violations of SMAQMD's daily NO_X threshold could affect both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the national ambient air quality standards (NAAQS) and California ambient air quality standards (CAAQS). Mitigation Measures AQ-1a and AQ-1b would be available to reduce NO_X emissions, and would thus address regional effects related to secondary ozone and PM formation.

CEQA Conclusion: NO_X emissions generated during construction of Alternative 4A would exceed SMAQMD regional threshold of significance. Since NO_X is a precursor to ozone and PM, violations of SMAQMD's daily NO_X threshold could affect both regional ozone and PM formation. The impact of generating NO_X emissions in excess of local air district thresholds would violate applicable air quality standards in the study area and could contribute to or worsen an existing air quality conditions. This would be a significant impact. Mitigation Measures AQ-1a and AQ-1b would be available to reduce NO_X emissions to a less-than-significant level by offsetting emissions to quantities below SMAQMD CEQA thresholds.

Mitigation Measure AQ-1a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SFNA to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable CEQA Thresholds for Other Pollutants[2]

Please refer to Mitigation Measure AQ-1a under Impact AQ-1 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-1b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SFNA to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable CEQA Thresholds for Other Pollutants

Please refer to Mitigation Measure AQ-1b under Impact AQ-1 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

[2] In the title of this mitigation measure, the phrase "for other pollutants" is intended to apply to other alternatives, where associated impacts on other pollutants may exceed thresholds other than NO_X.

Impact AQ-2: Generation of Criteria Pollutants in Excess of the YSAQMD Regional Thresholds during Construction of the Proposed Water Conveyance Facility

NEPA Effects: Construction emissions generated by Alternative 4A in the Yolo-Solano Air Quality Management District (YSAQMD) would be identical to those generated by Alternative 4. As shown in Table 22-99 in Appendix A of this RDEIR/SDEIS, criteria pollutant emissions would not exceed YSAQMD regional thresholds. Accordingly, construction of Alternative 4A would not contribute to or worsen existing air quality conditions. There would be no adverse effect.

CEQA Conclusion: Construction emission would not exceed YSAQMD's regional thresholds of significance. Accordingly, Alternative 4A would not contribute to or worsen existing air quality conditions. This impact would be less than significant. No mitigation is required.

Impact AQ-3: Generation of Criteria Pollutants in Excess of the BAAQMD Regional Thresholds during Construction of the Proposed Water Conveyance Facility

NEPA Effects: Construction emissions generated by Alternative 4A in the Bay Area Air Quality Management District (BAAQMD) would be identical to those generated by Alternative 4. As shown in Table 22-99 in Appendix A of this RDEIR/SDEIS, construction emissions would exceed BAAQMD's daily thresholds for the following pollutants and years, even with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

- Reactive organic gases (ROG): 2020–2028
- NO_X: 2018–2029

Since ROG and NO_X are precursors to ozone and NO_X is a precursor to PM, violations of BAAQMD's ROG and NO_X thresholds could affect both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the NAAQS and CAAQS. Mitigation Measures AQ-3a and AQ-3b are available to reduce ROG and NO_X emissions, and would thus address regional effects related to secondary ozone and PM formation.

CEQA Conclusion: Emissions of ROG and NO_X generated during construction would exceed BAAQMD regional thresholds of significance. Since ROG and NO_X are precursors to ozone and NO_X is a precursor to PM, violations of BAAQMD's ROG and NO_X thresholds could affect both regional ozone and PM formation. The impact of generating ROG and NO_X emissions in excess of BAAQMD's regional thresholds would therefore violate applicable air quality standards in the Study area and could contribute to or worsen an existing air quality conditions. This would be a significant impact. Mitigation Measures AQ-3a and AQ-3b would be available to reduce ROG and NO_X emissions to a less-than-significant level by offsetting emissions to quantities below BAAQMD CEQA thresholds.

Mitigation Measure AQ-3a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within BAAQMD/SFBAAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable BAAQMD CEQA Thresholds for Other Pollutants[3]

Please refer to Mitigation Measure AQ-3a under Impact AQ-3 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

[3] In the title of this mitigation measure, the phrase "for other pollutants" is intended to apply to other alternatives, where associated impacts on other pollutants may exceed thresholds other than NO_X.

Mitigation Measure AQ-3b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the BAAQMD/SFBAAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable BAAQMD CEQA Thresholds for Other Pollutants

Please refer to Mitigation Measure AQ-3b under Impact AQ-3 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-4: Generation of Criteria Pollutants in Excess of the SJVAPCD Regional Thresholds during Construction of the Proposed Water Conveyance Facility

NEPA Effects: Construction emissions generated by Alternative 4A in the San Joaquin Valley Air Pollution Control District (SJVAPCD) would be identical to those generated by Alternative 4. As shown in Table 22-99 in Appendix A of this RDEIR/SDEIS, construction emissions would exceed SJVAPCD's regional thresholds for the following pollutants and years, even with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

- ROG: 2020-2025
- NO_X: 2018–2028
- PM less than 10 microns in diameter (PM10): 2019–2025

Since ROG and NO_X are precursors to ozone and NO_X is a precursor to PM, violations of SJVAPCD's ROG and NO_X thresholds could affect both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the NAAQS and CAAQS. Similarly, exceedances of SJVAPCD's PM10 threshold could impede attainment of the NAAQS and CAAQS for PM10. Mitigation Measures AQ-4a and AQ-4b are available to reduce ROG, NO_X, and PM10 emissions, and would thus address regional effects related to secondary ozone and PM formation.

CEQA Conclusion: Emissions of ROG, NO_X, and PM10 generated during construction would exceed SJVAPCD's regional thresholds of significance. Since ROG and NO_X are precursors to ozone and NO_X is a precursor to PM, violations of SJVAPCD's ROG and NO_X thresholds could affect both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the NAAQS and CAAQS. Similarly, exceedances of SJVAPCD's PM10 threshold could impede attainment of the NAAQS and CAAQS for PM10. The impact of generating ROG, NO_X, and PM10 emissions in excess of SJVAPCD's regional thresholds would therefore violate applicable air quality standards in the study area and could contribute to or worsen an existing air quality condition. This would be a significant impact. Mitigation Measures AQ-4a and AQ-4b would be available to reduce ROG, NO_X, and PM10 emissions to a less-than-significant level by offsetting emissions to quantities below SJVAPCD CEQA thresholds.

Mitigation Measure AQ-4a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within SJVAPCD/SJVAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable SJVAPCD CEQA Thresholds for Other Pollutants[4]

Please refer to Mitigation Measure AQ-4a under Impact AQ-4 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-4b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SJVAPCD/SJVAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable SJVAPCD CEQA Thresholds for Other Pollutants

Please refer to Mitigation Measure AQ-4b under Impact AQ-4 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-5: Generation of Criteria Pollutants in Excess of the SMAQMD Regional Thresholds from Operation and Maintenance of the Proposed Water Conveyance Facility

NEPA Effects: The number of equipment and personnel required for routine and annual inspections is influenced by the physical water conveyance footprint (i.e., number and location of intakes). Since the water conveyance footprint under Alternative 4A would be identical to Alternative 4, operational activities required for Alternative 4A in the SMAQMD would be the same as those required for Alternative 4. Accordingly, operational emissions generated by Alternative 4A under the ELT and LLT conditions would be the same as those analyzed for Alternative 4 under the ELT and LLT conditions. As shown in Table 22-100 in Appendix A of this RDEIR/SDEIS, emissions under both conditions would not exceed SMAQMD's regional thresholds of significance. Accordingly, project operations would not contribute to or worsen existing air quality violations. There would be no adverse effect.

CEQA Conclusion: Emissions generated during operation and maintenance activities would not exceed SMAQMD regional thresholds of significance. Accordingly, Alternative 4A would not contribute to or worsen existing air quality conditions. This impact would be less than significant. No mitigation is required.

Impact AQ-6: Generation of Criteria Pollutants in Excess of the YSAQMD Regional Thresholds from Operation and Maintenance of the Proposed Water Conveyance Facility

NEPA Effects: No permanent features would be constructed in the YSAQMD that would require routine operations and maintenance. Accordingly, no operational emissions would be generated in the YSAQMD under either Alternative 4 or 4A. Alternative 4A would therefore neither exceed the YSAQMD regional thresholds of significance nor result in an adverse effect on air quality.

CEQA Conclusion: No operational emissions would be generated in the YSAQMD. Consequently, operation of Alternative 4A would not exceed the YSAQMD regional thresholds of significance. This impact would be less than significant. No mitigation is required.

---

[4] In the title of this mitigation measure, the phrase "for other pollutants" is intended to apply to other alternatives, where associated impacts on other pollutants may exceed thresholds other than NO_X.

Impact AQ-7: Generation of Criteria Pollutants in Excess of the BAAQMD Regional Thresholds from Operation and Maintenance of the Proposed Water Conveyance Facility

NEPA Effects: The number of equipment and personnel required for routine and annual inspections is influenced by the physical water conveyance footprint (i.e., size and location of the Clifton court forebay). Since the water conveyance footprint under Alternative 4A would be identical to Alternative 4, operational activities required for Alternative 4A in the BAAQMD would be the same as those required for Alternative 4. Accordingly, operational emissions generated by Alternative 4A under the ELT and LLT conditions would be the same as those analyzed for Alternative 4. As shown in Table 22-100 in Appendix A of this RDEIR/SDEIS, operational emissions under the ELT condition would not exceed BAAQMD's regional thresholds of significance. Accordingly, project operations would not contribute to or worsen existing air quality violations. There would be no adverse effect.

CEQA Conclusion: Emissions generated during operation and maintenance activities would not exceed BAAQMD regional thresholds of significance. Accordingly, Alternative 4A would not contribute to or worsen existing air quality conditions. This impact would be less than significant. No mitigation is required.

Impact AQ-8: Generation of Criteria Pollutants in Excess of the SJVAPCD Regional Thresholds from Operation and Maintenance of the Proposed Water Conveyance Facility

NEPA Effects: The number of equipment and personnel required for routine and annual inspections is influenced by the physical water conveyance footprint (i.e., size and location of the tunnel segments). Since the water conveyance footprint in SJVAPCD under Alternative 4A would be identical to Alternative 4, operational activities required for Alternative 4A in the SJVAPCD would be the same as those required for Alternative 4. Accordingly, operational emissions generated by Alternative 4A in SJVAPCD under the ELT and LLT conditions would be the same as those analyzed for Alternative 4. As shown in Table 22-100 in Appendix A of this RDEIR/SDEIS, operational emissions under the ELT condition would not exceed SJVAPCD's regional thresholds of significance. Accordingly, project operations would not contribute to or worsen existing air quality violations. There would be no adverse effect.

CEQA Conclusion: Emissions generated during operation and maintenance activities would not exceed SJVAPCD regional thresholds of significance. Accordingly, Alternative 4A would not contribute to or worsen existing air quality conditions. This impact would be less than significant. No mitigation is required.

Impact AQ-9: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter in Excess of SMAQMD's Health-Based Concentration Thresholds

NEPA Effects: Construction activity required for Alternative 4A within the SMAQMD would be equal to activity required for Alternative 4. Emissions and associated health risks from localized PM exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As shown in Table 22-101 in Appendix A of this RDEIR/SDEIS, construction of Alternative 4 would exceed SMAQMD's 24-hour PM10 threshold at 10 receptor locations. The exceedances would be temporary and occur intermittently due to soil disturbance (primarily entrained road dust). Mitigation Measure AQ-9 is available to reduce this effect

CEQA Conclusion: As shown in Table 22-102 in Appendix A of this RDEIR/SDEIS, construction of Alternative 4 would exceed SMAQMD's 24-hour PM10 threshold at 10 receptor locations. The exceedances would be temporary and occur intermittently due to soil disturbance (primarily entrained road dust). Mitigation Measure AQ-9 is available to reduce impacts to less than significant (see Table 22-102 in Appendix A of this RDEIR/SDEIS).

Mitigation Measure AQ-9: Implement Measures to Reduce Re-Entrained Road Dust and Receptor Exposure to PM2.5 and PM10

Please refer to Mitigation Measure AQ-9 under Impact AQ-9 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-10: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter in Excess of YSAQMD's Health-Based Concentration Thresholds

NEPA Effects: Construction activity required for Alternative 4A within the YSAQMD would be equal to activity required for Alternative 4. Emissions and associated health risks from localized PM exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As shown in Table 22-103 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 and PM10 concentrations under Alternative 4 are less than YSAQMD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 4A would not expose of sensitive receptors to adverse localized particulate matter concentrations.

CEQA Conclusion: As shown in Table 22-103 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 and PM10 concentrations under Alternative 4 are less than YSAQMD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 4A would not expose of sensitive receptors to significant localized particulate matter concentrations. This impact would be less than significant. No mitigation is required.

Impact AQ-11: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter in Excess of BAAQMD's Health-Based Concentration Thresholds

NEPA Effects: Construction activity required for Alternative 4A within the BAAQMD would be equal to activity required for Alternative 4. Emissions and associated health risks from localized PM exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As shown in Table 22-104 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 concentrations under Alternative 4 are less than BAAQMD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 4A would not expose of sensitive receptors to adverse localized particulate matter concentrations.

CEQA Conclusion: As shown in Table 22-104 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 concentrations under Alternative 4 are less than BAAQMD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 4A would not expose of sensitive receptors to significant localized particulate matter concentrations. This impact would be less than significant. No mitigation is required.

Impact AQ-12: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter in Excess of SJVAPCD's Health-Based Concentration Thresholds

NEPA Effects: Construction activity required for Alternative 4A within the SJVAPCD would be equal to activity required for Alternative 4. Emissions and associated health risks from localized PM exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As shown in Table 22-105 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 and PM10 concentrations under Alternative 4 are less than SJVAPCD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 4A would not expose of sensitive receptors to adverse localized particulate matter concentrations.

CEQA Conclusion: As shown in Table 22-105 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 and PM10 concentrations under Alternative 4 are less than SJVAPCD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 4A would not expose of sensitive receptors to significant localized particulate matter concentrations. This impact would be less than significant. No mitigation is required.

Impact AQ-13: Exposure of Sensitive Receptors to Health Threats from Localized Carbon Monoxide

NEPA Effects: Construction activity required for Alternative 4A would be equal to activity required for Alternative 4. Emissions and associated health risks from localized carbon monoxide (CO) exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As described under Alternative 4, given that 1) construction activities typically do not result in CO hot-spots, 2) onsite concentrations must comply with the Occupational Safety and Health Administration (OSHA) standards, and 3) CO levels dissipate as a function of distance, equipment-generated CO emissions (see Table 22-99 in Appendix A of this RDEIR/SDEIS) are not anticipated to result in adverse health threats to sensitive receptors.

With respect to CO hot-spot formation along construction haul routes, as shown in Table 19-25 in Appendix A of this RDEIR/SDEIS, the highest peak hour traffic volumes under BPBGPP—8,088 vehicles per hour—would occur on westbound Interstate 80 between Suisun Valley Road and SR 12. This is about half of the congested traffic volume modeled by BAAQMD (24,000 vehicles per hour) that would be needed to contribute to a localized CO hot-spot, and less than half of the traffic volume modeled by SMAQMD (31,600 vehicles per hour). Accordingly, construction traffic is not anticipated to result in adverse health threats to sensitive receptors.

CEQA Conclusion: Continuous engine exhaust may elevate localized CO concentrations. Receptors exposed to these CO "hot-spots" may have a greater likelihood of developing adverse health effects. Construction sites are less likely to result in localized CO hot-spots due to the nature of construction activities (Sacramento Metropolitan Air Quality Management District 2014), which normally utilize diesel-powered equipment for intermittent or short durations. Moreover, construction sites must comply with the OSHA CO exposure standards for onsite workers. Accordingly, given that construction activities typically do not result in CO hot-spots, onsite concentrations must comply with OSHA standards, and CO levels dissipate as a function of distance, equipment-generated CO emissions are not anticipated to result in significant health threats to sensitive receptors. Similarly, peak-hour construction traffic on local roadways would not exceed BAAQMD's or SMAQMD's conservative screening criteria for the formation potential CO hot-spots. This impact would be less than significant. No mitigation is required.

Impact AQ-14: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of SMAQMD's Chronic Non-Cancer and Cancer Risk Assessment Thresholds

NEPA Effects: Construction activity required for Alternative 4A within the SMAQMD would be equal to activity required for Alternative 4. Emissions and associated health risks from localized diesel particulate matter (DPM) exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As shown in Table 22-106 in Appendix A of this RDEIR/SDEIS, Alternative 4 would not exceed the SMAQMD's chronic non-cancer or cancer thresholds and, thus, would not expose sensitive receptors to substantial DPM concentrations. Therefore, the effect of exposure of sensitive receptors to DPM health threats during construction would not be adverse.

CEQA Conclusion: DPM generated during construction poses inhalation-related chronic non-cancer hazard and cancer risk if adjacent receptors are exposed to significant concentrations for prolonged durations. The DPM generated during Alternative 4A construction would not exceed the SMAQMD's chronic non-cancer or cancer thresholds, and thus would not expose sensitive receptors to substantial pollutant concentrations. Therefore, this impact for DPM emissions would be less than significant. No mitigation is required.

Impact AQ-15: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of YSAQMD's Chronic Non-Cancer and Cancer Risk Thresholds

NEPA Effects: Construction activity required for Alternative 4A within the YSAQMD would be equal to activity required for Alternative 4. Emissions and associated health risks from localized DPM exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As shown in Table 22-107 in Appendix A of this RDEIR/SDEIS, Alternative 4 would not exceed the YSAQMD's chronic non-cancer or cancer thresholds and, thus, would not expose sensitive receptors to substantial DPM concentrations. Therefore, the effect of exposure of sensitive receptors to DPM health threats during construction would not be adverse.

CEQA Conclusion: DPM generated during construction poses inhalation-related chronic non-cancer hazard and cancer risk if adjacent receptors are exposed to significant concentrations for prolonged durations. The DPM generated during Alternative 4A construction would not exceed the YSAQMD's chronic non-cancer or cancer thresholds, and thus would not expose sensitive receptors to substantial pollutant concentrations. Therefore, this impact for DPM emissions would be less than significant. No mitigation is required.

Impact AQ-16: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of BAAQMD's Chronic Non-Cancer and Cancer Risk Thresholds

NEPA Effects: Construction activity required for Alternative 4A within the BAAQMD would be equal to activity required for Alternative 4. Emissions and associated health risks from localized DPM exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As shown in Table 22-108 in Appendix A of this RDEIR/SDEIS, Alternative 4 would not exceed the BAAQMD's chronic non-cancer or cancer thresholds and, thus, would not expose sensitive receptors to substantial DPM concentrations. Therefore, the effect of exposure of sensitive receptors to DPM health threats during construction would not be adverse.

CEQA Conclusion: DPM generated during construction poses inhalation-related chronic non-cancer hazard and cancer risk if adjacent receptors are exposed to significant concentrations for prolonged durations. The DPM generated during Alternative 4A construction would not exceed the BAAQMD's chronic non-cancer or cancer thresholds, and thus would not expose sensitive receptors to substantial pollutant concentrations. Therefore, this impact for DPM emissions would be less than significant. No mitigation is required.

Impact AQ-17: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of SJVAPCD's Chronic Non-Cancer and Cancer Risk Thresholds

NEPA Effects: Construction activity required for Alternative 4A within the SJVAPCD would be equal to activity required for Alternative 4. Emissions and associated health risks from localized DPM exposure for Alternative 4 would therefore be representative of emissions and health risks generated by Alternative 4A. As shown in Table 22-109 in Appendix A of this RDEIR/SDEIS, Alternative 4 would not exceed the SJVAPCD's chronic non-cancer or cancer thresholds and, thus, would not expose sensitive receptors to substantial DPM concentrations. Therefore, the effect of exposure of sensitive receptors to DPM health threats during construction would not be adverse.

CEQA Conclusion: DPM generated during construction poses inhalation-related chronic non-cancer hazard and cancer risk if adjacent receptors are exposed to significant concentrations for prolonged durations. The DPM generated during Alternative 4A construction would not exceed the SJVAPCD's chronic non-cancer or cancer thresholds, and thus would not expose sensitive receptors to substantial pollutant concentrations. Therefore, this impact for DPM emissions would be less than significant. No mitigation is required.

Impact AQ-18: Exposure of Sensitive Receptors to Coccidioides immitis (Valley Fever)

NEPA Effects: The potential for Alternative 4A to expose receptors adjacent to the construction site to spores known to cause Valley Fever would be identical to Alternative 4. As discussed under Alternative 4, earthmoving activities during construction could release *C. immitis* spores if filaments are present and other soil chemistry and climatic conditions are conducive to spore development. Receptors adjacent to the construction area may therefore be exposed to increase risk of inhaling *C. immitis* spores and subsequent development of Valley Fever. Implementation of advanced air-district recommended fugitive dust controls outlined in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, would avoid dusty conditions and reduce the risk of contracting Valley Fever through routine watering and other controls. Therefore, the effect of exposure of sensitive receptors to increased Valley Fever risk during construction would not be adverse.

CEQA Conclusion: Construction of the water conveyance facility would involve earthmoving activities that could release *C. immitis* spores if filaments are present and other soil chemistry and climatic conditions are conducive to spore development. Receptors adjacent to the construction area may therefore be exposed to increase risk of inhaling *C. immitis* spores and subsequent development of Valley Fever. Implementation of air-district recommended fugitive dust controls outlined in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, would avoid dusty conditions and reduce the risk of contracting Valley Fever through routine watering and other controls. Therefore, this impact would be less than significant. No mitigation is required.

Impact AQ-19: Creation of Potential Odors Affecting a Substantial Number of People during Construction or Operation of the Proposed Water Conveyance Facility

NEPA Effects: Odors from construction would primarily originate from diesel equipment and excavated organic material. Since construction equipment activity and the quantity of excavated material under Alternative 4A would be identical to Alternative 4, the potential for Alternative 4A to expose receptors to nuisance odors during construction of the water conveyance facilities would be the same as Alternative 4. As discussed under Alternative 4, odors from construction activities would be localized and generally confined to the immediate area surrounding the construction site. Moreover, odors would be temporary and localized, and they would cease once construction activities have been completed. Thus, it is not anticipated that construction of water conveyance facilities would create objectionable odors from construction equipment or asphalt paving. Similarly, drying and stockpiling of removed muck and sediment will occur under aerobic conditions, which will limit any potential decomposition and associated malodorous products. Accordingly, tunnel and sediment excavation would not create objectionable odors.

With respect to odors during long-term operation, Alternative 4A would not result in the addition of odors facilities (e.g., wastewater treatment plants). Accordingly, similar to Alternative 4, long-term operation of the water conveyance facility would not result in objectionable odors. There would be no adverse effect.

CEQA Conclusion: Alternative 4A would not result in the addition of major odor producing facilities. Diesel emissions during construction could generate temporary odors, but these would quickly dissipate and cease once construction is completed. Likewise, potential odors generated during asphalt paving would be addressed through mandatory compliance with air district rules and regulations. While tunnel excavation would unearth approximately 27 million cubic yards of muck, geotechnical tests indicate that soils in the Plan Area have relatively low organic constituents. Moreover, drying and stockpiling of the removed muck will occur under aerobic conditions, which will further limit any potential decomposition and associated malodorous products. Accordingly, the impact of exposure of sensitive receptors to potential odors would be less than significant. No mitigation is required.

Impact AQ-20: Generation of Criteria Pollutants in the Excess of Federal *De Minimis* Thresholds from Construction and Operation and Maintenance of the Proposed Water Conveyance Facility

NEPA Effects: The potential for Alternative 4A to exceed the federal *de minimis* thresholds during construction of the water conveyance facilities would be identical to Alternative 4. As shown in Table 22-110 in Appendix A of this RDEIR/SDEIS, implementation of Alternative 4 would exceed the following federal *de minimis* thresholds during construction:

<u>Sacramento Federal Nonattainment Area (SFNA)</u>

- NO_X: 2019–2027

<u>San Joaquin Valley Air Basin (SJVAB)</u>

- ROG: 2020–2025
- NO_X: 2018–2028

<u>San Francisco Bay Area Air Basin (SFBAAB)</u>

- NO_X: 2024–2025

ROG and NO_X are precursors to ozone, for which the SFNA, SJVAB, and SFBAAB are in nonattainment for the NAAQS. Since project emissions exceed the federal *de minimis* thresholds for ROG (SJVAB only) and NO_X, a general conformity determination must be made to demonstrate that total direct and indirect emissions of ROG (SJVAB only) and NO_X would conform to the appropriate SFNA, SJVAB, and SFBAAB state implementation plans (SIPs) for each year of construction in which the *de minimis* thresholds are exceeded.

NO_X is also a precursor to PM and can contribute to PM formation. Sacramento County and the SJVAB are currently designated maintenance for the PM10 NAAQS, whereas the SJVAB, SFBAAB, and portions of the SFBA are designated nonattainment for the PM2.5 NAAQS. NO_X emissions in excess of 100 tons per year in Sacramento County and SJVAB trigger a secondary PM10 precursor threshold, whereas NO_X emissions in excess of 100 tons per year in the SFNA, SJVAB, or SFBAAB trigger a secondary PM2.5 precursor threshold. Since NOx emissions can contribute to PM formation, NO_X emissions in excess of these secondary precursor thresholds could conflict with the applicable PM10 and PM2.5 SIPs.

As shown in Table 22-110 in Appendix A of this RDEIR/SDEIS, NO_X emissions generated by construction activities in SFNA would exceed 100 tons in 2025. However, only 96 of these tons would be generated in Sacramento County. Accordingly, the project does not trigger the secondary PM10 precursor threshold in Sacramento County, but would trigger the secondary PM2.5 precursor threshold in 2025. The PM2.5 precursor threshold would also be exceeded in the SFBAAB in 2024 and 2025. The PM10 and PM2.5 precursor thresholds would be exceeded in the SJVAB in 2021 and 2022. Accordingly, secondary PM2.5 and PM10 (SJVAB only) effects must be considered in the general conformity determination.

A general conformity determination has been prepared for Alternative 4/4A and is included in Appendix 22E, *General Confomrity Determination,* of the Draft EIR/EIS. As shown in Appendix 22E of the Draft EIR/EIS, the federal lead agencies (Reclamation, USFWS, and NMFS) demonstrate that project emissions would not result in a net increase in regional ROG (SJVAB only) or NO_X emissions, as construction-related ROG (SJVAB only) and NO_X would be fully offset to zero through implementation of Mitigation Measures AQ-1a through AQ-4b which require additional onsite mitigation and/or offsets. Mitigation Measures AQ-1a through AQ-4b will ensure the requirements of the mitigation and offset program are implemented and conformity requirements for ROG (SJVAB only) and NO_X are met.

With respect to long-term operational emissions, the number of equipment and personnel required for routine and annual inspections is influenced by the physical water conveyance footprint (i.e., number and location of intakes). Since the water conveyance footprint under Alternative 4A would be identical to Alternative 4, operational activities required for Alternative 4A would be the same as those required for Alternative 4. Accordingly, operational emissions generated by Alternative 4A under the ELT and LLT conditions would be the same as those analyzed for Alternative 4. As, shown in Table 22-110 in Appendix A of this RDEIR/SDEIS, operational emissions under both conditions would not exceed the federal *de minimis* thresholds. No further analysis is required.

Mitigation Measure AQ-1a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SFNA to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable CEQA Thresholds for Other Pollutants

Please see Mitigation Measure AQ-1a under Impact AQ-1 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-1b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SFNA to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable CEQA Thresholds for Other Pollutants

Please see Mitigation Measure AQ-1b under Impact AQ-1 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-3a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within BAAQMD/SFBAAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable BAAQMD CEQA Thresholds for Other Pollutants[5]

Please refer to Mitigation Measure AQ-3a under Impact AQ-3 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-3b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the BAAQMD/SFBAAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable BAAQMD CEQA Thresholds for Other Pollutants

Please refer to Mitigation Measure AQ-3b under Impact AQ-3 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-4a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within SJVAPCD/SJVAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable SJVAPCD CEQA Thresholds for Other Pollutants

Please see Mitigation Measure AQ-4a under Impact AQ-4 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

[5] In the title of this mitigation measure, the phrase "for other pollutants" is intended to apply to other alternatives, where associated impacts on other pollutants may exceed thresholds other than NO_X.

Mitigation Measure AQ-4b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SJVAPCD/SJVAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable SJVAPCD CEQA Thresholds for Other Pollutants

Please see Mitigation Measure AQ-4b under Impact AQ-4 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

CEQA Conclusion: SFNA, SJVAB, and SFBAAB are classified as nonattainment areas with regard to the ozone NAAQS and the impact of increases in criteria pollutant emissions above the air basin *de minimis* thresholds could conflict with or obstruct implementation of the applicable air quality plans. Since construction emissions in the SFNA, SJVAB, and SFBAAB would exceed the *de minimis* thresholds for ROG (SJVAB only) and NO_X, this impact would be significant. Mitigation Measures AQ-1a, AQ-1b, AQ-3a, AQ-3b, AQ-4a, and AQ-4b would ensure project emissions would not result in an increase in regional ROG (SJVAB only) or NO_X emissions. These measures would therefore ensure total direct and indirect ROG (SJVAB only) and NO_X emissions generated by the project would conform to the appropriate air basin SIPs by offsetting the action's emissions in the same or nearby area to net zero. This impact would be less than significant.

Impact AQ-21: Generation of Cumulative Greenhouse Gas Emissions during Construction of the Proposed Water Conveyance Facility

NEPA Effects: Effects from GHG emissions generated by construction of the watery conveyance facilities under Alternative 4A would be identical to those described under Alternative 4. As shown in Table 22-111 in Appendix A of this RDEIR/SDEIS, construction of Alternative 4 would generate 3.0 million metric tons of carbon dioxide equivalent (CO_2e) after implementation of environmental commitments and state mandates. This is equivalent to adding 633,000 typical passenger vehicles to the road during construction (U.S. Environmental Protection Agency 2014). As discussed in Chapter 22, *Air Quality and Greenhouse Gases*, Section 22.3.2 of the Draft EIR/EIS, any increase in emissions above net zero associated with construction of the project water conveyance features would be adverse. Mitigation Measure AQ-21, which would develop a GHG Mitigation Program to reduce construction-related GHG emissions to net zero, is available address this effect.

CEQA Conclusion: Construction of Alternative 4A would generate a total of 3.0 million metric tons of GHG emissions. As discussed in Chapter 22, *Air Quality and Greenhouse Gases*, Section 22.3.2 of the Draft EIR/EIS, any increase in emissions above net zero associated with construction of the project water conveyance features would be significant. Mitigation Measure AQ-21 would develop a GHG Mitigation Program to reduce construction-related GHG emissions to net zero. Accordingly, this impact would be less-than-significant with implementation of Mitigation Measure AQ-21.

Mitigation Measure AQ-21: Develop and Implement a GHG Mitigation Program to Reduce Construction Related GHG Emissions to Net Zero (0)

Please see Mitigation Measure AQ-21 under Impact AQ-21 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-22: Generation of Cumulative Greenhouse Gas Emissions from Operation and Maintenance of the Proposed Water Conveyance Facility and Increased Pumping

NEPA Effects: Alternative 4A water conveyance operations would be similar to the range of possible operations for the spring and fall Delta outflow requirements that would occur under Alternative 4 Operational Scenario H3 and Alternative 4 Operational Scenario H4. Table 4.3.18-1 summarizes long-term operational GHG emissions associated with operations, maintenance, and increased SWP pumping under Alternative 4A at the ELT and LLT timeframes. Emissions are compared to both the No Action Alternative (NEPA point of comparison) and Existing Conditions (CEQA baseline). The equipment emissions presented in Table 4.3.18-1 are representative of project impacts for both the NEPA and CEQA analysis and are identical to emissions that would be generated under Alternative 4.

Table 4.3.18-1. GHG Emissions from Operation, Maintenance, and Increased SWP Pumping, Alternative 4A (Operational Scenarios H3 through H4) (metric tons/year)

Condition	Equipment CO_2	NEPA Point of Comparison (Electricity)		CEQA Baseline (Electricity)		NEPA Point of Comparison (Total)		CEQA Baseline (Total)	
		H3	H4	H3	H4	H3	H4	H3	H4
ELT	815	137,538	12,812	51,457	-46,611	138,353	13,627	52,272	-45,796
LLT	791	19,086	2,795	-2,489	-22,533	19,878	3,586	-1,698	-21,742

Note: The *NEPA point of comparison* compares total CO_2e emissions after implementation of Alternative 4 to the No Action Alternative (ELT), whereas the *CEQA baseline* compares total CO_2e emissions to Existing Conditions.

As shown in Table 4.3.18-1, operations, maintenance, and increased SWP pumping under Alternative 4A would generate 3,586 to 138,353 metric tons CO_2e per year, relative to the No Action Alternative. Emissions relative to existing conditions would range from a net reduction of 45,796 metric tons CO_2e per year to a net increase of 52,272 metric tons CO_2e per year. This increase relative to existing conditions is lower than emissions and potential effects analyzed under the Operational Scenario H1 for Alternative 4 (113,555 metric tons CO_2e).

As discussed in Impact AQ-22 in Chapter 22, *Air Quality and Greenhouse Gases*, of this RDEIR/SDEIS, analysis was undertaken to confirm additional energy demand and associated GHG emissions under Alternative 4 would not impede DWR's ability to achieve their Climate Action Plan (CAP) goals with implementation of BMPs and modification to DWR's Renewable Energy Procurement Program (REEP). The analysis presented in the chapter meets the consistency requirements detailed in the DWR CAP, therefore enabling the project to tier from the environmental document prepared for the CAP pursuant to CEQA Guidelines Section 15183.5. Since emissions under Alternative 4A would be lower than those analyzed for Alternative 4 (Operational Scenario H1) and because DWR demonstrated that implementation of Alternative 4 (Operational Scenario H1) would not adversely affect DWR's ability to achieve the GHG emissions reduction goals set forth in the CAP, Alternative 4A would be consistent with the analysis performed in the CAP and would not conflict with any of DWR's specific action GHG emissions reduction measures. There would be no adverse effect.

CEQA Conclusion: As discussed in Impact AQ-22 in Chapter 22, *Air Quality and Greenhouse Gases*, of this RDEIR/SDEIS, analysis was undertaken to confirm additional energy demand and associated GHG emissions under Alternative 4 would not impede DWR's ability to achieve their CAP goals with implementation of BMPs and modification to DWR's REEP. The analysis presented in the chapter meets the consistency requirements detailed in the DWR CAP, therefore enabling the project to tier from the environmental document prepared for the CAP pursuant to CEQA Guidelines Section 15183.5. As shown in Table 22-115, the assessment considers the amount of additional renewable energy that would need to be added to the REPP annually following construction in order for DWR to meet their long-term GHG reduction goals. Since emissions under Alternative 4A ELT would be lower than those analyzed for Alternative 4 ELT, and because DWR demonstrated that implementation of Alternative 4 (Operational Scenario H1) would not adversely affect DWR's ability to achieve the GHG emissions reduction goals set forth in the CAP, Alternative 4A would be consistent with the analysis performed in the CAP and would not conflict with any of DWR's specific action GHG emissions reduction measures. Prior adoption of the CAP by DWR already provides a commitment on the part of DWR to make all necessary modifications to DWR's REEP or any other GHG emission reduction measure in the CAP necessary to achieve DWR's GHG emissions reduction goals. Therefore no amendment to the approved CAP is necessary to ensure the occurrence of the additional GHG emissions reduction activities needed to account for project-related operational emissions. The effect of Alternative 4A with respect to GHG emissions is less than cumulatively considerable and therefore less than significant. No mitigation is required.

Impact AQ-23: Generation of Cumulative Greenhouse Gas Emissions from Increased CVP Pumping as a Result of Implementation of Water Conveyance Facility

NEPA Effects: Alternative 4A water conveyance operations would be similar to the range of possible operations for the spring and fall Delta outflow requirements that would occur under Alternative 4 Operational Scenario H3 and Alternative 4 Operational Scenario H4. Under Alternative 4A, operation of the CVP yields the generation of clean, GHG emissions-free, hydroelectric energy. This electricity is sold into the California electricity market or directly to energy users. Implementation of Alternative 4A could result in an increase of up to 89 GWh in the demand for CVP generated electricity at the ELT timeframe, which would result in a reduction of up to 89 GWh or electricity available for sale from the CVP to electricity users. This reduction in the supply of GHG emissions-free electricity to the California electricity users could result in a potential indirect effect of the project, as these electricity users would have to acquire substitute electricity supplies that may result in GHG emissions (although additional conservation is also a possible outcome).

It is unknown what type of power source (e.g., renewable, natural gas) would be substituted for CVP electricity or if some of the lost power would be made up with higher efficiency. Given State mandates for renewable energy and incentives for energy efficiency, it is possible that a considerable amount of this power would be replaced by renewable resources or would cease to be needed as a result of higher efficiency. However, to ensure a conservative analysis, indirect emissions were quantified for the entire quantity of electricity (up to 89 GWh) using the current and future statewide energy mix [adjusted to reflect California's Renewables Portfolio Standard (RPS)].

Substitution of up to 89 GWh of electricity with a mix of sources similar to the current statewide mix would result in emissions of up to 24,738 metric tons of CO_2e; however, under expected future conditions (after full implementation of the RPS), emissions would be up to 19,223 metric tons of CO_2e. While this effect is less than expected under Alternative 4, the emissions could contribute to a cumulatively considerable effect and are therefore adverse. The emissions would be caused by dozens of independent electricity users, who had previously bought CVP power, making decisions about different ways to substitute for the lost power. These decisions are beyond the control of Reclamation or any of the other project Lead Agencies. Further, monitoring to determine the actual indirect change in emissions as a result of project actions would not be feasible. In light of the impossibility of predicting where any additional emissions would occur, as well as Reclamation's lack of regulatory authority over the purchasers of power in the open market, no workable mitigation is available or feasible.

CEQA Conclusion: Operation of the CVP is a federal activity beyond the control of any State agency such as DWR, and the power purchases by private entities or public utilities in the private marketplace necessitated by a reduction in available CVP-generated hydroelectric power are beyond the control of the State, just as they are beyond the control of Reclamation. For these reasons, there are no feasible mitigation measures that could reduce this potentially significant indirect impact, which is solely attributable to operations of the CVP and not the SWP, to a less-than-significant level. This impact is therefore determined to be significant and unavoidable.

Impact AQ-24: Generation of Regional Criteria Pollutants from Implementation of Environmental Commitments 3, 4, 6–11

NEPA Effects: Effects of Alternative 4A related to the generation of regional criteria pollutants during implementation of Environmental Commitments 3, 4, and 6–11 would be similar to those described for Alternative 4. Habitat restoration and enhancement activities that require physical changes or heavy-duty equipment would generate construction emissions through earthmoving activities and heavy-duty diesel-powered equipment. Criteria pollutants from restoration and enhancement actions could exceed applicable general conformity *de minimis* levels and applicable local thresholds. The effect would vary according to the equipment used in construction of a specific environmental commitment, the location, the timing of the actions called for in the environmental commitment, and the air quality conditions at the time of implementation.

As described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, the Yolo Bypass Fisheries Enhancement (CM2) would not be completed under Alternative 4A. Similarly, Alternative 4A would only restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, and 6–11, as compared with 152,639 acres under Alternative 4. Therefore, the magnitude of emissions and regional air quality effects under Alternative 4A would likely be smaller than those associated with Alternative 4. Nevertheless, the effect of increases in emissions during implementation of Environmental Commitments 3, 4, and 6–11 in excess of applicable general conformity *de minimis* levels and air district regional thresholds could violate air basin SIPs and worsen existing air quality conditions. Mitigation Measure AQ-24 would be available to reduce this effect, but emissions would still be adverse.

CEQA Conclusion: Construction and operational emissions associated with the restoration and enhancement actions would result in a significant impact if the incremental difference, or increase, relative to Existing Conditions exceeds the applicable local air district thresholds. Mitigation Measure AQ-24 would be available to reduce this effect, but may not be sufficient to reduce emissions below applicable air quality management district thresholds. Consequently, this impact would be significant and unavoidable.

Mitigation Measure AQ-24: Develop an Air Quality Mitigation Plan (AQMP) to Ensure Air District Regulations and Recommended Mitigation are Incorporated into Future Conservation Measures and Associated Project Activities

Please see Mitigation Measure AQ-24 under Impact AQ-24 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-25: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter, Carbon Monoxide, and Diesel Particulate Matter from Implementation of Environmental Commitments 3, 4, 6–11

NEPA Effects: Construction activities and criteria pollutant emissions generated during implementation of Environmental Commitments 3, 4, and 6–11 would be similar to those described for Alternative 4. However, because Alternative 4A would only restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, and 6–11 as compared with 152,639 acres under CM4–CM11 under Alternative 4, the magnitude of emissions under Alternative 4A would likely be smaller than those associated with Alternative 4. Accordingly, health threats from receptor exposure to localized PM, CO, and DPM would likewise be smaller under Alternative 4A. Potential health effects from localized pollutant increases would vary according to the equipment used, the location and timing of the actions called for in the environmental commitment, the meteorological and air quality conditions at the time of implementation, and the location of receptors relative to the emission source. Increases in PM, CO, or DPM (cancer and non-cancer-risk) in excess of applicable air district thresholds at receptor locations would be adverse. Mitigation Measures AQ-24 and AQ-25 would be available to reduce this effect.

CEQA Conclusion: Construction and operational emissions associated with the restoration and enhancement actions under Alternative 4A would result in a significant impact if PM, CO, or DPM (cancer and non-cancer-risk) concentrations at receptor locations exceed the applicable local air district thresholds. Mitigation Measures AQ-24 and AQ-25 would ensure localized concentrations at receptor locations would be below applicable air quality management district thresholds (see Table 22-8 in Appendix A of this RDEIR/SDEIS). Consequently, this impact would be less than significant.

Mitigation Measure AQ-24: Develop an Air Quality Mitigation Plan (AQMP) to Ensure Air District Regulations and Recommended Mitigation are Incorporated into Future Conservation Measures and Associated Project Activities

Please see Mitigation Measure AQ-24 under Impact AQ-24 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-25: Prepare a Project-Level Health Risk Assessment to Reduce Potential Health Risks from Exposure to Localized DPM and PM Concentrations

Please see Mitigation Measure AQ-25 under Impact AQ-25 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-26: Creation of Potential Odors Affecting a Substantial Number of People from Implementation of Environmental Commitments 3, 4, 6–11

NEPA Effects: The potential for Alternative 4A to expose sensitive receptors to increased odors from implementation of Environmental Commitments 3, 4, and 6–11 would be similar to Alternative 4. As described under Alternative 4, diesel emissions from earthmoving equipment could generate temporary odors, but these would quickly dissipate and cease once construction is completed. The magnitude of diesel emissions and odors would likely be smaller than those associated with Alternative 4 due to the reduced restoration acreage under Alternative 4A. Similarly, potential odors generated by restored estuarine wetland, upland habitats, or tidal mudflats would likely be less under Alternative 4A. While restored land uses have the potential to generate odors from natural processes, the odors would be similar in origin and magnitude to the existing land use types in the restored area (e.g., managed wetlands). Accordingly, implementation of Environmental Commitments 3, 4, and 6–11 are not anticipated to result in additional odor complaints or public nuisance, relative to the No Action Alternative. Odor-related effects associated with Environmental Commitments 3, 4, and 6–11 would not be adverse.

CEQA Conclusion: Alternative 4A would not result in the addition of major odor producing facilities. Diesel emissions during construction could generate temporary odors, but these would quickly dissipate and cease once construction is completed. Increases in wetland, tidal, and upland habitats may increase the potential for odors from natural processes. However, the origin and magnitude of odors would be similar to the existing land use types in the restored area (e.g., managed wetlands). Accordingly, implementation of Environmental Commitments 3, 4, and 6–11 are not anticipated to result in additional odor complaints or public nuisance, relative to existing conditions. Odor impact of exposure of sensitive receptors to potential odors would be less than significant. No mitigation is required.

Impact AQ-27: Generation of Cumulative Greenhouse Gas Emissions from Implementation of Environmental Commitments 3, 4, 6–11

NEPA Effects: Effects of Alternative 4A related to the generation of GHG emissions during implementation of Environmental Commitments 3, 4, and 6–11 would be similar to those described for Alternative 4 for the identified commitments. As described under Alternative 4, construction equipment required for earthmoving could generate short-term GHG emissions. The magnitude of emissions would likely be smaller than those associated with Alternative 4 due to the reduced restoration acreage under Alternative 4A.

Implementing Environmental Commitments 3, 4, and 6–11 would affect long-term sequestration rates through land use changes, such as conversion of agricultural land to wetlands, inundation of peat soils, drainage of peat soils, and removal or planting of carbon-sequestering plants. Without additional information on site-specific characteristics associated with each of the restoration components, a complete assessment of GHG flux from Environmental Commitments 3, 4, and 6–11 and a comparison of potential effects relative to Alternative 4 are currently not possible. The effect of carbon sequestration and methane generation would vary by land use type, season, and chemical and biological characteristics. Mitigation Measures AQ-24 and AQ-27 would be available to reduce this effect. However, due to the potential for increases in GHG emissions from construction and land use change, this effect would be adverse.

CEQA Conclusion: The restoration and enhancement actions under Alternative 4A could result in a significant impact if activities are inconsistent with applicable GHG reduction plans, do not contribute to a lower carbon future, or generate excessive emissions, relative to other projects throughout the state. Mitigation Measures AQ-24 and AQ-27 would be available to reduce this impact, but may not be sufficient to reduce to a less-than-significant level. Consequently, this impact is would be significant and unavoidable.

Mitigation Measure AQ-24: Develop an Air Quality Mitigation Plan (AQMP) to Ensure Air District Regulations and Recommended Mitigation are Incorporated into Future Conservation Measures and Associated Project Activities

Please see Mitigation Measure AQ-24 under Impact AQ-24 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-27: Prepare a Land Use Sequestration Analysis to Quantify and Mitigate (as Needed) GHG Flux Associated with Conservation Measures and Associated Project Activities

Please see Mitigation Measure AQ-27 under Impact AQ-27 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

4.3.19 Noise

Impact NOI-1: Exposure of Noise-Sensitive Land Uses to Noise from Construction of Water Conveyance Facilities

NEPA Effects: The potential for Alternative 4A to expose noise-sensitive land uses to noise from construction of the water conveyance facilities would be identical to impacts described under Alternative 4. Noise would be generated by heavy-duty equipment operating at the various construction sites, as well as by haul trucks and worker vehicles traveling on local roadways. Construction noise would also affect onsite workers. However, occupational exposure to noise levels in excess of 85 A-weighted decibels (dBA) requires monitoring and mitigation to protect workers. Given that onsite workers would be protected under OSHA requirements, no adverse impacts would occur to workers. Accordingly, this analysis focuses exclusively on potential noise effects to noise-sensitive land uses adjacent to construction activities.

Potential reasonable worst-case noise levels generated at construction work areas were evaluated against the 60 dBA L_{eq} (1hr) daytime (7 a.m. to 10 p.m.) and 50 dBA L_{max} nighttime (10 p.m. to 7 a.m.) construction thresholds. Construction noise along roadways was evaluated against the 12 decibel (dB) traffic noise threshold. As described under Alternative 4, the effect of exposing noise-sensitive land uses to noise increases above established thresholds at intake work areas, conveyance and associated facility work areas, utility construction work areas, borrow/spoil work areas, and truck trips and worker commutes would be adverse. Mitigation Measures NOI-1a and NOI-1b would be available to reduce this effect, but not to a level that would avoid adverse conditions.

CEQA Conclusion: Construction activities would expose noise-sensitive land uses adjacent to intake, conveyance, forebay, barge facility, utility, and borrow/spoil work areas to noise levels above the 60 dBA L_{eq} (1hr) daytime and 50 dBA L_{max} nighttime threshold. Receptors near haul roads would also be exposed to noise levels in excess of the 12 dB traffic noise threshold. This would be a significant impact. Mitigation Measures NOI-1a and NOI-1b, which require noise-reducing construction practices and development of a complaint/response tracking program, would reduce noise impacts on sensitive land uses. However, it is not anticipated that feasible measures will be available in all situations to reduce construction noise to levels below the applicable thresholds. This impact would therefore be considered significant and unavoidable.

Mitigation Measures NOI-1a and NOI-1b would reduce noise impacts on sensitive land uses. Although implementation of these measures will reduce the impact, it is not anticipated that feasible measures will be available in all situations to reduce construction noise to levels below the applicable thresholds. This impact would therefore be significant and unavoidable.

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Please see Mitigation Measure NOI-1a under Impact NOI-1a in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Please see Mitigation Measure NOI-1b under Impact NOI-1a in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Impact NOI-2: Exposure of Sensitive Receptors to Vibration or Groundborne Noise from Construction of Water Conveyance Facilities

NEPA Effects: The potential for Alternative 4A to expose noise-sensitive land uses to vibration and groundborne noise from construction of the water conveyance facilities would be identical to impacts described under Alternative 4. Construction at the intake sites would involve use of impact pile driving, and tunnel construction would involve the use of tunnel boring machines (TBMs) and tunnel locomotives, both of which would cause groundborne vibration in localized areas. Groundborne vibrations from pile driving would be intermittent, and temporary, occurring over a two month period during the in-river work period (June 1 to October 31). Similarly, groundborne noise due to vibrations from tunnel locomotive passbys and TBMs would occur intermittently where tunnels are located under or near residential areas.

Vibration effects from pile driving were evaluated against a threshold of 0.2 inches per second peak particle velocity (in/sec PPV) at residential buildings within 70 feet of pile driving sites. As described under Alternative 4, groundborne vibration from impact pile driving is predicted to exceed vibration thresholds at 78 residential receptors in Sacramento County and 4 residential receptors in San Joaquin County. The effect of exposing sensitive receptors to groundborne vibration would be adverse. Mitigation Measure NOI-2 is available to reduce this effect, but not to a level that would avoid adverse conditions.

Vibration effects from tunneling locomotives and TBMs were evaluated against a threshold of 0.04 in/sec PPV. As described under Alternative 4, groundborne vibrations from the TBMs would not exceed 0.008 in/sec PPV and would therefore not result in adverse vibration effects to nearby sensitive receptors. Similarly, tunnel locomotives would be operated at slow speeds inside of tunnels and would not result in excessive vibrations. Groundborne noise from tunnel locomotive operation during construction is therefore not predicted to exceed groundborne noise thresholds or result in an adverse noise impact on sensitive receptors along the tunnel conveyance.

As outlined in Mitigation Measure NOI-2, the potential for tunneling induced ground vibration effects will be thoroughly analyzed in the preliminary and final design phases of the project, using site-specific geotechnical data and the expected TBM configuration. Potential effects on surface structures and human perception will be evaluated in detail during preliminary design. As additional precautions, and where necessary, a ground vibration monitoring program using seismographs and other high-precision equipment will be implemented during construction to ensure ground vibration is within the required contract limits.

CEQA Conclusion: Groundborne vibrations during tunneling would not exceed 0.008 in/sec PPV and would therefore be less than significant. Likewise, locomotives are not expected to generate significant noise levels because they will travel at low speeds between 5 and 10 miles per hour. However, the impact of exposing residential structures to groundborne vibration during intake construction would be significant as reasonable worst-case modeling indicates that up to 82 residential parcels could be exposed to vibration levels in excess of 0.2 in/sec PPV during intake pile driving. Although Mitigation Measure NOI-2 will reduce the impact, it is not anticipated that feasible measures will be available in all situations to reduce vibration to levels below the applicable thresholds. This impact would therefore be considered significant and unavoidable.

Mitigation Measure NOI-2: Employ Vibration-Reducing Construction Practices during Construction of Water Conveyance Facilities

Please see Mitigation Measure NOI-2 under Impact NOI-1a in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Impact NOI-3: Exposure of Noise-Sensitive Land Uses to Noise from Operation of Water Conveyance Facilities

NEPA Effects: The number and horsepower of pumping equipment at the intakes and combined pumping plan directly influence the potential for operational noise impacts. Since the number and horsepower of pumping equipment under Alternative 4A would be identical to Alternative 4, operational noise levels under Alternative 4A would be the same as those analyzed for Alternative 4. Since the analysis of Alternative 4 assumed 24 hours per day of pumping regardless of the pumping scenario (e.g., H1) or year (e.g., 2060), impacts would be the same under the ELT and LLT conditions.

Operation of pumping equipment at the intakes and combined pumping plant could result in increases in noise levels affecting nearby communities and residences. Noise would also affect onsite workers, although OSHA monitoring requirements would avoid adverse effects on personnel. Accordingly, this analysis focuses exclusively on potential noise effects on noise-sensitive land uses adjacent to the conveyance facilities.

Potential reasonable worst-case pump noise levels generated during operation of the intake and pump structures were evaluated against the 50 dBA L_{max} daytime (7 a.m. to 10 p.m.) and 45 dBA L_{max} nighttime (10 p.m. to 7 a.m.) operational thresholds. As described under Alternative 4, operational activities would exceed the daytime and nighttime thresholds at noise-sensitive land uses within 2,000 feet and 2,600 feet, respectively, from intake locations. Various residential, recreational, and agricultural receptors would therefore be exposed to adverse noise levels during operation. Mitigation Measure NOI-3 is available to address this effect.

CEQA Conclusion: The impact of exposing noise-sensitive land uses during operations to noise levels above the daytime (50 dBA L_{max}) or nighttime (45 dBA L_{max}) noise thresholds would be considered significant. Based on reasonable worst-case modeling, 70 agricultural parcels would be affected by daytime noise levels in excess of the operational threshold. The nighttime threshold would be exceeded at 110 agricultural parcels. Mitigation Measure NOI-3 would reduce operational noise levels below applicable thresholds, thus resulting in a less-than-significant level.

Mitigation Measure NOI-3: Design and Construct Intake Facilities and Other Pump Facilities Such That Operational Noise Does Not Exceed 50 dBA (One-Hour L_{eq}) during Daytime Hours (7:00 A.M. to 10:00 P.M.) or 45 dBA (One-Hour L_{eq}) during Nighttime Hours (10:00 P.M. to 7:00 A.M.) or the Applicable Local Noise Standard (Whichever Is Less) at Nearby Noise Sensitive Land Uses

Please see Mitigation Measure NOI-3 under Impact NOI-1a in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Impact NOI-4: Exposure of Noise-Sensitive Land Uses to Noise from Implementation of Proposed Environmental Commitments 3, 4, 6-10

NEPA Effects: The potential for Alternative 4A to expose noise-sensitive land uses to noise from implementation of Environmental Commitments 3, 4, and 6–10 would be similar to those described for Alternative 4. Restoration and enhancement activities that require heavy-duty equipment and construction vehicles would generate increases in ambient noise levels. The effect would vary according to the type of construction equipment and techniques used in construction of the specific environmental commitment, the location and timing of the actions called for in the environmental commitment, and the noise environment at the time of implementation.

As described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, the Yolo Bypass Fisheries Enhancement (CM2) would not be completed under Alternative 4A. Similarly, Alternative 4A would only restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, and 6-10 as compared with 152,639 acres under Alternative 4. Therefore, the magnitude of noise-generating activities under Alternative 4A would likely be smaller than those associated with Alternative 4. Nevertheless, receptors within 1,200 feet of an active restoration work area could be exposed to construction noise in excess of the daytime (7 a.m. to 10 p.m.) noise threshold of 60 dBA L_{eq} (1hr). The nighttime threshold of 50 dBA L_{max} would be exceeded within a distance of 2,800 feet. The effect of exposing sensitive land uses to increases in construction noise levels above thresholds would be adverse. Mitigation Measures NOI-1a and NOI-1b would be available to address this effect, but not to a level that would avoid adverse conditions.

CEQA Conclusion: Noise levels during implementation of Environmental Commitments 3, 4, and 6-10 are expected to vary according to the type of construction equipment and techniques used, but may exceed the daytime noise threshold within 1,200 feet of an active restoration work area and the nighttime threshold within 2,800 feet. The impact of exposing receptors to noise increases above established thresholds would be significant. Mitigation Measures NOI-1a and NOI-1b, which require noise-reducing construction practices and development of a complaint/response tracking program, would reduce noise impacts on sensitive land uses. However, it is not anticipated that feasible measures will be available in all situations to reduce construction noise to levels below the applicable thresholds. This impact would therefore be considered significant and unavoidable.

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Please see Mitigation Measure NOI-1a under Impact NOI-1a in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Please see Mitigation Measure NOI-1b under Impact NOI-1a in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

4.3.20 Hazards and Hazardous Materials

Impact HAZ-1: Create a Substantial Hazard to the Public or the Environment through the Release of Hazardous Materials or by Other Means during Construction of the Water Conveyance Facilities

NEPA Effects: The potential under Alternative 4A to create substantial hazards through release of hazardous materials during construction of conveyance facilities would be identical to those impacts described under Alternative 4 and would constitute an adverse effect on the physical environment. Potential effects include routine use of hazardous materials, possible natural gas accumulation in tunnels, contact with existing contaminants, constituents in RTM, effects of electrical transmission lines, conflicts with utilities containing hazardous materials, and routine transport of hazardous materials Mitigation Measures HAZ-1a, HAZ-1b, UT-6a, UT-6c, and Trans-1a would be available to reduce these effects.

CEQA Conclusion: During construction of the water conveyance facilities, the potential for direct impacts on construction personnel, the public and/or the environment associated with a variety of hazardous physical or chemical conditions under Alternative 4A would be identical to those described for Alternative 4. Such conditions may arise as a result of the intensity and duration of construction activities at the north Delta intakes, forebays, and conveyance pipelines and tunnels, and the hazardous materials that would be needed in these areas during construction. Potential hazards include the routine use of hazardous materials (as defined by Title 22 CCR Division 4.5); natural gas accumulation in water conveyance tunnels; the inadvertent release of existing contaminants in soil, sediment, and groundwater, or release of hazardous materials from existing infrastructure; disturbance of electrical transmission lines; and hazardous constituents present in RTM. Many of these physical and chemical hazardous conditions would occur in close proximity to the towns of Hood and Courtland during construction of the north Delta intakes. Additionally, the potential would exist for the construction of the water conveyance facilities to indirectly result in the release of hazardous materials through the disruption of existing road, rail, or river hazardous materials transport routes because construction would occur in the vicinity of three hazardous material transport routes, three railroad corridors, and waterways with barge traffic. These impacts are considered significant because the potential exists for substantial hazard to the public or environment to occur related to conveyance facility construction. However, implementation of Mitigation Measures HAZ-1a and HAZ-1b, UT-6a, and UT-6c (described in Chapter 20, *Public Services and Utilities*, of the Draft EIR/EIS), and TRANS-1a (described in Chapter 19, *Transportation*, of the Draft EIR/EIS), along with environmental commitments to prepare and implement SWPPPs, HMMPs, SPCCPs, SAPs, and a Barge Operations Plan (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) would reduce these impacts to a less-than-significant level by identifying and describing potential sources of hazardous materials so that releases can be avoided and materials can be properly handled; detailing practices to monitor pollutants and control erosion so that appropriate measures are taken; implementing onsite features to minimize the potential for hazardous materials to be released to the environment; minimizing risk associated with the relocation of utility infrastructure; and coordinating the transport of hazardous materials to reduce the risk of spills.

Mitigation Measure HAZ-1a: Perform Preconstruction Surveys, Including Soil and Groundwater Testing, at Known or Suspected Contaminated Areas within the Construction Footprint, and Remediate and/or Contain Contamination

Please see Mitigation Measure HAZ-1a under Impact HAZ-1 in the discussion of Alternative 4 in Chapter 24, *Hazards and Hazardous Materials*, of the Draft EIR/EIS.

Mitigation Measure HAZ-1b: Perform Pre-Demolition Surveys for Structures to Be Demolished within the Construction Footprint, Characterize Hazardous Materials and Dispose of Them in Accordance with Applicable Regulations

Please see Mitigation Measure HAZ-1b under Impact HAZ-1 in the discussion of Alternative 4 in Chapter 24, *Hazards and Hazardous Materials*, of the Draft EIR/EIS.

Mitigation Measure UT-6a: Verify Locations of Utility Infrastructure

Please see Mitigation Measure UT-6a under Impact UT-6 in the discussion of Alternative 1A in Chapter 20, *Public Services and Utilities*, of the Draft EIR/EIS.

Mitigation Measure UT-6c: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Worker and Public Health and Safety

Please see Mitigation Measure UT-6c under Impact UT-6 in the discussion of Alternative 1A in Chapter 20, *Public Services and Utilities*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please see Mitigation Measure TRANS-1a under Impact TRANS-1 in the discussion of Alternative 1A in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact HAZ-2: Expose Sensitive Receptors Located within 0.25 Mile of a Construction Site to Hazardous Materials, Substances, or Waste during Construction of the Water Conveyance Facilities

NEPA Effects: The potential under Alternative 4A to expose sensitive receptors, such as parks, schools, and hospitals within 0.25 mile to hazardous materials, hazardous substances or waste during construction would be identical to those impacts described under Alternative 4 and would not have an adverse effect on sensitive receptors because no parks or hospitals are located within 0.25 mile of the construction zone and environmental commitments such as SWPPPs, SPCCPs and HMMPs would be implemented to minimize potential effects on Excelsior Middle School (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

CEQA Conclusion: The potential for exposure of sensitive receptors to hazardous substances or conditions under Alternative 4A would be identical to the impacts described for Alternative 4. There are no parks or hospitals located within 0.25 mile of the water conveyance facilities alignment. However, Excelsior Middle School is located within 0.25 mile of a proposed permanent 230-kV transmission line. Additionally, under this alternative, an operable barrier would be constructed at the head of Old River near the Mossdale Village area of Lathrop, adjacent to land designated for public use and which could include future schools or parks. If a school or park were built prior to the completion of construction of the operable barrier, sensitive receptors would be in close proximity to Alternative 4A construction activities, creating the potential for an impact on those types of sensitive receptors. However, no school or park is currently proposed within 0.25 mile of the proposed operable barrier site.

Construction of the 230-kV transmission line would require the routine use of hazardous materials (e.g., fuels, solvents, oil and grease) because heavy machinery such as cranes, off-road work trucks, and dozers would be required. Consequently, there would be the risk of accidental spills and equipment leaks of these types of hazardous materials during construction of the transmission line. However, the quantities of hazardous materials likely to be used during construction activities are likely to be small. Were hazardous materials to be released inadvertently, spills or equipment leaks would be localized and minimal, and thus there would be no risk to anyone not in immediate proximity to these releases. Further, BMPs to minimize the potential for the accidental release of hazardous materials and to contain and remediate hazardous spills, as part of the SWPPPs, SPCCPs, and HMMPs, would be implemented (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Therefore, staff and students at Excelsior Middle School would not be at risk or adversely affected by exposure to hazardous materials, substances, or waste during construction of the water conveyance facilities. This impact would be less than significant because no sensitive receptors within 0.25 mile of a construction zone would be exposed to hazardous materials, substances, or waste. No mitigation is required.

Impact HAZ-3: Potential to Conflict with a Known Hazardous Materials Site and, as a Result, Create a Significant Hazard to the Public or the Environment

NEPA Effects: The potential for conflicts with, or exposure to known hazardous material sites during conveyance facility construction under Alternative 4A would be identical to those identified for Alternative 4 and would not have an adverse effect on the public or the environment because no sites are located within the construction footprint of the water conveyance facilities.

CEQA Conclusion: The potential for conflicts with or exposure to known hazardous material sites during conveyance facility construction under Alternative 4A would be identical to those identified for Alternative 4. Because there are no known sites of concern (SOCs) within the construction footprint of the water conveyance facility for Alternative 4 there would be no conflict with known hazardous materials sites during construction of the water conveyance facilities, and therefore, no related hazard to the public or the environment. Accordingly, there would be no impact. No mitigation is required. The potential for encountering unknown hazardous materials sites during the course of construction is discussed under Impact HAZ-1.

Impact HAZ-4: Result in a Safety Hazard Associated with an Airport or Private Airstrip within 2 Miles of the Water Conveyance Facilities Footprint for People Residing or Working in the Study Area during Construction of the Water Conveyance Facilities

NEPA Effects: The potential for construction of conveyance facilities under Alternative 4A to result in a safety hazard associated with activities within 2 miles of an airport or private airstrip is identical to effects described for Alternative 4. This potential effect is not adverse because, as part of an environmental commitment pursuant to the State Aeronautics Act (described in the Section 24.2.2.17 of Chapter 24, *Hazards and Hazardous Materials* in Appendix A of this RDEIR/SDEIS), DWR would coordinate with Caltrans' Division of Aeronautics to eliminate any potential conflicts prior to initiating construction and comply with its recommendations based on its investigations and compliance with the recommendations of the OE/AAA (for Byron and Franklin Field Airports).

CEQA Conclusion: The potential for construction of conveyance facilities under Alternative 4A to result in a safety hazard associated with activities within 2 miles of an airport or private airstrip is identical to impacts described for Alternative 4. The use of helicopters for stringing the proposed 230-kV transmission lines and relocating the existing 230-kV and 500-kV transmission lines, and of high-profile construction equipment (200 feet or taller), such as cranes, for installation of pipelines, and potentially pile drivers, such as would be used during the construction of the intakes, have the potential to result in safety hazards to aircraft during takeoff and landing if the equipment is operated too close to runways. Three private airports (Borges-Clarksburg Airport, Spezia Airport, and Flying B Ranch Airport) and two public airports (Byron Airport and Franklin Field Airport) are located within 2 miles of the construction footprint of several features of the water conveyance facilities for Alternative 4, including temporary and permanent transmission lines. Relocation of the existing 230-kV and 500-kV transmission lines is not expected to result in an air safety hazard because the nearest airport to the new location is greater than 3 miles away.

As described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, as part of an environmental commitment pursuant to the State Aeronautics Act (described in Section 24.2.2.17 in Chapter 24, *Hazards and Hazardous Materials* in Appendix A of this RDEIR/SDEIS), DWR would coordinate with Caltrans' Division of Aeronautics prior to initiating construction and comply with its recommendations based on its investigations and compliance with the recommendations of the OE/AAA (for Byron and Franklin Field Airports). These recommendations, which could include limitations necessary to minimize potential problems such as the use of temporary construction equipment, supplemental notice requirements, and marking and lighting high-profile structures, would reduce potential impacts on air safety. This impact would be less than significant because recommendations to avoid conflicts with existing airports located near construction areas would be implemented by DWR prior to construction as required by Caltrans. No mitigation is required.

Impact HAZ-5: Expose People or Structures to a Substantial Risk of Property Loss, Personal Injury or Death Involving Wildland Fires, Including Where Wildlands Are adjacent to Urbanized Areas or Where Residences Are Intermixed with Wildlands, as a Result of Construction, and Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The potential for construction of conveyance facilities under Alternative 4A to result in exposure of people or structures to risks associated with wildfire would be identical to the impacts described for Alternative 4. This potential effect is not adverse because no portion of Alternative 4A is located in or near an area designated as a High or Very High Fire Hazard Severity Zone and measures to prevent and control wildland fires would be implemented by DWR during construction, operation, and maintenance of the water conveyance facilities in full compliance with Cal-OSHA standards for fire safety and prevention.

CEQA Conclusion: The potential for construction of conveyance facilities under Alternative 4A to result in exposure of people or structures to risks associated with wildfire would be identical to the impacts described for Alternative 4. People or structures would not be subject to a significant risk of loss, injury, or death involving wildland fires during construction or operation and maintenance of the water conveyance facilities because the alternative would comply with Cal-OSHA fire prevention and safety standards; DWR would implement standard fire safety and prevention measures as part of an FPCP (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS); and because the water conveyance facilities would not be located in a High or Very High Fire Hazard Severity Zone. This impact would be less than significant because conditions do not exist near construction areas that would result in exposure of people or structures to significant risk of exposure to wildfire and DWR would implement standard fire safety and prevention measures. No mitigation is required.

Impact HAZ-6: Create a Substantial Hazard to the Public or the Environment through the Release of Hazardous Materials or by Other Means during Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The potential for operation and maintenance of the water conveyance facilities (excluding water supply operations) under Alternative 4A to result in a substantial hazard to the public or environment would be the same as described for Alternative 4. During routine operation and maintenance of the water conveyance facilities the potential would exist for the accidental release of hazardous materials and other potentially hazardous releases (e.g., contaminated solids and sediment), and for interference with air safety should high-profile equipment be required for maintenance of the proposed transmission lines near an airport. Accidental hazardous materials releases, such as chemicals directly associated with routine maintenance (e.g., fuels, solvents, paints, oils), are likely to be small, localized, temporary and periodic; therefore, they are unlikely to result in adverse effects on workers, the public, or the environment. Further, BMPs and measures implemented as part of SWPPPs, SPCCPs, SAPs and HMMPs would be developed and implemented as part of the project, as described under Impact HAZ-1, and in detail in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, which would reduce the potential for accidental spills to occur and would result in containment and remediation of spills should they occur. Approximately 10,800 cubic yards of dry sediment/solids would be produced annually as a result of maintenance of sedimentation basins and solids lagoons with three intakes operating. Potentially contaminated solids could pose a hazard to the environment if improper disposal occurred. This effect would be considered adverse because of the large volume of sediment/solids that would be handled and the potential for improper disposal. However, Mitigation Measure HAZ-6 would be available to reduce these effects. Under Mitigation Measure HAZ-6 solids from the solids lagoons would be sampled and characterized to evaluate disposal options, and disposed of accordingly at an appropriate, licensed facility.

CEQA Conclusion: The potential for operation and maintenance of conveyance facilities under Alternative 4A to result in a substantial hazard to the public or environment would be identical to the effects described for Alternative 4. The accidental release of hazardous materials (including contaminated solids and sediment) to the environment during operation and maintenance of the water conveyance facilities and the potential interference with air safety through the use of high-profile equipment for maintenance of proposed transmission lines could result in significant impacts on the public and environment because of the large scale of construction and the potential for accidental release of hazardous materials during construction. However, implementation of the BMPs and other activities required by SWPPPs, HMMPs, SAPs, SPCCPs, as well as adherence to all applicable FAA regulations (14 CFR Part 77) and, as part of an environmental commitment pursuant to the State Aeronautics Act (described in the *Regulatory Setting* section of Chapter 24, *Hazards and Hazardous Materials* in Appendix A of this RDEIR/SDEIS), coordination/compliance with Caltrans' Division of Aeronautics when performing work with high-profile equipment within 2 miles of an airport would ensure that impacts are reduced to a less-than-significant level. Contaminated solids could pose a hazard to the environment if improperly disposed of, and would be considered a significant impact because of the large volume of sediment/solids that would be handled and the potential for improper disposal. However, implementation of Mitigation Measure HAZ-6 would reduce this impact to a less-than-significant level by requiring sampling and characterizing solids from the solids lagoons to evaluate options to dispose of material at an appropriate, licensed facility.

Mitigation Measure HAZ-6: Test Dewatered Solids from Solids Lagoons Prior to Reuse and/or Disposal

Please see Mitigation Measure HAZ-6 under Impact HAZ-6 in the discussion of Alternative 4 in Chapter 24, *Hazards and Hazardous Materials*, of the Draft EIR/EIS.

Impact HAZ-7: Create a Substantial Hazard to the Public or the Environment through the Release of Hazardous Materials or by Other Means as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15 and 16

Effects of Alternative 4A related to the potential for release of hazardous materials from implementing these environmental commitments would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, under Alternative 4A the project would restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, 6–11 as compared with 83,800 acres under Alternative 4. Similarly, Environmental Commitment 16 would be implemented only at limited locations. Conservation Measures 2, 5, 13, 14, and 17–21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 4A would likely be smaller than those associated with Alternative 4.

NEPA Effects: Implementation of portions of Environmental Commitments 3, 4, 6–10, and 11, 12, 15 and 16 at limited locations could result in multiple potentially hazardous effects related to the release of or exposure to hazardous materials or other hazards including increased production, mobilization, and bioavailability of methylmercury; release of existing contaminants (e.g., pesticides in agricultural land); air safety hazards; and wildfires. These effects are considered adverse because of the potential for substantial hazards to occur while constructing restoration actions. However, implementation of Mitigation Measures HAZ-1a, HAZ-1b, UT-6a, UT-6c, and TRANS-1a and the environmental commitments including implementation of SWPPPS, HMMPs, SPCCPs, SAPs, and fire prevention and fire control BMPs as part of an FPCP (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) are available to reduce/minimize these potential effects.

CEQA Conclusion: The potential for impacts related to the release and exposure of workers and the public to hazardous substances or conditions during construction, operation, and maintenance of Environmental Commitments 3, 4, and 6–11 and Environmental Commitment 16, is considered significant because implementation of these environmental commitments would involve extensive use of heavy equipment during construction and transporting hazardous chemicals during operations and maintenance (e.g., herbicides for nonnative vegetation control). These chemicals could be inadvertently released, exposing construction workers or the public to hazards. Construction of restoration projects on or near existing agricultural and industrial land and/or SOCs may also result in a conflict with or exposure to known hazardous materials, and the use of high-profile equipment (i.e., 200 feet or higher) in close proximity to airport runways could result in safety hazards to air traffic. However in addition to implementation of SWPPPs, HMMPs, SPCCPs, SAPs, and fire prevention and fire control BMPs as part of an FPCP (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), Mitigation Measures HAZ-1a, HAZ-1b, UT-6a, UT-6c, and TRANS-1a would be implemented to ensure no substantial hazards to the public or the environment would occur from implementation of these environmental commitments and that impacts would be reduced to a less-than-significant level.

Mitigation Measure HAZ-1a: Perform Preconstruction Surveys, Including Soil and Groundwater Testing, at Known or Suspected Contaminated Areas within the Construction Footprint, and Remediate and/or Contain Contamination

Please refer to Mitigation Measure HAZ-1a under Impact HAZ-1 in the discussion of Alternative 4 in Chapter 24, *Hazards and Hazardous Materials*, of the Draft EIR/EIS. Implementation of this mitigation measure will result in the avoidance, successful remediation or containment of all known or suspected contaminated areas, as applicable, within the construction footprint, which would prevent the release of hazardous materials from these areas into the environment.

Mitigation Measure HAZ-1b: Perform Pre-Demolition Surveys for Structures to Be Demolished within the Construction Footprint, Characterize Hazardous Materials and Dispose of Them in Accordance with Applicable Regulations

Please refer to Mitigation Measure HAZ-1b under Impact HAZ-1 in the discussion of Alternative 4 in Chapter 24, *Hazards and Hazardous Materials*, of the Draft EIR/EIS. Implementation of this measure will ensure that hazardous materials present in or associated with structures being demolished will not be released into the environment.

Mitigation Measure UT-6a: Verify Locations of Utility Infrastructure

Please see Mitigation Measure UT-6a under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, of the Draft EIR/EIS.

Mitigation Measure UT-6c: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Worker and Public Health and Safety

Please see Mitigation Measure UT-6c under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please see Mitigation Measure TRANS-1a under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact HAZ-8: Increased Risk of Bird–Aircraft Strikes during Implementation of Environmental Commitments that Create or Improve Wildlife Habitat

Effects of Alternative 4A related to the potential for increased risk of aircraft bird strikes from implementing restoration actions that improve wildlife habitat would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 4A would restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, and 6–11 as compared with 83,800 acres with Conservation Measures 3–11 under Alternative 4. Therefore, the magnitude of effects under Alternative 4A would likely be smaller than those associated with Alternative 4.

NEPA Effects: Implementation of Environmental Commitments 3, 4, and 6–11 under Alternative 4A could result in an increase of aircraft bird strikes in the vicinity of restoration areas that attract waterfowl and other birds in proximity to local airports. This effect is considered adverse because of the potential to affect aircraft safety in the vicinity of restoration projects. Mitigation Measure HAZ-8 is available to reduce this effect.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, and 6–11, because they would create or improve wildlife habitat, could potentially attract waterfowl and other birds to areas in proximity to existing airport flight zones, and thereby potentially result in an increase in bird-aircraft strikes. The potential for this impact is considered significant because of the increased wildlife restoration projects that could occur in the vicinity of Travis Air Force Base; Rio Vista Municipal Airport; Funny Farm Airport; Sacramento International Airport; and Byron Airport. Mitigation Measure HAZ-8 could reduce the severity of this impact by minimizing bird strike hazards, but this impact would not be reduced to a less-than-significant level because of the inherent uncertainty related to bird strike risks for these future projects. Therefore this impact is significant and unavoidable.

Mitigation Measure HAZ-8: Consult with Individual Airports and USFWS, and Relevant Regulatory Agencies

Please see Mitigation Measure HAZ-8 under Impact HAZ-8 in the discussion of Alternative 4 in Chapter 24, *Hazards and Hazardous Materials*, of the Draft EIR/EIS.

4.3.21 Public Health

Impact PH-1: Increase in Vector-Borne Diseases as a Result of Construction and Operation of the Water Conveyance Facilities

NEPA Effects: The potential for Alternative 4A construction and operation to increase vector-borne diseases would be the same as described for Alternative 4 because all aspects of the water conveyance facility design, construction, and operation (excluding water supply operations) and maintenance of Alt 4A would be identical to Alt 4. Although the proposed conveyance facilities will increase surface water within the study area at the intakes, intermediate forebay, and Clifton Court Forebay, it is unlikely that these water bodies would provide suitable breeding habitat for mosquitoes given that the water in these forebays would not be stagnant and would generally be too deep to support substantial mosquito habitat. Shallow edges of the forebays could provide some suitable mosquito breeding habitat if emergent vegetation or other aquatic plants (e.g., pond weed) were allowed to grow. However, as part of the regular maintenance of these forebay areas, floating vegetation such as pond weed would be harvested to maintain flow and forebay capacity. To further minimize the potential for impacts related to increasing suitable vector habitat within the study area, DWR would consult and coordinate with San Joaquin County and Sacramento-Yolo County MVCDs and prepare and implement MMPs, as necessary, to control mosquitoes and reduce the likelihood that construction and operation of the water conveyance facilities would require an increase in mosquito abatement activities by the local MVCDs (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). BMP activities would be consistent with the CDPH's *Best Management Practices for Mosquito Control* plan (described in Section 25.2.3.4 in the Draft EIR/EIS). Accordingly, Alternative 4A would not substantially increase suitable vector habitat, and would not substantially increase vector-borne diseases. No adverse effects on public health would result because conditions for mosquito breeding at conveyance facilities would be minimized and standard practices to control mosquitos would be implemented.

CEQA Conclusion: The potential for construction and operation of conveyance facilities under Alternative 4A to result in an increase in exposure of people to vector-borne diseases would be identical to the impacts described for Alternative 4. Alternative 4A conveyance facilities that could create new water bodies at the intakes, intermediate forebay, and Clifton Court Forebay have the potential to provide habitat for vectors that transmit diseases (e.g., mosquitoes) because of the large volumes of water that would be held within these areas. However, during operations, the depth, design, and operation of conveyance facilities would prevent the development of suitable mosquito habitat. Specifically, the water bodies would be too deep and the constant movement of water would prevent mosquitoes from breeding and multiplying. To minimize the potential for impacts related to increasing suitable vector habitat within the study area, DWR would consult and coordinate with San Joaquin County and Sacramento-Yolo County MVCDs and prepare and implement MMPs. BMPs to be implemented as part of the MMPs would help control mosquitoes during construction and operation of the sedimentation basins, solids lagoons, the expanded Clifton Court Forebay, the intermediate forebay, and the intermediate forebay inundation area. Therefore, construction and operation of Alternative 4 would not result in a substantial increase in vector-borne diseases. This impact is considered to be less than significant because conditions for mosquito breeding at conveyance facilities would be minimized and standard practices to control mosquitos would be implemented. No mitigation is required.

Impact PH-2: Exceedances of Water Quality Criteria for Constituents of Concern Such That There Is an Adverse Effect on Public Health as a Result of Operation of the Water Conveyance Facilities

As described in detail in Section 4.3.4, *Water Quality*, of this RDEIR/SDEIS, the analysis of bromide and DOC (among other constituents) for Alternative 4A is based on modeling done for Alternative 4 in the ELT timeframe, which assumes implementation of Yolo Bypass Improvements and 25,000 acres of tidal natural communities restoration. As described in Section 4.1.2, *Description of Alternative 4A*, of the RDEIR/SDEIS, Yolo Bypass Improvements are not a component of Alternative 4A and Environmental Commitment 4 would restore approximately 59 acres of tidal wetlands, as opposed to the 65,000 acres contemplated under CM4. As explained in Section 4.3.4, *Water Quality*, in general, the significance of this difference is that the assessment of bromide for Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT), likely overestimates increases in bromide that could occur, particularly in the west Delta. Regardless, there is uncertainty in the results of all quantitative assessments that refer to modeling results, due to the differing assumptions used in the modeling and the description of Alternative 4A and the No Action Alternative (ELT).

NEPA Effects:

Disinfection Byproducts

The effects on DOC concentrations in the Delta under Alternative 4A would be similar to Alternative 4. Alternative 4A includes water conveyance operational criteria similar to Alternative 4 (Operational Scenario H), but would be limited to operations within the range of Scenarios H3 and H4, as fully described in Chapter 3, *Description of Alternatives*, of the Draft EIR/EIS and in Section 4.1.2, *Description of Alternative 4A*, of this RDEIR/SDEIS. To the extent that habitat restoration actions would alter hydrodynamics within the Delta region these effects are included in this assessment. However, there would be less potential for increased DOC concentrations at western Delta locations associated with habitat restoration and enhancement under this alternative because very little would occur relative to Alternative 4.

The geographic extent of effects related to long-term average DOC concentrations within Delta waters would be similar to that described for Alternative 4 but the magnitude of predicted change and relative frequency of concentration exceedences would be lower. Relative to the No Action Alternative (ELT), Alternative 4A would result in small increases (0.3 mg/L) in long-term average DOC concentrations for the modeled 16-year period and drought period at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, and Contra Costa Pumping Plant #1. The increases in average DOC concentrations would correspond to more frequent concentration threshold exceedances, with the greatest change occurring at Contra Costa Pumping Plant #1. The change in frequency of threshold concentration exceedances at other assessment locations would be similar or lower. In general, substantial change in ambient DOC concentrations would need to occur before significant changes in drinking water treatment plant design or operations are triggered. The increases in long-term average DOC concentrations estimated to occur at various Delta locations under Alternative 4A are of sufficiently small magnitude that they would not require existing drinking water treatment plants to substantially upgrade treatment for DOC removal above levels currently employed. Further, modeling results for Alternative 4A indicate that there would be predicted improvements in long-term average DOC concentrations at Barker Slough relative to the No Action Alternative (ELT and LLT) (see Section 4.3.4, *Water Quality*, of this RDEIR/SDEIS).

Therefore, changes in DOC concentrations in the Delta resulting from operation of the water conveyance facilities under Alternative 4A are not anticipated to contribute to increases in disinfection byproducts (DBPs).

As described in Section 4.3.4, *Water Quality*, of the RDEIR/SDEIS, operations and maintenance of the water conveyance facilities Alternative 4A, relative to the No Action Alternative (ELT and LLT), would result in increases in long-term average bromide concentrations in the South Fork Mokelumne River at Staten Island and the San Joaquin River at Buckley Cove, and small decreases at the other assessment locations. However, there would be an increased frequency of exceedance of the CALFED Drinking Water Program long-term goal of 50 µg/L and 100 µg/L bromide thresholds for protecting against the formation of DBPs in treated drinking water at the South Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. The use of seasonal intakes at these locations is largely driven by acceptable water quality, and thus has historically been opportunistic. Opportunity to use these intakes would remain, and the predicted increases in bromide concentrations at Antioch and Mallard Slough would not be expected to adversely affect municipal beneficial uses, or any other beneficial use, at these locations. Therefore, changes in bromide concentrations in the Delta resulting from operation of the water conveyance facilities under Alternative 4A are not anticipated to contribute to increases in DBPs.

Trace Metals

The changes in modeled trace metal concentrations of primarily human health and drinking water concern (arsenic, iron, manganese) in the Delta would be similar to those described for Alternative 4 (see Chapter 8, *Water Quality,* Section 8.3.3.9 of the Draft EIR/EIS).

The arsenic criterion was established to protect human health from the effects of long-term chronic exposure, while secondary MCLs for iron and manganese were established as reasonable federal regulatory goals for drinking water quality, and enforceable standards in California. Average concentrations for arsenic, iron, and manganese in the primary source water (Sacramento River, San Joaquin River, and the bay at Martinez) are below these criteria. No mixing of these three source waters could result in a metal concentration greater than the highest source water concentration, and, given that the modeled average water concentrations for arsenic, iron, and manganese do not exceed water quality criteria, more frequent exceedances of drinking water criteria in the Delta would not be an expected result under this alternative. Accordingly, no adverse effect on public health related to the trace metals arsenic, iron, or manganese from drinking water sources is anticipated.

Pesticides

The changes in modeled pesticide concentrations in the Delta under Alternative 4A would be similar to those described for Alternative 4 because the changes in average winter and summer flow rates relative to the No Action Alternative (ELT and LLT) are expected to be similar to or less than changes in flow rates under Alternative 4 in the Sacramento River at Freeport, American River at Nimbus, Feather River at Thermalito and the San Joaquin River at Vernalis. The modeled changes in the source water fractions of Sacramento River, San Joaquin River, and Delta agriculture water under Alternative 4A would not be of sufficient magnitude to substantially affect beneficial uses of the Delta. Based on the general observation that San Joaquin River, in comparison to the Sacramento River, is a greater contributor of organophosphate insecticides in terms of greater frequency of incidence and presence at concentrations exceeding water quality benchmarks, modeled increases in Sacramento River fraction at Banks and Jones would generally represent an improvement in export water quality respective to pesticides. Similarly, the flow changes in the LLT under Alternative 4A would not be expected to result in affects on beneficial uses of water in the Delta due to pesticides.

Therefore, it is not anticipated that there would be adverse effects on public health related to pesticides from drinking water sources.

Because there would be no increases in DBPs due to increases in bromide or DOC in Delta surface waters, and because the modeled changes in pesticide concentrations would not increase substantially in magnitude or frequency in the Delta, there would be no adverse effect on public health as a result of operation of the water conveyance facilities.

CEQA Conclusion: Under Alternative 4A, modeled long-term average pesticide levels in the Delta would be similar to or slightly less that described under Alternative 4 and would not be expected to increase substantially such that beneficial use impairments are made measurably worse. Long-term average bromide concentrations would increase in the South Fork Mokelumne River at Staten Island and decrease at all other assessment locations. However, there would be an increased frequency of exceedance of the 50 µg/L and 100 µg/L bromide thresholds for protecting against the formation of DBPs in treated drinking water at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. The use of seasonal intakes at these locations is largely driven by acceptable water quality, and thus has historically been opportunistic. Opportunity to use these intakes would remain, and the predicted increases in bromide concentrations at Antioch and Mallard Slough would not be expected to adversely affect municipal beneficial uses, or any other beneficial use, at these locations, and therefore would not be expected to contribute substantially to DBP formation. Operations and maintenance activities under Alternative 4A would not cause a substantial long-term change in DOC concentrations in the Delta, although there would be relatively small increases in long-term average DOC concentrations at some interior Delta locations. However, the increases are of sufficiently small magnitude that they would not require existing drinking water treatment plants to substantially upgrade treatment for DOC above levels currently employed, and therefore these increases would not be expected to contribute substantially to DBP formation. Further, there would be predicted improvements in long-term average DOC concentrations at Barker Slough relative to Existing Conditions. Average concentrations of trace metals in the Delta are not expected to increase substantially under Alternative 4A in the primary source water. Therefore, this alternative is not expected to cause additional exceedances of applicable water quality objectives by frequency, magnitude, and geographic extent such that significant impacts on any beneficial uses of waters in the affected environment would occur.

Because there would be no increases in DBPs due to increases in bromide or DOC in Delta surface waters, and because the modeled changes in trace metals pesticide concentrations would not increase substantially in magnitude or frequency in the Delta, there would be no significant impact on public health as a result of operation of the water conveyance facilities.

Impact PH-3: Substantial Mobilization of or Increase in Constituents Known to Bioaccumulate as a Result of Construction, Operation or Maintenance of the Water Conveyance Facilities

NEPA Effects: As described in Ch. 8, *Water Quality*, of the Draft EIR/EIS, modeling scenarios included assumptions regarding how certain habitat restoration activities (CM2 and CM4) would affect Delta hydrodynamics. The amount of tidal habitat restoration completed under Alternative 4A

(Environmental Commitment 4) would be substantially less than under Alternative 4 CM4. To the extent that restoration actions alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of operations-related water quality changes due to operation of the water conveyance facilities.

Three intakes would be constructed and operated under Alternative 4A. Sediment-disturbing activities during construction and maintenance of these intakes and other water conveyance facilities proposed near or in surface waters under this alternative could result in the disturbance of existing constituents in sediment, such as pesticides or methylmercury. In-channel construction activities, such as pile driving during the construction of cofferdams at the intakes and pier construction at the barge unloading facilities, which would occur over a period of 5 months, would result in the localized disturbance of river sediment. In addition, maintenance of the three proposed north Delta intakes and the intermediate forebay would entail periodic dredging for sediment removal at these locations. Sediment accumulation in both the northern and southern portion of the expanded Clifton Court Forebay is expected to be minimal in the ELT period as the need for dredging is anticipated to be every 50 years given the design. However, it is anticipated that there may be some sediment accumulation at the inlet structure of the northern portion of Clifton Court Forebay. Therefore, while overall sediment accumulation in this forebay is not expected to be substantial, some dredging may be required at the inlet structure to maintain an even flow path.

Pesticides

Legacy pesticides, such as organochlorines, have low water solubility; they do not readily volatilize and have a tendency to bond to particulates (e.g., soil and sediment), settle out into the sediment, and not be transported far from the source. If present in sediment within in-water construction areas, legacy pesticides would be disturbed locally and would not be expected to partition into the water column to any substantial degree. Therefore, no significant adverse effect on public health would result from construction.

Numerous pesticides are currently used throughout the affected environment. While some of these pesticides may be bioaccumulative, those present-use pesticides for which there is sufficient evidence of their presence in waters affected by SWP and CVP operations (i.e., organophosphate pesticides, such as diazinon, chlorpyrifos, diuron, and pyrethroids) are not considered bioaccumulative. Thus, changes in their concentrations would not directly cause bioaccumulative problems in aquatic life or humans. The effects of Alternative 4A on pesticide levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions and the No Action Alternative (ELT and LLT) would be similar to or slightly less than those described for the Alternative 4. Alternative 4A would not result in increased tributary flows that would mobilize organochlorine pesticides in sediments. Thus, the change in source water in the Delta associated with the change in water supply operations is not expected to adversely affect public health with respect to bioaccumulation of pesticides.

Methylmercury

If mercury is sequestered in sediments at water facility construction sites, it could become suspended in the water column during construction activities, opening up a new pathway into the food chain. Construction activities (e.g., pile driving and cofferdam installation) at intake sites or barge landing locations would result in a localized, short-term resuspension of sediment and an increase in turbidity that may contain elemental or methylated forms of mercury. Please see Chapter

8, Section 8.1.3.9, *Mercury*, of the Draft EIR/EIS for a discussion of methylmercury concentrations in sediments.

Changes in methylmercury concentrations under Alternative 4A are expected to be small. The greatest annual average methylmercury concentration for drought conditions would be 0.166 ng/L for the San Joaquin River at Buckley Cove (all scenarios) which was slightly lower than the No Action Alternative (ELT) (0.168 ng/L). Fish tissue estimates show only small or no increases in mercury concentrations based on long-term annual average concentrations for mercury at the Delta locations, but they would be different relative to the No Action Alternative (ELT). Under Operational Scenario H3 (Equation 2—see Chapter 8, *Water Quality*, of the Draft EIR/EIS) there would be 11% to 12% percent increases at Staten Island and Rock Slough relative to the No Action Alternative (ELT) in all modeled years. Under Operational Scenario H4 there would be an 11% decrease relative to the No Action Alternative (ELT) for drought years. These changes are expected to be within the uncertainty inherent in the modeling approach (see Section 4.3.4, *Water Quality*, of this RDEIR/SDEIS for a discussion of the uncertainty associated with bioaccumulation models), and would likely not be measurable in the environment. Therefore, modeled changes in mercury in the Delta and in fish tissues due to operation of Alternative 4A would not be expected to adversely affect public health. In the LLT, the primary difference would be changes in the Delta source water fractions to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of Alternative 4A and, therefore, at the LLT the effects of the alternative on mercury are expected to be similar to those described above.

In summary, operation of the water conveyance facilities under Alternative 4A would not alter bioaccumulative pesticide concentrations or mercury concentrations in the Delta such that there was an effect on public health. As such, there would be no adverse effect.

CEQA Conclusion: Operation of the water conveyance facilities under Alternative 4A is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because mercury concentrations are not expected to increase substantially relative to the Existing Conditions (see Section 4.3.4, *Water Quality*, of this RDEIR/SDEIS), no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Because any increases in mercury or methylmercury concentrations are not likely to be measurable, changes in mercury concentrations or fish tissue mercury concentrations would not make any existing mercury-related impairment measurably worse. Construction activities (e.g., pile driving and cofferdam installation) at intake sites or barge landing locations would result in a localized, short-term resuspension of sediment and an increase in turbidity that may contain elemental or methylated forms of mercury.

The effects of Alternative 4A on bioaccumulative pesticide levels in the Delta would be similar to or slightly less than those described for the Alternative 4. Alternative 4A would not result in increased tributary flows that would mobilize organochlorine pesticides in sediments. Thus, the change in source water in the Delta associated with the change in water supply operations is not expected to adversely affect public health with respect to bioaccumulation of pesticides. If present in sediment within in-water construction areas, legacy pesticides would be disturbed locally and would not be expected to partition into the water column to any substantial degree.

For these reasons, there would be no significant impact on public health due to mercury or bioaccumulative pesticides as a result of construction of or operation of the water conveyance facilities under Alternative 4A.

Impact PH-4: Expose Substantially More People to Transmission Lines Generating New Sources of EMFs as a Result of the Construction and Operation of the Water Conveyance Facilities

NEPA Effects: The potential for Alternative 4A transmission line construction and operation to expose people to new sources of EMFs would be identical to impacts described under Alternative 4. As described for Alternative 4, this effect would not be adverse because transmission lines would generally not be located in populated areas or within 300 feet of sensitive receptors and CPUC's EMF design guidelines would be implemented for any new temporary or new permanent transmission lines constructed and operated under Alternative 4A.

CEQA Conclusion: The potential for Alternative 4A transmission line construction and operation to expose people to new sources of EMFs would be identical to impacts described under Alternative 4. Under Alternative 4A, the majority of proposed temporary (69 kV and 230 kV) and permanent (230 kV) transmission lines would be located within the rights-of-way of existing transmission lines; any new temporary or permanent transmission lines not within the right-of-way of existing transmission lines would, for the most part, be located in sparsely populated areas generally away from existing sensitive receptors. None of the proposed temporary or permanent transmission lines would be within 300 feet of sensitive receptors. Further, the temporary transmission lines would be removed when construction of the water conveyance facility features is completed, so there would be no potential permanent effects. Therefore, these transmission lines would not substantially increase people's exposure to EMFs. This impact is considered to be less than significant because transmission lines would generally not be located in populated areas or within 300 feet of sensitive receptors and CPUC's EMF design guidelines would be implemented for any new temporary or permanent transmission lines constructed and operated under Alternative 4A. No mitigation is required.

Impact PH-5: Increase in Vector-Borne Diseases as a Result of Implementing Environmental Commitments 3, 4, 6-11

Effects of Alternative 4A related to the potential for increase in vector-borne diseases from implementing these Environmental Commitments would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 4A would restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, and 6–10 as compared with 83,800 acres under Alternative 4. Conservation Measures 2 and 5 would not be implemented as part of this alternative. Therefore, the potential for vector-borne disease effects under Alternative 4A would likely be less than the potential associated with Alternative 4.

NEPA Effects: Implementation of portions of Environmental Commitments 3, 4, and 6-11 under Alternative 4A would involve protecting and restoring wetland habitat that could potentially increase suitable mosquito habitat within the study area. This potential effect would not be adverse because the total wetland restoration acreage implemented under Alternative 4A would be substantially less than under Alternative 4, habitat creation would generally not be located near densely populated areas, and management plans under Environmental Commitment 11, *Natural Communities Enhancement and Management*, would be performed in consultation with the appropriate MVCDs to ensure MMPs are implemented to reduce mosquito breeding. Additionally, BMPs from the guidelines outlined in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, would be incorporated into Alternative 4A and executed to maintain proper water circulation and flooding during appropriate times of the year (e.g., fall) to prevent stagnant water and habitat for mosquitoes. This consultation would occur when specific restoration and enhancement projects and locations are identified.

CEQA Conclusion: The potential for impacts related to increases of vector-borne disease from mosquitos during construction, operation, and maintenance of portions of Environmental Commitment 3, 4, and 6–11 is considered less than significant because the total wetland restoration acreage implemented under Alternative 4A would be substantially less than under Alternative 4, habitat creation would generally not be located near densely populated areas, and management plans under Environmental Commitment 11 *Natural Communities Enhancement and Management*, would be performed in consultation with the appropriate MVCDs to ensure MMPs are implemented to reduce mosquito breeding. Additionally, BMPs from the guidelines outlined in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, would be incorporated into Alternative 4A and executed to maintain proper water circulation and flooding during appropriate times of the year (e.g., fall) to prevent stagnant water and habitat for mosquitoes. No mitigation is required.

Impact PH-6: Substantial Increase in Recreationists' Exposure to Pathogens as a Result of Implementing the Restoration Environmental Commitments

Effects of Alternative 4A related to the potential for increase in recreationists' exposure to pathogens from implementing portions of the habitat restoration environmental commitments would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 4A would restore up to 15,548 acres of habitat under Environmental Commitments 3, 4, and 6–11 as compared with 83,800 acres under Alternative 4. Conservation Measures 2 and 5 would not be implemented as part of this alternative. Therefore, the potential for exposure of recreationists to pathogens under Alternative 4A would likely be substantially less than the potential associated with Alternative 4.

NEPA Effects: The study area currently supports habitat types, such as tidal habitat, upland wetlands, and agricultural lands that produce pathogens as a result of the biological productivity in these areas (e.g., migrating birds, application of fertilizers, waste products of animals). The study area does not currently have pathogen concentrations that rise to the level of adversely affecting beneficial uses of recreation. However, as described for Alternative 4, any potential increase in pathogens associated with the proposed habitat restoration and enhancement would be localized and within the vicinity of the actual restoration. This localized increase is not expected to be of sufficient magnitude and duration to result in adverse effects on recreationists because these areas would generally not support livestock and most areas would not have public access.

CEQA Conclusion: The potential for an increase in recreationists' exposure to pathogens under Alternative 4A is considered less than significant because of the reduced amount of restored habitat conducive to pathogens that would be implemented under this alternative compared to Alternative 4, the localized nature of pathogens, and because the rapid die-off of pathogens in water would not create sufficient magnitudes of pathogen generation that could affect recreational beneficial uses. No mitigation is required.

Impact PH-7: Substantial Mobilization of or Increase in Constituents Known to Bioaccumulate as a Result of Implementing Environmental Commitments 4 and 10

Effects of Alternative 4A related to the potential to mobilize contaminants known to bioaccumulate (pesticides and methylmercury) from implementing portions of the restoration environmental commitments would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 4A would restore up to 1,067 acres of habitat under Environmental Commitments 4 and 10 as compared with 66,200 acres under Alternative 4. Conservation Measures 2 and 5 would not be implemented as part of this alternative. Therefore, the potential for mobilization of contaminants under Alternative 4A would likely be substantially less than the potential associated with Alternative 4.

NEPA Effects: The primary concern with habitat restoration regarding constituents known to bioaccumulate is the potential for mobilizing contaminants sequestered in sediments of the newly inundated floodplains and marshes. The mobilization depends on the presence of the constituent and the biogeochemical behavior of the constituent to determine whether it could re-enter the water column or be reintroduced into the food chain. This potential effect would not be adverse because the total tidal and nontidal habitat restoration acreage implemented under Alternative 4A would be substantially less than under Alternative 4;bioaccumulation of pesticides and/or methylmercury in the tidal and nontidal restoration areas are not expected to substantially affect public health because of the limited extent of restored habitat under Alternative 4A; the localized nature of pesticide bioaccumulation; and because current OEHHA standards would be enforced. Environmental Commitment 12, *Methylmercury Management*, would be implemented to reduce methylmercury production in restored habitats.

CEQA Conclusion: The potential for public health impacts related to mobilization of pesticides and methylmercury in habitat restoration areas related to Environmental Commitment s 4 and 10 is considered less than significant because the total wetland restoration acreage implemented under Alternative 4A would be substantially less than under Alternative 4A. Bioaccumulation of pesticides and/or methylmercury in the tidal and nontidal restoration areas are not expected to substantially affect public health because of the limited extent of restored habitat under Alternative 4A; the localized nature of pesticide bioaccumulation; and because current OEHHA standards would be enforced. Environmental Commitment 12, *Methylmercury Management*, would be implemented to reduce methylmercury production in restored habitats. No mitigation is required.

Impact PH-8: Increase in *Microcystis* Bloom Formation as a Result of Operation of the Water Conveyance Facilities.

NEPA Effects: Any modified reservoir operations under Alternative 4A are not expected to promote *Microcystis* production upstream of the Delta relative to the No Action Alternative (ELT and LLT) since large reservoirs upstream of the Delta are typically low in nutrient concentrations and phytoplankton outcompete cyanobacteria, including *Microcystis*. Further, in the rivers and streams of the Sacramento River watershed, watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), and the San Joaquin River upstream of the Delta, bloom development would be limited by high water velocity and low hydraulic residence times. These conditions would not be expected to change under Alternative 4A relative to the No Action Alternative (ELT and LLT)

Conditions in the Export Service Areas with implementation of water supply operations under Alternative 4A are not expected to become more conducive to *Microcystis* bloom formation relative to the No Action Alternative (ELT and LLT) because the fraction of water flowing through the Delta that would reach the existing south Delta intakes is not expected to be adversely affected by *Microcystis* blooms.

As indicated in Section 4.3.4, *Water Quality,* of this RDEIR/SDEIS, there was not modeling available that adequately accounted for the effects of operation of the water conveyance facilities and the hydrodynamic impacts of the environmental commitments on long-term average residence times in the Delta for Alternative 4A. Accordingly, the hydrodynamic effects of Alternative 4A on *Microcystis* were determined qualitatively and the effects discussed for the Delta are related entirely to operations and maintenance and not the hydrodynamic effects of the restoration actions. Although there is uncertainty, water supply operations under Alternative 4A are not expected to increase water residence times or ambient water temperatures throughout the Delta, including Banks and Jones pumping plants, relative to the No Action Alternative (ELT and LLT), and therefore Delta waters are not expected to be adversely affected by *Microcystis* blooms.

CEQA Conclusion: Relative to Existing Conditions, operation of the water conveyance facilities under Alternative 4A is not expected to promote *Microcystis* bloom formation in the reservoirs and watersheds upstream of the Delta because large reservoirs upstream are typically low in nutrient concentrations and phytoplankton outcompete cyanobacteria, including *Microcystis*, and high water velocity and low hydraulic residence times in the upstream area limit the development of *Microcystis* blooms.

The potential for *Microcystis* blooms in the Export Service Areas under Alternative 4A would be less than under Alternative 4, but source waters to the south Delta intakes could be affected by *Microcystis* due to an increase in Delta water temperatures associated with climate change and from an increase in water residence times. The impacts from increased water residence times in the Delta would be mostly related to tidal habitat restoration and improvements to the Yolo Bypass, which are assumed to occur separate from Alternative 4A, as well as to climate change and sea level rise. The combined effect of these factors on increasing *Microcystis* in source waters to the south Delta intakes would likely be a greater influence than that of Alternative 4A operations.

Water supply operations under the two Alternative 4A scenarios could result in localized increases in Delta residence times in some locations and decreased residence times in other Delta locations. As indicated in Section 4.3.4, *Water Quality,* of this RDEIR/SDEIS, there is substantial uncertainty regarding the extent that Alternative 4A operations and maintenance would result in a net increase in water residence times relative to Existing Conditions. Regardless of this uncertainty, it is likely that these potential effects under Alternative 4A would be relatively small compared to the combined effects of tidal habitat restoration and Yolo Bypass improvements unrelated to Alternative 4A, and sea level rise and climate change. Climate change in the ELT is expected to result in a 1.3-2.5°F increase in ambient Delta water temperatures relative to Existing Conditions. Given the combined effects of restoration activities unrelated to Alternative 4A, climate change, and sea level rise on increased water residence time, as well as the effects of climate change on Delta water temperatures, it is possible that *Microcystis* blooms in the Delta would increase in frequency, magnitude, and geographic extent, relative to Existing Conditions. However, although there is considerable uncertainty regarding this impact, while long-term water quality degradation may occur and, thus, impacts on beneficial uses could occur, these impacts are not related to implementation of Alternative 4A. Therefore, the effects on *Microcystis* due to operations under Alternative 4A would be less than significant. No mitigation is required.

Impact PH-9: Increase in *Microcystis* Bloom Formation as a Result of Implementing Environmental Commitment 4.

***NEPA Effects*:** Under Alternative 4A, Yolo Bypass Fisheries Enhancement would not occur, unlike under Alternative 4. However, improvements in the Yolo Bypass, as well as restoration of 8,000 acres of tidal habitat, would be implemented under a plan separate and distinct from Alternative 4A (see Section 4.1.2, *Description of Alternative 4A*, of this RDEIR/SDEIS). These activities are assumed to occur under both Alternative 4A and the No Action Alternative. Similar to Alternative 4 (under CM 4), there would be tidal habitat restoration in the Delta under Alternative 4A with implementation of Environmental Commitment 4. However, the 59 acres of tidal habitat restored under this alternative would be substantially fewer than under Alternative 4. As discussed in Section 4.3.4, *Water Quality,* of this RDEIR/SDEIS, implementation of Environmental Commitment 4 under Alternative 4A would have negligible effects in terms of the potential for creating conditions conducive to *Microcystis* bloom in the Delta relative to what could result from the development of 8,000 acres of tidal habitat and improvements in the Yolo Bypass in the ELT, which could increase water temperatures and hydraulic residence times relative to the No Action Alternative (LLT). Therefore, implementation of Environmental Commitment 4 under Alternative 4A would not be adverse because it would not increase *Microcystis* bloom formation.

CEQA Conclusion: Implementation of Environmental Commitment 4 (*Tidal Natural Communities Restoration*) under Alternative 4A would result in 59 acres of tidal restoration within the Delta. This would have a negligible effect on creating conditions conducive to *Microcystis* bloom formation, particularly relative to the development of 8,000 acres of tidal habitat and improvements to the Yolo Bypass in the ELT—activities separate and distinct from Alternative 4A. These activities would create shallow backwater areas that could result in a measureable increase in water temperatures and water residence times in the Delta, and therefore *Microcystis*, relative to Existing Conditions. Thus, implementation of Environmental Commitment 4 under Alternative 4A would be less than significant.

4.3.22 Minerals

Impact MIN-1: Loss of Availability of Locally Important Natural Gas Wells as a Result of Constructing the Water Conveyance Facilities

NEPA Effects: The locations of producing natural gas wells within the Alternative 4A construction footprint would be the same as indicated for Alternative 4. There are no producing wells within the construction footprint, the temporary construction work areas or the east-west transmission line alignment option.

Because no producing wells within the construction footprint would be permanently abandoned, construction of Alternative 4A would not result in reduced natural gas production in the study area. Alternative 4 would not affect any locally important natural gas wells or result in the loss of any portion of the area's natural gas production and the effects would not be adverse.

CEQA Conclusion: Because no natural gas wells would occur in the construction footprint there would not be any loss in active natural gas wells or change in the availability of natural gas production. The construction of Alternative 4A would not affect natural gas wells or gas production. No mitigation is required.

Impact MIN-2: Loss of Availability of Extraction Potential from Natural Gas Fields as a Result of Constructing the Water Conveyance Facilities

NEPA Effects: The extent of construction and permanent footprint and resulting loss of extraction potential for natural gas fields would be the same as described under Alternative 4. Alternative 4A water conveyance facilities would permanently reduce the land surface available for vertical extraction of natural gas from directly underlying gas fields, however most of the affected gas fields could be accessed from other overlying areas. Similarly, effects on potential gas extraction resulting from construction work areas would be small and temporary and would not prevent recovery of natural gas. Therefore, there would be no short or long-term adverse effect on natural gas extraction potential from construction of Alternative 4A.

CEQA Conclusion: Although the Alternative 4 conveyance facilities would reduce the land surface available for vertical extraction of natural gas from underlying gas fields, the proportion of these gas fields affected would be small (less than approximately 3% of the areal extent of natural gas field areas intersected). Additionally, there would be no substantial loss of existing production or permanent loss of access to the resource because the gas fields would continue to be accessible using conventional or directional drilling techniques. Accordingly, this impact would be less than significant. No mitigation is required.

Impact MIN-3: Loss of Availability of Locally Important Natural Gas Wells as a Result of Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The operation of the water conveyance facilities under Alternative 4A would include moving water, both in infrastructure that would be constructed under this alternative and in the natural channels. These operations would not cause additional effects on natural gas wells beyond those related to water conveyance construction. Maintenance of the water conveyance facilities under Alternative 4A would be the same as discussed for Alternative 4. These activities would not affect natural gas wells or resource recovery. Accordingly, the operation and maintenance associated with the water conveyance facilities under Alternative 4A would not result in adverse effects on access to or use of existing active wells. Accordingly, there would be no adverse effect on natural gas wells from operation and maintenance of Alternative 4A.

CEQA Conclusion: The operation and maintenance associated with the water conveyance facilities under Alternative 4A would have no impact on access to natural gas wells, either for operating and maintaining existing active wells, or modifying plugged inactive wells, because operation and routine maintenance such as painting, cleaning, repairs, levee and landscape maintenance, and similar activities would not cause the abandonment of wells, eliminate access to wells, or reduce production. Therefore, this impact would be less than significant. No mitigation is required.

Impact MIN-4: Loss of Availability of Natural Gas Fields as a Result of Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The operation of the water conveyance facilities under Alternative 4A would include moving water, both in infrastructure that would be constructed under this alternative and in the natural channels. These operations would not cause additional effects on access to natural gas fields beyond those related to water conveyance construction. Maintenance of the water conveyance facilities under Alternative 4A would be the same as discussed for Alternative 4. These activities would not affect access to natural gas fields. Accordingly, the operation and maintenance associated with the water conveyance facilities under Alternative 4A would not result in adverse effects on access to or use of existing active wells, or accessing plugged inactive wells. Accordingly, there would be no adverse effect from operation and maintenance.

CEQA Conclusion: The operation and maintenance associated with the water conveyance facilities under Alternative 4A would have no impact on access to natural gas wells, either for operating and maintaining existing active wells, or modifying plugged inactive wells, because operation and routine maintenance such as painting, cleaning, repairs, levee and landscape maintenance, and similar activities would not cause the abandonment of wells, eliminate access to wells, or reduce production. Therefore, this impact would be less than significant. No mitigation is required.

Impact MIN-5: Loss of Availability of Locally Important Natural Gas Wells as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

The type of effects on locally important natural gas wells associated with Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar to those described for Alternative 4. However, as described under Section 4.1, *Introduction*, of this RDEIR/SDEIS, environmental commitments occurring under Alternative 4A would affect much less land within the Plan Area when compared to Alternative 4. Therefore, the magnitude of effects of Alternative 4A on mineral resources within the Plan Area would be smaller than those disclosed under Alternative 4.

NEPA Effects: Because locations for these activities have not been determined, the extent of the effect of implementing restoration actions on locally important natural gas wells cannot be precisely determined. It is anticipated that restoration actions expected under Alternative 4A would result in adverse effects on locally important natural gas wells however to a lesser degree than under Alternative 4 because less land would be restored. Similar to Alternative 4, natural gas wells located in areas that would be permanently inundated could remain productive with the use of protective cages or platforms. However, for those instances, modification and maintenance of wells may not be cost effective. It is likely that any producing wells in proposed permanent inundation areas would need to be abandoned because modifications to these wells would not be feasible.

The number of active wells directly affected would vary, depending on the specific lands inundated by Environmental Commitments 4 and 10. The active wells that would be affected could be maintained in place if they were in seasonally inundated locations. In permanently flooded areas, the active wells could be replaced using conventional or directional drilling techniques at a location outside the inundation zone to maintain production. The likelihood of this replacement would depend on the availability of land for lease and the cost of the new construction. If a large number of wells had to be abandoned and could not be redrilled, there could be a locally adverse effect related to permanent elimination of a substantial portion of a county's active natural gas wells. Mitigation Measure MIN-5A is available to address this effect.

Natural gas wells in areas that would remain uplands could remain operational and unaffected if they are avoided when restoration activities are implemented and access to the gas well can be maintained. Maintaining access to an oil or gas well is defined by the California Department of Conservation as (1) maintaining rig access to the well, and (2) not building over, or in close proximity to, the well (California Department of Conservation, Division of Oil, Gas, and Geothermal Resources 2007).

CEQA Conclusion: Although the number of natural gas wells likely to be affected may be a small percentage of the total wells in the study area, and some wells may be relocated using conventional or directional drilling, there is potential to affect a significant number of locally important gas wells. Consequently, this impact is considered significant. Because implementation of Mitigation Measure MIN-5A cannot assure that all or a substantial portion of a county's existing natural gas wells will remain accessible after implementation of this alternative, this impact is significant and unavoidable.

Mitigation Measure MIN-5: Design Environmental Commitments 4 and 10 to Avoid Displacement of Active Natural Gas Wells to the Extent Feasible

During final design of Environmental Commitments 4 and 10, the project proponents will avoid permanent inundation of or construction over active natural gas well sites where feasible to minimize the need for well abandonment or relocation.

Impact MIN-6: Loss of Availability of Extraction Potential from Natural Gas Fields as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Because locations of restoration actions occurring under Alternative 4A have not been determined, the extent of the effect of implementing these actions on natural gas fields within the Plan Area cannot be precisely determined. It is anticipated that restoration actions expected under Alternative 4A would result in adverse effects on the potential to extract natural gas from these fields however to a lesser degree than under Alternative 4 because less land would be restored. Similar to Alternative 4, some natural gas fields could be permanently inundated resulting in potential losses in production. However, most natural gas fields would still be accessible from outside the inundated areas using either conventional or directional drilling, although feasibility of access would depend on the exact configuration of inundation and the availability of adjacent drilling sites. Although the overall extent of affected natural gas fields in the region is low, there remains the potential for a locally adverse effect on access to natural gas fields because the resource may be permanently covered (inundated) or otherwise become inaccessible to recovery. Mitigation Measure MIN-6 is available to lessen this effect.
