Section 4
New Alternatives: Alternatives 4A, 2D, and 5A

4.1 Introduction

As stated in Section 1, *Introduction*, the RDEIR/SDEIS considers additional sub-alternatives that meet the goals of restoring the ecological functions of the Delta and improving water supply reliability. These alternatives were developed in response to input from the public on the Draft EIR/EIS comment period as well as from agencies. Specifically among the comments received on the Draft EIR/EIS was the suggestion that DWR should pursue permit terms shorter than 50 years due to the levels of uncertainty regarding both the long-term effectiveness of habitat restoration in recovering fish populations and the future effects of climate change on the Delta and the Sacramento River watershed. Other comments suggested that the proposed conveyance facilities should be untethered from the habitat restoration components of the BDCP, with the latter to be pursued separately.

Consistent with this input, the Lead Agencies are analyzing an alternative implementation strategy considered within the new alternatives in this RDEIR/SDEIS (Alternatives 4A, 2D, and 5A) (see Figure 4.1-1). The alternative implementation strategy would achieve the project objectives and purpose and need by constructing conveyance facility improvements and associated ecosystem improvements. These changes are necessary for the SWP and CVP to address more immediate water supply reliability needs while reducing the severity of existing ongoing environmental impacts. The strategy would achieve the latter objective and purpose in part by reducing reverse flows and direct fish species impacts associated with the existing south Delta intakes. The alternative implementation strategy allows for other state and federal programs to address the long term conservation efforts for species recovery in programs separate from the proposed project.

The primary differences between Alternatives 4A, 2D, and 5A presented in this RDEIR/SDEIS and Alternatives 4, 2A, and 5 presented in the BDCP Draft EIR/EIS are as follows. The California Department of Water Resources (DWR) would not seek 50-year permits under the federal and state endangered species laws for Alternatives 4A, 2D, or 5A. The originally proposed BDCP habitat restoration measures and related Conservation Measures (CMs) (i.e., CM2 through CM21) would not be included as parts of Alternatives 4A, 2D, and 5A, except to the extent required to mitigate significant environmental effects under CEQA and meet the regulatory standards of ESA Section 7 and California Endangered Species Act (CESA) Section 2081(b).

Alternatives 4A, 2D, and 5A would not serve as habitat conservation plans/natural community conservation plans (HCPs/NCCPs) under ESA Section 10 and the NCCPA, but rather would achieve incidental take authorization under ESA Section 7 and CESA Section 2081(b).

Alternatives 4A, 2D, and 5A would enable DWR to construct and operate new conveyance facilities that improve conditions for endangered and threatened aquatic species in the Delta while at the same time improving water supply reliability, consistent with California law (see, e.g., Cal.Wat. Code, § 85001[c]). Implementing the conveyance facilities alone, as now proposed under Alternatives 4A, 2D, and 5A, would help resolve many of the concerns with the current south Delta conveyance system, and would help reduce threats to endangered and threatened species in the Delta. For instance, implementing a dual conveyance system would align water operations to better reflect natural seasonal flow patterns by creating new water diversions in the north Delta equipped with state-of-the-art fish screens, thus reducing reliance on south Delta exports.

The existing operation of the SWP and CVP pumps in the south Delta can cause reversals in river flows, potentially altering salmon migratory patterns and contributing to the decline of sensitive fish species such as delta smelt. The new system would reduce the ongoing physical impacts associated with sole reliance on the southern diversion facilities and allow for greater operational flexibility to better protect fish. Minimizing south Delta pumping would provide more natural east–west flow patterns. The new diversions would also help protect critical water supplies against the threats of sea level rise and earthquakes. Alternatives 4A, 2D, and 5A comprise only the conveyance facilities and operations that formerly constituted CM1 and no longer includes habitat restoration measures beyond those needed to provide mitigation for specific regulatory compliance purposes. However habitat restoration is still recognized as a critical component of the State's long-term plans for the Delta, and such endeavors will likely be implemented over time under actions separate and apart from the chosen alternative. If Alternative 4A, 2D, or 5A is approved at the end of the CEQA/NEPA process, restoration of habitat in the Delta, beyond these alternatives' mitigation requirements, will instead occur through California EcoRestore[1], and these activities will be further developed and evaluated independent of the water conveyance facilities. Although DWR and Reclamation have identified these alternatives with a new implementation strategy, they are nevertheless consistent with the Coordinated Operation Agreement (COA) governing the coordinated operation of the federal Central Valley Project (CVP) and State Water Project (SWP). These new alternatives would, like Alternative 4, address compliance with federal and state endangered species laws with respect to the operation of the existing SWP Delta intake and conveyance facilities, as well as for the construction and operation of conveyance facilities for the movement of water entering the Delta from the Sacramento Valley watershed to the existing SWP and CVP pumping plants in the southern Delta.

4.1.1 Rationale for Revisions to the Proposed Project

At their cores, both CEQA and NEPA are intended to allow agency decision makers and members of the public to consider the environmental consequences of proposed actions and to consider ways of reducing or avoiding adverse impacts. The statutes function best when agencies use the information they acquire through the environmental review process to modify their proposed actions to make them more environmentally benign.

California courts have recognized that project changes are a desirable and foreseeable byproduct of the CEQA process. In fact, courts have noted that CEQA "encourages" public agencies to revise projects in light of new information revealed during the CEQA process.[2] Indeed, as the courts have emphasized, "one of the major objectives of the CEQA process …[is] to foster better (more environmentally sensitive) projects through revisions which are precipitated by the preparation of EIRs."[3] It is thus "the very nature of CEQA" that "projects will be 'modified' to protect the environment."[4]

3 / *County of Orange v. Superior Court* (2003) 113 Cal.App.4th 1, 10.

4 *Ibid.*

As further noted by the courts, "[t]he CEQA reporting process is not designed to freeze the ultimate proposal in the precise mold of the initial project; indeed, new and unforeseen insights may emerge during investigation, evoking revision of the original proposal."[5] Project reductions, in particular, are encouraged to the extent that they address environmental needs and facilitate the goals of CEQA. In certain situations, for example, an agency may approve only a portion of the project analyzed in an EIR.[6] As one court summarized these points, "'CEQA compels an interactive process of assessment of environmental impacts and responsive project modification which must be genuine. It must be open to the public, premised upon a full and meaningful disclosure of the scope, purposes, and effect of a consistently described project, with flexibility to respond to unforeseen insights that emerge from the process.' In short, a project must be open for public discussion and subject to agency modification during the CEQA process."[7]

NEPA imposes similar obligations on federal agencies and, like CEQA, encourages project revisions based on environmental concerns brought to light during the environmental review process. Although NEPA, unlike CEQA, is considered a "purely procedural statue" (meaning that it does not mandate particular results), it provides the necessary process to ensure that federal agencies take a "hard look" at the environmental consequences of their actions.[8]

NEPA and its implementing regulations specifically require federal officials to consider the recommendations of other government entities and the public who present reasonable solutions or alternative approaches that may improve a proposed action. When preparing a Final EIS, a federal lead agency must respond to comments on a Draft EIS in one of several ways, "including by modifying alternatives including the proposed action and by developing and evaluating alternatives not previously given serious consideration by the agency."[9] As stated in the NEPA regulations, "[u]ltimately, of course, it is not better documents but better decisions that count. NEPA's purpose is not to generate paperwork—even excellent paperwork—but to foster excellent action. The NEPA process is intended to help public officials make decisions that are based on understanding of environmental consequences, and take actions that protect, restore, and enhance the environment."[10]

Accordingly, like CEQA, NEPA encourages agencies to make changes to proposed projects based on information gathered during the environmental review process and based on public comments received on a Draft EIS. The NEPA regulations note that "[a]n agency can modify a proposed action in light of public comments received in response to a draft EIS."[11] Moreover, federal courts have long recognized that "agencies must have some flexibility to modify alternatives canvassed in the Draft

EIS to reflect public input."[12] Indeed, the very purpose of a Draft EIS and the ensuing comment period is to elicit suggestions and criticisms to enhance the proposed project.[13]

As the forgoing discussion demonstrates, a primary measure of success under both CEQA and NEPA is when the environmental review process and public comments prompt the lead agencies to make changes that result in a project that is better than the original proposal. That is precisely what has occurred here. Because of the robust public response during the extended public comment period on the Draft EIR/EIS, as well as the data acquired during the environmental review process, the Lead Agencies have been able to better identify and understand the proposed project's potential adverse effects, and have been able to identify a solution that will reduce many of these impacts and ease the burden on the environment and Delta communities.

4.1.2 Description of Alternative 4A

This section provides description of the components and operation of water conveyance facilities, ESA and CESA compliance process, and environmental commitments that will implemented under Alternative 4A. Table 4.4-1 below, provides a brief summary comparison of these elements between Alternatives 4A and 4.

4.1.2.1 Water Conveyance Facility Construction and Maintenance

Under Alternative 4A, water conveyance facilities would be constructed and maintained identically to those proposed and analyzed under Alternative 4 (including the modifications described in Section 3, *Conveyance Facility Modifications to Alternative 4*, of this RDEIR/SDEIS). Water would primarily be conveyed from the north Delta to the south Delta through pipelines/tunnels. Water would be diverted from the Sacramento River through three fish-screened intakes on the east bank of the Sacramento River between Clarksburg and Courtland (Intakes 2, 3, and 5). Water would travel from the intakes to a sedimentation basin before reaching the tunnels. From the intakes water would flow into an initial single-bore tunnel, which would lead to an intermediate forebay on Glannvale Tract. From the southern end of this forebay, water would pass through an outlet structure into a dual-bore tunnel where it would flow by gravity to the south Delta. Water would then reach pumping plants northeast of the Clifton Court Forebay, where it would be pumped into the north cell of the expanded Clifton Court Forebay from the tunnels. The forebay would be dredged and redesigned to provide an area that would isolate water flowing from the new north Delta facilities from water diverted from south Delta channels.

Table 4.1-1. Comparison of Alternative 4 and Alternative 4A

Element of Project Description	Alternative 4 (BDCP)	Alternative 4A
ESA Compliance	Section 10 (DWR)/Section 7 (Reclamation)	Section 7
California Endangered Species law Compliance	NCCPA	2081(b) permit
Facilities	Modified Pipeline/Tunnel Alignment: 3 intakes, 9,000 cfs	Modified Pipeline/Tunnel Alignment: 3 intakes, 9,000 cfs
Operations	Dual Conveyance; Operational Scenarios H1–H4 with Decision Tree (see Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS); evaluated at LLT	Dual Conveyance; Operational Scenario H3+ (a new operational scenario which includes a criterion for spring outflow bounded by the criteria associated with Scenarios H3 and Scenario H4, as described in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS); evaluated as Scenarios H3–H4 at early long-term (ELT, which is associated with conditions around 2025)
Conservation Measures/ Environmental Commitments	Conservation Measures 2–21; includes Yolo Bypass Improvements and 65,000 acres of tidal wetland restoration	Environmental Commitments 3, 4, 6, 7, 8, 9, 10, 11, 12, 15, 16; includes up to 59 acres of tidal wetland restoration
CEQA Baseline	Existing Conditions	Existing Conditions
NEPA Baseline	No Action Alternative at LLT	No Action Alternative at ELT

A map and a schematic diagram depicting the conveyance facilities associated with Alternative 4A are provided in Mapbook Figure M3-4 in the Mapbook Volume and Figure 3-10 in Appendix A of this RDEIR/SDEIS. A new pumping facility would be constructed northeast of the north cell of the expanded Clifton Court Forebay, along with control structures to regulate the relative quantities of water flowing from the north Delta and the south Delta to the Banks and Jones Pumping Plants. Alternative 4A would entail the continued use of the SWP/CVP south Delta export facilities.

All aspects of water conveyance facility design, construction, and maintenance would be identical to those described for Alternative 4 in the revised text in Chapter 3, Sections 3.4, 3.5.9, and 3.6.1 and Appendix 3C, as provided in Appendix A, *Revisions to the Draft EIR/EIS*, of this RDEIR/SDEIS.

4.1.2.2 Water Conveyance Facility Operations

Operational components of the water conveyance facilities under Alternative 4A would be similar, but not identical, to those described under Scenario H in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS. Alternative 4A starting operations will be determined through the continued coordination process as outlined in the Section 7 consultation process and 2081(b) permit prior to the start of construction. An adaptive management and monitoring program, as described below, will be implemented to develop additional science during the course of project construction and operation to inform and improve conveyance facility operational limits and criteria. Additionally, operational elements associated with Fremont Weir modifications would not be incorporated as part of this alternative, because Yolo Bypass improvements contemplated in the BDCP (under CM2) would not be implemented as part of Alternative 4A; instead, they would be assumed to occur as part of the No Action Alternative because they are required by the existing BiOps (see below). For a detailed characterization of operational criteria, please refer to Table 4.1-2.[14]

Implementation of the proposed project will include operations of both new and existing water conveyance facilities once the new north Delta facilities are completed and become operational, thereby enabling joint management of north and south Delta diversions. Operational limits included in this proposed project for south Delta export facilities would supplement the south Delta operational limits currently implemented in compliance with the USFWS (2008) and NMFS (2009) BiOps. The proposed project also incorporates existing criteria from the 2008 and 2009 BiOps (including Fall X2), and adds additional criteria for spring outflow and new minimum flow criteria at Rio Vista from January through August. The North Delta Diversions and the head of Old River barrier are new facilities for the CVP and SWP and will be operated consistent with the proposed operating criteria for each of these facilities. All other criteria included in the USFWS (2008) and NMFS (2009) BiOps and D-1641will continue to be complied with, subject to adjustments made pursuant to the adaptive management process as already described in the 2008 and 2009 BiOps, as part of the continued operations of the CVP and SWP. The proposed project includes modified or new operations of only the following:

- North Delta bypass flows
- South Delta export operations (including export rates and OMR flows)
- Head of Old River barrier operations
- Spring Delta outflow
- Rio Vista minimum flow standard in January through August

The proposed criteria are further described in the following subsections and in Table 4.1-2. The proposed project operations include a preference for south Delta pumping in July through September to provide limited flushing for improving general water quality conditions and reduced residence times.

The Longfin Smelt is a species listed under the California Endangered Species Act (CESA). Therefore, it will be necessary to meet CESA permit issuance criteria for this species. To avoid a reduction in overall abundance for this species, the proposed project includes spring outflow criteria, which are intended to be provided through the acquisition of water from willing sellers. If sufficient water cannot be acquired for this purpose, the spring outflow criteria will be accomplished through operations of the SWP and CVP to the extent an obligation is imposed on either the SWP or CVP under federal or applicable state law. Best available science, including that developed through a collaborative science program, will be used to analyze and make recommendations on the role of such flow in supporting Longfin Smelt abundance to DFW, who will determine if it is necessary to meet CESA permitting criteria.

As described in Section 4.1.2.4, *Collaborative Science and Adaptive Management Program*, for Alternative 4A will be used to consider and address scientific uncertainty regarding the Delta ecosystem and to inform implementation of the operational criteria in the existing BiOps for the

[14] Note that these proposed operational criteria would only take effect after the proposed conveyance facilities are operational. Until that time, operations would occur as described in the USFWS 2008 and NMFS 2009 BiOps or as modified by the outcome of ongoing ESA compliance processes pertaining to operation of the existing facilities.

coordinated operations of the SWP and CVP and the 2081b permit for the SWP facilities and operations, as well as for the new biological opinion and 2081b for this proposed project. Hypotheses will be tested using the following steps:

1. Clearly articulate the management objectives of the actions, along with the criteria that will be used to assess the efficacy of the actions.
2. Clearly articulate the scientific uncertainties and specific hypotheses designed to reduce that uncertainties regarding questions of management importance.
3. Develop and implement a science plan and data collection program to test the hypotheses and reduce the relevant uncertainties.
4. Based on the data collected and analysis of the data, the Collaborative Science process will prepare a written report that presents findings and synthesis of the analyses for submittal to an independent panel review process.

Table 4.1-2. New and Existing Water Operations Flow Criteria and Relationship to Assumptions in CALSIM Modeling

Parameter	Criteria	Summary of CALSIM Modeling[a]
New Criteria Included in Alternative 4A		
North Delta bypass flows	• Initial Pulse Protection: ○ Low-level pumping of up to 6% of total Sacramento River flow such that bypass flow never falls below 5,000 cfs. No more than 300 cfs can be diverted at any one intake. ○ If the initial pulse begins and ends before Dec 1, post-pulse criteria for May go into effect after the pulse until Dec 1. On Dec 1, the Level 1 rules defined in Table 3-16 in the Draft EIR/EIS apply unless a second pulse occurs. If a second pulse occurs, the second pulse will have the same protective operation as the first pulse. • Post-pulse Criteria (specifies bypass flow required to remain downstream of the North Delta intakes): ○ October, November: bypass flows of 7,000 cfs before diverting at the North Delta intakes. ○ July, August, September: bypass flows of 5,000 cfs before diverting at the North Delta intakes. • December through June: post-pulse bypass flow operations will not exceed Level 1 pumping unless specific criteria have been met to increase to Level 2 or Level 3 as defined in the Section 3.6.4 of the Draft EIR/EIS. If those criteria are met, operations can proceed as defined in Table 3.4.1-2 in the BDCP Public draft. The specific criteria for transitioning between and among pulse protection, Level 1, Level 2, and/or Level 3 operations, will be developed and based on real-time fish monitoring and hydrologic/behavioral cues upstream of and in the Delta. During operations, adjustments are expected to be made to improve water supply and/or migratory conditions for fish by making real-time adjustments to the pumping levels at the north Delta diversions. These adjustments would be managed under Real Time Operations (RTO).	• Same as CM1 criteria, as proposed in the Draft BDCP (hereafter “CM1 criteria”).

Parameter	Criteria	Summary of CALSIM Modeling[a]
South Delta operations	• October, November: No south Delta exports during the D-1641 San Joaquin River 2-week pulse, no Old and Middle River (OMR) flow restriction during 2 weeks prior to pulse, and a monthly average of −5,000 cfs in November after pulse. • December: OMR flows will not be more negative than an average of −5,000 cfs when the Sacramento River at Wilkins Slough pulse triggers, and no more negative than an average of −2,000 cfs when the delta smelt action 1 triggers. No OMR flow restriction prior to the Sacramento River pulse, or delta smelt action 1 triggers. • January, February[15]: OMR flows will not be more negative than an average of 0 cfs during wet years, −3,500 cfs during above-normal years, or −4,000 cfs during below-normal to critical years, except −5,000 in January of dry and critical years. • March[16]: OMR flows will not be more negative than an average of 0 cfs during wet or above- normal years or −3,500 cfs during below-normal and dry year and −3,000 cfs during critical years. • April, May: Allowable OMR flows depend on gaged flow measured at Vernalis, and will be determined by a linear relationship. If Vernalis flow is below 5,000 cfs, OMR flows will not be more negative than−2,000 cfs. If Vernalis is 6,000 cfs, OMR flows will not be less than +1,000 cfs. If Vernalis is 10,000 cfs, OMR flows will be at least 1,000 cfs. If Vernalis exceeds 10,000 cfs, OMR flows will be at least +2,000 cfs. If Vernalis is 15,000 cfs, OMR flows will be at least +3,000 cfs. If Vernalis is at or exceeds 30,000 cfs, OMR flows will be at least 6,000 cfs. • June: Similar to April, allowable flows depend on gaged flow measured at Vernalis. However, if Vernalis is less than 3,500 cfs, OMR flows will not be more negative than −3,500 cfs. If Vernalis exceeds 3,500 cfs and up to 10,000 cfs, OMR flows will be at least 0 cfs. If Vernalis exceeds 10,000 cfs and up to 15,000 cfs, OMR flows will be at least +1,000 cfs. If Vernalis exceeds 15,000 cfs, OMR flows will be at least +2,000 cfs. • July, August, September: No OMR flow constraints.	• October, November: Assumed no south Delta exports during the D-1641 San Joaquin River 2-week pulse, no OMR restriction during 2 weeks prior to pulse, and −5,000 cfs in November after pulse. • December: −5,000 cfs only when the Sacramento River pulse based on the Wilkins Slough flow (same as the pulse for the north Delta diversion) occurs, if no OMR requirement was applied. If the USFWS (2008) BiOp Action 1 is triggered, after which −2,000 cfs requirement is assumed. • April, May: OMR requirement for the Vernalis flows falling between the specified flows were determined by linear interpolation. When Vernalis flow is between 5,000 cfs and 6,000 cfs, OMR requirement is determined by linearly interpolating between −2,000 cfs and +1,000 cfs. • January–March and July–September: Same as CM1 criteria

[15] Sacramento River 40-30-30 index based water year types. For January and February, anticipated water year type based on the forecasted hydrology will be used. The frequency of exceedance of the forecasted hydrology will be consistent with current practices. CALSIM II modeling uses previous water year type for October through January, and the current water year type from February onwards.

[16] Sacramento River 40-30-30 index based water year types. For March, anticipated water year type based on the forecasted hydrology will be used. The frequency of exceedance of the forecasted hydrology will be consistent with current practices. CALSIM II modeling uses previous water year type for October through January, and the current water year type from February onwards.

Parameter	Criteria	Summary of CALSIM Modeling[a]
Head of Old River gate operations	• October 1–November 30th: RTO management in order to protect the D-1641 pulse flow designed to attract upstream migrating adult Fall-Run Chinook Salmon. HORB will be closed approximately 50% during the time immediately before and after the SJR pulse and that it will be fully closed during the pulse unless new information suggests alternative operations are better for fish. • January: When salmon fry are migrating, (determined based on real time monitoring), initial operating criterion will be to close the gate subject to RTO for purposes of water quality, stage, and flood control considerations. • February–June 15th: Initial operating criterion will be to close the gate subject to RTO for purposes of water quality, stage, and flood control considerations. The agencies will actively explore the implementation of reliable juvenile salmonid tracking technology which may enable shifting to a more flexible real time operating criterion based on the presence/absence of covered fishes. • June 16 to September 30, December: Operable gates will be open.	• Assumed 50% open from January 1 to June 15, and during days in October prior to the D-1641 San Joaquin River pulse. Closed during the pulse. 100% open in the remaining months.
Spring outflow	• March, April, May: To ensure maintenance of longfin smelt abundance, initial operations will provide a March–May average Delta outflow bounded by the requirements of Scenario H3, which are consistent with D-1641 standards, and Scenario H4, which would be scaled to Table 3-24 in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS. Over the course of the 2081(b) permit term the longfin smelt indices of annual recruitment based upon the 1980–2011 trend in recruitment relative to winter-spring flow conditions will be used to evaluate the effect of operations on longfin smelt (i.e., evaluate positive cohort over cohort population growth). Adjustments to the criteria above and these outflow targets may be made using the Adaptive Management Process and the best available scientific information available regarding all factors affecting longfin smelt abundance.[17]	• Same as CM1 criteria, assuming outflow from export reductions first, then Oroville releases
Rio Vista minimum flow standard	• January through August: flows will exceed 3,000 cfs • September through December: flows per D-1641	• Same as CM1 criteria
Key Existing Criteria Included in Modeling		
Fall outflow	• September, October, November implement the USFWS (2008) BiOp Fall X2 requirements. However, similar to spring Delta outflow and consistent with the existing RPA adaptive management process, adjustments to these outflow targets may be made using the Adaptive Management and Monitoring Program described below and the best available scientific information available regarding all factors affecting delta smelt abundance.	• Same as CM1 criteria.

[17] For example, if best available science resulting from collaborative scientific research program shows that Longfin Smelt abundance can be maintained in the absence of spring outflow, and DFW concurs, an alternative operation for spring outflow could be to follow flow constraints established under D-1641.

Parameter	Criteria	Summary of CALSIM Modeling[a]
Winter and summer outflow	• Flow constraints established under D-1641 will be followed if not superseded by criteria listed above.	• Same as CM1 criteria.
Delta Cross Channel Gates	• Operations as required by NMFS (2009) BiOp Action 4.1 and D-1641.	• Delta Cross Channel gates are closed for a certain number of days during October 1 through December 14 based on the Wilkins Slough flow, and the gates may be opened if the D-1641 Rock Slough salinity standard is violated because of the gate closure. Delta Cross Channel gates are assumed to be closed during December 15 through January 31. February 1 through June 15, Delta Cross Channel gates are operated based on D-1641 requirements.
Suisun Marsh Salinity Control Gates	• Gates would continue to be closed up to 20 days per year from October through May.	Not modeled in CALSIM II; only in DSM2.
Export to inflow ratio	• Operation criteria are the same as defined under D-1641. • The D-1641 export/inflow (E/I) ratio calculation was designed to protect fish from south Delta entrainment. For Alternative 4A, Reclamation and DWR propose that the North Delta Diversion (NDD) does not affect either Delta inflows or exports as they relate to the E/I ratio calculation. In other words, Sacramento River inflow is defined as flows downstream of the NDD and only south Delta exports are included for the export component of the criteria.	• Combined export rate is defined as the diversion rate of the Banks Pumping Plant and Jones Pumping Plant from the south Delta channels. • Delta inflow is defined as the sum of the Sacramento River flow downstream of the proposed north Delta diversion intakes, Yolo Bypass flow, Mokelumne River flow, Cosumnes River flow, Calaveras River flow, San Joaquin River flow at Vernalis, and other miscellaneous in-Delta flows.

[a] See Table C.A-1, CALSIM II Modeling Assumptions for Existing Conditions (EBC1), No Action Alternative (EBC2) and BDCP Operational Scenarios, in Section B.3.4, *Alternative 4 Decision Tree Scenarios H1, H2, H3 and H4*, in Appendix 5A, *Modeling Technical Appendix*, of the Draft EIR/EIS.

Application of Flow Criteria

Flow criteria are applied seasonally (month by month) and according to the following five water-year types. Under the observed hydrologic conditions over the 82-year period (1922–2003), the number of years of each water-year type is included below. The water-year type classification for the majority of the criteria mentioned here, unless noted differently, is based on the Sacramento Valley 40-30-30 Water Year Index defined under D-1641.

- Wet water year: the wettest 26 years of the 82-year hydrologic data record, or 32% of years.
- Above-normal water year: 12 years of 82, or 15%.
- Below-normal water year: 14 years of 82, or 17%.
- Dry water year: 18 years of 82, or 22%.
- Critical water year: 12 years of 82, or 15%.

Water operations under Alternative 4A are then constrained as shown in Table 4.1-2.

Proposed New Flow Criteria for North Delta SWP and CVP Export Facilities

Diversions from the north would be greatest in wetter years and lowest in drier years, when south Delta diversions would provide the majority of the CVP and SWP south of Delta exports. In order to avoid impacts to listed species, north Delta bypass flow requirements were developed in coordination with the fisheries agencies, and are described below. Additionally, Alternative 4A operations include a preference for south Delta pumping in July through September to avoid water quality degradation in the south Delta.

The objectives of the north Delta diversion bypass flow criteria include regulation of flows to 1) maintain fish screen sweeping velocities; 2) reduce upstream transport from downstream channels in the channels downstream of the intakes; 3) support salmonid and pelagic fish transport and migration to regions of suitable habitat; 4) reduce losses to predation downstream of the diversions; and 5) maintain or improve rearing habitat conditions in the north Delta.

To ensure that these objectives are met, diversions must be restricted at certain times of the year (mostly from December through June) when juvenile covered fish species are present. This is achieved by restricting the diversion to low level pumping (diversion of 6% of Sacramento River flow measured upstream of the intakes up to 900 cfs [300 cfs per intake]) when the juvenile fish begin their outmigration, which generally coincides with seasonal high flows triggered by fall/winter rains (called *pulse flows*); followed by a ramping up of diversion rates, while ensuring flows are adequate to be protective of aquatic species, during the remainder of the outmigration (called *post-pulse operations*). The protections allowed during these pulses are intended to achieve safe juvenile passage past the intakes to well downstream of lower Delta channels that might otherwise lead them away from their primary migration route. Additional but less restrictive requirements apply for the late spring to late fall period.

The initial pulse of juvenile fish migration is a natural occurrence caused by the first substantial runoff event of the season. This can occur as early as October or as late as February, but usually happens in December or January. During the initial pulse, flows will be minimally diminished, with diversions limited to low-level pumping to the extent allowed. If the initial pulse occurs prior to Dec 1, then an assessment will be made to decide if equivalent protection is required in the event a second pulse occurs. A flow condition will be categorized as an initial pulse based on real-time monitoring of flow at Wilkins Slough and juvenile fish movement.

At the end of the initial pulse phase, post-pulse operations will apply, with potential adjustments made based on real-time operations as described in Table 4.1-2. The conditions that trigger the transition from the initial pulse protection to post-pulse operations are described in Chapter 3 of the Draft EIR/EIS, along with bypass operating rules for the post-pulse phase, which provide maximum allowable levels of diversion for a given Sacramento River inflow measured upstream of the intakes. Additionally, as described in Table 4.1-2, there will be biologically-based triggers to allow for transitioning between and among the different diversion levels.

In July through September, the bypass rules are less restrictive, allowing for a greater proportion of the Sacramento River to be diverted, as described in Table 4.1-2. In October through November the bypass amount is increased from 5,000 cfs to 7,000 cfs, allowing a smaller proportion of the Sacramento River to be diverted.

Proposed New Flow Criteria for CVP and SWP South Delta Export Facilities

The objectives of the south Delta flow criteria are to minimize take at south Delta pumps by reducing incidence and magnitude of reverse flows during critical periods for fish species. The south Delta channel flow criteria are based on the parameters for Old and Middle River (OMR) flows as summarized below, and Head of Old River Barrier operations. Additionally, Alternative 4A operations include a preference for south Delta pumping in July through September to provide limited flushing flows to avoid water quality degradation in the south Delta.

OMR Flows

The OMR flow criteria chiefly serve to constrain the magnitude of reverse flows in the Old and Middle Rivers for entrainment protection and minimization of adverse indirect effects. The criteria are derived from fish protection triggers described in the USFWS (2008) and NMFS (2009) BiOps RPA Actions, and are described in Table 4.1-2. The proposed OMR flow criteria are used to constrain the south Delta exports, if the OMR flow requirements under current BiOps are not as constraining as the proposed criteria. These newly proposed OMR criteria (and associated Head of Old River Barrier operations) are in response to expected facility changes under the proposed project, and only applicable after the proposed north Delta diversion becomes operational.

In April, May, and June, OMR minimum allowable values would be based upon the San Joaquin River inflow relationship to OMR (Table 4.1-2). In October and November, OMR and south Delta export restrictions are based upon State Water Board D-1641 pulse trigger, as follows.[18]

- Two weeks before State Water Board D-1641 pulse trigger: no OMR restrictions.
- During State Water Board D-1641 pulse trigger: no south Delta exports.
- Two weeks following State Water Board D-1641 pulse trigger: OMR operated to be no more negative than -5,000 cfs through November.

[18] For the purposes of modeling, it was assumed that the D-1641 pulse in San Joaquin River occurs in the last 2 weeks of October.

Additionally, new criteria based on the water year type in December through March would be implemented as described in detail in Table 4.1-2. The new criteria generally provide more positive OMR flows under the wetter years compared to the requirements under the current BiOps.

Operations of the New Head of Old River Operable Barrier

Operations for the Head of Old River gate would be managed as follows.

- **October 1 – November 30**: Real Time Operation (RTO) management and HORB will be closed in order to protect the D-1641 pulse flow designed to attract upstream migrating adults.
- **January**: When salmon fry are migrating (determined based on real time monitoring), initial operating criterion will be to close the gate subject to RTO for purposes of water quality, stage, and flood control considerations.
- **February – June 15**: The gate will be closed, but subject to RTO for purposes of water quality, stage, and flood control considerations. The agencies will actively explore the implementation of reliable juvenile salmonid tracking technology which may enable shifting to a more flexible real time operating criterion based on the presence/absence of covered fishes.
- **June 16 to September 30, December**: Operable gates will be open.

Real-Time Operational Decision-Making Process

RTO Team decisions are expected to be needed during at least some part of the year at the Head of Old River gate and the north and south Delta diversion facilities. The RTO Team in making operational decisions that depart from the criteria used in the modeling will take into account upstream operational constraints, such as coldwater pool management, instream flow, and temperature requirements. The extent to which real time adjustments that may be made to each parameter related to these facilities shall be limited by the criteria and/or ranges is set out in Table 4.1-2. Any modifications to the parameters subject to real time operational adjustments or to the criteria and/or ranges set out in Table 4.1-2 shall occur only through the adaptive management, as discussed below.

Head of Old River gate. Operations for the Head of Old River gate would be managed under RTOs as set forth in Table 4.1-2.

North Delta diversions. North Delta bypass flows will be managed according to the criteria described in Table 4.1-2. Additional biologically-based triggers for adjustments between and among Levels I, II, and III, are under development through the ESA consultation process.

South Delta diversions. The south Delta diversions will be managed under RTO to achieve OMR criteria, throughout the year based on fish protection triggers (e.g., salvage density, calendar, species distribution, entrainment risk, turbidity, and flow based triggers). Increased restrictions as well as relaxations of the OMR criteria may occur as a result of observed physical and biological information. Additionally, as described above for the north Delta diversions, RTO would also be managed to distribute pumping activities amongst the three north Delta and two south Delta intake facilities to maximize both survival of covered fish species in the Delta and water supply.

Timing for Implementation of Operations

Implementation of Alternative 4A will include operations of both new and existing water conveyance facilities as described above and in Table 4.1-2, once the new north Delta facilities are constructed and become operational, thereby enabling joint operations of north and south Delta diversions. Until that time, operations will be governed by existing and applicable requirements and standards included in the NMFS (2009) and USFWS (2008) BiOps and D-1641, as may be amended, and any other regulatory and contractual obligations.

4.1.2.3 Environmental Commitments

To achieve the applicable regulatory standards under ESA Section 7 and CESA Section 2081(b) while also complying with NEPA and CEQA, a subset of those activities proposed in the conservation strategy for the Draft BDCP would be implemented under Alternative 4A. Specifically, portions of the actions proposed under CM3, CM4, CM6, CM7, CM8, CM9, CM10, CM11, CM12, CM15, and CM16 would be included in Alternative 4A. As preserved within Alternative 4A, however, these activities are no longer "conservation measures." The reason for not using this familiar term is to avoid creating confusion regarding the rationale for retaining these activities within Alternative 4A. The term "conservation measure" is often used in the context of Habitat Conservation Plans under Section 10(a)(2) of the ESA and Natural Community Conservation Plans under the NCCPA.

Alternative 4A contemplates ESA compliance through Section 7 of the ESA and Section 2081 of CESA, rather than through ESA Section 10 and NCCPA Section 2835. As such, different terminology has been adopted to reflect the difference in permitting strategies under state and federal endangered species laws. These repackaged and limited elements of the original BDCP Conservation Measures are instead referred to as "Environmental Commitments" (ECs). As noted, these Environmental Commitments are actions primarily intended to satisfy CEQA, CESA Section 2081, and ESA Section 7. To minimize confusion, they are numbered to track the parallel BDCP Conservation Measures: Environmental Commitments 3, 4, 6, 7, 8, 9, 10, 11, 12, 15, and 16, as summarized in Table 4.1-3. A summary of these commitments is presented below and consists primarily of habitat restoration, protection, enhancement, and management activities necessary to mitigate for adverse effects from construction of the proposed water conveyance facilities, along with species-specific resource restoration and protection principles to ensure that implementation of these commitments would achieve the intended mitigation of impacts (for a list of these standards, along with species-specific mitigation needs, see Table 4.1-8).[19] Where impact statements or mitigation measures refer to Conservation Measures, these statements have been changed in the analysis for Alternative 4A to refer instead to the parallel Environmental Commitments. Additionally, pertinent elements included as Avoidance and Minimization Measures (AMMs) and the proposed Adaptive Management and Monitoring Program would be implemented as applicable to the activities proposed under Alternative 4A.[20] These, too, would serve a mitigation function under CEQA. All of these components would function as *de facto* CEQA and NEPA mitigation measures for the construction and operations-related impacts of Alternative 4A. Details regarding the implementation of these activities under Alternative 4A are provided below and in Table 4.1-3.

---

[19] While these are distinct from the environmental commitments described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS (as modified in this RDEIR/SDEIS, as shown in Appendix A hereto), both sets of commitments would apply to implementation of Alternative 4A.

[20] Specifically, AMMs 1–7, 10, 12–15, 18, 20–25, 30, and 37 would be carried forward under implementation of this alternative.

The RDEIR/SDEIS describes and analyzes Environmental Commitments 3, 4, 6–12, 15, and 16 at a level of detail consistent with that applied to these activities under other alternatives in the Draft EIR/EIS. (See CEQA Guidelines, § 15126.4[a][1][D] [EIRs must discuss significant effects of mitigation measures, "but in less detail than the significant effects of the project as proposed"]; see also *California Native Plant Society v. City of Rancho Cordova* (2009) 172 Cal.App.4th 603, 621-625 [lead agency did not violate CEQA by failing to identify the off-site location at which mitigation for impacts to on-site wetlands would be carried out].) Specific locations for implementing many of the activities associated with these commitments have not been identified at this time. Therefore, the analyses consider typical construction, operation, and maintenance activities that would be undertaken for implementation of the habitat restoration and enhancement and stressor reduction efforts. Where appropriate and necessary, implementation of individual projects associated with an environmental commitment would be subject to additional environmental review. (See CEQA Guidelines, §§ 15162–15164; 40 C.F.R. § 1502.9[c].)

Note that many of the actions that are part of the BDCP conservation strategy but not proposed to be implemented under Alternative 4A would continue to be pursued as part of existing but separate projects and programs associated with (1) the 2008 and 2009 USFWS and NMFS BiOps (e.g., Yolo Bypass improvements and habitat enhancements, 8,000 acres of tidal habitat restoration), (2) California EcoRestore, and (3) the 2014 California Water Action Plan. Those actions are separate from, and independent of, Alternative 4A. Therefore, for the purposes of Alternative 4A, these elements (and their associated environmental effects) are considered either as part of the No Action Alternative, as described in Section 4.2, *Impacts of No Action Alternative Early Long-Term*, or as part of the cumulative impact analysis, as described in Section 5, *Revisions to Cumulative Impact Analyses*, of this RDEIR/SDEIS.

Table 4.1-3. Environmental Commitments under Alternative 4A

Environmental Commitment 3: Natural Communities Protection and Restoration	
Valley/Foothill Riparian	103 acres
Grassland	1,060 acres
Vernal Pool Complex and Alkali Seasonal Wetland Complex	150 acres
Nontidal Marsh	119 acres
Cultivated Lands	11,870 acres
Total:	**Up to 13,302 acres**
Environmental Commitment 4: Tidal Natural Communities Restoration	Up to 59 acres
Environmental Commitment 6: Channel Margin Enhancement	Up to 4.6 levee miles
Environmental Commitment 7: Riparian Natural Community Restoration	Up to 251 acres
Environmental Commitment 8: Grassland Natural Community	Up to 1,070 acres
Environmental Commitment 9: Vernal Pool and Alkali Seasonal Wetland Complex Restoration	Up to 34 acres
Environmental Commitment 10: Nontidal Marsh Restoration	Up to 832 acres
Environmental Commitment 11: Natural Communities Enhancement and Management	At sites protected or restored under Environmental Commitments 3–10
Environmental Commitment 12: Methylmercury Management	At sites restored under Environmental Commitment 4
Environmental Commitment 15: Localized Reduction of Predatory Fishes	At north Delta intakes and at Clifton Court Forebay
Environmental Commitment 16: Nonphysical Fish Barrier	At Georgiana Slough

Environmental Commitment 3: Natural Communities Protection and Restoration

This action would consist of the acquisition of lands for protection and restoration of listed species habitat in perpetuity and would be implemented in the same way as described in Conservation Measure 3 in the Draft BDCP but over less area. For the purposes of Alternative 4A, this action would entail protection of approximately 13,302 acres, of natural communities and cultivated land, as shown in Table 4.1-3. This protection and restoration would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 4: Tidal Natural Communities Restoration

This action would consist of the restoration of tidal natural communities and transitional uplands and would be implemented in the same way as described in Conservation Measure 4 in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS, but over less area. For the purposes of analysis of Alternative 4A, this action would entail restoration of up to 59 acres (including transitional uplands), as shown in Table 4.1-3. This analysis assumes that none of these 59 acres of tidal restoration will be done in the Suisun Marsh area. Tidal habitat restoration would mitigate for the physical loss of aquatic habitat associated with construction of the north Delta intake facilities. The current proposed mitigation acreage is anticipated to be 59 acres. However, actual acreage may change based on further discussions with NMFS, USFWS, and DFW pertaining to the actual value of the current habitat and/or the appropriate ratio of mitigation or based on footprint changes. Based on initial discussions, the maximum ratio applied to tidal wetland mitigation is 3:1, and therefore would not exceed 177 acres for this alternative.

Environmental Commitment 6: Channel Margin Enhancement

This action would consist of the enhancement of channel margin habitat and would be implemented in the same way as described in Conservation Measure 6 in the Draft BDCP but over less linear distance. For the purposes of Alternative 4A, this action would entail enhancement of approximately 4.6 levee miles, as shown in Table 4.1-3. This would mitigate for the loss of salmonid habitat associated with construction and operations of the north Delta intake facilities.

Environmental Commitment 7: Riparian Natural Community Restoration

This action would consist of the restoration of riparian natural communities and would be implemented in the same way as described in Conservation Measure 7 in the Draft BDCP but over less area. For the purposes of Alternative 4A, this action would entail restoration of approximately 251 acres, as shown in Table 4.1-3. This would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 8: Grassland Natural Community

This action would consist of the restoration of grassland habitat and would be implemented in the same way as described in Conservation Measure 8 in the Draft BDCP but over less area. For the purposes of Alternative 4A, this action would entail restoration of approximately 1,070 acres as shown in Table 4.1-3. This would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 9: Vernal Pool and Alkali Seasonal Wetland Complex Restoration

This action would consist of the restoration of vernal pool and alkali seasonal wetland complex and would be implemented in the same way as described in Conservation Measure 9 in the Draft BDCP but over less area. For the purposes of Alternative 4A, this action would entail restoration of approximately 34 total acres of vernal pool complex and/or alkali seasonal wetland complex, as shown in Table 4.1-3. This would mitigate for the loss of species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 10: Nontidal Marsh Restoration

This action would consist of the restoration of nontidal marsh and would be implemented in the same way as described in Conservation Measure 10 in the Draft BDCP but over less area. For the purposes of Alternative 4A, this action would entail restoration of approximately 832 acres of nontidal marsh, as shown in Table 4.1-3. This would mitigate for the loss of species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 11: Natural Communities Enhancement and Management

This action would apply to all protected and restored habitats under Alternative 4A and would be implemented, where applicable, to manage and enhance these lands consistent with the approach described under Conservation Measure 11 in the Draft BDCP. These actions would support mitigation for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 12: Methylmercury Management

This action would minimize conditions that promote production of methylmercury in restored tidal wetland areas and its subsequent introduction to the foodweb, and to listed species in particular. Implementation of this action would be consistent with the revised description of Conservation Measure 12 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). The portions of the measure applicable to effects in the Yolo Bypass would not apply because Yolo Bypass improvements would not be implemented as part of this alternative.

Environmental Commitment 15: Localized Reduction of Predatory Fishes (Predator Control)

This action would reduce populations of predatory fishes at locations of high predation risk (i.e., predation hotspots) associated with construction and operation of the proposed water conveyance facilities. Implementation of this action would be consistent with the revised description of Conservation Measure 15 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS); however, for the purposes of Alternative 4A, this action would be applied only to the reach of the Sacramento River adjacent to the north Delta intakes and to Clifton Court Forebay. EC15 would remove predator refuge habitat and reduce predator abundance in the construction areas. At a minimum, EC15 will target the removal of an amount of predator refuge commensurate with the amount that may be created by construction of water conveyance facilities. These measures are expected to fully mitigate any indirect effect on predation rates associated with construction and operations.

Environmental Commitment 16: Nonphysical Fish Barrier

This action would be implemented to address effects related to survival of outmigrating juvenile salmonids by installing a nonphysical barrier at Georgiana Slough to redirect fish away from channels and river reaches in which survival is lower than in alternate routes. Implementation of this action would be consistent with the revised description of Conservation Measure 16 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS); however, for the purposes of Alternative 4A, this action would be applied only to Georgiana Slough. This commitment would mitigate for effects on salmonid survival associated with operation of north Delta intakes and associated flows.

Avoidance and Minimization Measures

AMMs 1–7, 10–18, 20–25, 27, 30, and 37–39 would apply to all construction activities under Alternative 4A and would be implemented, where applicable, to avoid and minimize impacts on listed species, consistent with the approach described in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and in Appendix D, *Substantive BDCP Revisions,* of this RDEIR/SDEIS. These actions would minimize the risk of impacts on species resulting from construction activities.

4.1.2.4 Collaborative Science and Adaptive Management Program

Considerable scientific uncertainty exists regarding the Delta ecosystem, including the effects of CVP and SWP operations and the related operational criteria. To address this uncertainty, DWR, Reclamation, DFW, USFWS, NMFS, and the public water agencies will establish a robust program of collaborative science, monitoring, and adaptive management. For the purposes of analysis, it is assumed that the Collaborative Science and Adaptive Management Program (AMMP) developed for Alternative 4A would not, by itself, create nor contribute to any new significant environmental effects; instead, the AMMP would influence the operation and management of facilities and protected or restored habitat associated with Alternative 4A.

Collaborative science and adaptive management will support the proposed project by helping to address scientific uncertainty where it exists, and as it relates to the benefits and impacts of the construction and operations of the new water conveyance facility and existing CVP and SWP facilities. Specifically, collaborative science and adaptive management will, as appropriate, develop and use new information and insight gained during the course of project construction and operation to inform and improve:

- the design of fish facilities including the intake fish screens;
- the operation of the water conveyance facilities under the Section 7 biological opinion and 2081b permit; and
- habitat restoration and other mitigation measures conducted under the biological opinions and 2081b permits.

In summary, the broad purposes of the program will be to: 1) undertake collaborative science, 2) guide the development and implementation of scientific investigations and monitoring for both permit compliance and adaptive management, and 3) apply new information and insights to management decisions and actions. Each purpose is further described below.

Collaborative Science

The program will provide guidance and recommendations on relevant science related to the operations of the CVP and SWP within the Delta to inform implementation of the existing BiOps for the coordinated operations of the SWP and CVP and the 2081b permit for the SWP facilities and operations, as well as for the new biological opinion and 2081b for this proposed project. The collaborative science effort will build on the progress being made by the existing Collaborative Science and Adaptive Management Program (CSAMP) that was established to make recommendations on the science needed to inform implementation of or potential changes to the existing BiOps for the SWP and CVP operations, and proposed alternative management actions. The CSAMP process and its Collaborative Adaptive Management Team (CAMT) rely on the Delta Science Program to provide independent peer review of both science proposals and products.

Results from the collaborative science produced under the program would inform policy makers from the agencies implementing or overseeing the proposed project. These policy makers would determine whether and how to act on the information within the regulatory contexts of the biological opinions, 2081b permits, and other relevant authorizations (e.g., Corps permits, State Board authorizations).

Monitoring

Monitoring is a critical element of the adaptive management program and a required component of ESA Section 7 biological opinions and CESA 2081b permits. In addition, monitoring is a critical element of the collaborative science process that informs adaptive management decision-making. The proposed compliance and effectiveness monitoring program for the CESA 2081b permit is described in Chapter 6 of that permit application. These monitoring programs overlap but have distinct elements owing to their overlapping but distinct species lists. Collaborative science for the proposed project will have the following primary functions:

- lead active evaluation through studies, monitoring, and testing of current and new hypotheses associated with key water operating parameters, habitat restoration, and other mitigation;
- gather and synthesize relevant scientific information;
- develop new modeling or predictive tools to improve water management in the Delta; and
- inform the testing and evaluation of alternative operational strategies and other management actions to improve performance from both biological and water supply perspectives.

Monitoring is essential to carry out this collaborative science process.

Management Recommendations, Decisions, and Actions

The collaborative science effort is expected to inform operational decisions within the ranges established by the biological opinion and 2081b permit for the proposed project. However, if new science suggests that operational changes may be appropriate that fall outside of the operational ranges evaluated in the biological opinion and authorized by the 2081b permit, the appropriate agencies will determine, within their respective authorities, whether those changes should be implemented. An analysis of the biological effects of any such changes will be conducted to determine if those effects fall within the range of effects analyzed and authorized under the biological opinion and 2081b permit. If NMFS, USFWS, or DFW determine that impacts to listed species are greater than those analyzed and authorized under the biological opinion and 2081b permit, consultation may need to be reinitiated and/or the permittees may need to seek a 2081b permit amendment. Likewise, if an analysis shows that impacts to water supply are greater than those analyzed in the EIR/EIS, it may be necessary to complete additional environmental review to comply with CEQA or NEPA.

The collaborative science process will also inform the design and construction of the fish screens on the new intakes. This requires active study to maximize water supply, ensure flexibility in their design and operation, and minimize effects to covered species. The collaborative science process will similarly inform adaptive management of habitat restoration and other mitigation measures required by the existing and new biological opinions and 2081b permit.

Structure of Collaborative Science

As mentioned above, the collaborative science elements of the program will build on the experience gained in the CSAMP process. CSAMP employs a two-tiered organizational structure comprised of: 1) a Policy Group made up of agency directors and top-level executives from participating entities, and 2) the CAMT, including designated managers and scientists to serve as a working group functioning under the direction of the Policy Group. Collaborative science for the proposed project is expected to follow a similar model in which management decisions are made by the appropriate agencies within their authorities (see *Management Recommendations, Decisions, and Actions* section above) and collaborative science is undertaken by managers and scientists from participating entities, and other stakeholders as will be described in the Memorandum of Agreement (MOA, see below). In keeping with the existing CSAMP model, future members of the collaborative science process will have expertise or technical skills that would enable them to contribute to the tasks outlined above. Membership from each group will be limited to maintain the effectiveness of the group. Other senior scientists may be invited to participate by mutual consent. If useful, the group could form technical subgroups or use existing subgroups to inform its work. Decisions about what science to pursue would be made by consensus. The group will integrate the work of relevant existing groups and processes (e.g., Delta Science Program and Interagency Ecological Program) to avoid duplicating work.

Funding for Collaborative Science

Collaborative science and monitoring conducted to support the proposed project will be implemented, when feasible, using existing resources from state, federal, and other programs, and the mitigation program of the water conveyance facility. The mitigation program of the water conveyance facility has money dedicated to the monitoring necessary to support effective implementation of mitigation actions.

Proponents of the collaborative science and monitoring program will agree to provide or seek additional funding when existing resources are insufficient to complete the goals and tasks outlined above. The budget for collaborative science will be based on annual workplans that establish approved costs, identify funding sources, and serve as the basis for tracking actual performance. Contracting mechanisms would be developed to facilitate delivery of funding to meet short-term and long-term needs of the collaborative science program to the maximum extent possible while maintaining compliance with applicable contracting laws and regulations. In addition, the parties above will ensure the availability of funding for monitoring and other requirements defined in the biological opinion and 2081b permit.

Memorandum of Agreement

Commitments to adaptive management and collaborative science will be secured through a MOA between DWR, Reclamation, the public water agencies, DFW, NMFS, and USFWS. Details of the collaborative science and adaptive management process, including adaptive management decision-making, an organizational structure for adaptive management decisions, and funding for collaborative science will be developed through the MOA, as needed.

Scientific Basis for Adaptive Management

Adaptive management is a systematic process to continually improve management policies and practices by learning from our actions (Holling 1978; Walters 1986). It requires well-articulated management objectives to guide decisions about what science to try, and explicit assumptions about expected outcomes to compare against actual outcomes (Williams et al. 2009). Adaptive management uses a process to clearly articulate objectives, identify management alternatives, predict management consequences, recognize key uncertainties in advance, and monitor and evaluate outcomes. This structured and systematic process is what differentiates adaptive management from a trial and error approach (National Research Council 2004a; Williams 2011a). Learning, facilitated through deliberate design and testing, is an integral component of adaptive management (Williams et al. 2009; Allen et al. 2011; Williams 2011a).

Adaptive management is a particularly useful framework in the face of scientific uncertainty. The principles of adaptive management lend themselves to water management and ecological restoration in the Bay-Delta (CALFED Bay-Delta Program 2000; Reed et al. 2007, 2010; Healey 2008; Dahm et al. 2009; National Research Council 2011; Parker et al. 2011, 2012; Delta Stewardship Council 2013). In particular, a National Research Council (2011) panel found that despite the challenges, there often is no better option for implementing water management regimes. The adaptive management program for the proposed project will be designed and implemented with these principals and scientific guidance in mind.

4.1.3 Description of Alternative 2D

This section provides description of the components and operation of water conveyance facilities, ESA and CESA compliance process, and environmental commitments that will be implemented under Alternative 2D. Table 4.4-4 below, provides a brief summary comparison of these elements between Alternatives 4A, 2A, and 2D.

4.1.3.1 Water Conveyance Facility Construction and Maintenance

Under Alternative 2D, water conveyance facilities would be constructed and maintained similarly to those proposed and analyzed under Alternative 4 (including the modifications described in Section 3, *Conveyance Facility Modifications to Alternative 4,* of this RDEIS/SDEIS); however, this alternative would entail five intakes in the same locations as those under Alternative 2A (as shown in Figure 3-2 of the Draft EIR/EIS), rather than three. Water would primarily be conveyed from the north Delta to the south Delta through pipelines and tunnels. Water would be diverted from the Sacramento River through five fish-screened intakes on the east bank of the Sacramento River between Freeport and Courtland (Intakes 1–5) and would be conveyed to a sedimentation basin before reaching the tunnels. From the intakes, water would flow into an initial single-bore tunnel, which would lead to an intermediate forebay on Glannvale Tract. From the southern end of this forebay, water would pass through an outlet structure into a dual-bore tunnel where it would flow by gravity to the south Delta. Water would then reach pumping plants northeast of the Clifton Court Forebay, where it would be pumped from the tunnels into the north cell of the expanded Clifton Court Forebay. The forebay would be dredged and redesigned to provide an area that would isolate water flowing from the new north Delta facilities from water diverted from south Delta channels.

Table 4.1-4. Comparison of Alternatives 4, 2A, and 2D

Element of Project Description	Alternative 4 (BDCP)	Alternative 2A	Alternative 2D
ESA Compliance	Section 10 (DWR)/Section 7 (Reclamation)	Section 10 (DWR)/Section 7 (Reclamation)	Section 7
California Endangered Species law Compliance	NCCPA	NCCPA	2081(b) permit
Facilities	Modified Pipeline/Tunnel Alignment: 3 intakes, 9,000 cfs	Pipeline/Tunnel Alignment: 5 intakes, 15,000 cfs	Modified Pipeline/Tunnel Alignment: 5 intakes, 15,000 cfs
Operations	Dual Conveyance; Operational Scenarios H1–H4 with Decision Tree (see Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS); evaluated at LLT	Dual Conveyance; Operational Scenario B (see Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS); evaluated at LLT	Dual Conveyance; Operational Scenario B without Fremont Weir modifications; evaluated at ELT
Conservation Measures/ Environmental Commitments	Conservation Measures 2–21; includes Yolo Bypass Improvements and 65,000 acres of tidal wetland restoration	Conservation Measures 2–21; includes Yolo Bypass Improvements and 65,000 acres of tidal wetland restoration	Environmental Commitments 3, 4, 6, 7, 8, 9, 10, 11, 12, 15, 16; includes up to 65 acres of tidal wetland restoration
CEQA Baseline	Existing Conditions	Existing Conditions	Existing Conditions
NEPA Baseline	No Action Alternative at LLT	No Action Alternative at LLT	No Action Alternative at ELT

A map and a schematic diagram depicting the conveyance facilities associated with the modified pipeline/tunnel alignment are provided in Mapbook Figure M3-4 in the Mapbook Volume and Figure 3-10 in Appendix A of this RDEIR/SDEIS (note, however, that these figures depict three intake locations, rather than five; all five intake locations for Alternative 2D are shown in Figure 3-2 of the Draft EIR/EIS). Each additional intake site would also require associated ancillary facilities and features, including box conduits under a widened and raised levee section, a relocated segment of State Route (SR) 160, sedimentation basins, drying lagoons, an outlet shaft, and an elevated pad hosting an electrical substation, an electrical building, and other storage buildings. During construction it is assumed that a temporary work area would surround each permanent intake site and would include a fuel station and concrete batch plant. Construction of Intake 1 would also require an additional segment of single-bore tunnel (connecting Intakes 1 and 2), as well as an expanded reusable tunnel material (RTM) area to accommodate the material associated with this tunnel. Similarly, an extension of the proposed temporary 69kV power line would be required to connect to Intake 1 during construction.

As proposed for Alternative 4, a new pumping facility would be constructed northeast of the north cell of the expanded Clifton Court Forebay, along with control structures to regulate the relative quantities of water flowing from the north Delta and the south Delta to the Banks and Jones Pumping Plants. Alternative 2D would entail the continued use of the SWP/CVP south Delta export facilities.

All other aspects of water conveyance facility design, construction, and maintenance would be similar to those described for Alternative 4 in the revised text in Chapter 3, Sections 3.4, 3.5.9, and 3.6.1 and Appendix 3C, as provided in Appendix A, *Revisions to the Draft EIR/EIS*, of this RDEIR/SDEIS.

4.1.3.2 Water Conveyance Facility Operations

Operational components of the water conveyance facilities under Alternative 2D would be similar, but not identical, to those described under Scenario B in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS. Operational elements associated with Fremont Weir modifications would not be incorporated as part of this alternative, because Yolo Bypass improvements contemplated for Alternative 2A (under CM2 of the Draft BDCP) would not be implemented as part of Alternative 2D; instead, they would be assumed to occur as part of the No Action Alternative because they are required by the existing BiOps. For a detailed characterization of operational criteria, please refer to Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS.[21]

Implementation of Alternative 2D would include operations of both new and existing water conveyance facilities once the new north Delta facilities are completed and become operational, thereby enabling joint management of north and south Delta diversions. Operations included in this alternative for south Delta export facilities would replace the south Delta operations currently implemented in compliance with the USFWS (2008) and NMFS (2009) BiOps. The north Delta intakes and the head of Old River barrier would be new facilities for the SWP and CVP and would be operated as described in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS. The design of the HORB is not yet complete, and should design change substantially from what is assumed in this RDEIR/SDEIS, such that there is a potential for new effects, additional CEQA and/or NEPA review would be required. Compliance with all other criteria included in the USFWS (2008) and NMFS (2009) BiOps and State Water Resources Control Board Water Right Decision 1641 (D-1641), including Fall X2, the E:I ratio, and operations of the Delta Cross Channel gates and the Suisun Marsh Salinity Control Gates, will continue as part of the continued operations of the CVP and SWP. As such, when compared to operations under the No Action Alternative, Alternative 2D includes modified or new operations and criteria of only the following elements.

- North Delta intake facilities.
- South Delta export operations.
- Head of Old River barrier operations.
- Rio Vista minimum flow standard in January through August.

[21] Note that these proposed operational criteria would only take effect after the proposed conveyance facilities are operational. Until that time, operations would occur as described in the USFWS 2008 and NMFS 2009 BiOps or as modified by the outcome of ongoing ESA compliance processes pertaining to operation of the existing facilities.

Alternative 2D operations include a preference for south Delta pumping in July through September to provide limited flushing for improving general water quality conditions and reduced residence times.

Real-Time Operational Decision-Making Process

RTOs are expected to be needed during at least some part of the year at the Head of Old River gate and the north and south Delta diversion facilities. In making operational decisions, the RTO Team will take into account upstream operational constraints such as coldwater pool management, instream flow, and temperature requirements. The extent to which real time adjustments that may be made to each parameter related to these facilities shall be limited by the criteria and/or ranges is set out in Table 4.1-2 of this RDEIR/SDEIS. Any modifications to the parameters subject to real time operational adjustments or to the criteria and/or ranges set out in Table 4.1-2 shall occur only through the adaptive management.

Head of Old River gate. Operations for the Head of Old River gate would be managed under RTOs as set forth in Table 4.1-2.

North Delta diversions. Operations for North Delta bypass flows will be managed according to the criteria described in Table 4.1-2.

South Delta diversions. The south Delta diversions will be managed under RTO to achieve OMR criteria, throughout the year based on fish protection triggers (e.g., salvage density, calendar, species distribution, entrainment risk, turbidity, and flow based triggers). Increased restrictions as well as relaxations of the OMR criteria may occur as a result of observed physical and biological information. Additionally, as described above for the north Delta diversions, RTO would also be managed to distribute pumping activities amongst the five north Delta and two south Delta intake facilities to maximize both survival of covered fish species in the Delta and water supply.

Timing for Implementation of Operations

Implementation of Alternative 2D would include operations of both new and existing water conveyance facilities as described above, once the new north Delta facilities are completed and become operational, thereby enabling joint management of north and south Delta diversions. Until that time, operations will be governed by existing and applicable requirements and standards included in the NMFS (2009) and USFWS (2008) BiOps and D-1641, and any regulations that supersede those requirements.

4.1.3.3 Environmental Commitments

To achieve the applicable regulatory standards under ESA Section 7 and CESA Section 2081(b) while also complying with NEPA and CEQA, a subset of those activities proposed in Alternative 2A would be implemented under Alternative 2D. Specifically, portions of the actions proposed under CM3, CM4, CM6, CM7, CM8, CM9, CM10, CM11, CM12, CM15, and CM16 would be included in Alternative 2D.

As described in Section 4.1.2.3 for Alternative 4A, these repackaged and limited elements of the original BDCP Conservation Measures are instead referred to as "Environmental Commitments" for the purposes of Alternative 2D: Environmental Commitments 3, 4, 6, 7, 8, 9, 10, 11, 12, 15, and 16, as summarized in Table 4.1-5 of this RDEIR/SDEIS. These commitments consist primarily of habitat restoration, protection, enhancement, and management activities necessary to offset—that is, mitigate for—adverse effects from construction of the proposed water conveyance facilities, along with species-specific resource restoration and protection principles to ensure that implementation of these commitments would achieve the intended mitigation of impacts (for a list of these standards, along with species-specific mitigation needs, see Table 4.1-8 of this RDEIR/SDEIS).[22] Where impact statements or mitigation measures refer to Conservation Measures, these statements have been changed in the analysis for Alternative 2D to refer instead to the parallel Environmental Commitments. Additionally, pertinent elements included as Avoidance and Minimization Measures and the proposed Adaptive Management and Monitoring Program would be implemented as applicable to the activities proposed under Alternative 2D.[23] These, too, would serve a mitigation function under CEQA. All of these components would function as *de facto* CEQA and NEPA mitigation measures for the construction and operations-related impacts of Alternative 2D. Details regarding the implementation of these activities under Alternative 2D are provided below and in Table 4.1-5 of this RDEIR/SDEIS.

The RDEIR/SDEIS describes and analyzes Environmental Commitments 3, 4, 6, 7, 8, 9, 10, 11, 12, 15, and 16 at a level of detail consistent with that applied to these activities under other alternatives in the Draft EIR/EIS. (See CEQA Guidelines, § 15126.4[a][1][D] [EIRs must discuss significant effects of mitigation measures, "but in less detail than the significant effects of the project as proposed"]; see also *California Native Plant Society v. City of Rancho Cordova* (2009) 172 Cal.App.4th 603, 621-625 [lead agency did not violate CEQA by failing to identify the off-site location at which mitigation for impacts to on-site wetlands would be carried out].) Specific locations for implementing many of the activities associated with these commitments have not been identified at this time. Therefore, the analyses consider typical construction, operation, and maintenance activities that would be undertaken for implementation of the habitat restoration and enhancement and stressor reduction efforts. Where appropriate and necessary, implementation of individual projects associated with an environmental commitment would be subject to additional environmental review. (See CEQA Guidelines, §§ 15162–15164; 40 C.F.R. § 1502.9[c].)

Note that many of the actions formerly part of Alternative 2A but not proposed to be implemented under Alternative 2D would continue to be pursued as part of existing but separate projects and programs associated with (1) the 2008 and 2009 USFWS and NMFS BiOps (e.g., Yolo Bypass improvements, 8,000 acres of tidal habitat restoration), (2) California EcoRestore and (3) the 2014 California Water Action Plan. Those actions are separate from, and independent of, Alternative 2D. Therefore, for the purposes of Alternative 2D, these elements (and their associated environmental effects) are considered either as part of the No Action Alternative, as described in Section 4.2, *Impacts of No Action Alternative Early Long-Term*, or as part of the cumulative impact analysis, as described in Section 5, *Revisions to Cumulative Impact Analyses*, of this RDEIR/SDEIS.

[22] While these are distinct from the environmental commitments described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS, both sets of commitments would apply to implementation of Alternative 2D.
[23] Specifically, AMMs 1–7, 10, 12–15, 18, 20–25, 30, and 37 would be carried forward under implementation of this alternative.

Table 4.1-5. Environmental Commitments under Alternative 2D

Environmental Commitment 3: Natural Communities Protection and Restoration	
Valley/Foothill Riparian	122 acres
Grassland	1,089 acres
Vernal Pool Complex and Alkali Seasonal Wetland Complex	150 acres
Nontidal Marsh	187 acres
Cultivated Lands	13,410 acres
Total:	**Up to 14,958 acres**
Environmental Commitment 4: Tidal Natural Communities Restoration	Up to 65 acres
Environmental Commitment 6: Channel Margin Enhancement	Up to 5.5 levee miles
Environmental Commitment 7: Riparian Natural Community Restoration	Up to 297 acres
Environmental Commitment 8: Grassland Natural Community	Up to 1,099 acres
Environmental Commitment 9: Vernal Pool and Alkali Seasonal Wetland Complex Restoration	Up to 34 acres
Environmental Commitment 10: Nontidal Marsh Restoration	Up to 1,307 acres
Environmental Commitment 11: Natural Communities Enhancement and Management	At sites protected or restored under Environmental Commitments 3–10
Environmental Commitment 12: Methylmercury Management	At sites restored under Environmental Commitment 4
Environmental Commitment 15: Localized Reduction of Predatory Fishes	At north Delta intakes and at Clifton Court Forebay
Environmental Commitment 16: Nonphysical Fish Barrier	At Georgiana Slough

Environmental Commitment 3: Natural Communities Protection and Restoration

This action would consist of the acquisition of lands for protection and restoration of listed species habitat in perpetuity and would be implemented in the same way as described in Conservation Measure 3 in the Draft BDCP but over less area. For the purposes of Alternative 2D, this action would entail protection of approximately 14,958 acres, of natural communities and cultivated land, as shown in Table 4.1-5. This protection and restoration would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 4: Tidal Natural Communities Restoration

This action would consist of the restoration of tidal natural communities and transitional uplands and would be implemented in the same way as described in Conservation Measure 4 in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS, but over less area. For the purposes of analysis of Alternative 2D, this action would entail restoration of approximately 65 acres (including transitional uplands), as shown in Table 4.1-5. This analysis assumes that none of these 65 acres of tidal restoration will be done in the Suisun Marsh area. Tidal habitat restoration would mitigate for the physical loss of aquatic habitat associated with construction of the north Delta intake facilities. The current proposed acreage is a total of 65 acres. However, actual acreage may change based on further discussions with NMFS, USFWS, and DFW pertaining to the actual value of the current habitat and/or the appropriate ratio of mitigation or based on footprint changes. Based on initial discussions, the maximum ratio applied to tidal wetland mitigation is 3:1, and therefore would not exceed 195 acres for this alternative.

Environmental Commitment 6: Channel Margin Enhancement

This action would consist of the enhancement of channel margin habitat and would be implemented in the same way as described in Conservation Measure 6 in the Draft BDCP but over less linear distance. For the purposes of Alternative 2D, this action would entail enhancement of approximately 5.5 levee miles, as shown in Table 4.1-5. This would mitigate for the loss of salmonid habitat associated with construction of the north Delta intake facilities.

Environmental Commitment 7: Riparian Natural Community Restoration

This action would consist of the restoration of riparian natural communities and would be implemented in the same way as described in Conservation Measure 7 in the Draft BDCP but over less area. For the purposes of Alternative 2D, this action would entail restoration of approximately 297 acres, as shown in Table 4.1-5. This would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 8: Grassland Natural Community

This action would consist of the restoration of grassland habitat and would be implemented in the same way as described in Conservation Measure 8 in the Draft BDCP but over less area. For the purposes of Alternative 2D, this action would entail restoration of approximately 1,099 acres as shown in Table 4.1-5. This would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 9: Vernal Pool and Alkali Seasonal Wetland Complex Restoration

This action would consist of the restoration of vernal pool and alkali seasonal wetland complex and would be implemented in the same way as described in Conservation Measure 9 in the Draft BDCP but over less area. For the purposes of Alternative 2D, this action would entail restoration of up to 34 total acres of vernal pool complex and/or alkali seasonal wetland complex, as shown in Table 4.1-5. This would mitigate for the loss of species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 10: Nontidal Marsh Restoration

This action would consist of the restoration of nontidal marsh and would be implemented in the same way as described in Conservation Measure 10 in the Draft BDCP but over less area. For the purposes of Alternative 2D, this action would entail restoration of up to 1,307 acres of nontidal marsh, as shown in Table 4.1-5. This would mitigate for the loss of species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 11: Natural Communities Enhancement and Management

This action would apply to all protected and restored habitats under Alternative 2D and would be implemented, where applicable, to manage and enhance these lands consistent with the approach described under Conservation Measure 11 in the Draft BDCP. These actions would support mitigation for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 12: Methylmercury Management

This action would minimize conditions that promote production of methylmercury in restored tidal wetland areas and its subsequent introduction to the foodweb, and to listed species in particular. Implementation of this action would be consistent with the revised description of Conservation Measure 12 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). The portions of the measure applicable to effects in the Yolo Bypass would not apply because Yolo Bypass improvements would not be implemented as part of this alternative.

Environmental Commitment 15: Localized Reduction of Predatory Fishes (Predator Control)

This action would reduce populations of predatory fishes at locations of high predation risk (i.e., predation hotspots) associated with construction and operation of the proposed water conveyance facilities. Implementation of this action would be consistent with the revised description of Conservation Measure 15 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS); however, for the purposes of Alternative 2D, this action would be applied only to the reach of the Sacramento River adjacent to the north Delta intakes and to Clifton Court Forebay. This commitment would mitigate for effects on salmonid predation associated with operation of new conveyance facilities. There is also a potential for incidental benefits to other listed species as a result of this commitment.

Environmental Commitment 16: Nonphysical Fish Barrier

This action would be implemented to address effects related to survival of outmigrating juvenile salmonids by installing a nonphysical barrier at Georgiana Slough to redirect fish away from channels and river reaches in which survival is lower than in alternate routes. Implementation of this action would be consistent with the revised description of Conservation Measure 16 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS); however, for the purposes of Alternative 2D, this action would be applied only to Georgiana Slough. This commitment would mitigate for effects on salmonid survival associated with operation of north Delta intakes and associated flows.

Avoidance and Minimization Measures

AMMs 1–7, 10–15, 18, 20–25, 27, 30, and 37-39 would apply to all construction activities under Alternative 2D and would be implemented, where applicable, to avoid and minimize impacts on listed species, consistent with the approach described in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and in Appendix D of this RDEIR/SDEIS. These actions would minimize the risk of impacts on species resulting from construction activities.

Collaborative Science and Adaptive Management Program

Considerable scientific uncertainty exists regarding the Delta ecosystem, including the effects of CVP and SWP operations and the related operational criteria. To address this uncertainty, DWR, Reclamation, DFW, USFWS, NMFS, and the public water agencies will establish a robust program of collaborative science, monitoring, and adaptive management. For the purposes of analysis, it is assumed that the Collaborative Science and Adaptive Management Program (AMMP) developed for Alternative 2D would not, by itself, create nor contribute to any new significant environmental effects; instead, the AMMP would influence the operation and management of facilities and protected or restored habitat associated with Alternative 2D.

Collaborative science and adaptive management will support the proposed project by helping to address scientific uncertainty where it exists, and as it relates to the benefits and impacts of the construction and operations of the new water conveyance facility and existing CVP and SWP facilities. Specifically, collaborative science and adaptive management will, as appropriate, develop and use new information and insight gained during the course of project construction and operation to inform and improve:

- the design of fish facilities including the intake fish screens;
- the operation of the water conveyance facilities under the Section 7 biological opinion and 2081b permit; and
- habitat restoration and other mitigation measures conducted under the biological opinions and 2081b permits.

In summary, the broad purposes of the program will be to: 1) undertake collaborative science, 2) guide the development and implementation of scientific investigations and monitoring for both permit compliance and adaptive management, and 3) apply new information and insights to management decisions and actions. For additional information on how the AMMP would be implemented, see Section 4.1.2.4 in this RDEIR/SDEIS.

4.1.4 Description of Alternative 5A

This section provides description of the components and operation of water conveyance facilities, ESA and CESA compliance process, and environmental commitments that will be implemented under Alternative 5A. Table 4.4-6 below, provides a brief summary comparison of these elements between Alternatives 4, 5, and 5A.

4.1.4.1 Water Conveyance Facility Construction and Maintenance

Under Alternative 5A, water conveyance facilities would be constructed and maintained similarly to those proposed and analyzed under Alternative 4 (including the modifications described in Section 3, *Alternative 4: Conveyance Facility Modifications,* of this RDEIR/SDEIS); however, this alternative would entail one intake (Intake 2), rather than three. Water would be conveyed from the north Delta to the south Delta through pipelines and tunnels. Water would be diverted from the Sacramento River through one fish-screened intake on the east bank of the Sacramento River near Clarksburg (Intake 2). Water would travel from the intake to a sedimentation basin before reaching the tunnel. From the intake water would flow into an initial single-bore tunnel, which would lead to an intermediate forebay on Glannvale Tract. From the southern end of this forebay, water would pass through an outlet structure into a dual-bore tunnel where it would flow by gravity to the south Delta. Water would then reach pumping plants northeast of the Clifton Court Forebay, where it would be pumped from the tunnels into the north cell of the expanded Clifton Court Forebay. The forebay would be dredged and redesigned to provide an area that would isolate water flowing from the new north Delta facilities from water diverted from south Delta channels.

Table 4.1-6. Comparison of Alternatives 4, 5, and 5A

Element of Project Description	Alternative 4 (BDCP)	Alternative 5	Alternative 5A
ESA Compliance	Section 10 (DWR)/Section 7 (Reclamation)	Section 10 (DWR)/Section 7 (Reclamation)	Section 7
California Endangered Species law Compliance	NCCPA	NCCPA	2081(b) permit
Facilities	Modified Pipeline/Tunnel Alignment: 3 intakes, 9,000 cfs	Pipeline/Tunnel Alignment: 1 intake, 3,000 cfs	Modified Pipeline/Tunnel Alignment: 1 intake, 3,000 cfs
Operations	Dual Conveyance; Operational Scenarios H1–H4 with Decision Tree (see Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS); evaluated at LLT	Dual Conveyance; Operational Scenario C; evaluated at LLT	Dual Conveyance; Operational Scenario C without Fremont Weir modifications; evaluated at ELT
Conservation Measures/ Environmental Commitments	Conservation Measures 2–21; includes Yolo Bypass Improvements and 65,000 acres of tidal wetland restoration	Conservation Measures 2–21; includes Yolo Bypass Improvements and 65,000 acres of tidal wetland restoration	Environmental Commitments 3, 4, 6, 7, 8, 9, 10, 11, 12, 15, and 16; includes up to 55 acres of tidal wetland restoration
CEQA Baseline	Existing Conditions	Existing Conditions	Existing Conditions
NEPA Baseline	No Action Alternative at LLT	No Action Alternative at LLT	No Action Alternative at ELT

A map and a schematic diagram depicting the conveyance facilities associated with the modified pipeline/tunnel alignment are provided in Mapbook Figure M3-4 in the Mapbook Volume and Figure 3-10 in Appendix A of this RDEIR/SDEIS (note, however, that these figures depict three intake locations, rather than one). Construction of a single intake site (Intake 2) would preclude the need for ancillary facilities and features associated with Intakes 3 and 5, including box conduits under widened and raised levee sections, relocated segments of SR 160, sedimentation basins, drying lagoons, outlet shafts, and elevated pads hosting an electrical substation, an electrical building, and other storage buildings. During construction, temporary work areas, fuel stations, and concrete batch plants associated with Intakes 3 and 5 would also not be required. Similarly, Alternative 5A would not require construction of a single-bore tunnel between Intake 5 and the intermediate forebay, nor temporary 69kV power line segments connecting to substations at Intakes 3 or 5. Under Alternative 5A, an operable barrier would not be constructed at the head of Old River.

As proposed for Alternative 4, a new pumping facility would be constructed northeast of the north cell of the expanded Clifton Court Forebay, along with control structures to regulate the relative quantities of water flowing from the north Delta and the south Delta to the Banks and Jones Pumping Plants. Alternative 5A would entail the continued use of the SWP/CVP south Delta export facilities.

All other aspects of water conveyance facility design, construction, and maintenance would be similar to those described for Alternative 4 in the revised text in Chapter 3, Sections 3.4, 3.5.9, and

3.6.1 and Appendix 3C, as provided in Appendix A, *Revisions to the Draft EIR/EIS*, of this RDEIR/SDEIS.

4.1.4.2 Water Conveyance Facility Operations

Operational components of the water conveyance facilities under Alternative 5A would be similar, but not identical, to those described under Scenario C in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS. Operational elements associated with Fremont Weir modifications would not be incorporated as part of this alternative, because Yolo Bypass improvements contemplated for Alternative 5 (under CM2) would not be implemented as part of Alternative 5A; instead, they would be assumed to occur as part of the No Action Alternative because they are required by the existing BiOps. For a detailed characterization of operational criteria, please refer to Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS.[24]

Implementation of Alternative 5A would include operations of both new and existing water conveyance facilities once the new north Delta facilities are completed and become operational, thereby enabling joint management of north and south Delta diversions. The north Delta intake would be a new facility for the SWP and CVP and would be operated as described in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS. Compliance with all other criteria included in the USFWS (2008) and NMFS (2009) BiOps and State Water Resources Control Board Water Right Decision 1641 (D-1641), including Fall X2, the E:I ratio, and operations of the Delta Cross Channel gates and the Suisun Marsh Salinity Control Gates, will continue as part of the operation of the CVP and SWP. As such, when compared with operations under the No Action Alternative, Alternative 5A includes modified or new operations and criteria of only the following elements.

- North Delta intake facilities.
- Rio Vista minimum flow standard in January through August.

Alternative 5A operations include a preference for south Delta pumping in July through September to provide limited flushing for improving general water quality conditions and reduced residence times.

Real-Time Operational Decision-Making Process

RTOs are expected to be needed during at least some part of the year at the north and south Delta diversion facilities. In making operational decisions, the RTO Team will take into account upstream operational constraints, such as coldwater pool management, instream flow, and temperature requirements. The extent to which real time adjustments that may be made to each parameter related to these facilities shall be limited by the criteria and/or ranges is set out in Table 4.1-2 of this RDEIR/SDEIS. Any modifications to the parameters subject to real time operational adjustments or to the criteria and/or ranges set out in Table 4.1-2 shall occur only through the adaptive management.

North Delta diversions. Operations for North Delta bypass flows will be managed according to the criteria described in Table 4.1-2.

[24] Note that these proposed operational criteria would only take effect after the proposed conveyance facilities are operational. Until that time, operations would occur as described in the USFWS 2008 and NMFS 2009 BiOps or as modified by the outcome of ongoing ESA compliance processes pertaining to operation of the existing facilities.

South Delta diversions. The south Delta diversions will be managed under RTO to achieve OMR criteria, throughout the year based on fish protection triggers (e.g., salvage density, calendar, species distribution, entrainment risk, turbidity, and flow based triggers). Increased restrictions as well as relaxations of the OMR criteria may occur as a result of observed physical and biological information. Additionally, as described above for the north Delta diversion, RTO would also be managed to distribute pumping activities among the north Delta and two south Delta intake facilities to maximize both survival of covered fish species in the Delta and water supply.

Timing for Implementation of Operations

Implementation of Alternative 5A would include operations of both new and existing water conveyance facilities as described above, once the new north Delta facilities are completed and become operational, thereby enabling joint management of north and south Delta diversions. Until that time, operations will be governed by existing and applicable requirements and standards included in the NMFS (2009) and USFWS (2008) BiOps and D-1641, and any regulations that supersede those requirements.

4.1.4.3 Environmental Commitments

To achieve the applicable regulatory standards under ESA Section 7 and CESA Section 2081(b) while also complying with NEPA and CEQA, a subset of those activities proposed in Alternative 5 would be implemented under Alternative 5A. Specifically, portions of the actions proposed under CM3, CM4, CM6, CM7, CM8, CM9, CM10, CM11, CM12, CM15, and CM16 would be included in Alternative 5A.

As described in Section 4.1.2.3 for Alternative 4A, these repackaged and limited elements of the original BDCP Conservation Measures are instead referred to as “Environmental Commitments” for the purposes of Alternative 5A: Environmental Commitments 3, 4, 6, 7, 8, 9, 10, 11, 12, 15, and 16, as summarized in Table 4.1-7. These commitments consist primarily of habitat restoration, protection, enhancement, and management activities necessary to offset—that is, mitigate for—adverse effects from construction of the proposed water conveyance facilities, along with species-specific resource restoration and protection principles to ensure that implementation of these commitments would achieve the intended mitigation of impacts (for a list of these standards, along with species-specific mitigation needs, see Table 4.1-8).[25] Where impact statements or mitigation measures refer to Conservation Measures, these statements have been changed in the analysis for Alternative 5A to refer instead to the parallel Environmental Commitments. Additionally, pertinent elements included as Avoidance and Minimization Measures and the proposed Adaptive Management and Monitoring Program would be implemented as applicable to the activities proposed under Alternative 5A.[26] These, too, would serve a mitigation function under CEQA. All of these components would function as *de facto* CEQA and NEPA mitigation measures for the construction and operations-related impacts of Alternative 5A. Details regarding the implementation of these activities under Alternative 5A are provided below and in Table 4.1-7.

The RDEIR/SDEIS describes and analyzes Environmental Commitments 3, 4, 6, 7, 8, 9, 10, 11, 12, 15, and 16 at a level of detail consistent with that applied to these activities under other alternatives in

[25] While these are distinct from the environmental commitments described in Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS, both sets of commitments would apply to implementation of Alternative 5A.

[26] Specifically, AMMs 1–7, 10, 12–15, 18, 20–25, 30, and 37 would be carried forward under implementation of this alternative.

the Draft EIR/EIS. (See CEQA Guidelines, § 15126.4[a][1][D] [EIRs must discuss significant effects of mitigation measures, "but in less detail than the significant effects of the project as proposed"]; see also *California Native Plant Society v. City of Rancho Cordova* (2009) 172 Cal.App.4th 603, 621-625 [lead agency did not violate CEQA by failing to identify the off-site location at which mitigation for impacts to on-site wetlands would be carried out].) Specific locations for implementing many of the activities associated with these commitments have not been identified at this time. Therefore, the analyses consider typical construction, operation, and maintenance activities that would be undertaken for implementation of the habitat restoration and enhancement and stressor reduction efforts. Where appropriate and necessary, implementation of individual projects associated with an Environmental Commitment would be subject to additional environmental review. (See CEQA Guidelines, §§ 15162–15164; 40 C.F.R. § 1502.9[c].)

Note that many of the actions formerly part of Alternative 5 but not proposed to be implemented under Alternative 5A would continue to be pursued as part of existing but separate projects and programs associated with (1) the 2008 and 2009 USFWS and NMFS BiOps (e.g., Yolo Bypass improvements, 8,000 acres of tidal habitat restoration), (2) California EcoRestore and (3) the 2014 California Water Action Plan. Those actions are separate from, and independent of, Alternative 5A. Therefore, for the purposes of Alternative 5A, these elements (and their associated environmental effects) are considered either as part of the No Action Alternative, as described in Section 4.2, *Impacts of No Action Alternative Early Long-Term*, of this RDEIR/SDEIS, or as part of the cumulative impact analysis, as described in Section 5, *Revisions to Cumulative Impact Analyses,* of this RDEIR/SDEIS.

Table 4.1-7. Environmental Commitments under Alternative 5A

Environmental Commitment 3: Natural Communities Protection and Restoration	
Valley/Foothill Riparian	91 acres
Grassland	1,034 acres
Vernal Pool Complex and Alkali Seasonal Wetland Complex	150 acres
Nontidal Marsh	118 acres
Cultivated Lands	11,330 acres
Total:	**Up to 12,724 acres**
Environmental Commitment 4: Tidal Natural Communities Restoration	Up to 55 acres
Environmental Commitment 6: Channel Margin Enhancement	Up to 3.1 levee miles
Environmental Commitment 7: Riparian Natural Community Restoration	Up to 222 acres
Environmental Commitment 8: Grassland Natural Community Restoration	Up to 1,044 acres
Environmental Commitment 9: Vernal Pool and Alkali Seasonal Wetland Complex Restoration	Up to 34 acres
Environmental Commitment 10: Nontidal Marsh Restoration	Up to 826 acres
Environmental Commitment 11: Natural Communities Enhancement and Management	At sites protected or restored under Environmental Commitments 3–10
Environmental Commitment 12: Methylmercury Management	At sites restored under Environmental Commitment 4
Environmental Commitment 15: Localized Reduction of Predatory Fishes	At north Delta intake and at Clifton Court Forebay
Environmental Commitment 16: Nonphysical Fish Barrier	At Georgiana Slough

Environmental Commitment 3: Natural Communities Protection and Restoration

This action would consist of the acquisition of lands for protection and restoration of listed species habitat in perpetuity and would be implemented in the same way as described in Conservation Measure 3 in the Draft BDCP but over less area. For the purposes of Alternative 5A, this action would entail protection of approximately 12,724 acres, of natural communities and cultivated land, as shown in Table 4.1-7. This protection and restoration would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 4: Tidal Natural Communities Restoration

This action would consist of the restoration of tidal natural communities and transitional uplands and would be implemented in the same way as described in Conservation Measure 4 in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS, but over less area. For the purposes of analysis of Alternative 5A, this action would entail restoration of approximately 55 acres (including transitional uplands), as shown in Table 4.1-7. This analysis assumes that none of these 55 acres of tidal restoration will occur in the Suisun Marsh area. Tidal habitat restoration would mitigate for the physical loss of aquatic habitat associated with construction of the north Delta intake facilities. The current proposed mitigation acreage is a total of 55 acres. However, actual acreage may change based on further discussions with NMFS, USFWS, and DFW pertaining to the actual value of the current habitat and/or the appropriate ratio of mitigation or based on footprint changes. Based on initial discussions, the maximum ratio applied to tidal wetland mitigation is 3:1, and therefore would not exceed 165 acres for this alternative.

Environmental Commitment 6: Channel Margin Enhancement

This action would consist of the enhancement of channel margin habitat and would be implemented in the same way as described in Conservation Measure 6 in the Draft BDCP but over less linear distance. For the purposes of Alternative 5A, this action would entail enhancement of approximately 3.1 levee miles, as shown in Table 4.1-7. This would mitigate for the loss of salmonid habitat associated with construction of the north Delta intake facilities.

Environmental Commitment 7: Riparian Natural Community Restoration

This action would consist of the restoration of riparian natural communities and would be implemented in the same way as described in Conservation Measure 7 in the Draft BDCP but over less area. For the purposes of Alternative 5A, this action would entail restoration of approximately 222 acres, as shown in Table 4.1-7. This would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 8: Grassland Natural Community

This action would consist of the restoration of grassland habitat and would be implemented in the same way as described in Conservation Measure 8 in the Draft BDCP but over less area. For the purposes of Alternative 5A, this action would entail restoration of approximately 1,044 acres as shown in Table 4.1-7. This would mitigate for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 9: Vernal Pool and Alkali Seasonal Wetland Complex Restoration

This action would consist of the restoration of vernal pool and alkali seasonal wetland complex and would be implemented in the same way as described in Conservation Measure 9 in the Draft BDCP but over less area. For the purposes of Alternative 5A, this action would entail restoration of approximately 34 total acres of vernal pool complex and/or alkali seasonal wetland complex, as shown in Table 4.1-7. This would mitigate for the loss of species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 10: Nontidal Marsh Restoration

This action would consist of the restoration of nontidal marsh and would be implemented in the same way as described in Conservation Measure 10 in the Draft BDCP but over less area. For the purposes of Alternative 5A, this action would entail restoration of approximately 826 acres of nontidal marsh, as shown in Table 4.1-7. This would mitigate for the loss of species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 11: Natural Communities Enhancement and Management

This action would apply to all protected and restored habitats under Alternative 5A and would be implemented, where applicable, to manage and enhance these lands consistent with the approach described under Conservation Measure 11 in the Draft BDCP. These actions would support mitigation for the loss of terrestrial species habitat associated with construction of the water conveyance facilities.

Environmental Commitment 12: Methylmercury Management

This action would minimize conditions that promote production of methylmercury in restored tidal wetland areas and its subsequent introduction to the foodweb, and to listed species in particular. Implementation of this action would be consistent with the revised description of Conservation Measure 12 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS). The portions of the measure applicable to effects in the Yolo Bypass would not apply because Yolo Bypass improvements would not be implemented as part of this alternative.

Environmental Commitment 15: Localized Reduction of Predatory Fishes (Predator Control)

This action would reduce populations of predatory fishes at locations of high predation risk (i.e., predation hotspots) associated with construction and operation of the proposed water conveyance facilities. Implementation of this action would be consistent with the revised description of Conservation Measure 15 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS); however, for the purposes of Alternative 5A, this action would be applied only to the reach of the Sacramento River adjacent to the north Delta intake and to Clifton Court Forebay. This commitment would mitigate for effects on salmonid predation associated with operation of new conveyance facilities. There is also a potential for incidental benefits to other listed species as a result of this commitment.

Environmental Commitment 16: Nonphysical Fish Barrier

This action would be implemented to address effects related to survival of outmigrating juvenile salmonids by installing a nonphysical barrier at Georgiana Slough to redirect fish away from channels and river reaches in which survival is lower than in alternate routes. Implementation of this action would be consistent with the revised description of Conservation Measure 16 (see Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS); however, for the purposes of Alternative 5A, this action would be applied only to Georgiana Slough. This commitment would mitigate for effects on salmonid survival associated with operation of north Delta intakes and associated flows.

Avoidance and Minimization Measures

Actions associated with AMMs 1–7, 10–15, 18, 20–25, 27, 30, and 37–39 would apply to all construction activities under Alternative 5A and would be implemented, where applicable, to avoid and minimize impacts on listed species, consistent with the approach described in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP, and in Appendix D of this RDEIR/SDEIS. These actions would minimize the risk of impacts on species resulting from construction activities.

Collaborative Science and Adaptive Management Program

Considerable scientific uncertainty exists regarding the Delta ecosystem, including the effects of CVP and SWP operations and the related operational criteria. To address this uncertainty, DWR, Reclamation, DFW, USFWS, NMFS, and the public water agencies will establish a robust program of collaborative science, monitoring, and adaptive management. For the purposes of analysis, it is assumed that the Collaborative Science and Adaptive Management Program (AMMP) developed for Alternative 5A would not, by itself, create nor contribute to any new significant environmental effects; instead, the AMMP would influence the operation and management of facilities and protected or restored habitat associated with Alternative 5A.

Collaborative science and adaptive management will support the proposed project by helping to address scientific uncertainty where it exists, and as it relates to the benefits and impacts of the construction and operations of the new water conveyance facility and existing CVP and SWP facilities. Specifically, collaborative science and adaptive management will, as appropriate, develop and use new information and insight gained during the course of project construction and operation to inform and improve:

- the design of fish facilities including the intake fish screens;
- the operation of the water conveyance facilities under the Section 7 biological opinion and 2081b permit; and
- habitat restoration and other mitigation measures conducted under the biological opinions and 2081b permits.

In summary, the broad purposes of the program will be to: 1) undertake collaborative science, 2) guide the development and implementation of scientific investigations and monitoring for both permit compliance and adaptive management, and 3) apply new information and insights to management decisions and actions. For additional information on how the AMMP would be implemented, see Section 4.1.2.4 in this RDEIR/SDEIS.

4.1.5 Approach to Environmental Analysis for Alternatives 4A, 2D, and 5A

The Lead Agencies have attempted to retain as much of the methodology and terminology that was used in the analyses of other alternatives as possible for the analysis of Alternatives 4A, 2D, and 5A. This section underscores key similarities and differences in the terminology applied in the Draft BDCP, Draft EIR/EIS, and this RDEIR/SDEIS.

Under Alternatives 4A, 2D, and 5A, it is assumed that the environmental setting and area of potential impact are consistent with those analyzed under the alternatives evaluated in the Draft EIR/EIS. While there is no requirement that activities take place within a "Plan Area" under the regulatory approach that would be pursued under these alternatives, it is assumed that activities associated with these alternatives would occur within this same geographical area; therefore, the term Plan Area is still applied in the impact analysis of Alternatives 4A, 2D, and 5A (and associated figures, tables, etc.). Similarly, "Conservation Zones" and "Restoration Opportunity Areas" are still applied where applicable to indicate the areas within which Environmental Commitments would be implemented. As noted in Chapter 1, *Introduction,* Section 1.5 of the Draft EIR/EIS, the "study area" for the actions evaluated in this RDEIR/SDEIS is larger than the proposed Plan Area, because some of the effects of implementing the proposed project would extend beyond the boundaries of this region. Resource-specific study areas are defined in the introductions to the analyses in Chapters 5–30 of the Draft EIR/EIS.

As described above, various activities associated with the Draft BDCP conservation strategy would also apply to these alternatives. However, activities referred to as Conservation Measures under the BDCP (as an HCP/NCCP), are instead called Environmental Commitments for the purposes of Alternatives 4A, 2D, and 5A. However, other activities associated with the Draft BDCP conservation strategy are retained for discussion of Alternatives 4A, 2D, and 5A, including the role of avoidance and minimization measures[27] and the implementation of an adaptive management and monitoring program, with text provided as needed to clarify differences from those activities under their "parent" alternatives, as described in the Draft EIR/EIS. In some cases, resource restoration and protection principles have been added to provide additional detail regarding implementation of the Environmental Commitments (see Table 4.1-8 of this RDEIR/SDEIS). In the context of the Draft BDCP, these were often characterized as biological goals and objectives. As part of the ESA Section 7 consultation process, these elements may function (and be referred to) as "conservation measures" for mitigation purposes. However, for the purposes of the RDEIR/SDEIS, these activities are considered part of the alternative and are not defined as "mitigation measures" in order to avoid confusion with those measures proposed for the purposes of CEQA and NEPA compliance. As described in Section 1, *Introduction*, the RDEIR/SDEIS references the Draft BDCP where appropriate.

[27] In response to comments contending that DWR, as Lead Agency, had failed to "comply" with the *Lotus v. Department of Transportation* (223 Cal.App.4th 645) decision, DWR and the US Bureau of Reclamation, as Federal Lead Agency, have modified Appendix 3B, *Environmental Commitments*, as part of this RDEIR/SDEIS. Avoidance and minimization measures (AMMs) and Conservation Measures (for Alternatives 1A, 1B, 1C, 2A, 2B, 2C, 3, 4, 5, 6A, 6B, 6C, 7, 8, and 9)/Environmental Commitments (for Alternatives 4A, 2D, and 5A) that have been incorporated in this analysis as project features which will help avoid or minimize significant environmental effects (serving a similar role as environmental commitments) have been added to this appendix. In addition to other refinements, Appendix 3B now includes, after a summary of each mitigating project feature, one or more narrative discussions explaining both how it tends to reduce the severity of environmental effects and whether or not the level of impact reduction is sufficient to render the effects less-than-significant.

Any new information developed for the BDCP since the December 2013 public draft that is needed to adequately disclose environmental effects of Alternatives 4A, 2D, and 5A, or other alternatives is included in Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS.

The Section 7 and 2081(b) consultation processes address a smaller list of species than the list of BDCP covered species (Table 1-3 in the Draft BDCP). Alternatives 4A, 2D, and 5A would not include a list of "covered species;" however, this RDEIR/SDEIS retains analysis of these species, to the extent that implementation of these alternatives could result in impacts. See Section 4.3.7, *Fish and Aquatic Resources*, and 4.3.8, *Terrestrial Biological Resources*, of this RDEIR/SDEIS for impact analyses pertaining to aquatic and terrestrial species. Similarly, the concept of "covered activities" would not pertain to Alternatives 4A, 2D, and 5A. For the purposes of these alternatives, the activities considered for their potential to result in environmental impacts consist of construction and operation of proposed and existing SWP and CVP facilities in the Delta, along with implementation of Environmental Commitments designed to mitigate these effects. Operation and maintenance of the proposed North Bay Aqueduct Alternate Intake Project would not be included as a part of Alternatives 4A, 2D, and 5A; therefore, impacts from operating this proposed facility are not considered in the analysis of these alternatives.

Table 4.1-8. Terrestrial Biology Resource Restoration and Protection Principles for Implementing Environmental Commitments.

Resource[28]	Resource Restoration and Protection Principles
Landscape Level	L1 - Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands. L2 - Protect and improve habitat linkages that allow terrestrial species to move between protected habitats within and adjacent to the project area. L3 - Increase native species diversity and relative cover of native plant species, and reduce the introduction and proliferation of nonnative species.
Natural Communities	
Valley/Foothill Riparian	VFR1 - Restore, maintain, and enhance riparian areas to provide a mix of early-, mid- and late-successional habitat types with a well-developed understory of dense shrubs. VFR2 - Maintain a single contiguous patch of 100 acres of mature riparian forest in either CZ 4 or CZ 7. VFR3 - The mature riparian forest intermixed with a portion of the early- to mid-successional riparian vegetation will be a minimum patch size of 50 acres and minimum width of 330 feet.
Vernal Pool/Alkali Seasonal Wetland Complex	VP/AW1 - Protect existing vernal pool complex in the greater Byron Hills area primarily in core vernal pool recovery areas identified in the *Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon* (U.S. Fish and Wildlife Service 2005). VP/AW2 - Restore vernal pool and alkali seasonal wetland complex to achieve no net loss of wetted acreage. VP/AW3 - Increase the size and connectivity of protected vernal pool and alkali seasonal wetland complex in the greater Byron Hill area. VP/AW4 - Provide appropriate seasonal flooding characteristics for supporting

[28] Only species that required specific restoration guidelines were included in this table. Some of the natural community level resource guidelines benefit some species and there are also specific AMMs that address other species needs.

Resource[28]	Resource Restoration and Protection Principles
	and sustaining vernal pool and alkali seasonal wetland complex species. VP/AW5 - In grasslands surrounding protected and created vernal pools and alkali seasonal wetlands complex, increase the extent, distribution, and density of native perennial grasses intermingled with other native species, including annual grasses, geophytes, and other forbs. VP/AW6 - In grasslands surrounding protected and created vernal pool and alkali seasonal wetlands, increase burrow availability for burrow-dependent species. VP/AW7 - In grasslands surrounding protected and restored vernal pool and alkali seasonal wetlands, increase prey abundance and accessibility, especially small mammals and insects, for grassland-foraging species.
Grassland	G1 - Restore grasslands to connect fragmented patches of protected grassland and to provide upland habitat. G2 - Protect up to six acres of stock ponds and other aquatic features within protected grasslands to provide aquatic breeding habitat for native amphibians and aquatic reptiles. G3 - Restore and sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states. G4 - Increase the extent, distribution, and density of native perennial grasses intermingled with other native species, including annual grasses, geophytes, and other forbs. G5 - Increase burrow availability for burrow-dependent species. G6 - Increase prey abundance and accessibility, especially of small mammals and insects, for grassland-foraging species. G7 - Maintain and enhance aquatic features in grasslands to provide suitable inundation depth and duration and suitable composition of vegetative cover to support breeding for covered amphibian and aquatic reptile species. G8 - Protect grassland on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit. G9 - Create or protect high-value upland giant garter snake habitat adjacent to the nontidal perennial aquatic habitat being restored and created. G10 - Protect 647 acres of grassland in the Byron Hills area.
Cultivated Lands	CL1 - Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands. CL2 - Target cultivated land conservation to provide connectivity between other conservation lands
Wildlife Species	
Valley Elderberry Longhorn Beetle	VELB1 - Mitigate impacts on elderberry shrubs by creating valley elderberry longhorn beetle habitat consistent with the U.S. Fish and Wildlife Service valley elderberry longhorn beetle conservation guidelines (provided in BDCP Appendix 3.F of the Draft BDCP) and planting elderberry shrubs in high-density clusters. VELB2 - Site valley elderberry longhorn beetle habitat restoration within drainages immediately adjacent to or in the vicinity of sites confirmed to be occupied by valley elderberry longhorn beetle.

Resource[28]	Resource Restoration and Protection Principles
Western Pond Turtle	WPT1 - Create and protect nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities, which will include suitable habitat characteristics for western pond turtle.
Giant Garter Snake	GGS1 - Created aquatic habitat for the giant garter snake will be connected to the protected rice land or equivalent-value habitat. GGS2 - Protect giant garter snakes on restored and protected nontidal marsh and adjacent uplands and from incidental injury or mortality by establishing 200-foot buffers between protected giant garter snake habitat and roads (other than those roads primarily used to support adjacent cultivated lands and levees). Establish giant garter snake reserves at least 2,500 feet from urban areas or areas zoned for urban development. GGS3 - Protect, restore, and/or create rice land or equivalent-value habitat (e.g., perennial wetland) for the giant garter snake in Conservation Zones 4 and/or 5. GGS4 - Create or protect high-value upland giant garter snake habitat adjacent to the nontidal perennial aquatic habitat being restored and created. GGS5 - Create connections from the Coldani Marsh/White Slough subpopulation to other areas in the giant garter snake's historical range in the Stone Lakes vicinity by protecting 255 acres of rice land or equivalent-value habitat (e.g., perennial wetland) for the giant garter snake in CZ 4 and/or CZ 5. Any portion of the 255 acres may consist of muted tidal freshwater emergent wetland and may overlap with the 160 acres of tidally restored freshwater emergent wetland if it meets specific giant garter snake habitat criteria.
California Black Rail	CBR1 - At the ecotone that will be created between restored tidal wetlands and transitional uplands (Environmental Commitment 4), provide for at least 22 acres of California black rail habitat (Schoenoplectus and Typha-dominated tidal and nontidal freshwater emergent wetland in patches greater than 0.55 acres in the central Delta) consisting of shallowly inundated emergent vegetation at the upper edge of the marsh (within 50 meters of upland refugia habitat) with adjacent riparian or other shrubs that will provide upland refugia, and other moist soil perennial vegetation. If feasible, create the 22 acres of tidal habitat in a single patch in a location that is contiguous with occupied California black rail habitat. CBR2 - Create topographic heterogeneity in restored tidal wetlands (Environmental Commitment 4).
Greater Sandhill Crane	GSC1 - Protect high- to very high-value habitat for greater sandhill crane (see Table 12-4A-28 in Section 4.3.8, *Terrestrial Biological Resources*, of this RDEIR/SDEIS for definition of habitat values), with at least 80% maintained in very high-value types in any given year. This protected habitat will be within 2 miles of known roosting sites in Conservation Zones 3, 4, 5, and/or 6 and will consider sea level rise and local seasonal flood events, greater sandhill crane population levels, and the location of foraging habitat loss. Patch size of protected cultivated lands will be at least 160 acres. GSC2 - Create at least 320 acres of managed wetlands (part of the nontidal wetland restoration acreage) in minimum patch sizes of 40 acres within the Greater Sandhill Crane Winter Use Area in CZs 3, 4, 5, or 6, with consideration of sea level rise and local seasonal flood events. The wetlands will be located within 2 miles of existing permanent roost sites and protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of 2:1 upland to wetland to provide buffers around the wetlands. GSC3 - Create at least two 90-acre wetland complexes within the Stone Lakes

Resource[28]	Resource Restoration and Protection Principles
	National Wildlife Refuge project boundary. The complexes will be no more than 2 miles apart and will help provide connectivity between the Stone Lakes and Cosumnes River Preserve greater sandhill crane populations. Each complex will consist of at least three wetlands totaling at least 90 acres of greater sandhill crane roosting habitat, and will be protected in association with other protected natural community types (excluding nonhabitat cultivated lands) at a ratio of at least 2:1 uplands to wetlands (i.e., two sites with at least 90 acres of wetlands each). One of the 90-acre wetland complexes may be replaced by 180 acres of cultivated lands (e.g., cornfields) that are flooded following harvest to support roosting cranes and provide highest-value foraging habitat, provided such substitution is consistent with the long-term conservation goals of Stone Lakes National Wildlife Refuge for greater sandhill crane. GSC4 - Create an additional 95 acres of roosting habitat within 2 miles of existing permanent roost sites. The habitat will consist of active cornfields that are flooded following harvest to support roosting cranes and that provide highest-value foraging habitat. Individual fields will be at least 40 acres and can shift locations throughout the Greater Sandhill Crane Winter Use Area, but will be sited with consideration of the location of roosting habitat loss and will be in place prior to roosting habitat loss.
Swainson's Hawk	SH1 - Conserve 1 acre of Swainson's hawk foraging habitat for each acre of lost foraging habitat in minimum patch sizes of 40 acres. SH2 - Protect Swainson's hawk foraging habitat with at least 50% in very high-value habitat (see Table 12-4A-35 in Section 4.3.8, *Terrestrial Biological Resources*, of this RDEIR/SDEIS for a definition habitat value) production and above -1 foot above mean sea level.
Tricolored Blackbird	TB1 - Protect and manage occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat located within 3 miles of high-value foraging habitat in Conservation Zones 1, 2, 8, or 11. Nesting habitat will be managed to provide young, lush stands of bulrush/cattail emergent vegetation and prevent vegetation senescence. TB2 - Protect high- to very high-value breeding-foraging habitat within 5 miles of occupied or recently occupied (within the last 15 years) tricolored blackbird nesting habitat. At least 130 acres will be within 3 miles of the 42 acres of nontidal wetland nesting habitat protected. TB3 - Protect moderate-, high-, or very high-value cultivated lands as nonbreeding foraging habitat, at least 50% of which is of high or very high value. TB4 - Nonbreeding roosting habitat mitigation needs assumed to be met through early-successional riparian (blackberry) and tidal (scirpus) restoration.
Riparian Brush Rabbit	RBR1 - Of the protected valley/foothill riparian natural community, protect and maintain 19 acres of early- to mid-successional riparian habitat that meets the ecological requirements of the riparian brush rabbit and that is within or adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat. RBR2 - Restore and maintain 19 acres of early- to mid-successional riparian brush rabbit habitat that meets the ecological requirements of the riparian brush rabbit and that is within or adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat. RBR3 - Create and maintain high-water refugia in the 19 acres of restored riparian brush rabbit habitat and the 19 acres of protected riparian brush rabbit habitat, through the retention, construction and/or restoration of high-ground habitat on mounds, berms, or levees, so that refugia are no further apart than 20 meters.

Resource[28]	Resource Restoration and Protection Principles
	RBR4 - In protected riparian areas that are occupied by riparian brush rabbit, monitor for and control nonnative predators that are known to prey on riparian brush rabbit. RBR5 - Of the 1,060 acres of grasslands protected, protect 227 acres of grasslands on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit.
Plant Species	
Vernal Pools Species	VPS1 - Protect at least two currently unprotected occurrences of alkali milk-vetch in the Altamont Hills or Jepson Prairie core recovery areas.
Alkali Seasonal Wetland Species	ASWS1 - Protect two currently unprotected occurrences of San Joaquin spearscale in Conservation Zones 1, 8, or 11.
Tidal Wetland Species	TWS1 - No net loss of Mason's lilaeopsis and delta mudwort occurrences within restoration sites. TWS2 - No net loss of Delta tule pea and Suisun Marsh aster occurrences within restoration sites.

4.1.6 Assumptions for the Purposes of Analysis

For the purposes of analyzing the environmental effects associated with Alternatives 4A, 2D, and 5A, a number of assumptions were necessary.

Environmental Baselines and Implementation Schedule

The same "Existing Conditions" baseline defined in the Draft EIR/EIS applies to Alternatives 4A, 2D, and 5A, for the purposes of CEQA impact analysis. Therefore, all CEQA conclusions associated with Alternative 4A, 2D, and 5A are made in comparison to the same Existing Conditions baseline applied for all other alternatives. However, because of the different approach for ESA compliance envisioned under Alternatives 4A, 2D, and 5A, the No Action Alternative, as applied to these new alternatives only, has been modified for the purposes of making NEPA determinations with respect to Alternatives 4A, 2D, and 5A in the RDEIR/SDEIS. Specifically, this RDEIR/SDEIS includes revisions made to the No Action Alternative required under NEPA and for the purpose of providing a logical point of comparison for the NEPA analysis of Alternatives 4A, 2D, and 5A. Because Alternatives 4A, 2D, and 5A, contemplate a shorter permit period for project implementation than the other alternatives, the new "No Action Alternative Early Long-Term" (No Action Alternative ELT) is used as the NEPA point of comparison for these alternatives. The No Action Alternative ELT is described and analyzed in Section 4.2. However, because the project would continue indefinitely, the analysis qualitatively examines impacts at the Late Long-Term timeframe for Alternatives 4A, 2D, and 5A, but does not make a CEQA or NEPA conclusion based off the No Action Alternative LLT baseline. Where impacts do not differ between the early long-term and the late long-term, this analysis is not specifically called out. For the other action alternatives in the Draft EIR/EIS, including Alternative 4, that contemplated an HCP/NCCP permit term of 50 years, the No Action Alternative, as found in the Draft EIR/EIS, remains unchanged, as it, too, had a time horizon of 50 years.

Under Alternatives 4A, 2D, and 5A, the 2009 NMFS BiOp RPAs related to Yolo Bypass improvements (Actions I.6.1, I.6.2, and I.7) and the 2008 USFWS BiOp RPA related to 8,000 acres of tidal habitat restoration (Component 4) would be considered part of the No Action Alternative. Under Alternatives 4A, 2D, and 5A, the BDCP would no longer be the vehicle to implement these actions;

instead, they would be pursued and implemented as part of existing processes, including the development of the *Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan* and the BiOps on the Coordinated Long-Term Operation of the CVP and SWP. Because a 50-year permit would not be pursued under Alternatives, 4A, 2D, and 5A, impact analyses reliant on physical modeling (primarily CALSIM II and DSM2) use "Early Long-Term" model results. However, because the project would continue indefinitely, the analysis qualitatively examines impacts at the Late Long-Term timeframe for Alternatives 4A, 2D, and 5A. Where impacts do not differ between the early long-term and the late long-term, this analysis is not specifically called out.

Physical Modeling

As described above, impact analyses reliant on physical modeling apply results consistent with an "Early Long-Term" timeframe. Based on the assumptions used for the original purposes of these model runs, these results also assume implementation of two elements, Yolo Bypass improvements and 25,000 acres of tidal wetland restoration. These two elements were included in the modeling because they were components of Alternative 4, for which the modeling was originally conducted. These two elements, however, are not proposed as part of Alternatives 4A, 2D, or 5A. Instead, these two elements would be pursued and implemented separately as part of other ongoing BiOp RPA efforts rather than as part of Alternatives 4A, 2D, and 5A. Even so, the Lead Agencies have determined that they may reasonably rely on the modeling conducted for Alternative 4 to accurately predict the environmental effects of Alternative 4A. At the time the Lead Agencies developed Alternative 4 in concept and wanted to test it as a potentially viable new subalternative, the Lead Agencies already possessed ELT modeling outputs for Alternative 4, which included the two elements. The Lead Agencies conducted additional sensitivity modeling to assess whether or not the existing ELT modeling for Alternative 4 accurately predicted the environmental effects of Alternative 4A. The new assessment concluded in the affirmative on that question. Their conclusions from this sensitivity analysis comparison are provided in Appendix B, *Supplemental Modeling for Alternative 4A*, of this RDEIR/SDEIS. Additionally, as described in Table 4.1-2 in this RDEIR/SDEIS, the operations for Alternative 4A include a new criterion for spring outflow longfin smelt. For the purposes of impact analysis under Alternative 4A, applicable analyses evaluate a range of impacts, bounded by the early long-term modeling results generated for Alternative 4, Scenarios H3 and Scenario H4.

4.2 Impacts of No Action Alternative Early Long-Term

The addition of Alternatives 4A, 2D, and 5A, as described above in Section 4.1, *Introduction*, requires a new No Action Alternative to be defined that matches the time horizon for the new alternatives and provides a baseline or point of comparison for NEPA purposes. This section provides a brief overview of the No Action Alternative Early Long Term (ELT) assumptions and provides analysis of the No Action Alternative (ELT) impacts compared against existing conditions.

The No Action Alternative (ELT) includes most of the assumptions used for the No Action Alternative Late Long Term (LLT) as described in Appendix 3D of the Draft EIR/EIS including continued SWP/CVP operational assumptions used in CALSIM II modeling and on-going programs, projects and polices that would continue in the absence of action alternatives. Two exceptions include planned Yolo Bypass improvements and habitat restoration required by the USFWS BiOp. Because Alternatives 4A, 2D, and 5A do not include these Yolo Bypass and habitat restoration actions they are now assumed for the No Action Alternative (ELT); they are actions that would be required to occur with or without implementation of Alternatives 4A, 2D, or 5A.

Other programs, projects, and policies assumed for the No Acton Alternative (LLT) are also assumed for the No Action Alternative (ELT) but the ELT period assumes a shorter time horizon of approximately 15 years following project approval. These programs, projects and policies are presented in Draft EIR/EIS Tables 3D-1 and 3D-2 in Appendix 3D, *Defining Existing Conditions, No Action Alternative, No Project Alternative, and Cumulative Impact Conditions* and include those with clearly defined management and/or operational plans, including facilities under construction as of February 13, 2009. In general, these actions are consistent with the continuation of existing management direction or level of management for plans, policies, and operations by the NEPA Lead Agencies and other agencies, and are summarized in Table 3D-4 of the Draft EIR/EIS, Appendix 3D, *Defining Existing Conditions, No Action Alternative, No Project Alternative, and Cumulative Impact Conditions*. The No Action Alternative (ELT) assumptions also include facilities and programs that have received approvals and permits or foreseeably will be approved and permitted during the ELT time period because those programs were consistent with existing management direction as of the Notice of Preparation, as summarized in Table 3D-4 (Draft EIR/EIS, Appendix 3D, *Defining Existing Conditions, No Action Alternative, No Project Alternative, and Cumulative Impact Conditions*). The effects of climate change and sea level rise will foreseeably have some effect on the Delta environment during the ELT time period[1] and are included in the No Action Alternative (ELT) CALSIM modeling and analysis.

Inclusion of future projects or actions in the No Action Alternative does not represent a decision by any agency to pursue those project or actions. Reclamation has included in the No Action Alternative future projects or actions that Reclamation believes are reasonably foreseeable to occur. To the extent such future projects or actions require approval by another federal agency, Reclamation's decision to include these future action projects or actions in the No Action Alternative should not be interpreted as approval by any federal agency.

[1] ELT is modeled at 2025. Late-long term timeframe is modeled at 2060.

4.2.1 No Action Alternative (ELT) Assumptions for State Water Project and Central Valley Project

No Action Alternative (ELT) includes continuation of operations of the SWP and CVP as described in the Biological Assessment (BA) on the Continued Long-term Operations of the Central Valley Project and the State Water Project (August 2008) with operational assumptions modified by the 2009 NMFS BiOp and 2008 USFWS BiOp. The operational assumptions for the No Action Alternative (ELT) are identical to those assumed for the No Action Alternative (LLT) for a shorter time period and do not include "Near Term Future Projects" or "Other Future Projects" included in the 2008 BA that are not actionable enough to assume in CALSIM II modeling of SWP/CVP operations. The Sacramento River Reliability Project is not included in the No Action Alternative (ELT) because the environmental documentation is not complete, and therefore, specific construction and operational criteria are not defined. The South Delta Improvement Program is not included in the No Action Alternative (ELT) because DWR is developing alternative plans at this time. Detailed assumptions for the CVP and SWP operations are also represented in hydrological and water quality analytical models, as described in Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS.

4.2.2 No Action Alternative (ELT) Assumptions for Ongoing Programs and Policies

The No Action Alternative (ELT) assumes continued implementation of operations, maintenance, enforcement, and protection programs by federal, state, and local agencies and non-profit groups in areas relevant to the action alternatives, as summarized in Table 3D-2 and 3D-4 of the Draft EIR/EIS. Many of the ongoing programs include development of future projects that would require separate environmental documentation. The future projects are not included in the No Action Alternative (ELT) assumptions unless they meet the definition of No Action Alternative or are defined well enough to be assumed in the No Action Alternative (ELT).

4.2.3 No Action Alternative (ELT) Assumptions for Biological Opinions

The same NMFS and USFWS BiOp actions assumed for the No Action Alternative (LLT) are assumed for the No Action Alternative (ELT), as described above and presented in Table 3D-5 of the Draft EIR/EIS and include the Lower Putah Creek enhancements, Lisbon Weir improvements, changes in Delta Cross Channel operations, San Joaquin River inflow to export ratio requirements, Old and Middle River flow management, and Tracy Fish Collection and Skinner Fish Collection Facility improvements, among other related actions. In general, actions required under the 2008 and 2009 NMFS and USFWS BiOps were included in the No Action Alternative (ELT) analysis if they were found to be well-defined enough to allow for a meaningful analysis and are likely to be implemented in the absence of the action alternatives.

The future actions not included in the modeling of No Action Alternative (ELT) include facilities or changes in operations under implementation of the NMFS BiOp and the USFWS BiOp that would require further study and subsequent implementation as well as future actions required by the Biological Opinions which cannot be analyzed (such as convening a working group to make certain findings). As noted above, the No Action Alternative (ELT) includes Yolo Bypass improvements and

8,000 acres of habitat enhancements. These actions were subsumed by the BDCP action alternatives and thus, were not included in the No Action Alternative (LLT) assumptions. Because Alternatives 4A, 2D, and 5A do not include these actions they are now included in the No Action Alternative (ELT) assumptions and evaluated qualitatively.

4.2.4 Water Supply

Under the No Action Alternative, the facilities and operations of the SWP and CVP would continue to be similar to Existing Conditions with the following changes.

- Effects of sea level rise and climate change on system operations as discussed in Section 5.3.1.1 of the Draft EIR/EIS.
- An increase in demands and the buildout of facilities associated with water rights and CVP and SWP contracts of about 443 TAF per year, north of Delta at the future level of development. This is an increase in CVP Municipal and Industrial (M&I) service contracts (253 TAF per year) and water rights (184 TAF per year) related primarily to urban M&I use, especially in the communities in El Dorado, Placer, and Sacramento Counties.
- An increase in demands associated with SWP contracts, up to full contract amounts, south of Delta at the future level of development. SWP M&I demands, which under the existing level of development vary on hydrologic conditions between 3.0 and 4.1 MAF per year, under the future condition are at maximum contract amounts in all hydrologic conditions. This represents a potential 25% increase on average in south of Delta demands under SWP M&I contracts between existing and future levels of development due to assumed additional development and demographics.
- New urban intake/Delta export facilities:
    - Freeport Regional Water Project (see Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS for information on additional EBMUD demand of about 26 TAF/YR on average with increased demand in dry years)
    - 30 million-gallon-per-day City of Stockton Delta Water Supply Project
    - Delta-Mendota Canal–California Aqueduct Intertie
    - Contra Costa Water District Alternative Intake and 55 TAF/YR increased demand
    - South Bay Aqueduct rehabilitation, to 430 cfs capacity, from the junction with California Aqueduct to Alameda County Flood Control and Water Conservation District Zone 7.
- An increase in supplies for wildlife refuges including Firm Level 2 supplies of about 8 TAF per year at the future level of development. In addition, there is a shift in refuge demands from south to north (24 TAF per year reduction in south of Delta and 32 TAF per year increase in north of Delta).
- Implementation of the Fall X2 RPA action (see Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS), which requires maintenance of X2 at specific locations in wet and above normal years in September and October, plus releases in November to augment Delta outflow dependent on hydrology.

- Increased demands for cross-Delta water transfers, with the frequency of such transfers increasing from about 52 percent of years to 68 percent of years, and average annual transfer volume increasing from 146,000 acre-feet to 280,000 acre-feet compared to existing conditions.

A detailed description of the modeling assumptions associated with the No Action Alternative is included in Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS.

Ongoing Plans, Policies, and Programs

The programs, plans, and projects included under the No Action Alternative (ELT) are summarized in the Draft EIR/EIS Chapter 3, *Description of Alternatives*. Most of the projects would not affect SWP/CVP water supply availability under the No Action Alternative (ELT) as compared to Existing Conditions. The projects that could affect SWP/CVP water supply availability are summarized in Table 5-3 in the Draft EIR/EIS, along with their anticipated effects on water supply.

Model simulation results for the No Action Alternative (ELT) compared to Existing Conditions are discussed in the following sections and summarized in Tables B.1-1 through B.1-3.

Change in Delta Outflow

Average annual Delta outflow would increase by 625 TAF (4%) at Year 2025 (ELT) as compared to Existing Conditions. Changes in Delta outflow would result from the seasonal changes in the timing of precipitation and runoff due to climate change, with higher outflows in December through March and lower outflows in April through June, as shown in Figure 4.3.1-1. The increase in Delta outflow in September and October in wet and above normal years would be due to increased outflow to meet Fall X2 and because higher outflows are needed to meet Fall X2 requirements as a result of sea level rise and salinity intrusion into the Delta under future 2025 climate conditions. The changes in the timing of seasonal outflows are more prominent in wet years as compared to dry years, as shown in Figures 4.3.1-2 and 4.3.1-3.

Change in SWP and CVP Reservoir Storage

In comparison to Existing Conditions under the No Action Alternative (ELT), there would be a decrease in carryover storage at the end of September for Lake Oroville, Trinity Lake, Shasta Lake, and Folsom Lake in all years. Lake Oroville storage would decrease by 430 TAF (21%) in September average end of month storage. Trinity, Shasta, and Folsom lakes September carryover would decrease by 119 TAF (9%), 249 TAF (9%), and 80 TAF (15%), respectively under No Action Alternative at ELT as compared to Existing Conditions.

These changes in storage would reduce the ability of the CVP and SWP to meet system water demands and environmental water needs. Adaption measures would need to be implemented on upstream operations to manage coldwater pool storage levels under future sea level rise and climate change conditions. As described in the methods section of Chapter 5, *Water Supply*, in the Draft EIR/EIS, model results when storages are at or near dead pool may not be representative of actual future conditions because changes in assumed operations may be implemented to avoid these conditions.

Potential for Abrupt Disruptions of South of Delta Water Supplies

The levee system in the Delta is composed of approximately 1,115 miles of levees in the Delta and another 230 miles of levees in the Suisun Marsh area (California Department of Water Resources 2005). Some of these are project levees that are part of the State Plan of Flood Control (SPFC) and subject to state and federal oversight and regulation. The majority of Delta Levees are non-project levees, built and improved by local interests, primarily to drain islands and tracts in the Delta so they could be put into agricultural use (California Department of Water Resources 2005); they also serve other purposes, including preservation of water quality and conveyance for export water flows. These levees were built without State and/or federal assistance but have status under California Water Code. The non-project levees are under the jurisdiction of public agencies (reclamation districts) and eligible for State assistance due to their acknowledged special benefits to State interests. There are also other levees that may be owned by private or public entities that do not have the same eligibility status as the Delta's non-project levees.

A breach of one or more levees and the associated island flooding could affect Delta water quality and SWP and CVP operations. Depending on the hydrology and the size and locations of the breaches and flooded islands, salt water may be pulled into the interior Delta from Suisun and San Pablo bays. When certain islands are flooded, Delta exports may need to drastically decrease or even cease to avoid drawing saline water toward the Banks and Jones Pumping Plants.

Although the condition of the Delta levees is improving due to the investment of State funds, the failure of an individual levee could happen at any time because the Delta islands are below sea level. Such a sunny day failure occurred in 2004 on Middle River, which flooded Upper and Lower Jones Tract, inundating 12,000 acres of farmland with about 160,000 af of water. Following the levee break, Delta export pumping was curtailed for several days to prevent the intrusion of saline water into the Delta. Water shipments down the California Aqueduct were continued through unscheduled releases from San Luis Reservoir Also, Shasta and Oroville reservoir releases were increased to provide for salinity control in the Delta.

According to the Delta Risk Management Strategy (DRMS), Phase 1: Risk Analysis (California Department of Water Resources 2007), the risk of levee failure in the Delta is significant. Since 1900, 158 levee failures have occurred (California Department of Water Resources 2008b). Some islands have been flooded and recovered multiple times. A few islands, such as Franks Tract, have never been recovered.

Levee failures may be isolated events that affect only a single island, or they may involve multiple islands at the same time. The potential for a single-island event to affect conveyance depends on the location of the island, the conditions in the Delta, and timing of the event. The failure of an island located along current conveyance routes (e.g., Old and Middle rivers) could have a much greater effect on Delta water exports than a failure at some other locations. In addition, because the operation of the export pumps varies over the course of a year, the effects of a single-island levee failure event on conveyance would vary from no effect to disruption of pumping for several days or weeks, according to the time of year at which it occurred.

As discussed in the No Action Alternative discussion in Chapter 5, *Water Supply* of the Draft EIR/EIS, sea-level rise could result in an increased risk of levee failure if the levees are not maintained and improved to accommodate the additional load. However, the State has programs and partners in the local agencies to support necessary levee improvements to minimize any increase in risk. It will be important to continue supporting these programs and to provide funds for the improvement of the levees in order to minimize the potential for inundation of the Delta islands. Without the programs and funding, the potential effects on Delta water supplies could be very significant.

Seismically Induced Levee Failure

The Delta is in an area of moderate seismic risk. A moderate to strong earthquake could cause simultaneous levee failures on several Delta islands, with resultant flooding. The potential for levee failure to result from a seismic event was the subject of analyses conducted by the CALFED program and Phase I of the DRMS. In 2002, the Working Group on California Earthquake Probabilities estimated that an earthquake of magnitude 6.7 or greater has a 62 percent probability of occurring in the San Francisco Bay Area before 2032, and could cause 20 or more islands to flood at the same time (URS Corporation and Benjamin & Associates 2009).

As discussed in the DRMS analysis, a major earthquake could flood many islands simultaneously, which would result in the influx of saline water into the Delta and could require the immediate cessation of water exports. The subsequent repair of levee breaches after the earthquake could require several months, after which the Delta would have to be restored to a fresh condition. Freshening the Delta could involve releases from upstream reservoirs to flush saline water from the Delta. Emergency provisions of existing laws may be used in order to provide the ability to pump water for SWP and CVP to avoid or minimize adverse health and safety effects resulting from the reduced water supply conditions related to a seismic event.

Flood-Related Failures

The potential for a flood event to result in damage to levees, structures, and result in the loss of life has been evaluated in several studies, including DRMS and the Central Valley Flood Protection Plan (California Department of Water Resources 2011b). Generally, these studies have focused on characterizing the potential flood risk, estimating the extent of flood damage, and describing options to mitigate flood risks and reduce flood damage. Storm-related flooding tends to fill the Delta and Suisun Marsh with fresh water, thereby making disruption of the export supply less likely. The 2009 SWP Reliability Report (California Department of Water Resources 2010a) acknowledges the potential for disruption of Delta exports from a flood event would depend on the number of flooded islands, the timing and size of the flood flows, and the water quality in the Delta and Suisun Bay at the time of the flood.

Funding from the Delta Levees Subventions and Delta Special Flood Control Projects Programs have assisted reclamation districts with system maintenance, levee repairs, and levee improvements, which have improved overall levee performance in the Delta. The annual funding has ranged from 2 million to 50 million dollars. Continued funding of those programs would likely result in additional improvements to levee performance. However, the cost of a comprehensive program to manage risk across the Delta has been estimated at between $10.5 and $17.5 billion (California Department of Water Resources 2011c). Costs of this magnitude likely exceed the funding ability of local reclamation districts and may not be available from the State or federal governments. Thus, the ability to implement widespread levee improvements in advance of anticipated increases in flood peaks or sea-level rise or due to climate change is uncertain.

As noted above, the potential consequences for water exports as a result of a levee failure during flood conditions would depend on the specific levee reach and its relation to export conveyance. Since the Delta and Suisun Marsh will contain significantly more fresh water, the potential for salt contamination and any need to curtail exports for water quality reasons is reduced. However, once flood flows subside, saline water would be expected to re-enter the Delta system. The levee breaches remaining after the flood could have altered flow patterns in the Delta and would have to be evaluated for their effects on exports and in-Delta water quality. Where adverse effects remain, closure of the breaches would restore the function of the levee system in preserving water quality and conveyance. It is unlikely that a single-island failure during flood conditions could result in a reduction or disruption to Delta water exports, although it is possible that multiple-island levee failure events, unless repaired, could affect water exports for a longer period.

Potential Effects on the Export of Delta Water Supplies from Levee Failure

In the past several years, DWR USACE the Delta Protection Commission, and local agencies have worked to improve the response to an in-Delta flood emergency, such as a levee failure. As a result, DWR and local agencies are better prepared to respond effectively through improved planning and coordination and the stockpiling of materials. Thus, in the event of a threatened levee breach, local agencies will respond immediately and will notify the County Office of Emergency Services and DWR Flood Center of an event. If needed, additional supplies and support are available. If a levee breach were to occur on a single island (such as occurred at Jones Tract), a unified response effort would be pursued. As part of the implementation of that response, planning teams consider impacts on systems, including the export water system. If the export water system were compromised, restoration of its full function would be incorporated into the response plan so that repairs could be completed in a relatively short timeframe (e.g., a few weeks or months). Thus, for most single-island events, the effect on Delta water exports would generally be limited to a relatively short interruption, until it is confirmed that the resumption of exports would not draw saline water into the Delta.

Various analyses have been undertaken to understand the risk and probability of a more widespread levee failure event, and to determine the potential impact to conveyance of water across the Delta. This included DRMS, an action envisioned by the CALFED ROD in 2000, which provided data to meet the requirements of Assembly Bill (AB) 1200 (California Department of Water Resources and California Department of Fish and Game 2008). Adopted by the legislature in 2005, AB 1200 amended the California Water Code[2] to require that DWR conduct an analysis of the potential for potential impacts on Delta water supplies from subsidence, earthquakes, floods, and changes in precipitation, temperature, and ocean levels. For further discussion of impacts of seismic risks and climate change see Appendix 3E, *Potential Seismic and Climate Change Risks to SWP/CVP Water Supplies*, of the Draft EIR/EIS.

Appendix 5B, *Responses to Reduced South of Delta Water Supplies*, of the Draft EIR/EIS discusses the potential responses of urban and agricultural water users to abrupt disruptions in Delta water supplies. As discussed more fully therein, urban water user responses could include increased reliance on reservoir storage, expanded groundwater reliance, increased water transfers from agricultural uses to urban uses, increased use on recycled water, and water use restrictions. Responses from agricultural water users could include increased reliance on reservoir storage, expanded groundwater reliance, and water conservation measures.

[2] California Water Code § 139.2: The department shall evaluate the potential impacts on water supplies derived from the Sacramento-San Joaquin Delta based on 50-, 100-, and 200-year projections for each of the following possible impacts on the delta: (1) Subsidence; (2) Earthquakes; (3) Floods; (4) Changes in precipitation, temperature, and ocean levels; (5) A combination of the impacts specified in paragraphs (1) to (4), inclusive.

Indirect effects of changes in Delta exports due to abrupt reductions in Delta water supply are further addressed in Section 4.2.29, *Growth Inducement and Other Indirect Effects,* and other sections of this RDEIR/SDEIS addressing specific resources.

Change in Delta Exports

Average annual Delta exports (SWP and CVP exports through Banks and Jones Pumping Plants) under the No Action Alternative (ELT) would be reduced by about 416 TAF (8%) as compared to Existing Conditions (Table B.1-2 in Appendix B of this RDEIR/SDEIS) because of sea level rise and climate change, increased outflows to meet Fall X2 in wet and above normal years, increased projected urban water demands, and other changes explained previously in this section, as shown in Figures 4.3.1-15 through 4.3.1-17. Figure 4.3.1-18 shows that annual Delta exports would be reduced in almost all years under the No Action Alternative (ELT) as compared to Existing Conditions. Increased system inflow during January through March due to climate change would not result in increased exports during this period generally because of limited demands and limited conveyance and storage capacity in these months. Average monthly total SWP and CVP exports, as shown in Figures 4.3.1-19 through 4.3.1-21, exhibit reductions in the fall months because of increased Delta outflow for Fall X2. Export reductions that begin in June and continue through Fall under the No Action Alternative (ELT) as compared to Existing Conditions are due to reduced carryover storage and increased urban demands.

Overall, SWP and CVP water exports would decrease under the No Action Alternative (ELT) as compared to Existing Conditions and could result in reductions in CVP and SWP deliveries. The following summarizes the types of responses to the reductions in water supply that are anticipated to occur. Monthly Delta export patterns are presented in Figures 4.3.1-19 through 4.3.1-21.

Urban Responses

Exports of Delta water supplies have been reduced as a result of legislative and regulatory actions. Additional regulatory actions could result in further reductions, although a specific estimate would be difficult to quantify. Prior responses from urban water agencies in periods of drought provide useful examples of how those agencies could respond to further reductions of Delta water supplies. Reductions that occur as a result of regulatory or policy decisions are likely to remain in place for some time (unless and until some alternative program or projects can address the underlying issues which were the impetus for the regulatory action). Thus, it is likely that any such reductions would at a minimum remain in place for a period of years, or could essentially be permanent.

The effect on individual water agencies would vary considerably, as some are almost entirely reliant on exports of Delta water supplies, while for others these sources provide only a portion of their water supply portfolios, and other water sources could remain available. For example, in 2010, supplies exported from, or diverted in, the Delta comprised approximately 89 percent of the total water supplies for the Zone 7 Water Agency (Zone 7 Water Agency 2010), while the SWP provides less than 30 percent of water supplies for Metropolitan.

The responses of urban water users of reduced exports of Delta water supplies are discussed further in Appendix 5B, *Responses to Reduced South of Delta Water Supplies*, of the Draft EIR/EIS. As described therein, responses could include voluntary conservation measures, increased reliance on reservoir storage, increased reliance on groundwater, implementation of contingency planning efforts, increased use of recycled water, increased water transfers, increased reliance on desalination as a water supply, and water use restrictions.

Agricultural Responses

The San Joaquin Valley is among the most productive agricultural regions in the world, each year generating more than $23 billion in farm output and supporting more than 200,000 jobs. This success can largely be attributed to the availability of water supplies through the Delta and delivered by the SWP and CVP.

As noted above, exports of Delta water supplies have been reduced as a result of legislative and regulatory actions. Responses from individual agricultural water agencies and agriculture overall, to previous reductions and during periods of drought provide useful examples of how those agencies would respond. Reductions that occur as a result of a regulatory or policy decision are assumed to remain in place for some time. Thus, it is likely that any such reductions would remain for several years or could be permanent.

The responses of water agencies to extended droughts provide good insights into the effects of further reductions in exports of Delta water supplies. The 1987–1992 drought had severe impacts on water agencies. Many purchased water from alternative sources to offset reduced Delta supplies, often at very high costs that some clients were unable to afford. Farmers responded to the resultant higher costs by increasing their own groundwater pumping and reducing their purchases from water agencies, but also fallowed large acreages of both annual and permanent crop land. The financial viability of some water agencies themselves suffered and was reflected in increased credit risks and downgrades by credit rating agencies because of these reduced supplies (Moody's Investors Service 1994).

The effect on individual agricultural agencies would vary considerably, as some are almost entirely reliant on exports of Delta water supplies, while for others these sources provide only a portion of their water supply portfolios, and those other water sources could remain available. For example, during the period of 1978 to 2006, Westlands Water District relied on CVP deliveries for an average of 73 percent of its total supplies (Westlands Water District 2007).

The responses of agricultural water users of reduced exports of Delta water supplies are discussed further in Appendix 5B, *Responses to Reduced South of Delta Water Supplies*, of the Draft EIR/EIS. As described therein, responses could include increased reliance on reservoir storage, increased reliance on groundwater, and water conservation programs.

Increased Transfer Demand

Demands for supplemental water supplies to offset declines in SWP and CVP allocations will increase. Demand for cross-Delta water transfers will increase, with the frequency of such transfers increasing from about 52 percent of years to 68 percent of years compared to existing conditions. The demand increases by project are: from about 23 percent of years to 39 percent of years for the SWP, and from about 51 percent of years to 67 percent of years for the CVP. The average annual transfer demand volume could increase from about 146,000 acre-feet to about 280,000 acre-feet, assuming an estimated maximum cross-Delta transfer supply of 600,000 acre-feet in any one year. Cross-Delta Transfer capacity would restrict the actually realized increase in transfer volumes to less than the amounts stated by an unknown degree, but the increase in the frequency of Cross-Delta transfers would likely occur as predicted as a result of the predicted 14 percent reduction in Delta exports for SWP and CVP Project deliveries.

As noted elsewhere, the decreases in project deliveries (and consequential increase in transfer demand) are caused by (1) an increase in demands associated with water rights, the buildout of planned facilities, and greater use of existing CVP and SWP contracts which cumulatively result in about 443 TAF per year additional consumptive use per year north of Delta at the future level of development; (2) climate change and sea level rise; and (3) depending on alternative, assumption of certain added Delta outflows to benefit fish.

Indirect effects of changes in Delta exports are further addressed in Section 4.2.29, *Growth Inducement and Other Indirect Effects*, and other sections of this RDEIR/SDEIS addressing specific resources.

Change in SWP and CVP Deliveries

Impact WS-1: Changes in SWP CVP Water Deliveries during Construction

No construction or modification to SWP or CVP facilities would occur under the No Action Alternative (ELT).

***CEQA Conclusion*: ** No construction or modification to SWP or CVP facilities would occur under the No Action Alternative (ELT).

Impact WS-2: Change in SWP and CVP Deliveries

The effects of sea level rise and climate change, increase in north of Delta urban demands and implementation of Fall X2 in wet and above normal years under the No Action Alternative (ELT) would cause changes in SWP and CVP deliveries as compared to Existing Conditions.

Under No Action Alternative (ELT) average annual total CVP deliveries would be similar with a slight increase of 9 TAF (0%) and average annual total south of the Delta CVP deliveries would decrease by about 150 TAF (7%) as compared to deliveries under Existing Conditions. Average annual CVP north of Delta agricultural deliveries would be reduced by 47 TAF (20%) and exhibit reductions in about 75% of years under the No Action Alternative at Year 2025 (ELT) as compared to Existing Conditions, as shown in Figure 4.3.1-22. Average annual CVP south of Delta agricultural deliveries would be reduced by 120 TAF (12%) and exhibit reductions in about 85% of the years, as shown in Figure 4.3.1-23. Average annual CVP north of Delta M&I deliveries would increase by 181 TAF (86%) due to the increase in urban demand. Deliveries would increase in all years, as shown in Figure 4.3.1-24. Average annual CVP south of Delta M&I deliveries would be reduced by 6 TAF (5%) in about 75% of the years, as shown in Figure 4.3.1-25.

Under No Action Alternative (ELT), model results show a 18 TAF (1%) decrease in CVP Settlement Contract deliveries and a 8 TAF (2%) decrease in CVP Level 2 Refuge Water Supplies during dry and critical years compared to the Existing Conditions. This is because Shasta Lake storage would decline to dead pool more frequently due to the shift in runoff patterns from climate change, sea level rise, increased releases for Fall X2, and increased demands as explained above. Results show no changes in deliveries to CVP Exchange Contractors. As described in the methods section in Chapter 5, *Water Supply*, of the Draft EIR/EIS, model results and potential changes under these extreme reservoir storage conditions may not be representative of actual future conditions because changes in assumed operations may be implemented to avoid these conditions.

Under No Action Alternative (ELT), average annual total SWP deliveries would decline by 236 TAF (6%). Average annual total SWP south of Delta deliveries (including Article 56[3] and Article 21) would be reduced by about 219 TAF (8%) and exhibit reductions in about 90% of the years under No Action Alternative at 2025 (ELT) as compared to Existing Conditions, as shown in Figure 4.3.1-26. Average annual SWP Table A deliveries would reduce by 114 TAF (4%) and average annual SWP south of Delta Table A deliveries (including Article 56) would be reduced by about 129 TAF (5%). Table A deliveries would be reduced in about 80% of the years, as shown in Figure 4.3.1-27. Average annual SWP south of Delta Article 21 deliveries would be reduced by about 106 TAF (67%) and would decrease in almost all years, as shown in Figure 4.3.1-28. There would be an average annual decrease of 44 TAF (5%) in SWP Feather River Service Area deliveries during dry and critical years compared to the Existing Conditions.

Overall, SWP and CVP water deliveries would decrease under the No Action Alternative (ELT) as compared to Existing Conditions.

For a discussion of the potential responses of SWP and CVP water users to reduced SWP and CVP deliveries, please refer to Appendix 5B, *Responses to Reduced South of Delta Water Supplies*, of the Draft EIR/EIS. As explained therein, responses of urban water users could include voluntary conservation measures, increased reliance on reservoir storage, increased reliance on groundwater, implementation of contingency planning efforts, increased use of recycled water, increased water transfers, increased reliance on desalination as a water supply, and water use restrictions. Responses of agricultural water users could include increased reliance on reservoir storage, increased reliance on groundwater, and water conservation programs.

Indirect effects of changes in water deliveries are further addressed in Section 4.2.29, *Growth Inducement and Other Indirect Effects,* and other sections of this RDEIR/SDEIS addressing specific resources.

CEQA Conclusion: The reductions in SWP and CVP water deliveries under the No Action Alternative (ELT) as compared to Existing Conditions would be mainly due to a combination of effects of sea level rise and climate change, increased future upstream and in-delta water demand (having priority over SWP and CVP rights) and implementation of Fall X2. Indirect effects of changes in water deliveries are addressed in Section 4.2.29, *Growth Inducement and Other Indirect Effects,* and other sections of this RDEIR/SDEIS addressing specific resources.

Impact WS-3: Effects of Water Transfers on Water Supply

Demands for supplemental water supplies to offset declines in SWP and CVP allocations will increase. Demand for cross-Delta water transfers will increase, with the frequency of such transfers increasing from about 52 percent of years to 68 percent of years, increasing from about 23 percent of years to 39 percent of years for the SWP, and from about 51 percent of years to 67 percent of years for the CVP. The average annual transfer demand volume could increase from about 146,000

[3] In accordance with Monterey Agreement Article 56, SWP contractors may choose to keep a portion of their allocated water in a certain year in project surface conservation facilities and request it in a subsequent year. Article 56 deliveries in this document refers to water that was previously stored in project storage facilities delivered to contractors in a certain year.

acre-feet to about 280,000 acre-feet, assuming an estimated maximum cross-Delta transfer supply of 600,000 acre-feet in any one year. Cross-Delta transfer capacity would restrict the actually realized increase in transfer volumes to less than the amounts stated by an unknown degree, but the increase in the frequency of Cross-Delta transfers would likely occur as predicted as a result of the predicted 14 percent reduction in Delta exports for project deliveries.

CEQA Conclusion: Demands for supplemental water supplies to offset declines in SWP and CVP allocations will increase, and demand for cross-Delta water transfers will increase, due to reductions in SWP and CVP water deliveries. The reductions in SWP and CVP water deliveries under the No Action Alternative as compared to Existing Conditions would be mainly due to a combination of effects of sea level rise and climate change, increased future upstream and in-Delta water demand or in-basin consumptive use (having priority over SWP and CVP rights) and implementation of Fall X2.

4.2.5 Surface Water

The No Action Alternative (ELT) would include continued implementation of existing maintenance, enforcement, and protection programs by federal, state, and local agencies, as well as projects that are permitted or under construction. Under the No Action Alternative (ELT), operations of the SWP CVP facilities would be similar to those under Existing Conditions with the following changes.

- Effects of sea level rise and climate change on system operations as discussed in Section 6.3.1.1, *Quantitative Analysis of Surface Water Resources*, of the Draft EIR/EIS.
- An increase in demands and the buildout of facilities associated with water rights and CVP and SWP contracts of about 443 TAF per year, north of Delta at the future level of development. This is an increase in CVP M&I service contracts (253 TAF per year) and water rights (184 TAF per year) related primarily to urban M&I use, especially in the communities in El Dorado, Placer, and Sacramento Counties.
- An increase in demands associated with SWP contracts, up to full contract amounts, south of Delta at the future level of development. SWP M&I demands, which under the existing level of development vary on hydrologic conditions between 3.0 and 4.1 MAF per year, under the future condition are at maximum contract amounts in all hydrologic conditions. This represents a potential 25% increase on average in south of Delta demands under SWP M&I contracts between existing and future levels of development due to assumed additional development and demographics.
- New urban intake/Delta export facilities:
    - Freeport Regional Water Project (see Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS for information on additional EBMUD demand of about 26 TAF/YR on the average with increased demand in dry years)
    - 30 million-gallon-per-day City of Stockton Delta Water Supply Project
    - Delta-Mendota Canal–California Aqueduct Intertie
    - Contra Costa Water District Alternative Intake and 55 TAF/YR increased demand
    - South Bay Aqueduct rehabilitation, to 430 cfs capacity, from the junction with California Aqueduct to Alameda County Flood Control and Water Conservation District Zone 7.

- An increase in supplies for wildlife refuges including Firm Level 2 supplies of about 8 TAF per year at the future level of development. In addition, there is a shift in refuge demands from south to north (24 TAF per year reduction in south of Delta and 32 TAF per year increase in north of Delta).
- Implementation of the Fall X2 RPA action (see Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS), which requires maintenance of X2 at specific locations in wet and above normal years in September and October, plus releases in November to augment Delta outflow depending on hydrology.

A detailed description of the modeling assumptions associated with the No Action Alternative is included in Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS. Impacts on surface water conditions related to climate change and sea level rise are further described in Appendix 3E, *Potential Seismic and Climate Change Risks to SWP/CVP Water Supplies*, of the Draft EIR/EIS.

Model results discussed for this alternative are summarized in Tables B.2-1 through B.2-6.

Section 6.3.2, *Determination of Effects*, of the Draft EIR/EIS includes the criteria used to determine an adverse effect under NEPA or a significant impact under CEQA for the Surface Water Impacts.

SWP CVP Reservoir Storage and Related Changes to Flood Potential

Impact SW-1: Changes in SWP or CVP Reservoir Flood Storage Capacity

Reservoir storage in Shasta Lake, Folsom Lake, and Lake Oroville during the October through June period is compared to the flood storage capacity of each reservoir to identify the number of months when the reservoir storage is close to the flood storage capacity.

Under the No Action Alternative (ELT), the number of months where the reservoir storage is close to the flood storage capacity in Shasta Lake, Folsom Lake, and Lake Oroville would be fewer than under Existing Conditions, as shown in Tables B.2-1 through B.2-6. The changes in flood storage capacity are due to water releases to meet increased demands under the No Action Alternative (ELT) compared to Existing Conditions, and changes due to sea level rise and climate change. The changes in reservoir flood storage capacity would provide additional flexibility for flood management.

***CEQA Conclusion*:** Under No Action Alternative (ELT) the number of months where the reservoir storage is close to the flood storage capacity in Shasta Lake, Folsom Lake, and Lake Oroville would be less than under Existing Conditions because of the changes due to higher releases for increased demands under the No Action Alternative, implementation of Fall X2, and changes due to sea level rise and climate change. No Action Alternative (ELT) would not cause consistently higher storages in the upper Sacramento River watershed during the October through June period. Accordingly, No Action Alternative (ELT) would result in a less-than-significant impact on flood management.

Highest Monthly Flows in Sacramento and San Joaquin Rivers and Related Changes to Flood Potential

Impact SW-2: Changes in Sacramento and San Joaquin River Flood Flows

Analysis of monthly flows in high flow conditions could be indicative of the potential for changes in flood management in the Sacramento River at Freeport, San Joaquin River at Vernalis, Sacramento

River upstream of Walnut Grove (downstream of proposed north Delta intake locations), Trinity River downstream of Lewiston Dam, American River downstream of Nimbus Dam, Feather River downstream of Thermalito Dam, and Yolo Bypass at Fremont Weir.

Sacramento River at Bend Bridge

Highest monthly flows that occur in Sacramento River at Bend Bridge are shown in Figures 4.3.2-1 and 4.3.2-2 during wet years and over the long-term average.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under the No Action Alternative (ELT) would increase by 1% of the channel capacity (100,000 cfs) as compared to the flows under Existing Conditions, as shown in Tables B.2-1 through B.2-3 in Appendix B of this RDEIR/SDEIS. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

Sacramento River at Freeport

Highest monthly flows that occur in Sacramento River at Freeport are shown in Figures 4.3.2-3 and 4.3.2-4 during wet years and over the long-term average.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under the No Action Alternative (ELT) would increase by no more than 1% of the channel capacity (110,000 cfs) as compared to the flows under Existing Conditions, as shown in Tables B.2-1 through B.2-3. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

San Joaquin River at Vernalis

Highest monthly flows that occur in San Joaquin River at Vernalis are shown in Figures 4.3.2-5 and 4.3.2-6 during wet years and over the long-term average.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) would increase by no more than 1% of channel capacity under the No Action Alternative (ELT) as compared to the flows under Existing Conditions, as shown in Tables B.2-1 through B.2-3. The changes primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

Sacramento River at Locations Upstream of Walnut Grove (downstream of north Delta intakes)

Highest monthly flows that occur in the n the Sacramento River upstream of Walnut Grove are shown in Figures 4.3.2-7 and 4.3.2-8 during wet years and over the long-term average.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under the No Action Alternative (ELT) would increase by no more than 1% of the channel capacity (110,000 cfs) as compared to the flows under Existing Conditions, as shown in Tables B.2-1 through B.2-3 of the Draft EIR/EIS. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

Trinity River Downstream of Lewiston Dam

Highest monthly flows that occur in the Trinity River downstream of Lewiston Dam are shown in Figures 4.3.2-9 and 4.3.2-10 during wet years and over the long-term average.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under the No Action Alternative (ELT) would increase by no more than 3% of the channel capacity (6,000 cfs), as shown in Tables B.2-1 through B.2-3. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

American River Downstream of Nimbus Dam

Highest monthly flows that occur in the American River downstream of Nimbus Dam are shown in Figures 4.3.2-11 and 4.3.2-12 during wet years and over the long-term average.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under the No Action Alternative (ELT) would increase by no more than 1% of channel capacity (152,000 cfs), as shown in Tables B.2-1 through B.2-3 of the Draft EIR/EIS. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

Feather River Downstream of Thermalito Dam

Highest monthly flows that occur in the Feather River downstream of Thermalito Dam are shown in Figures 4.3.2-13 and 4.3.2-14 during wet years and over the long-term average.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under the No Action Alternative (ELT) would increase by no more than 1% of the channel capacity (210,000 cfs) as compared to the flows under Existing Conditions, as shown in Tables B.2-1 through B.2-3. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

Yolo Bypass at Fremont Weir

Water generally spills into Yolo Bypass at Fremont Weir when the combined flows in the Sacramento River and Feather River upstream of Fremont Weir and flows from Sutter Bypass exceed 56,000 cfs. The Yolo Bypass floodplain capacity can accommodate a flow at Fremont Weir up to 343,000 cfs. Highest monthly spills into the Yolo Bypass at Fremont Weir during wet years is shown in Figure 4.3.2-15.

Average of highest spills simulated (flows with probability of exceedance of 10% or less) under the No Action Alternative (ELT) would increase by no more than 1% of the channel capacity (343,000 cfs) as compared to the flows under Existing Conditions, as shown in Tables B.2-1 through B.2-3. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

Overall, the peak flows simulated in CALSIM show increases from 0% to 3% in certain locations under the No Action Alternative (ELT). However, these changes are primarily due to the change in flow patterns due to sea level rise and climate change. As described in Section 6.3.1.2, *Methods for Analysis of Flood Management along Major Rivers*, in Appendix A of this RDEIR/SDEIS, the flood management criteria for maintaining adequate flood storage space in the reservoirs (as defined by the USACE and DWR for flood control release criteria) were not modified to adapt to the changes in runoff due to climate change. No changes in monthly allowable storage values related to CALSIM II model assumptions were included because these changes were not defined under the alternatives to achieve the project objectives or purpose and need for Alternative 4A. If USACE and DWR modify allowable storage values in the future in response to climate change, it is anticipated that the surface water flows and related water supply and water quality conditions would change.

CEQA Conclusion: No Action Alternative (ELT) could result in an increase in potential risk for flood management compared to Existing Conditions because of the changes due to sea level rise and climate change. It is expected that flood management criteria would be modified in the future to reduce risks due to sea level rise and climate change. This potential impact is considered significant.

Reverse Flows in Old and Middle River

Impact SW-3: Change in Reverse Flow Conditions in Old and Middle Rivers

Reverse flow conditions for Old and Middle River flows in all months on a long-term average basis under the No Action Alternative (ELT) are more positive as compared to Existing Conditions, except in April and May. In these months, Old and Middle River flows are less negative due to reduced south Delta exports because of the sea level rise and climate change, increased demands in north of the Delta, and operations to comply with Fall X2 (Figure 4.3.2-16).

CEQA Conclusion: There would be less reverse flows in Old and Middle Rivers under the No Action Alternative (ELT) compared to Existing Conditions in June through March, due to reduced south Delta exports because of sea level rise and climate change, increased demands north of the Delta, and operations to comply with Fall X2. Reverse flows would become more negative in April and May under the No Action Alternative (ELT) compared to Existing Conditions.

Ongoing Plans, Policies, and Programs

The programs, plans, and projects included under the No Action Alternative ELT are summarized in Chapter 3, *Description of Alternatives*, of the Draft EIR/EIS. Most of the projects would not affect surface water resources under the No Action Alternative compared to Existing Conditions. The projects that could potentially affect SWP/ CVP surface water conditions are summarized in Table 6-8 of the Draft EIR/EIS.

CEQA Conclusion: In total, the ongoing programs and plans under the No Action Alternative (ELT) would not result in significant impacts on surface water resources based upon information presented in related environmental documentation.

4.2.6 Groundwater

Delta Region

The effects of the No Action Alternative (ELT) as considered for the purposes of Alternatives 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 7, *Groundwater*, Section 7.3.3.1 of the Draft EIR/EIS.

Groundwater resources are not anticipated to be substantially affected in the Delta Region under the No Action Alternative (ELT) because surface water inflows to this area are sufficient to satisfy most of the agricultural, industrial, and municipal water supply needs.

Changes in Delta Groundwater Levels. Groundwater levels in the Delta for the No Action Alternative (ELT) would be strongly influenced by surface water flows in the Sacramento River that fluctuate due to moderate sea level rise, climate change and due to surface water operations. Sea level rise under the No Action Alternative (ELT) would be less than that described under the No Action Alternative (LLT), therefore, impacts on the Suisun Marsh area groundwater levels would be less than under the No Action Alternative (LLT). In most other areas of the Delta, groundwater levels under the No Action Alternative (ELT) would be similar to Existing Conditions.

Changes in Delta Groundwater Quality. As described above, groundwater levels would be similar under Existing Conditions and the No Action Alternative (ELT) except for a localized area around Suisun Marsh. Therefore, changes in groundwater conditions under the No Action Alternative (ELT) are not anticipated to alter regional patterns of groundwater flow or quality, compared with Existing Conditions.

Changes in Delta Agricultural Drainage. Changes in agricultural drainage are anticipated to be similar or less under the No Action Alternative (ELT) as compared to the No Action Alternative (LLT). As described in Section 7.3.3.1 of the Draft EIR/EIS, due to fluctuations in groundwater levels that occur with moderate sea level rise and climate change, some areas of the Delta might experience rises in groundwater levels in the vicinity of rivers and in the Suisun Marsh area under the No Action Alternative (ELT) compared to Existing Conditions. This could affect agricultural drainage. However, changes are anticipated to be minor and these areas would be surrounded by larger regional flow patterns that would remain largely unchanged under the No Action Alternative (ELT).

CEQA Conclusion: Groundwater resources are not anticipated to be substantially affected in the Delta Region under the No Action Alternative (ELT) because surface water inflows to this area are sufficient to satisfy most of the agricultural, industrial, and municipal water supply needs. Therefore the No Action Alternative (ELT) would have less than significant impacts on Delta groundwater levels, groundwater quality, and agricultural drainage because changes in groundwater flows and groundwater use are not anticipated to occur due to the abundant surface water in the Delta.

SWP CVP Export Service Areas

Under the No Action Alternative (ELT), surface water supplies to the Export Service Areas would continue to decline based on water modeling and operational assumptions described in Chapters 5 and 6 in the Draft EIR/EIS which project reductions in SWP/CVP water supply availability, compared to Existing Conditions. In addition, decreases in SWP/CVP surface water deliveries in the Export Service Areas for the No Action Alternative (ELT) compared to Existing Conditions also occur due to sea level rise and climate change, as described in Chapter 5, *Water Supply*, in the Draft EIR/EIS.

CVHM simulation assumptions for the No Action Alternative (ELT) are similar to those for the No Action Alternative (LLT).

Groundwater conditions under the No Action Alternative (ELT) (with future projected sea level rise and climate change at approximately year 2025) compared to Existing Conditions are provided in the descriptions that follow. The comparison is made through a review of simulated groundwater resources conditions in the San Joaquin and Tulare Basins.

CEQA Conclusion:

San Joaquin Basin

Forecasted groundwater flow in the San Joaquin Basin under the No Action Alternative (ELT) is generally toward the San Joaquin River from the margins of the basin and to the northwest toward the Delta. As compared to Existing Conditions, groundwater levels would decline by up to 10 feet beneath the Corcoran Clay in portions of the San Joaquin Basin (see Figure 4.2.3-1) under the No Action Alternative (ELT). This reduction in groundwater levels could substantially affect groundwater resources in the San Joaquin Basin by reducing well yields of nearby agricultural and municipal wells. Therefore, the No Action Alternative (ELT).would result in a significant impact on groundwater resources.

Tulare Basin

Forecasted groundwater flow in the Tulare Basin under the No Action Alternative (ELT) is complex because of the spatially variable water use over such a large area. Forecasted groundwater flow in the Tulare Basin is generally away from the margins of the basin toward areas of substantial groundwater production. As compared to Existing Conditions, groundwater levels would decline up to 100 feet with a small area that could see water level declines of as much as 250 feet beneath the Corcoran Clay in dry years in portions of the Tulare Basin irrigated areas, notably the Westside and Northern Pleasant Valley basins (WBS 14) in the western portion (see Figure 4.2.3-1) under the No Action Alternative (ELT). The forecasted maximum groundwater level changes occur in August because agricultural groundwater pumping is typically highest during this month.

The anticipated reduction in groundwater levels could substantially affect groundwater resources in the Tulare Basin in terms of affecting well yields of nearby agricultural and municipal wells, groundwater supplies, and groundwater recharge and therefore, the No Action Alternative (ELT) would result in a significant impact on groundwater resources.

The increase in groundwater pumping that could occur under the No Action Alternative (ELT) compared to Existing Conditions in portions of the Export Service Areas in response to reduced SWP/CVP water supply availability could induce the local migration of poor-quality groundwater into areas of good-quality groundwater. However, it is not anticipated to alter regional groundwater flow patterns and would not be considered a significant impact on groundwater quality.

Other Portions of the Export Service Areas

The total long-term average annual water deliveries to the CVP and SWP Export Service Areas in portions outside of the Central Valley under the No Action Alternative (ELT) would be slightly less than under Existing Conditions, but more than under No Action Alternative (LLT). The reduction in surface water deliveries could result in an increase in groundwater pumping and the associated decrease in groundwater levels. The anticipated reduction in groundwater levels could substantially affect groundwater resources in the in terms of affecting well yields of nearby agricultural and municipal wells, groundwater supplies, and groundwater recharge. Therefore, the No Action Alternative (ELT) would have a significant impact on groundwater resources.

However, in the Central Coast and Southern California, overdrafted basins have, for the most part, been adjudicated to control the amount of pumping, thus reducing the amount of groundwater resource availability. In addition, many groundwater basins in the San Francisco Bay Area, Central Coast, and Southern California rely on SWP CVP surface water to recharge groundwater basins.

4.2.7 Water Quality

The analysis of effects of the No Action Alternative (ELT) on boron, bromide, chloride, DOC, EC, and nitrate in the Delta and SWP/CVP Export Service Areas is based on modeling conducted for the No Action Alternative in the ELT, which assumed no implementation of Yolo Bypass improvements or tidal habitat restoration. However, as described in Section 4.1.6, *Assumptions for Purpose of Analysis*, of the RDEIR/SDEIS, enhancements to the Yolo Bypass and 8,000 acres of tidal habitat restoration areas would be developed under the No Action Alternative (ELT). In general, the significance of this difference is the assessment of bromide, chloride and EC for the No Action Alternative (ELT), relative to Existing Conditions, likely underestimates increases in bromide, EC, and chloride that could occur, particularly in the west Delta. Nevertheless, there is notable uncertainty in the results of all quantitative assessments that refer to modeling results, due to the differing assumptions used in the modeling and the description of the No Action Alternative (ELT).

Impact WQ-1: Effects on Ammonia Concentrations Resulting from Facilities Operations and Maintenance

The effects of the No Action Alternative (ELT) on ammonia levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative (LLT) discussed in Chapter 8, *Water Quality*, Section 8.3.3.1, in the Draft EIR/EIS. This is because factors which affect ammonia levels in these areas would be similar at the ELT and LLT timeframes. The Sacramento Regional County Sanitation District will have completed modifications to the Sacramento Regional Wastewater Treatment Plant (SRWTP) in the ELT that will substantially reduce ammonia in the treated wastewater discharge and thus substantially lower concentrations of ammonia in the Sacramento River downstream of the SRWTP relative to Existing Conditions. A substantial decrease in Sacramento River ammonia concentrations is expected to decrease ammonia concentrations for all areas that are influenced by Sacramento River water, which includes various locations in the Delta and at Jones and Banks Pumping Plants where Delta water is exported to the SWP/CVP Export Service Areas. At locations which are not influenced notably by Sacramento River water, concentrations are expected to remain relatively unchanged relative to Existing Conditions. Based on these factors and for the reasons described for the No Action Alternative (LLT) in Section 8.3.3.1 in the Draft EIR/EIS, the effects on ammonia from implementing the No Action Alternative (ELT) would not be adverse.

CEQA Conclusion: The effects of the No Action Alternative (ELT) on ammonia levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative (LLT). This is because factors that would directly affect ammonia levels in the surface waters of these areas are expected to be similar in the ELT and LLT. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because ammonia concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Ammonia is not CWA Section 303(d) listed within the affected environment and thus any minor increases that may occur in some areas would not make any existing ammonia-related impairment measurably worse because no such impairments currently exist. Because ammonia is not bioaccumulative, minor increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered less than significant.

Impact WQ-3: Effects on Boron Concentrations Resulting from Existing Facilities Operations and Maintenance

Upstream of the Delta

The effects of the No Action Alternative (ELT) on boron concentrations in reservoirs and rivers upstream of the Delta would be similar to those effects described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. There would be no expected change to the sources of boron in the Sacramento River and east-side tributary watersheds, and changes in the magnitude and timing of reservoir releases and river flows upstream of the Delta would have negligible, if any, effect on the concentration of boron in the rivers and reservoirs of these watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly compared to Existing Conditions in association with climate change and increased water demands. The reduced flow would result in possible increases in long-term average boron concentrations of up to about 0.5% relative to the Existing Conditions (Table Bo-1 in Appendix B of this RDEIR/SDEIS). Consequently, the increases in lower San Joaquin River boron levels under the No Action Alternative (ELT), relative to Existing Conditions, would be small and not adversely affect any beneficial uses of the lower San Joaquin River.

Delta

Relative to Existing Conditions, the No Action Alternative (ELT) would result in similar or decreased long-term annual average boron concentrations at all of the Delta assessment locations for the 16-year period modeled (i.e., 1976–1991) (Table Bo-2 in Appendix B of this RDEIR/SDEIS). For the drought year period modeled (i.e., 1987–1991), the No Action Alternative (ELT) would result in increased annual average concentrations only at the Sacramento River at Emmaton (i.e., up to a maximum 3% increase) relative to Existing Conditions.

With respect to the 2,000 µg/L EPA drinking water human health advisory objective (i.e., for children) and agricultural objective of 500 µg/L contained in the San Francisco Bay RWQCB (Region 2) Basin Plan, the long-term annual average boron concentrations, for either the 16-year period or drought period modeled, are low and would not exceed these objectives at any of the eleven Delta assessment locations (Table Bo-3 in Appendix B of this RDEIR/SDEIS). The maximum long-term average concentration of about 417 µg/L in the Sacramento River at Mallard Island under the No Action Alternative (ELT) represents a slight decrease from the Existing Conditions. Accordingly, the long-term assimilative capacity with respect to both objectives would not change substantially, thus boron levels that may occur under the No Action Alternative (ELT), relative to Existing Conditions, would not be expected to adversely affect municipal water supply beneficial uses of the Delta.

SWP/CVP Export Service Areas

Under the No Action Alternative (ELT), a relatively small increase would occur in the long-term average boron concentration at the Jones Pumping Plant, relative to the Existing Conditions (i.e., up to 1% for both the 16-year and drought period modeled) and a small decrease would occur at the Banks Pumping Plant (i.e., reduced 1%) (Table Bo-2 in Appendix B of this RDEIR/SDEIS). The small change in boron concentrations exported from the Delta would not be expected to measurably affect boron levels in the lower San Joaquin River at Vernalis or the existing CWA Section 303(d) impairment in the lower San Joaquin River and associated TMDL actions for reducing boron loading.

In summary, the effects of additional future climate change/sea level rise under the No Action Alternative (ELT) condition would result in relatively small changes in long-term average boron concentrations in the lower San Joaquin River and several Delta locations. However, the predicted changes would not be expected to cause exceedances of applicable objectives or further measurable water quality degradation, and thus would not constitute an adverse effect on water quality. The changes to long-term and monthly average boron concentrations at locations upstream of the Delta, in the Delta, and the SWP/CVP Export Service areas under the No Action Alternative (ELT) would be similar or lower in magnitude relative to effects described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 in the Draft EIR/EIS.

CEQA Conclusion: The effects of the No Action Alternative (ELT) on boron levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative (LLT). This is because factors that would directly affect boron levels in the surface waters of these areas are expected to be similar at the ELT and LLT timeframes. As such, the No Action Alternative (ELT) is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because boron concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Additionally, the changes in long-term average boron concentrations in exported water would not result in further degradation or the existing impairment and CWA Section 303(d) listing of boron in the lower San Joaquin River for the agricultural water supply beneficial use to be discernibly worse. Boron is not a bioaccumulative constituent, thus any increased concentrations under the No Action Alternative (ELT) would not result in adverse boron bioaccumulation effects to aquatic life or humans. Based on these findings, this impact is determined to be less than significant.

Impact WQ-5: Effects on Bromide Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the No Action Alternative (ELT) on bromide concentrations in reservoirs and rivers upstream of the Delta would be similar to those effects described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, because factors affecting bromide concentrations in these water bodies would be the same in the ELT. There would be no expected change to the sources of bromide in the Sacramento River and east-side tributary watersheds, and changes in the magnitude and timing of reservoir releases north and east of the Delta would have negligible, if any, effect on the sources, and ultimately the concentration of bromide in the Sacramento River, the eastside tributaries, and the various reservoirs of the related watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly (1%) compared to Existing Conditions in association with climate change and increased water demands, but the associated change would less in the LLT, and any associated bromide increase would not be substantial, as described for the LLT. Moreover, there are no existing municipal intakes on the lower San Joaquin River. Consequently, the No Action Alternative (ELT) would not be expected to adversely affect the MUN beneficial use, or any other beneficial uses, of the Sacramento River, the San Joaquin River, the eastside tributaries, or their associated reservoirs upstream of the Delta due to changes in bromide concentrations.

Delta

Estimates of bromide concentrations at Delta assessment locations were generated using a mass balance approach, and using relationships between EC and chloride and between chloride and bromide and DSM2 EC output. See Chapter 8, *Water Quality*, Section 8.3.1.3 in Appendix A of the RDEIR/SDEIS for more information regarding these modeling approaches. The assessment below identifies changes in bromide at Delta assessment locations based on both approaches.

Relative to Existing Conditions, the No Action Alternative (ELT) would result in small decreases in long-term average bromide concentrations at all modeled Delta assessment locations except the Sacramento River at Emmaton (Table Br-1 in Appendix B of this RDEIR/SDEIS). For the entire period modeled (1976–1991) the long-term average increase in bromide concentration at Emmaton would be <1%. Long-term average concentrations of seawater-derived constituents generally decrease under the No Action Alternative (ELT) relative to Existing Conditions because the No Action Alternative (ELT) includes Fall X2 operations, while Existing Conditions does not (Appendices 3D, *Defining Existing Conditions, No Action Alternative, No Project Alternative, and Cumulative Impact Condition*, and 5A, *BDCP/EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS). Therefore, even though sea level rise is included in the No Action Alternative (ELT), and not in Existing Conditions, the effect of Fall X2 on bromide is generally greater than sea level rise.

The modeled frequency with which bromide concentrations would exceed bromide thresholds would change only slightly at Delta assessment locations (Table Br-1 in Appendix B of this RDEIR/SDEIS). Small increases in exceedance of 100 μg/L, which is the concentration believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts, would occur at some Delta interior and western Delta assessment locations. In the Delta interior at Rock Slough and Franks Tract, the frequency of exceeding 100 μg/L would increase by up to 2%. In the western Delta, the frequency of exceeding 100 μg/L would increase by up to 5% at Emmaton. As described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, the resulting bromide concentrations would not be expected to adversely affect MUN beneficial uses, or any other beneficial use, particularly when considering the relatively small change in long-term annual average concentration.

Results of the modeling approach which used relationships between EC and chloride and between chloride and bromide were consistent with the discussion above, and assessment of bromide using these data results in the same conclusions as are presented above for the mass-balance approach (Table Br-2 in Appendix B of this RDEIR/SDEIS).

SWP/CVP Export Service Areas

Under the No Action Alternative (ELT), long-term average bromide concentrations at the Banks and Jones Pumping Plants would decrease by as much as 6% relative to Existing Conditions (Table Br-1 in Appendix B of this RDEIR/SDEIS), based on the mass balance modeling results. The frequency with which bromide would exceed bromide concentration thresholds at the Banks and Jones Pumping Plants, relative to Existing Conditions, would remain unchanged (Table Br-1 in Appendix B of this RDEIR/SDEIS). Consequently water exported into the SWP/CVP Export Service Areas through these south Delta pumps would be of similar or slightly better quality with regard to bromide under the No Action Alternative (ELT), relative to Existing Conditions. Results of the modeling approach which used relationships between EC and chloride and between chloride and bromide were consistent these results, and assessment of bromide using these modeling results leads to the same conclusions as presented for the mass balance approach (Table Br-2 in Appendix B of this RDEIR/SDEIS).

In summary, the effects of additional future climate change/sea level rise under the No Action Alternative (ELT) condition would result in relatively small changes in long-term average bromide concentrations in the lower San Joaquin River and several Delta locations. However, the predicted changes would not be expected to cause exceedances of applicable objectives or further measurable water quality degradation, and thus would not constitute an adverse effect on water quality. The changes to long-term and monthly average boron concentrations at locations upstream of the Delta, in the Delta, and the SWP/CVP Export Service areas under the No Action Alternative (ELT) would be similar or lower in magnitude relative to effects described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS.

Maintenance of SWP and CVP facilities under the No Action Alternative (ELT) would not be expected to create new sources of bromide or contribute towards a substantial change in existing sources of bromide in the affected environment. Maintenance activities would not be expected to cause any substantial change in bromide such that MUN beneficial uses, or any other beneficial use, would be adversely affected anywhere in the affected environment.

CEQA Conclusion: While greater water demands under the No Action Alternative (ELT) would alter the magnitude and timing of reservoir releases north and east of the Delta, these activities would have negligible, if any, effect on the sources of bromide, and ultimately the concentration of bromide in the Sacramento River, the San Joaquin River, the eastside tributaries, and the various reservoirs of the related watersheds, as described for the No Action Alternative (LLT).

Relative to Existing Conditions, the No Action Alternative (ELT) would result in small decreases in average bromide concentrations at all modeled Delta assessment locations except the Sacramento River at Emmaton, where the bromide concentration would increase, though by <1%. Small increases in bromide threshold exceedances would occur at some Delta interior and western Delta assessment locations, including Rock Slough, Franks Tract, and Emmaton, but the resulting conditions would not be expected to adversely affect MUN beneficial uses, or any other beneficial use.

The assessment of effects on bromide in the SWP/CVP Export Service Areas is based on assessment of changes in bromide concentrations at Banks and Jones Pumping Plants Average bromide concentrations at the Banks and Jones Pumping Plants are predicted to decrease by as much as 6% relative to Existing Conditions while exceedance of bromide concentration thresholds at the Banks and Jones Pumping Plants would remain unchanged.

Based on the above, the No Action Alternative (ELT) would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria because none exist for bromide. The No Action Alternative (ELT) would not result in any substantial change in long-term average bromide concentration or exceed 50 and 100 µg/L assessment threshold concentrations by frequency, magnitude, and geographic extent that would result in adverse effects on any beneficial uses within affected water bodies. Bromide is not a bioaccumulative constituent and thus concentrations under this alternative would not result in bromide bioaccumulating in aquatic organisms. Increases in exceedances of the 100 µg/L assessment threshold concentration would be 5% or less at all locations assessed, which is considered to be less-than substantial long-term degradation of water quality. The levels of bromide degradation that may occur under the No Action Alternative (ELT) would not be of sufficient magnitude to cause substantially increased risk for adverse effects on any beneficial uses of water bodies within the affected environment. Bromide is not CWA Section 303(d) listed and thus the minor increases in long-term average bromide concentrations would not affect existing beneficial use impairment because no such use impairment currently exists for bromide. Based on these findings, this impact is less than significant.

Impact WQ-7: Effects on Chloride Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the No Action Alternative (ELT) on chloride concentrations in reservoirs and rivers upstream of the Delta would be similar to those effects described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, because factors affecting chloride concentrations in these water bodies would be the same in the early long-term timeframe. There would be no expected change to the sources of chloride in the Sacramento River and east-side tributary watersheds, and changes in the magnitude and timing of reservoir releases north and east of the Delta would have negligible, if any, effect on the sources, and ultimately the concentration of chloride in the Sacramento River, the eastside tributaries, and the various reservoirs of the related watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly (1%) compared to Existing Conditions in association with climate change and increased water demands, but the associated change would less than under the LLT, and any associated chloride increase would be less than substantial, as described for the LLT. Moreover, there are no existing municipal intakes on the lower San Joaquin River. Consequently, the No Action Alternative (ELT) would not be expected to cause exceedance of chloride objectives or substantially degrade water quality with respect to chloride and thus would not adversely affect any beneficial uses of the Sacramento River, the San Joaquin River, the eastside tributaries, or their associated reservoirs upstream of the Delta.

Delta

Estimates of chloride concentrations at Delta assessment locations were generated using a mass balance approach and EC chloride relationships and DSM2 EC output. See Chapter 8, *Water Quality*, Section 8.3.1.3, of the Draft EIR/EIS for more information regarding these modeling approaches. The assessment below identifies changes in chloride at Delta assessment locations based on both approaches.

Relative to Existing Conditions, the mass balance modeling predicts that the No Action Alternative (ELT) would result in similar, or in small decreases in, long-term average chloride concentrations for the 16-year period modeled (i.e., 1976–1991) at all Delta assessment locations except the Sacramento River at Emmaton and the San Joaquin River at Antioch (in Appendix B of this RDEIR/SDEIS Table Cl-4 in Appendix B of this RDEIR/SDEIS). In the Sacramento River at Emmaton, there would be a 1 mg/L (<1%) increase in the long-term average chloride concentration, and 49 mg/L (10%) increase in the drought period modeled (i.e., 1987–1991) chloride concentration. This increase is less than the increase that would occur under Alternative 4 (LLT). At Antioch, the long-term average chloride concentration would decrease, but the drought period concentration would increase by 4 mg/L (<1%). Long-term average concentrations of seawater-derived constituents would generally decrease under the No Action Alternative (ELT) relative to Existing Conditions because the No Action Alternative (ELT) includes Fall X2, while Existing Conditions does not (Appendices 3D, *Defining Existing Conditions, No Action Alternative, No Project Alternative, and*

Cumulative Impact Condition, and 5A, *BDCP/EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS). Therefore, even though sea level rise is included in the No Action Alternative (ELT), and not in Existing Conditions, the effect of Fall X2 on chloride is generally greater than sea level rise.

The comparison to Existing Conditions reflects changes in chloride due to both increased demands and changed hydrology and Delta hydrodynamic conditions associated with climate change and sea level rise. The following outlines the modeled chloride changes relative to the applicable objectives and effects on beneficial uses in Delta waters.

Municipal and Industrial Beneficial Uses Relative to Existing Conditions

Estimates of chloride concentrations generated using EC chloride relationships were used to evaluate the 150 mg/L Bay-Delta WQCP objective for municipal and industrial beneficial uses on a basis of the percent of years the chloride objective would be exceeded for the 16-year period modeled. The objective is exceeded if chloride concentrations exceed 150 mg/L for a specified number of days in a given water year at Antioch or Contra Costa Pumping Plant #1. For the No Action Alternative (ELT), the frequency of objective exceedance would decrease relative to Existing Conditions. The frequency of exceedance of the 150 mg/L objective is predicted to be 6.7% of years under Existing Conditions and 0% under the No Action Alternative (Table Cl-1 in Appendix B of this RDEIR/SDEIS).

Evaluation of the 250 mg/L Bay-Delta WQCP objective for chloride utilized results from both the mass balance approach and EC chloride relationships. The basis for the evaluation was the predicted number of days the objective would be exceeded for the modeled 16-year period.

Based on the mass-balance approach, there would be an increased frequency of exceedance of the 250 mg/L objective under the No Action Alternative (ELT), relative to Existing Conditions, in the Sacramento River at Emmaton, the San Joaquin River at Antioch, and the Sacramento River at Mallard Island. At Emmaton, the frequency of objective exceedance would increase from 55% under Existing Conditions to 60% under the alternative during the drought period; when the entire modeled period is considered, there would be a decrease in the frequency of objective exceedance. At Antioch, the frequency of objective exceedance would increase from 66% to 70% for the entire period modeled, and from 82% to 85% during the drought period modeled. In the Sacramento River at Mallard Island, the frequency of objective exceedance would increase from 85% to 86% for the entire period modeled (Table Cl-2 in Appendix B of this RDEIR/SDEIS).

The mass balance results also indicate reduced assimilative capacity with respect to the 250 mg/L objective during certain months and locations. In the San Joaquin River at Antioch, there would be a reduction in assimilative capacity in March and April of up to 20% for the 16-year period modeled, and a 52% reduction during the drought period modeled (Table Cl-10 in Appendix B of this RDEIR/SDEIS). Assimilative capacity at the Contra Costa Pumping Plant #1 also would be reduced, in February and March, by up to 11%.

When utilizing the EC-chloride relationship to model chloride concentrations for the 16-year period, trends in frequency of exceedance of the 250 mg/L objective and use of assimilative capacity are similar to that discussed above for the mass balance modeling approach (Tables Cl-3 and Cl-11 in Appendix B of this RDEIR/SDEIS).

Based on the additional predicted seasonal and annual exceedances of Bay Delta WQCP objectives for chloride, and the associated long-term water quality degradation and use of assimilative capacity, the potential exists for adverse effects on the municipal and industrial beneficial uses in the western Delta, particularly at Antioch, through reduced opportunity for diversion of water with acceptable chloride levels.

CWA Section 303(d) Listed Water Bodies–Relative to Existing Conditions

Tom Paine Slough in the southern Delta is on the state's CWA Section 303(d) list for chloride with respect to the secondary MCL of 250 mg/L. Monthly average chloride concentrations at the Old River at Tracy Road for the 16-year period modeled, which represents the nearest DSM2-modeled location to Tom Paine Slough, would be well below the MCL and generally would be similar to Existing Conditions (Figure Cl-1 in Appendix B of this RDEIR/SDEIS).

Suisun Marsh also is on the state's CWA Section 303(d) list for chloride in association with the Bay-Delta WQCP objectives for maximum allowable salinity during the months of October through May, which establish appropriate seasonal salinity conditions for fish and wildlife beneficial uses. The Sacramento River at Mallard Island, Sacramento River at Collinsville, and Montezuma Slough at Beldon's Landing within the marsh are DSM2-modeled locations representative of source water quality conditions for the marsh that is supported by inflowing flood tide waters from the west, and ebb tide flows of Sacramento River water into Montezuma Slough through the Suisun Marsh Salinity Control Gates located near Collinsville. Long-term average chloride concentrations at the Sacramento River at the Mallard Island for the 16-year period modeled would decrease by 93 mg/L (-4%) relative to Existing Conditions (Table Cl-4 in Appendix B of this RDEIR/SDEIS). The plots of monthly average chloride concentrations for the Sacramento River at Collinsville (Figure Cl-3 in Appendix B of this RDEIR/SDEIS) and Montezuma Slough at Beldon's Landing (Figure Cl-4 in Appendix B of this RDEIR/SDEIS) for the 16-year period modeled indicate that, relative to Existing Conditions, chloride concentrations would be similar or lower during the months of October through May. Consequently, chloride concentrations at Tom Paine Slough and Suisun Marsh would not be further degraded on a long-term basis or adversely affect necessary actions to reduce chloride loading for any TMDLs developed.

SWP/CVP Export Service Areas

Under the No Action Alternative (ELT), long-term average chloride concentrations at the Banks and Jones Pumping Plants would decrease by 6% and 5%, respectively, relative to Existing Conditions for the 16-year period modeled, based on mass-balance modeling results (Table Cl-4 in Appendix B of this RDEIR/SDEIS). However, the frequency of objective exceedance would increase at both pumping plants, relative to Existing Conditions, for both the 16-year period and the drought period modeled (Table Cl-2 in Appendix B of this RDEIR/SDEIS). Results of the modeling approach which utilized a EC chloride relationship are consistent these results, and assessment of chloride using these modeling output results in the same conclusions as for the mass-balance approach (Table Cl-3 and Table Cl-5 in Appendix B of this RDEIR/SDEIS).

Maintenance of SWP and CVP facilities under the No Action Alternative (ELT) would not be expected to create new sources of chloride or contribute towards a substantial change in existing sources of chloride in the affected environment. Maintenance activities would not be expected to cause any substantial change in chloride such that any beneficial uses would be adversely affected anywhere in the affected environment.

CEQA Conclusion**:** Chloride is not a constituent of concern in the Sacramento River watershed upstream of the Delta, thus river flow rate and reservoir storage reductions that would occur under the No Action Alternative (ELT), relative to Existing Conditions, would not be expected to result in a substantial adverse change in chloride levels. Additionally, relative to Existing Conditions, the No Action Alternative (ELT) would not result in reductions in river flow rates (i.e., less dilution) or increased chloride loading such that there would be any substantial increase in chloride concentrations upstream of the Delta in the San Joaquin River watershed.

It is expected there would be changes in Delta chloride levels in response to a shift in the Delta source water percentages under this alternative or some degradation of these water bodies. Relative to Existing Conditions, the No Action Alternative (ELT) would result in increased chloride concentrations such that frequency of exceedance of the 250 mg/L Bay-Delta WQCP objective would increase in the San Joaquin River at Antioch (by 4%) and in the Sacramento River at Mallard Island (by 1%), and long-term degradation may occur, that may result in adverse effects on the municipal and industrial water supply beneficial use. With respect to CWA Section 303(d) listings, the similar average chloride concentrations would not cause further degradation on a long-term basis that would adversely affect necessary actions to reduce chloride loading for any TMDLs developed for Tom Paine Slough and Suisun Marsh.

Long-term average chloride concentrations would be reduced in water exported from the Delta to the CVP/SWP Export Service Areas thus reflecting a potential improvement to chloride loading in the lower San Joaquin River.

Chloride is not a bioaccumulative constituent, thus any increased concentrations under the No Action Alternative (ELT) would not result in adverse chloride bioaccumulation effects to aquatic life or humans.

Based on these findings, this impact is determined to be significant due to increased chloride concentrations and objective exceedances, and additional long-term degradation, in the western Delta and associated effects on the municipal and industrial water supply beneficial uses.

Impact WQ-9: Effects on Dissolved Oxygen Resulting from Facilities Operations and Maintenance

The effects of the No Action Alternative (ELT) on DO levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because the factors that would affect DO levels in the surface waters of these areas would be the same in the ELT as in the LLT. For the reasons described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, the effects on DO from implementing the No Action Alternative (ELT) is determined to not be adverse.

CEQA Conclusion: The effects of the No Action Alternative (ELT) on DO levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative (LLT). This is because the factors that would affect DO levels in the surface waters of these areas would be similar in the ELT and LLT. There would be no substantial, and likely no measurable, long-term change in DO levels Upstream of the Delta, in the Plan Area, or the SWP/CVP Export Service Areas under the No Action Alternative relative to Existing Conditions. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would adversely affect beneficial uses. Because no substantial changes in DO levels are expected, long-term water quality degradation would not be expected, and, thus, beneficial uses would not be expected to be adversely affected. Various Delta waterways are CWA Section 303(d)-listed for low DO, but because no substantial decreases in DO levels are expected, greater degradation and impairment of these areas is not expected to occur. Based on these findings, this impact is considered less than significant.

Impact WQ-11: Effects on Electrical Conductivity Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the No Action Alternative (ELT) on EC levels in reservoirs and rivers upstream of the Delta would be similar to those effects described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. The extent of new urban growth would be less in the early long-term, thus discharges of EC-elevating parameters in runoff and wastewater discharges to water bodies upstream of the Delta would be expected to be less than in the LLT. However, the state is regulating point source discharges of EC-related parameters and implementing a program to further loading of EC-related parameters to tributaries. Based on these considerations, and those described in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, EC levels (highs, lows, typical conditions) in the Sacramento River and its tributaries, the eastside tributaries, or their associated reservoirs upstream of the Delta would not be expected to be outside the ranges occurring under Existing Conditions.

For the San Joaquin River, increases in EC levels under the No Action Alternative (ELT) could occur, but would be slightly less than those described for No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because the effects of climate change and increase water demands on flows, which could effect dilution of high EC discharges, would be less in the early long-term. The implementation of the adopted TMDL for the San Joaquin River at Vernalis and the ongoing development of the TMDL for the San Joaquin River upstream of Vernalis are expected to contribute to improved EC levels. Based on these considerations, substantial changes in EC levels in the San Joaquin River relative to Existing Conditions would not be expected of sufficient magnitude and geographic extent that would result in adverse effects on any beneficial uses, or substantially degrade the quality of these water bodies, with regard to EC.

Delta

Similar to the No Action Alternative (LLT), the No Action Alternative (ELT) would result in a fewer number of days when interior and southern Bay-Delta WQCP compliance locations would exceed EC objectives or be out of compliance with the EC objectives (Table EC-1 in Appendix B of this RDEIR/SDEIS). However, western Delta locations—Sacramento River at Emmaton and San Joaquin River at Jersey Point (fish and wildlife objective)—would experience an increased frequency of exceedance of EC objectives, where sea level rise and increased water demands would combine to cause increases in EC, relative to Existing Conditions (Table EC-1 in Appendix B of this RDEIR/SDEIS). The number of days the EC levels would exceed objectives and be out of compliance at these locations would be less at the ELT than the LLT. Further, average EC levels at western, interior, and southern Delta compliance locations, other than the Sacramento River at Emmaton, would decrease relative to Existing Conditions. The increase in exceedances at Jersey Point would be from 0% under Existing Conditions to 3% under No Action Alternative (ELT), which represents a very small increase for this objective. Further discussion of EC increases relative to this objective can be found in Appendix 8H, *Electrical Conductivity* Attachment 2 in Appendix A of this

RDEIR/SDEIS. Average EC at Emmaton would increase by 1% for the entire modeled period (1976–1991) and 11% for the drought period modeled (1987–1991), relative to Existing Conditions (Table EC-2 in Appendix B of this RDEIR/SDEIS), similar to increases that would occur in the LLT. Given that the western Delta is CWA Section 303(d) listed as impaired due to elevated EC the increase in the incidence of exceedance of EC objectives and average EC levels at Emmaton has the potential to contribute to additional impairment and adversely affect beneficial uses.

Also similar to the No Action Alternative (LLT), relative to Existing Conditions, the No Action Alternative (ELT) would result in increased average EC in Suisun Marsh during the months of January through May. The average EC increases would be lower in magnitude than in the LLT, ranging from 0.1–0.4 mS/cm, depending on the location and month (Tables EC-3 through EC-7 in Appendix B of this RDEIR/SDEIS). For the reasons described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, the small increase in EC relative to Existing Conditions would not be expected to adversely affect beneficial uses of Suisun Marsh under the No Action Alternative (ELT). While Suisun Marsh is CWA Section 303(d) listed as impaired because of elevated EC, the potential increases in long-term average EC concentrations, relative to Existing Conditions, would not be expected to contribute to additional impairment, because the increase would be so small (<1 mS/cm) as to not be measurable and beneficial uses would not be adversely affected.

SWP/CVP Export Service Areas

The frequency of exceedance of EC objectives at the Banks and Jones Pumping Plants under the No Action Alternative (ELT) would be slightly higher than that described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS (Table EC-2 in Appendix B of this RDEIR/SDEIS). The frequency of exceedance of the Bay-Delta WQCP 1,000 μmhos/cm objective would increase from 1% to 3% at Banks Pumping Plant and from 0% to 1% at Jones Pumping Plant. However, similar to the No Action Alternative (LLT), average EC levels for the entire period modeled would decrease at the Banks and Jones Pumping Plants relative to Existing Conditions in the ELT time period (Table EC-2 in Appendix B of this RDEIR/SDEIS). For the reasons described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1, the slight increase in frequency of exceedance of the EC objective under the No Action Alternative (ELT) would not be expected to adversely affect agricultural beneficial uses of this water. Further, the No Action Alternative (ELT) would not cause long-term degradation of EC levels in the SWP/CVP Export Service Areas, relative to Existing Conditions or contribute to additional CWA Section 303(d) impairment related to elevated EC in the SWP CVP Export Service Areas waters, because long-term average EC levels would be lower in the exported water. The lower average EC in the exported water would be expected to result in an improvement in lower San Joaquin River EC levels, as these levels are related, in part, by the irrigation deliveries from the Delta.

In summary, the increased frequency of exceedance of EC objectives and increased drought period average EC levels that would occur in the western Delta under the No Action Alternative (ELT) would contribute to adverse effects on the agricultural beneficial uses. Given that the western Delta is Clean Water Act Section 303(d) listed as impaired due to elevated EC, the increase in the incidence of exceedance of EC objectives and increases in drought period average EC in the western Delta under the No Action Alternative has the potential to contribute to additional beneficial use impairment. These increases in EC constitute an adverse effect on water quality.

***CEQA Conclusion*:** River flow rate and reservoir storage reductions that would occur under the No Action Alternative (ELT), relative to Existing Conditions, would not be expected to result in a substantial adverse change in EC levels in the reservoirs and rivers upstream of the Delta, given that: changes in the quality of watershed runoff and reservoir inflows would not be expected to occur in the future; the state's aggressive regulation of point-source discharge effects on Delta salinity-elevating parameters and the expected further regulation as salt management plans are developed; the salt-related TMDLs adopted and being developed for the San Joaquin River; and the expected improvement in lower San Joaquin River average EC levels commensurate with the lower EC of the irrigation water deliveries from the Delta.

Relative to Existing Conditions, the No Action Alternative (ELT) would not result in any substantial increases in long-term average EC levels in the SWP CVP Export Service Areas At the Jones and Banks Pumping Plants there would be only a, respective, 1–2% increase in exceedance of the EC objective when the entire period modeled is considered. Average EC levels for the entire period modeled would decrease at both plants. Because the EC objective is for agricultural beneficial use protection, for which longer-term crop exposure to elevated EC waters is a concern, the minimal increase in the frequency of exceedance of the EC objective at the pumping plants for the entire period modeled coupled with the long-term average decrease in EC levels at the pumping plants would not adversely affect this beneficial use.

In the Plan Area, the No Action Alternative (ELT) would result in an increase in the frequency with which Bay-Delta WQCP EC objectives are exceeded in the Sacramento River at Emmaton. Further, long-term average EC levels would increase by 1% for the entire period modeled and 11% during the drought period modeled at Emmaton. The increases in drought period average EC levels that would occur in the Sacramento River at Emmaton would further degrade existing EC levels and thus contribute additionally to adverse effects on the agricultural beneficial use. Because EC is not bioaccumulative, the increases in long-term average EC levels would not directly cause bioaccumulative problems in aquatic life or humans. The western Delta is CWA Section 303(d) listed for elevated EC and the increases in long-term average EC and increased frequency of exceedance of EC objectives that would occur in the Sacramento River at Emmaton could make beneficial use impairment measurably worse. This impact is considered significant.

Impact WQ-13: Effects on Mercury Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the No Action Alternative (ELT) on mercury levels in surface waters upstream of the Delta relative to Existing Conditions would be similar to those described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 in the Draft EIR/EIS. This is because factors which affect mercury concentrations in surface waters upstream of the Delta are similar in the ELT and LLT under the No Action Alternative. For the reasons stated for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, any modified reservoir operations and subsequent changes in river flows at the ELT, relative to Existing Conditions, are expected to have negligible, if any, effects on average reservoir and river mercury concentrations in the Sacramento River watershed upstream of the Delta. Any negligible changes in mercury concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to mercury. Both waterborne methylmercury concentrations and largemouth bass fillet mercury concentrations are expected to remain above guidance levels at upstream of Delta locations, but will not change substantially relative to Existing Conditions due to changes in flows under the No Action Alternative (ELT).

Delta

Similar to the No Action Alternative (LLT), the No Action Alternative (ELT) would have very little effect on mercury or methylmercury concentrations in the Delta (Tables Hg-1 and Hg-2 in Appendix B of this RDEIR/SDEIS), to the extent that these changes would likely not be measurable. Because of this, use of assimilative capacity for mercury would be negligible. Any small changes would not be expected to result in adverse effects to beneficial uses.

Similarly, estimates of fish tissue mercury concentrations and exceedance quotients show almost no differences would occur among sites for the No Action Alternative (ELT) as compared to Existing Conditions for the Delta sites (Tables Hg-3 and Hg-4 in Appendix B of this RDEIR/SDEIS). Peak exceedance quotients for drought conditions are all at the San Joaquin River at Buckley Cove (4.3 for Existing Conditions; 4.6 for the No Action Alternative (ELT); Eq2 model, Table Hg-4 in Appendix B of this RDEIR/SDEIS). These small differences of less than 10% are not expected to further degrade water quality, with regards to mercury, by measurable levels, and thus beneficial use impairment would not be made discernibly worse. Similar to waterborne concentrations of methylmercury, the fish tissue concentrations and exceedance quotients would be highest at the San Joaquin River, Buckley Cove site during drought years (Tables Hg-3 and Hg-4 in Appendix B of this RDEIR/SDEIS). All modeled fish tissue mercury concentrations exceed tissue guidelines, with exceedance quotients greater than 1 (Tables Hg-3 and Hg-4 in Appendix B of this RDEIR/SDEIS). Because the increases are relatively small, and it is not evident that substantive increases are expected at numerous locations throughout the Delta, these changes are expected to be within the uncertainty inherent in the modeling approach, and would likely not be measurable in the environment. See Appendix 8I, *Mercury*, in Appendix A of this RDEIR/SDEIS, for a complete discussion of the uncertainty associated with the fish tissue estimates.

The bioaccumulation models contain multiple sources of uncertainty associated with their development. These are related to: analytical variability; temporal and/or seasonal variability in Delta source water concentrations of methylmercury; interconversion of mercury species (i.e., the non-conservative nature of methylmercury as a modeled constituent); and limited sample size (both in number of fish and time span over which the measurements were made), among others. Although there is considerable uncertainty in the models used, the results serve as a reasonable approximations of a very complex process. Considering the uncertainty, small (i.e., <20–25%) increases or decreases in modeled fish tissue mercury concentrations at a low number of Delta locations (i.e., 2–3) should be interpreted to be within the uncertainty of the overall approach, and not predictive of actual adverse effects. Larger increases, or increases evident throughout the Delta, can be interpreted as more reliable indicators of potential adverse effects.

SWP/CVP Export Service Areas

The analysis of mercury and methylmercury in the SWP/CVP Export Service Areas was based on concentrations estimated at the Banks and Jones Pumping Plants. Concentrations changes at these locations are expected to be very small, and likely not measurable. Thus, any change in use of assimilative capacity is also expected to be small and not measurable. Any increases in mercury concentrations that may occur in water exported via Banks and Jones Pumping Plants are not expected to result in adverse effects to beneficial uses or substantially degrade the quality of exported water, with regards to mercury.

Relative to Existing Conditions, the No Action Alternative (ELT) would result in small changes (less than 3%) in estimated methylmercury concentrations in largemouth bass. All modeled methylmercury concentrations in largemouth bass exceed fish tissue guidelines (Tables Hg-5 through Hg-8 in Appendix B of this RDEIR/SDEIS).

CEQA Conclusion**:** Under the No Action Alternative (ELT), greater water demands and climate change would alter the magnitude and timing of reservoir releases and river flows upstream of the Delta in the Sacramento River watershed and east-side tributaries, relative to Existing Conditions. Concentrations of mercury and methylmercury upstream of the Delta will not be substantially different relative to Existing Conditions due to the lack of important relationships between mercury/methylmercury concentrations and flow for the major rivers.

Methylmercury concentrations exceed criteria at all locations in the Delta for Existing Conditions and no assimilative capacity exists. However, monthly average waterborne concentrations of total and methylmercury, over the period of record, are very similar to each other among Alternatives. Similarly, estimates of fish tissue mercury concentrations show almost no differences would occur among sites for the No Action Alternative (ELT) as compared to Existing Conditions for Delta sites.

Assessment of effects of mercury in the SWP and CVP Export Service Areas were based on effects on mercury concentrations and fish tissue mercury concentrations at the Banks and Jones Pumping Plants. The Banks and Jones Pumping Plants are expected to show very small concentration changes or changes in fish tissue concentration of mercury for the No Action Alternative (ELT) as compared to Existing Conditions.

As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because mercury concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Because any increases in mercury or methylmercury concentrations are not likely to be measurable, changes in mercury concentrations or fish tissue mercury concentrations would not make any existing mercury-related impairment measurably worse. In comparison to Existing Conditions, the No Action Alternative (ELT) would not increase levels of mercury by frequency, magnitude, and geographic extent such that the affected environment would be expected to have measurably higher body burdens of mercury in aquatic organisms, thereby substantially increasing the health risks to wildlife (including fish) or humans consuming those organisms. Based on these findings, this impact is considered less than significant.

Impact WQ-15: Effects on Nitrate Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the No Action Alternative (ELT) on nitrate levels in surface waters upstream of the Delta relative to Existing Conditions would be similar to those described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because factors which affect nitrate concentrations in surface waters upstream of the Delta are similar in the

ELT and LLT under the No Action Alternative. For the reasons stated for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, any modified reservoir operations and subsequent changes in river flows at the ELT, relative to Existing Conditions, are expected to have negligible, if any, effects on average reservoir and river nitrate concentrations in the Sacramento River watershed upstream of the Delta. In the San Joaquin River watershed, nitrate concentrations are higher than in the Sacramento watershed, owing to use of nitrate-based fertilizers throughout the lower watershed. The correlation between historical water year average nitrate concentrations and water year average flow in the San Joaquin River at Vernalis is a weak inverse relationship—that is, generally higher flows result in lower nitrate concentrations, while low flows result in higher nitrate concentrations (linear regression r^2=0.49; Figure 2, Appendix 8J, *Nitrate*, of the Draft EIR/EIS). Under the No Action Alternative (ELT), average flows at Vernalis would decrease an estimated 1% relative to Existing Conditions, which is less than the 6% decrease in average flows estimated to occur at the LLT. Given these relatively small decreases in flows and the weak correlation between nitrate and flows in the San Joaquin River, it is expected that nitrate concentrations in the San Joaquin River would be minimally affected, if at all, by anticipated changes in flow rates under the No Action Alternative (ELT).

Delta

Results of the mass balance calculations indicate that under the No Action Alternative (ELT), relative to Existing Conditions, nitrate concentrations throughout the Delta would remain low (<1.4 mg/L-N) relative to adopted objectives (Table N-1 in Appendix B, of this RDEIR/SDEIS). Although changes at specific Delta locations and for specific months may be substantial on a relative basis (Table N-2, in Appendix B of this RDEIR/SDEIS), the absolute concentration of nitrate in Delta waters would remain low (<1.4 mg/L-N) in relation to the drinking water MCL of 10 mg/L-N, as well as all other relevant nitrate thresholds (see Chapter 8, *Water Quality*, Section 8.3.17 in the Draft EIR/EIS). Long-term average nitrate concentrations are anticipated to remain below 1 mg/L-N at all 11 Delta assessment locations except the San Joaquin River at Buckley Cove, where early long-term average concentrations would be somewhat above 1 mg/L-N. Nevertheless, at this location, early long-term average nitrate concentration would be somewhat reduced under the No Action Alternative (ELT), relative to Existing Conditions. No additional exceedances of the MCL are anticipated at any location (Table N-1, in Appendix B of this RDEIR/SDEIS). On a monthly average basis and a long-term annual average basis, for all modeled years (1976–1991) and for the drought period (1987–1991) only, use of assimilative capacity available under Existing Conditions, relative to the drinking water MCL of 10 mg/L-N, would be low or negligible (i.e., <1%) for all locations and months (Table N-3, in Appendix B of this RDEIR/SDEIS). Nitrate concentrations, change in nitrate concentrations relative to existing conditions, and use of assimilative capacity with regard to nitrate at various locations throughout the Delta under the No Action Alternative (ELT) would be approximately the same as would occur in the LLT.

As described in for the No Action Alternative for the LLT in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, actual nitrate on concentrations would likely be higher than the modeling results indicate at certain locations under the No Action Alternative (ELT). This is because the mass balance modeling does not account for contributions from the SRWTP, which would be implementing nitrification/partial denitrification, or Delta wastewater treatment plant dischargers that practice nitrification, but not denitrification. However, for the reasons described for the No Action Alternative (LLT), additional nitrate contributions and resulting concentrations that may occur at certain locations within the Delta at the ELT would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the water quality at these locations, with regard to nitrate.

SWP/CVP Export Service Areas

Assessment of effects of the No Action Alternative (ELT) on nitrate in the SWP/ CVP Export Service Areas is based on effects on nitrate at the Banks and Jones Pumping Plants.

Results of the mass balance calculations indicate that under the No Action Alternative (ELT), relative to Existing Conditions, early long-term average nitrate concentrations at Banks and Jones pumping plants are anticipated to change negligibly (Table N-1, in Appendix B of this RDEIR/SDEIS), as is also expected for the LLT (see Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS). No exceedances of the 10 mg/L MCL would occur (Table N-1, in Appendix B of this RDEIR/SDEIS). On a monthly average basis and on a long-term annual average basis, for all modeled years and for the drought period only, use of assimilative capacity available under Existing Conditions relative to the MCL would be negligible (i.e., <1%) for both Banks and Jones Pumping Plants (Table N-3, in Appendix B of this RDEIR/SDEIS). As discussed above, in the Delta region, nitrate concentrations would be higher than indicated in the modeling results for areas receiving Sacramento River water, including Banks and Jones pumping plants. However, long-term average nitrate concentrations would be expected to decrease under the No Action Alternative (ELT), relative to Existing Conditions. Resultant nitrate concentrations in water exported via Banks and Jones pumping plants under the No Action Alternative (ELT) are not expected to result in adverse effects to beneficial uses of exported water or substantially degrade the quality of exported water, with regard to nitrate.

In summary, based on the discussion above, effects on nitrate of facilities operation and maintenance are considered not adverse.

CEQA Conclusion: For the same reasons described for the LLT in Chapter 8, *Water Quality*, Section 8.3.3.1 in the Draft EIR/EIS, any modified reservoir operations and subsequent changes in river flows under the No Action Alternative (ELT), relative to Existing Conditions, are expected to have negligible, if any, effects on reservoir and river nitrate concentrations upstream of Freeport in the Sacramento River watershed and upstream of the Delta in the San Joaquin River watershed.

In the Delta, results of the mass balance calculations indicate that under the No Action Alternative (ELT), relative to Existing Conditions, nitrate concentrations throughout the Delta are anticipated to remain low (<1.4 mg/L-N) relative to adopted objectives. No additional exceedances of the 10 mg/L MCL are anticipated at any location, and use of assimilative capacity available under Existing Conditions, relative to the drinking water MCL of 10 mg/L-N, would be low or negligible (i.e., <1%) for all locations and months.

Results of the mass balance calculations indicate that under the No Action Alternative (ELT), relative to Existing Conditions, average nitrate concentrations at Banks and Jones pumping plants are anticipated to change negligibly. No additional exceedances of the MCL are anticipated, and use of assimilative capacity available under Existing Conditions, relative to the MCL would be negligible (i.e., <1%) for both Banks and Jones pumping plants for all months.

Based on the above, there would be no substantial, long-term increase in nitrate concentrations in the rivers and reservoirs upstream of the Delta, in the Delta Region, or the waters exported to the SWP/CVP Export Service Areas under the No Action Alternative (ELT), relative to Existing Conditions. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment from nitrate. Because nitrate concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Nitrate is not CWA Section 303(d) listed within the affected environment and thus any minor increases that may occur in some areas would not make any existing nitrate-related impairment measurably worse because no such impairments currently exist. Because nitrate is not bioaccumulative, minor increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered less than significant.

Impact WQ-17: Effects on Dissolved Organic Carbon Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

While increased water demands and climate change under the No Action Alternative (ELT) would alter the magnitude and timing of reservoir releases north, south and east of the Delta, these activities would have no substantial effect on the various watershed sources of DOC. Moreover, long-term average flow and DOC at Sacramento River at Hood and San Joaquin River at Vernalis are poorly correlated; therefore, changes in river flows would not be expected to cause a substantial long-term change in DOC concentrations upstream of the Delta. Consequently, long-term average DOC concentrations under the No Action Alternative (ELT) would not be expected to change by frequency, magnitude and geographic extent, relative to Existing Conditions and, and thus, would not adversely affect the MUN beneficial use, or any other beneficial uses, in water bodies of the affected environment located upstream of the Delta.

Delta

Relative to the Existing Conditions, the No Action Alternative (ELT) would result in no changes, or a 0.1 mg/L decrease, in the long-term average DOC concentrations at the 11 assessment locations for the modeled 16-year period. However, the average DOC concentrations would increase slightly (i.e., up to 0.1 mg/L) in the modeled drought period (1987–1991) only at the Jones pumping plant location (Appendix B, *Supplemental Modeling for Alternative 4A*, Table DOC-1, of this RDEIR/SDEIS). At all 11 assessment locations, the range of frequency with which average DOC concentrations would exceed the 2 mg/L threshold concentration under the No Action Alternative (ELT) would be similar to Existing Conditions (i.e., 93–100%) for the modeled 16-year period and the drought period. The frequency with which DOC concentration would exceed the 3 mg/L and 4 mg/L thresholds also would be similar at most of the assessment locations, with exception of predicted changes at both the Banks and Jones pumping plants.

At the Banks pumping plant, the frequency with which DOC concentration would exceed 3 mg/L would increase from 64% under Existing Conditions to 69% under the No Action Alternative (ELT) for the 16-year period (and increase from 57% to 68% during the drought year period) (Appendix B, *Supplemental Modeling for Alternative 4A*, Table DOC-1, of this RDEIR/SDEIS). The relative frequencies of exceedance of 3 mg/L at the Jones pumping plant would be similar to the Banks pumping plant for the modeled 16-year and drought periods. The relative increase in the frequency with which DOC concentrations would exceed 4 mg/L at both the Banks and Jones pumping plants would be minimal (i.e., up to a 3% increased frequency at the Jones pumping plant). While the No

Action Alternative (ELT) would generally lead to similar or slightly higher long-term average DOC concentration in the western and interior Delta locations, the predicted changes would not be expected to be of magnitude that would adversely affect MUN beneficial uses, or any other beneficial use, particularly when considering the relatively small change in long-term annual average concentration (i.e., ≤0.1 mg/L).

SWP/CVP Export Service Areas

With respect to the potential for effects of the No Action Alternative (ELT), the long-term average DOC concentrations in water exported at the Banks and Jones pumping plants would not change measurably relative to Existing Conditions (i.e., up to 0.1 mg/L at Jones pumping plant for the modeled drought period) (Appendix B, *Supplemental Modeling for Alternative 4A*, Table DOC-1, of this RDEIR/SDEIS). Relatively small increases in the frequency of average DOC concentrations in exports exceeding the 3 and 4 mg/L thresholds would be predicted to occur at both Banks and Jones pumping plants. However, the predicted changes in long-term average DOC concentrations would not be expected to be of sufficient magnitude to adversely affect the MUN beneficial use, or any other beneficial use, within the SWP/CVP Export Service Areas. Long-term average DOC concentrations, and frequency of exceedance of threshold concentrations, would decrease slightly at Barker Slough under the No Action Alternative (ELT) relative to Existing Conditions.

In summary, the potential operations- and maintenance-related changes to DOC concentrations under the No Action Alternative (ELT) at locations upstream of the Delta, in the Delta, and the SWP/CVP Export Service areas would generally be similar to, or of lower magnitude, than the effects described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because less changes in water demands and climate change would occur in the ELT compared to the LLT, and thus factors affecting DOC concentrations, would be lower in these water bodies in the ELT.

Maintenance of SWP and CVP facilities under the No Action Alternative (ELT) would not be expected to create new sources of DOC or contribute towards a substantial change in existing sources of DOC in the affected environment.

CEQA Conclusion: The effects of the No Action Alternative (ELT) on DOC concentrations in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar, or of lower magnitude, than the effects described for the No Action Alternative (LLT). While greater water demands and climate change under the No Action Alternative (ELT) would alter the magnitude and timing of reservoir releases north, south and east of the Delta, these activities would have no substantial effect on the various watershed sources of DOC. Based on the above, the No Action Alternative (ELT) would not result in any substantial increase in the frequency with which long-term average DOC concentrations exceed the 2, 3, or 4 mg/L levels at any of the 11 assessment locations relative to Existing Conditions.

The predicted change in long-term average DOC concentrations relative to Existing Conditions would not be expected to be of sufficient magnitude to adversely affect MUN beneficial uses, nor would there be any long-term water quality degradation with respect to DOC. DOC is not bioaccumulative and thus would not directly cause bioaccumulative problems in aquatic life or humans. Finally, DOC is not causing beneficial use impairments and thus is not CWA Section 303(d) listed for any water body within the affected environment. Because long-term average DOC concentrations would not be expected to increase substantially, no significant impacts on beneficial uses would occur. Based on these findings, this impact would be less than significant.

Impact WQ-19: Effects on Pathogens Resulting from Facilities Operations and Maintenance

The effects of the No Action Alternative (ELT) on pathogen levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1. of the Draft EIR/EIS. This is because the factors that would affect pathogen levels in the surface waters of these areas would be similar in the ELT and LLT. The difference in reservoir storage, river flows, and associated changes in Delta source water fractions due to climate change and water demands would not alter the pathogen sources in these waters. Thus, for the reasons described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1of the Draft EIR/EIS, the effects on pathogens from implementing the No Action Alternative (ELT) is determined to not be adverse.

CEQA Conclusion: The effects of the No Action Alternative (ELT) on pathogen levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative. This is because the factors that would affect pathogen levels in the surface waters of these areas would be similar in the ELT and LLT. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because pathogen concentrations are not expected to increase substantially, no long-term water quality degradation for pathogens is expected to occur and, thus, no adverse effects on beneficial uses would occur. The San Joaquin River in the Stockton Deep Water Ship Channel is Clean Water Act Section 303(d) listed for pathogens. Because no measurable increase in Deep Water Ship Channel pathogen concentrations are expected to occur on a long-term basis, further degradation and impairment of this area is not expected to occur. Finally, pathogens are not bioaccumulative constituents. This impact is considered less than significant.

Impact WQ-21: Effects on Pesticide Concentrations Resulting from Facilities Operations and Maintenance

The effects of the No Action Alternative (ELT) on pesticide levels in surface waters upstream of the Delta, within the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to or less than those expected to occur at the LLT, described in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because at the ELT, the primary factor that will influence pesticide concentrations in surface waters upstream of the Delta, the effect of timing and magnitude of reservoir releases on dilution capacity, is expected to change to a similar or less degree than under the No Action Alternative (LLT). As shown in Tables P-1 throughP-4, in Appendix B of this RDEIR/SDEIS, changes in average winter and summer flow rates at the ELT relative to Existing Conditions are expected to be similar to or less than changes in flow rates expected at the LLT (Appendix 8L, *Pesticides* Tables 1–4, of the Draft EIR/EIS) in the Sacramento River at Freeport, American River at Nimbus, Feather River at Thermalito and the San Joaquin River at Vernalis (shown in Tables 1-4 in Appendix 8L, *Pesticides*, of the Draft EIR/EIS). Similarly, at the ELT, the primary factor that will influence pesticide concentrations in surface waters of the Delta and in the SWP/CVP Export Service areas (i.e., changes in San Joaquin River, Sacramento River and Delta agriculture source water fractions at various Delta locations, including Banks and Jones pumping plants) is expected to change by a similar or less degree than at the LLT. The percent change in monthly average source water fractions at the ELT are similar to or less than changes expected at the LLT (Appendix 8D *Source Water Fingerprinting Results* Figures 1–22, of the Draft EIR/EIS).

Development of 8,000 acres of tidal habitat under the No Action Alternative (ELT) could result in a limited reduction in pesticide use throughout the Delta through the potential repurposing of active or fallow agricultural land for natural habitat purposes. In the short-term, the repurposing of agricultural land associated with these measures may expose water used for habitat restoration to pesticide residues. Moreover, the fisheries enhancements to the Yolo Bypass that would occur under the No Action Alternative (ELT) could be managed alongside continuing agriculture, where pesticides may be used on a seasonal basis and where water during flood events may come in contact with residues of these pesticides. However, rapid dissipation would be expected, particularly in the large volumes of water involved in flooding, such that aquatic life toxicity objectives would not be exceeded by frequency, magnitude, and geographic extent whereby adverse effects on beneficial uses would be expected.

***CEQA Conclusion*:** As discussed above, the effects of the No Action Alternative (ELT) on pesticide levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1. of the Draft EIR/EIS. As such, the No Action Alternative (ELT) would not result in any substantial change in long-term average pesticide concentration or result in substantial increase in the anticipated frequency with which long-term average pesticide concentrations would exceed aquatic life toxicity thresholds or other beneficial use effect thresholds upstream of the Delta, at the 11 assessment locations analyzed for the Delta, or the SWP CVP Export Service Areas. Numerous pesticides are currently used throughout the affected environment, and while some of these pesticides may be bioaccumulative, those present-use pesticides for which there is sufficient evidence for their presence in waters affected by SWP and CVP operations (i.e., diazinon, chlorpyrifos, diuron, and pyrethroids) are not considered bioaccumulative, and thus changes in their concentrations would not directly cause bioaccumulative problems in aquatic life or humans. Furthermore, while there are numerous CWA Section 303(d) listings throughout the affected environment that name pesticides as the cause for beneficial use impairment, the modeled changes in upstream river flows and Delta source water fractions would not be expected to make any of these beneficial use impairments measurably worse. Because long-term average pesticide concentrations are not expected to increase substantially, no long-term water quality degradation with respect to pesticides is expected to occur and, thus, no adverse effects on beneficial uses would occur. This impact is considered less than significant.

Impact WQ-23: Effects on Phosphorus Concentrations Resulting from Facilities Operations and Maintenance

The effects of the No Action Alternative (ELT) on phosphorus levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to or less than those described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because factors which affect phosphorus levels in surface waters of these areas would be similar at the ELT and LLT under the No Action Alternative. Phosphorus concentrations may increase during January through March at locations in the Delta where the source fraction of San Joaquin River water increases, due to the higher concentration of phosphorus in the San Joaquin River during these months compared to Sacramento

River water or San Francisco Bay water. However, based on the DSM2 fingerprinting results (see Figures B.4-1 through B.4-22 in Appendix B of this RDEIR/SDEIS), together with source water concentrations (presented in Chapter 8, *Water Quality*, Figure 8-56, of the Draft EIR/EIS), the magnitude of increases during these months is expected to be negligible (i.e., <0.01 mg/L) at all Delta locations. Thus, phosphorus levels in the Delta and waters exported from Banks and Jones pumping plants to the SWP/CVP Export Service Areas are expected to change less at the ELT compared to the LLT. For the reasons described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS and those described above, the effects on phosphorus from implementing the No Action Alternative (ELT) is determined to not be adverse.

***CEQA Conclusion*:** The effects of the No Action Alternative (ELT) on phosphorus levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1.of the Draft EIR/EIS. This is because factors that would directly affect phosphorus levels in the surface waters of these areas are expected to be the same or change to a lesser degree than at the LLT. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because phosphorus concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Phosphorus is not CWA Section 303(d) listed within the affected environment and thus any minor increases that may occur in some areas would not make any existing phosphorus-related impairment measurably worse because no such impairments currently exist. Because phosphorus is not bioaccumulative, minor increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. This impact is considered less than significant.

Impact WQ-25: Effects on Selenium Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the No Action Alternative (ELT) on selenium concentrations in reservoirs and rivers upstream of the Delta would be similar to those effects described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1. of the Draft EIR/EIS. There would be no expected change to the sources of selenium in the Sacramento River and east-side tributary watersheds, and changes in the magnitude and timing of reservoir releases and river flows upstream of the Delta would have negligible, if any, effect on the concentration of selenium in the rivers and reservoirs of these watersheds.

Selenium concentrations in the San Joaquin River upstream of the Delta comply with NTR criteria and Basin Plan objectives at Vernalis under Existing Conditions, and they are expected to do so under the No Action Alternative (ELT). This is because a TMDL has been developed by the Central Valley Water Board (2001), the Grassland Bypass Project has established limits that will result in reduced inputs of selenium to the Delta, and the Central Valley Water Board (2010a) and State Water Board (2010d, 2010e) have established Basin Plan objectives that are expected to result in decreasing discharges of selenium from the San Joaquin River to the Delta, Further, modeling of flows for the San Joaquin River at Vernalis indicates that average annual flows under the No Action Alternative (ELT) will vary by less than 10% from Existing Conditions (Appendix 5A, *BDCP EIR/EIS*

Modeling Technical Appendix, of the Draft EIR/EIS). Given these relatively small decreases in flows and the considerable variability in the relationship between selenium concentrations and flows in the San Joaquin River, it is expected that selenium concentrations in the San Joaquin River would be minimally affected, if at all, by anticipated changes in flow rates under the No Action Alternative (ELT).

In summary, any negligible changes in selenium concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to selenium.

Delta

Relative to Existing Conditions, the No Action Alternative (ELT) would result in little to no change in average selenium concentrations in water at all modeled Delta assessment locations. Long-term average concentrations would be the same or lower, with the exception of Old River at Rock Slough during the drought (1987–1991) period modeled and Jones pumping plant for the entire (1976–1991) period modeled (Appendix B, *Supplemental Modeling for Alternative 4A*, Table Se-1, of this RDEIR/SDEIS). Long-term average concentrations at these locations would increase negligibly (by 0.01µg/L). The long-term average selenium concentrations in water under the No Action Alternative (ELT) would range from 0.09–0.39 µg/L (Appendix B, *Supplemental Modeling for Alternative 4A*, Table Se-1, of this RDEIR/SDEIS), which would be well below the EPA draft water quality criterion of 1.3 µg/L. Thus, the No Action Alternative (ELT) would not result in selenium concentration increases in water that would substantially degrade water quality.

Relative to Existing Conditions, the No Action Alternative (ELT) would result in little to no change in estimated selenium concentrations in most biota (whole-body fish, bird eggs [invertebrate diet], bird eggs [fish diet], and fish fillets), with the largest increase being 0.01 mg/kg dry weight (dw) (Appendix B, *Supplemental Modeling for Alternative 4A*, Table Se-2a, of this RDEIR/SDEIS). During the drought period, concentrations of selenium in sturgeon in the western Delta would increase slightly, with about a 0.05 mg/kg dw (<1 percent) increase for the San Joaquin River at Antioch (Appendix B, *Supplemental Modeling for Alternative 4A*, Tables Se-5 and Se-6, of this RDEIR/SDEIS).

All Toxicity Level Exceedance Quotients for whole fish, bird eggs, and fish fillets are less than 1.0, indicating low probability of adverse effects (Appendix B, *Supplemental Modeling for Alternative 4A*, Table Se-3, of this RDEIR/SDEIS). Low Toxicity Threshold Exceedance Quotients for selenium concentrations in sturgeon from the western Delta exceed 1.0 for the drought period, indicating a higher probability for adverse effects for drought years (Appendix B, *Supplemental Modeling for Alternative 4A*, Table Se-7, of this RDEIR/SDEIS). Relative to Existing Conditions, Exceedance Quotients would increase by 0.00–0.01, indicating that there would essentially be no increased risk of toxicity associated with selenium concentrations under the No Action Alternative (ELT).

In summary, relative to Existing Conditions, the No Action Alternative (ELT) would result in essentially no change in selenium concentrations throughout the Delta. The No Action Alternative (ELT) would not be expected to substantially increase the frequency with which applicable water quality criteria, or toxicity or level of concern thresholds would be exceeded in the Delta or substantially degrade the quality of water in the Delta, with regard to selenium.

SWP/CVP Export Service Areas

Relative to Existing Conditions, the No Action Alternative (ELT) would result in little to no change in average selenium concentrations in water at the south Delta pumping plants. At the Banks pumping plant, there would be no change in long-term average concentrations for the entire period modeled or the drought period modeled (Appendix B, *Supplemental Modeling for Alternative 4A*, Table Se-1, of this RDEIR/SDEIS). At the Jones pumping plant, selenium concentrations would increase by 0.01 μg/L for the entire period modeled (Appendix B, Table Se-1). Furthermore, the modeled selenium concentrations in water for the No Action Alternative (ELT) would range from 0.21–0.29 μg/L, well below the USEPA water quality criterion of 1.3 μg/L (Appendix B, *Supplemental Modeling for Alternative 4A*, Table Se-1, of this RDEIR/SDEIS).

Similarly, the No Action Alternative (ELT) would result in little to no change in estimated selenium concentrations in biota (whole-body fish, bird eggs [invertebrate diet], bird eggs [fish diet], and fish fillets), and concentrations of selenium in biota would not be expected to exceed any toxicity or level of concern benchmarks for biota (Appendix B, *Supplemental Modeling for Alternative 4A*, Tables Se-2a and Se-3, of this RDEIR/SDEIS).

Residence time of water in the Delta is not expected to change substantially under the No Action Alternative (ELT) relative to Existing Conditions. Thus, any minor residence time changes would not be expected to affect selenium bioaccumulation or fish tissue and bird egg concentrations of selenium.

In summary, relative to Existing Conditions, the No Action Alternative (ELT) would result in essentially no change in selenium concentrations in the SWP/CVP Export Service Areas, because there would essentially be no change in selenium concentrations at the Bank and Jones pumping plants. Thus, the No Action Alternative (ELT) would not be expected to substantially increase the frequency with which applicable water quality criteria, or toxicity and level of concern benchmarks would be exceeded in the Export Service Areas or substantially degrade the quality of water in the Export Service Areas, with regard to selenium.

CEQA Conclusion: There are no substantial point sources of selenium in watersheds upstream of the Delta, and no substantial nonpoint sources of selenium in the watersheds of the Sacramento River and the eastern tributaries. Nonpoint sources in the San Joaquin Valley that contribute selenium to the Delta will be controlled through a TMDL developed by the Central Valley Water Board (2001) for the lower San Joaquin River, established limits for the Grassland Bypass Project, and Basin Plan objectives (Central Valley Water Board 2010d and State Water Board 2010d, 2010e) that are expected to result in decreasing discharges of selenium from the San Joaquin River to the Delta. Consequently, any modified reservoir operations and subsequent changes in river flows under the No Action Alternative (ELT), relative to Existing Conditions, are expected to cause negligible changes in selenium concentrations in water. Any negligible changes in selenium concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to selenium.

Relative to Existing Conditions, modeling estimates indicate that the No Action Alternative (ELT) would result in essentially no change in selenium concentrations throughout the Delta, with all changes on the order of 0.01 μg/L or less. Furthermore, there would not be an increased risk of exceeding toxicity and level of concern benchmarks for biota.

Assessment of effects of selenium in the SWP/CVP Export Service Areas is based on effects on selenium concentrations at the Banks and Jones pumping plants. Relative to Existing Conditions, the No Action Alternative (ELT) would result in no change in long-term average selenium concentrations at the Bank pumping plant, and very little increase (0.01 µg/L) at the Jones pumping plant.

Based on the above, selenium concentrations that would occur in water under this alternative would not cause additional exceedances of applicable state or federal numeric or narrative water quality objectives/criteria, or other relevant water quality effects thresholds identified for this assessment by frequency, magnitude, and geographic extent that would result in adverse effects to one or more beneficial uses within affected water bodies. In comparison to Existing Conditions, water quality conditions under this alternative would not increase levels of selenium by frequency, magnitude, and geographic extent such that the affected environment would be expected to have measurably higher body burdens of selenium in aquatic organisms, thereby substantially increasing the health risks to wildlife (including fish) or humans consuming those organisms. Water quality conditions under this alternative with respect to selenium would not cause long-term degradation of water quality in the affected environment, and therefore would not result in use of available assimilative capacity such that exceedances of water quality objectives/criteria would be likely and would result in substantially increased risk for adverse effects to one or more beneficial uses. This alternative would not further degrade water quality by measurable levels, on a long-term basis, for selenium and, thus, cause the CWA Section 303(d)-listed impairment of beneficial use to be made discernibly worse. This impact is considered less than significant.

Impact WQ-27: Effects on Trace Metal Concentrations Resulting from Facilities Operations and Maintenance

The effects of the No Action Alternative (ELT) on trace metal concentrations in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because the factors that would affect trace metal concentrations in the surface waters of these areas would be the same in the ELT as in the LLT. For the reasons described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, the effects on trace metal concentrations from implementing the No Action Alternative (ELT) is determined to not be adverse.

CEQA Conclusion: The effects of the No Action Alternative (ELT) on trace metal concentrations in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative. This is because the factors that would affect trace metal concentrations in the surface waters of these areas would be similar in the ELT and LLT. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because trace metal concentrations are not expected to increase substantially, no long-term water quality degradation for trace metals is expected to occur and, thus, no adverse effects to beneficial uses would occur. Furthermore, negligible change in long-term trace metal concentrations throughout the affected environment would not be expected to make any existing beneficial use impairments measurably worse. The trace metals discussed in this assessment are not considered bioaccumulative, and thus would not directly cause bioaccumulative problems in aquatic life or humans. This impact is considered less than significant.

Impact WQ-29: Effects on TSS and Turbidity Resulting from Facilities Operations and Maintenance

The effects of the No Action Alternative (ELT) on TSS and turbidity levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because the factors that would affect TSS and turbidity levels in the surface waters of these areas would be the same in the ELT as in the LLT. For the reasons described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, the effects on TSS and turbidity from implementing the No Action Alternative (ELT) is determined to not be adverse.

CEQA Conclusion: The effects of the No Action Alternative (ELT) on TSS and turbidity levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the No Action Alternative. This is because the factors that would affect TSS and turbidity levels in the surface waters of these areas would be similar in the ELT and LLT. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives where such objectives are not exceeded under Existing Conditions. Because TSS concentrations and turbidity levels are not expected to be substantially different from Existing Conditions, long-term water quality degradation is not expected, and, thus, beneficial uses are not expected to be adversely affected. Finally, TSS and turbidity are neither bioaccumulative nor Clean Water Act section 303(d) listed constituents. This impact is considered less than significant.

Impact WQ-31: Water Quality Effects Resulting from Construction-Related Activities

The effects of construction-related activities and potential water quality effects that would occur under the No Action Alternative (ELT) in association with projects other than Alternative 4A would be similar to those described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because many construction-related activities that could affect the surface waters in the project area are ongoing (e.g., urban development), or recurring (e.g., maintenance activities for channels and levees, sediment dredging), and thus are expected to result in generally similar effects in the ELT and LLT. While the timing of construction of planned projects, described under the No Action Alternative (ELT) (e.g., restoration projects), is uncertain relative to the Existing Conditions, the potential construction-related contaminant discharges that may occur under the No Action Alternative (ELT) would be avoided and minimized upon implementation of BMPs and adherence to permit terms and conditions. Consequently, construction-related activities would not be expected to cause constituent discharges of sufficient magnitude to result in a substantial increased frequency of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in water bodies upstream of the Delta, within the Delta, or in the SWP/CVP Export Service Areas.

CEQA Conclusion: Alternative 4A construction-related contaminant discharges under the No Action Alternative (ELT) would not occur. Other reasonably foreseeable projects that are independent from Alternative 4A would result in construction-related impacts that are temporary and intermittent in nature and would involve negligible, if any, discharges of bioaccumulative or CWA Section 303(d) listed constituents to water bodies of the affected environment. As such, construction activities would therefore not contribute to bioaccumulation of contaminants in organisms or humans or cause Section 303(d) impairments to be discernibly worse. Relative to Existing Conditions, the construction-related effects of other projects in the Delta would not be expected to cause or contribute to a substantial increased frequency of exceedances of water quality objectives/criteria, or substantially degrade water quality on a long-term average basis with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in water bodies upstream of the Delta, within the Delta, or in the SWP/CVP Export Service Areas. Based on these findings, this impact is determined to be less than significant.

Impact WQ-32: Effects on *Microcystis* Bloom Formation Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the No Action Alternative (ELT) on *Microcystis* levels, and thus microcystin concentrations, in surface waters upstream of the Delta relative to Existing Conditions would be similar to those described for the No Action Alternative in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is because factors that would affect *Microcystis* levels in these areas would be the same in the ELT and the LLT. In the rivers and streams of the Sacramento River watershed, watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), and the San Joaquin River upstream of the Delta, under Existing Conditions, bloom development is limited by high water velocity and low residence times. These conditions are not expected to change under the No Action Alternative (ELT).

Delta

In the Delta, enhancements to the Yolo Bypass and 8,000 acres of tidal habitat would be developed under the No Action Alternative (ELT). The hydrodynamic effects of these actions could lead to increased residence times in the affected Delta sub-regions relative to Existing Conditions. As described in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS, climate change and sea level rise are also expected to cause slight increases in water residence times throughout the Delta at the LLT. At the ELT the incremental contribution of climate change and sea level rise to increased water residence times would be less than that at the LLT.

Due to the assumed effects of climate change, Delta water temperatures are expected to increase relative to Existing Conditions under the No Action Alternative (ELT), although the magnitude of increase would be less at the ELT (1.3–2.5°F) compared to the LLT (2.9–4.9°F). Increasing water temperatures could lead to earlier attainment of the water temperature threshold of 19°C required to initiate *Microcystis* bloom formation, and thus earlier occurrences of *Microcystis* blooms in the Delta, relative to Existing Conditions. Elevated ambient water temperatures in the Delta, and thus an increase in *Microcystis* bloom duration and magnitude, are expected under the No Action Alternative (ELT), relative to Existing Conditions. However, the effects of elevated ambient water temperatures on *Microcystis* at the ELT are expected to be less than would occur at the LLT.

The combination of increased water residence times in the Delta, due to assumed restoration activities, and increased water temperatures, due to climate change, could lead to measurable increases in the frequency, magnitude, and geographic extent of *Microcystis* blooms throughout the

Delta at the ELT, relative to Existing Conditions. It is not expected that the effects on *Microcystis* in the Delta that could occur at the ELT would be significantly different than those that could occur at LLT.

SWP/CVP Export Service Area

The effects of the No Action Alternative (ELT) on *Microcystis* levels, and thus microcystin concentrations, in SWP/CVP Export Service Areas, relative to Existing Conditions, would be similar to or slightly less than those described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. This is for two reasons. First, the assessment of effects on *Microcystis* in the SWP/CVP Export Service Areas is based on the assessment of *Microcystis* production in source waters to Banks and Jones pumping plants, and the effects on *Microcystis* at Banks and Jones pumping plants is not expected to be different at the ELT and LLT for the reason discussed for the "Delta" above. Second, changes in ambient air temperatures due to climate change are expected to be less at the ELT compared to the LLT, as described for the "Delta" above. Thus, effects of climate change on the potential for environmental conditions in the SWP/CVP Export Service Areas to become more conducive for *Microcystis* growth, relative to Existing Conditions, are expected to be less at the ELT than at the LLT.

CEQA Conclusion: For the reasons described above, the effects of the No Action Alternative (ELT) on Microcystis levels, and thus microcystin concentrations, in surface waters upstream of the Delta, within the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to or less than those described for the No Action Alternative (LLT) in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. As such, the No Action Alternative (ELT) would not be expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. Microcystis and microcystins are not CWA Section 303(d) listed within the affected environment and thus any increases that could occur in some areas would not make any existing Microcystis impairment measurably worse because no such impairments currently exist. Because Microcystis and microcystins are not bioaccumulative, increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. However, because it is possible that under the No Action Alternative (ELT) increases in the frequency, magnitude, and geographic extent of Microcystis blooms in the Delta would occur due to both increased water temperatures from climate change, as well as increased water residence times related to restoration activities, long-term water quality degradation may occur in the Delta and water exported from the Delta to the SWP/CVP Export Service Areas. Thus, impacts on beneficial uses could occur. This impact is considered significant.

Impact WQ-33: Effects on San Francisco Bay Water Quality Resulting from Facilities Operations and Maintenance

The effects of the No Action Alternative (ELT) on San Francisco Bay water quality would be similar to or slightly less than those described for the No Action Alternative (LLT), in Chapter 8, *Water Quality*, Section 8.3.3.1 of the Draft EIR/EIS. The primary difference in the ELT is that the effects of climate change on upstream hydrology and sea level rise in the Delta and Bay would be less, and there would be less water demand. However, for the same reasons described for the LLT, upstream constituent concentrations and Delta outflow would not be altered sufficiently by these differences to cause substantial water degradation or contribute to adverse effects to beneficial uses in San Francisco Bay.

CEQA Conclusion: The No Action Alternative (ELT) would not be expected to cause long-term degradation of water quality in San Francisco Bay resulting in sufficient use of available assimilative capacity such that occasionally exceeding water quality objectives/criteria would be likely and would result in substantially increased risk for adverse effects to one or more beneficial uses. Further, this alternative would not be expected to cause additional exceedance of applicable water quality objectives/criteria in the San Francisco Bay by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. Any changes in boron, bromide, chloride, and DOC in the San Francisco Bay would not adversely affect beneficial uses, because the uses most affected by changes in these parameters, MUN and AGR, are not beneficial uses of the Bay. Further, no substantial changes in dissolved oxygen, pathogens, pesticides, trace metals or turbidity or TSS are anticipated in the Delta, relative to Existing Conditions, therefore, no substantial changes in these constituents levels in the Bay are anticipated. Changes in Delta salinity would not contribute to measurable changes in Bay salinity, as the change in Delta outflow would be two to three orders of magnitude lower than (and thus minimal compared to) the Bay's tidal flow and thus, have minimal influence on salinity changes. Adverse changes in *Microcystis* levels that could occur in the Delta would not cause adverse *Microcystis* blooms in the Bay, because *Microcystis* are intolerant of the Bay's high salinity and, thus have not been detected downstream of Suisun Bay. The reduction in total nitrogen load (associated with the SRWTP improvements) and changes in phosphorus load, relative to Existing Conditions, are expected to have minimal effect on water quality degradation, primary productivity, or phytoplankton community composition. As with the LLT, the change in mercury and methylmercury load (which is based on source water and Delta outflow), relative to Existing Conditions, would be within the level of uncertainty in the mass load estimate and not expected to contribute to water quality degradation, make the CWA section 303(d) mercury impairment measurably worse or cause mercury/methylmercury to bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Similarly, based on LLT estimates, the increase in selenium load would be minimal, and total and dissolved selenium concentrations would be expected to be the same as Existing Conditions, and less than the target associated with white sturgeon whole-body fish tissue levels for the North Bay. Thus, the change in selenium load is not expected to contribute to water quality degradation, or make the CWA section 303(d) selenium impairment measurably worse or cause selenium to bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. This impact is considered less than significant.

4.2.8 Geology and Seismicity

The effects of the No Action Alternative (ELT) as considered for the purposes of Alternative 4A, 2D, and 5A would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 9, *Geology and Seismicity*, Section 9.3.3.1 of the Draft EIR/EIS. The No Action Alternative (ELT) considers changes in risk from geology and seismicity that would take place as a result of the continuation of existing plans, policies, and operations, as described in Chapter 3, *Description of Alternatives*, of the Draft EIR/EIS. Due to the shorter time frame, the magnitude of total geologic and seismic impacts on construction associated with development and habitat restoration activities within the Plan Area would be less under the ELT timeframe than that considered in 2060 due to less development in the region.

4.2.8.1 Earthquake Induced Ground Shaking, Liquefaction and Slope Instability

Under the No Action Alternative (ELT) it is anticipated that the current hazard resulting from earthquake-induced ground shaking from regional and local faults would be similar to that under the No Action Alternative (LLT) presented in the Draft EIR/EIS. This would continue to present a risk of levee failure and subsequent flooding of Delta islands, with a concomitant influx of seawater into the Delta, thereby adversely affecting water quality and water supply. It is also anticipated that the current hazard of earthquake-induced liquefaction triggered by regional and local faults would persist. Liquefaction would continue to present a risk of levee failure and subsequent flooding of Delta islands, with concomitant water quality and water supply effects from seawater intrusion as described in Appendix 3E, *Potential Seismicity and Climate Change Risks to SWP/CVP Water Supplies*.

Ongoing and reasonably foreseeable future projects in parts of the Delta are expected to upgrade the levees to a “flood-safe” condition under the 100-year return flood elevation. Given the shorter timeframe, fewer projects would be implemented in the No Action Alternative (ELT). Regardless, these projects would provide very little levee foundation strengthening and improvements directed at improving the stability of the levees to better withstand ground shaking, liquefaction, and slope instability.

4.2.8.2 Tsunami and Seiche

Under the No Action Alternative (ELT) it is anticipated that the current hazard resulting from tsunami and seismically induced seiche on Delta and Suisun Marsh levees would be similar to that under the No Action Alternative (LLT). The geometry of existing water bodies in the Delta and Suisun Marsh and distance to seismic sources generally are not conducive to the occurrence of a substantial seismically induced seiche, as described in Section 9.1.1.3 of the Draft EIR/EIS. However, because of its proximity to the potentially active West Tracy fault, there is a potential hazard for a seiche to occur in the Clifton Court Forebay (Fugro Consultants 2011).

4.2.8.3 Ongoing Plans, Policies, and Programs

The programs, plans, and projects included in Table 9-13 of the Draft EIR/EIS would apply to the No Action Alternative (ELT). Although not specifically directed at mitigating potential damage to levees caused by a tsunami and seiche, the ongoing and reasonably foreseeable future projects directed to upgrade levees to a “flood-safe” condition under the 100-year return flood elevation or projects involving other similar levee improvements may provide some benefit to withstanding the potential effect of a tsunami and seiche.

Given the shorter timeframe, fewer projects would be implemented in the No Action Alternative (ELT), but there would be an indirect and beneficial effect upon the potential hazard of tsunami and seiche in the Delta due to improvements in levee infrastructure as a part of implementation of these projects or programs.

4.2.8.4 Climate Change and Catastrophic Seismic Risks

The Delta and vicinity is within a highly active seismic area, with a generally high potential for major future earthquake events along nearby and/or regional faults, and with the probability for such events increasing over time. Under the No Action Alternative (ELT), it is anticipated that the potential for significant damage to, or failure of, these structures during a major local seismic event would be identical to that under the No Action Alternative (LLT) presented in the Draft EIR/EIS. In the instance of a large seismic event, levees constructed on liquefiable foundations are expected to experience large deformations (in excess of 10 feet) under a moderate to large earthquake in the region. There would potentially be loss, injury or death resulting from ground rupture, ground shaking and liquefaction.

***CEQA Conclusion*:** In total, the plans and programs under the No Action Alternative ELT would result in a beneficial effect on an undetermined extent of levees in the Delta. Under the No Action Alternative ELT, these plans, policies, and programs would have an indirect and beneficial effect upon the potential hazard of tsunami and seiche in the Delta. These plans and programs, however, would not decrease the risks associated with climate change or a catastrophic seismic event, as discussed above and more thoroughly in Appendix 3E, *Seismic and Climate Change Risks to SWP/CVP Water Supplies.* The impact of the No Action Alternative (ELT) related to geology and seismicity would be less than significant.

4.2.9 Soils

The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 10, *Soils*, Section 10.3.3.1 of the Draft EIR/EIS. The No Action Alternative (ELT) includes projects and programs with defined management or operational plans, including facilities under construction because those actions would be consistent with the continuation of existing management direction or level of management for plans, policies, and operations by the project proponents and other agencies. Under the No Action Alternative (ELT), the condition of soils would continue largely as they have under Existing Conditions. Due to the shorter time frame compared to the No Action Alternative (LLT), the magnitude of total impacts to soils resulting from construction associated with development and habitat restoration activities within the Plan Area would be less under the ELT timeframe than that considered in 2060 due to less development in the region.

Accelerated Soil Erosion

As with the No Action Alternative (LLT), current rates of water and wind erosion would continue under the No Action Alternative (ELT) as a result of agricultural practices as well as levee stabilization, dredge spoil disposal, and habitat restoration projects. There would be less erosion than under the No Action Alternative (LLT) due to a smaller scale of farming and project construction that would be completed during this timeframe. Federal, state, and local regulations, codes, and permitting programs would continue to require implementation of measures to prevent nonagricultural accelerated erosion and sediment transport associated with construction.

The loss of topsoil as a result of excavation, overcovering, and inundation would continue in the Delta and statewide under the No Action Alternative ELT as a result of numerous land development and habitat restoration projects. However, it would be less than under the No Action Alternative (LLT) described in Chapter 10, *Soils*, Section 10.3.3.1 of the Draft EIR/EIS, due to the shorter timeframe.

Land subsidence in the Delta and the Suisun Marsh would continue to varying degrees under the No Action Alternative (ELT). It is anticipated that the current rate of subsidence would continue. Several projects are now underway that would have a beneficial effect on subsidence, some with the explicit goal of controlling or reversing subsidence. While fewer projects would be implemented during the ELT, the level of subsidence would also be less than under the No Action Alternative (LLT).

Ongoing and reasonably foreseeable future projects in the Plan Area are likely to encounter expansive, corrosive, and compressible soils. However, federal and state design guidelines and building codes would continue to require that the facilities constructed as part of these projects incorporate design measures to avoid the adverse effects of such soils.

Plans and programs that would occur in the No Action Alternative (ELT) would result in the loss of at least 3,618 acres of topsoil from overcovering or inundation. Because of the amount of topsoil that would be lost under the No Action alternative (ELT), these plans, policies, and programs would be deemed to have direct and adverse effects on topsoil loss in the Delta.

Subsidence would be controlled or reversed on approximately 308 acres, resulting in a beneficial effect.

CEQA Conclusion: In total, the plans and programs under the No Action Alternative (ELT) would result in the loss of at least 3,618 acres of topsoil from overcovering or inundation between the present and 2025. This would constitute a significant impact. Subsidence would be controlled or reversed on approximately 308 acres, resulting in a beneficial impact.

4.2.10 Fish and Aquatic Resources

Covered Fish Species

Many of the projects and programs that would occur under the No Action Alternative (ELT) would be similar to those included in the alternatives and would have similar potential effects. These effects would also be similar between the different covered species. Therefore, the following assessment addresses all the covered species as a group for some potential effects (e.g., water quality effects), but addresses individual species for other mechanisms where the effects could be measurably different among species (e.g., entrainment).

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-NAA1: Effects of Construction of Facilities on Covered Fish Species

The construction effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. Construction of future projects would continue largely as it has under Existing Conditions and would include continued implementation of SWP and CVP operations, maintenance, enforcement, and protection programs by federal, state, and local agencies and non-profit groups, as well as projects that are permitted or assumed to be constructed in the early long-term period. However, due to the shorter time frame, the magnitude of in-water construction projects including water supply and habitat restoration activities within the Plan Area would be less than that considered under the No Action Alternative (LLT) in 2060. Similarly, aquatic impacts associated with climate change (including temperature and water quality) would be anticipated to be lower than consideration of the No Action Alternative (LLT).

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic*

Resources, Section 11.3.4.1 of the Draft EIR/EIS. Overall, the potential impact mechanisms on covered fish species from construction of other projects under the No Action Alternative (ELT) would include effects from increased turbidity, accidental spills, disturbance of contaminated sediment, underwater noise, fish stranding, in-water work activities, loss of spawning, rearing or migration habitat, and predation. However, these effects would be less than significant because of the limited extent, intensity, and duration of expected construction and maintenance projects in the Plan Area. In addition, any such construction projects would be subject to a separate environmental compliance process, with permit stipulations that would include the implementation of project-specific AMMs, BMPs, environmental commitments and/or mitigation measures. This would include project-specific erosion and sediment control plans; hazardous materials management plans; SWPPPs; spill prevention and control plans; and limiting in-water activities to periods of low flow and/or to times when covered fish species are not likely to be present. Therefore, the construction-related effects under the No Action Alternative (ELT) would be less than significant.

Impact AQUA-NAA2: Effects of Maintenance of Facilities on Covered Fish Species

The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. Construction of future projects would continue largely as it has under Existing Conditions and would include continued implementation of SWP CVP operations, maintenance, enforcement, and protection programs by federal, state, and local agencies and non-profit groups, as well as projects that are permitted or assumed to be constructed by in the early long-term period. However, due to the shorter time frame, the magnitude of the maintenance of in-water construction projects including water supply and habitat restoration activities within the Plan Area would be less than that considered in 2060. Similarly, aquatic impacts associated with climate change (including temperature and water quality) would be anticipated to be lower than consideration of the No Action Alternative (LLT).

CEQA Conclusion: The conclusion provided in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS and above for the construction activity effects (Impact AQUA-NAA1), would typically be very similar to those expected to occur during maintenance activities, and therefore this impact would be less than significant.

Water Operations of Water Conveyance Facilities

Impact AQUA-NAA3: Effects of Water Operations on Entrainment of Covered Fish Species

Numerous methods were used to estimate entrainment losses under No Action Alternative (LLT), and a complete analysis can be found in the Draft BDCP Appendix 5B, *Entrainment*, Section B.5, *Methods of Biological Analysis*, and Section B.6, *Results* (hereby incorporated by reference).

The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1, of the Draft EIR/EIS. However, due to the earlier time frame, the magnitude of operational effects within the Plan Area generally would be slightly greater than that considered in 2060, i.e., slightly greater entrainment at the early long-term timeframe than at the late long-term time frame because of slightly greater south Delta exports (see, for example, Figure 5.B.4-2 in Draft BDCP Appendix 5B, *Entrainment*, Section 5.B.4.2, *Difference in Exports from the South Delta Pumps under the BDCP [*hereby incorporated by reference]). Aquatic impacts associated with climate change (including temperature and water quality) would be anticipated to be lower than under the No Action Alternative (LLT).

Delta Smelt

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. Despite modeled increases in entrainment in the No Action (ELT) compared to the Existing Condition, the differences are not expected to reach the level of adverse effects on delta smelt populations (less than 5% of the population). Entrainment of delta smelt is regulated by the USFWS 2008 BiOp, which includes operational criteria and continued improvements in water export processes, fish screens, and fish salvage operations at the south Delta facilities. These activities are expected to occur in the ELT and LLT time periods and therefore, there would be little difference between the previously modeled No Action Alternative (LLT) and the No Action Alternative (ELT). Along with other improvements in SWP/CVP facilities and operations expected to occur in the future, the effect would be less than significant.

Longfin Smelt

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. Operational activities associated with water exports from SWP/CVP south Delta facilities during the No Action Alternative (ELT) period would not result in an overall substantial increase in entrainment for longfin smelt under most circumstances. Improvements in water export and fish salvage operations as a result of on-going studies, and the implementation of the SWP California Department of Fish and Wildlife longfin smelt Incidental Take Permit No. 2081-2009-001-03 (California Department of Fish and Game 2009) are expected to result in a less-than-significant impact.

Chinook Salmon

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. General on-going improvements implemented under Existing Conditions during the NAA timeframe are expected to reduce entrainment losses of Chinook salmon through the implementation of the NMFS and USFWS BiOp requirements (National Marine Fisheries Service 2009a; U.S. Fish and Wildlife Service 2008). Additionally, Implementation of RPA Action I.7 (Reduce Migratory Delays and Loss of Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in the Yolo Bypass) in the No Action Alternative (ELT) would reduce loss of Chinook salmon at the Fremont Weir and other structures in the Yolo Bypass. Yolo Bypass Restoration would provide improved connectivity and passage for Central Valley spring-run Chinook and an increase in Chinook salmon within the project area. This may result in an increase in salmon entrainment; however, the overall number of Chinook salmon will increase. Therefore, the overall effects for the No Action Alternative (ELT) are expected to be less than significant, and likely to be generally beneficial.

Steelhead

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic*

Resources, Section 11.3.4. of the Draft EIR/EIS 1. Implementation of RPA Action I.7 (Reduce Migratory Delays and Loss of Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in the Yolo Bypass) in the No Action Alternative (ELT) would reduce loss of steelhead at the Fremont Weir and other structures in the Yolo Bypass. Yolo Bypass Restoration would provide improved connectivity and passage for Central Valley steelhead and an increase in steelhead within the project area. This may result in an increase in steelhead entrainment; however, the overall number of steelhead would increase. Additionally, on-going and future operational improvements at the SWP and CVP south Delta facilities would likely result in a general decrease in entrainment for juvenile steelhead under the No Action Alternative (ELT). Potential impacts of the No Action Alternative (ELT) on entrainment of steelhead could be slightly beneficial.

Sacramento Splittail

The methods used to estimate juvenile splittail entrainment are detailed in Appendix 5B *Entrainment,* Section B.5.4.5 of the Draft BDCP.

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. Structural and operational changes associated with water exports from SWP/CVP south Delta facilities are not expected to result in an overall increase in per capita entrainment for Sacramento splittail under the No Action Alternative (ELT), and could be somewhat beneficial. Therefore, impacts of the No Action Alternative on entrainment are considered less than significant.

Sturgeon

Available information on the distribution and abundance of sturgeon in the Plan Area is provided in Appendix 11A, *Covered Fish Species Descriptions*, of the Draft BDCP.

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. Implementation of RPA Action I.7 (Reduce Migratory Delays and Loss of Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in the Yolo Bypass) in the No Action Alternative (ELT) would reduce loss of sturgeon at the Fremont Weir and other structures in the Yolo Bypass. Yolo Bypass Restoration would provide improved connectivity and passage for green sturgeon and an increase in sturgeon within the project area. This may result in an increase in sturgeon entrainment; however, the overall number of sturgeon will increase. Structural and operational changes associated with water exports from south SWP/CVP facilities are not expected to substantially change the entrainment of sturgeon under the No Action Alternative (ELT), based on continued improvements implemented under the 2009 NMFS and 2008 USFWS BiOps. Overall, impacts of water operations on sturgeon entrainment would be less than significant.

Lamprey

Although somewhat limited, the available information on the distribution and abundance of lamprey in the Plan Area is provided in Appendix 11A, *Covered Fish Species Descriptions*, of the Draft BDCP.

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic*

Resources, Section 11.3.4.1 of the Draft EIR/EIS. Structural and operational activities associated with water exports from south Delta SWP/CVP facilities are not expected to substantially change entrainment of lamprey under the No Action Alternative (ELT). Overall, the entrainment impacts of water operations to Pacific and river lamprey are considered less than significant.

Impact AQUA-NAA4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Covered Fish Species

The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. However, due to the earlier time frame, the magnitude of operational effects within the Plan Area would be slightly greater than that considered in 2060 as there would be less operational constraints resulting from climate change and sea level rise. Aquatic impacts associated with climate change (including temperature and water quality) would be anticipated to be lower than those assumed for the No Action Alternative (LLT) and therefore the overall effect would be similar or slightly lower in the early long-term timeframe than the late long-term timeframe.

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. The effect of the NAA operations on delta smelt, longfin smelt, and Sacramento splittail spawning habitat is not adverse, because there would be little change in spawning conditions attributable to continued operations. Longfin smelt spawning flows would be slightly reduced (less than 2%) relative to Existing Conditions when climate change effects are accounted for under No Action Alternative (ELT) conditions, but not to an adverse level. However, Shasta Reservoir storage volume at the end of May would be lower than storage volume under Existing Conditions in below normal, dry, and critical water years due to climate change effects, indicating a small–to-moderate impact from summer water flows and temperatures. Decreased summer flows in the upstream tributaries as a result of climate change could adversely affect spawning habitat and egg survival for some covered fish species, such as spring-run and winter-run Chinook salmon, although no major or consistent effects were identified. The No Action Alternative (ELT) modeling also does not account for changes that may occur upstream to mitigate climate change effects, such as habitat restoration and improvements in passage that are included in the NMFS BiOp as RPAs. Because the changes in modeled flows were not substantial and because improvements are a required component in the NMFS BiOp, the effect is less than significant.

Impact AQUA-NAA5: Effects of Water Operations on Rearing Habitat for Covered Fish Species

The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. However, due to the earlier time frame, the magnitude of operational effects within the Plan Area generally would be slightly greater than that considered in 2060 as there would be less operational constraints resulting from climate change and sea level rise. Aquatic impacts associated with climate change (including temperature and water quality) would be anticipated to be lower than those described for the No Action Alternative (LLT). Aquatic impacts associated with climate change would be anticipated to be lower than those assumed for the No Action Alternative (LLT) and the overall effect would be similar or slightly less in the early long-term timeframe than the late long-term timeframe.

An additional project not considered in Chapter 11 for the No Action Alternative (LLT) and included in this analysis are the actions covered by the Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan (Bureau of Reclamation and California Department of Water Resources 2012). These actions are intended to address two of the Reasonable and Prudent Alternative (RPA) actions outlined in the NMFS (2009) BiOp: RPA Action I.6.1 and RPA Action 1.7. RPA Action I.6.1 (Restoration of Floodplain Rearing Habitat) requires increased seasonal inundation in the lower Sacramento River Basin, and RPA Action I.7 (Reduce Migratory Delays and Loss of Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in the Yolo Bypass) requires multispecies fish passage improvements and assessment of their performance.

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. However, implementation of RPA Action 1.6.1 would result in improved rearing conditions for Sacramento splittail, salmonids, and green and white sturgeon. The overall effects of the No Action Alternative (ELT) would be less than significant for the other covered fish species.

Impact AQUA-NAA6: Effects of Water Operations on Migration Habitat for Covered Fish Species

The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. However, due to the earlier time frame, the magnitude of operational effects alone within the Plan Area generally would be slightly greater than that considered in 2060 as there would be less operational constraints resulting from climate change and sea level rise. Aquatic impacts associated with climate change would be anticipated to be lower than those assumed for the No Action Alternative (LLT) and the overall effect would be similar or slightly less in the early long-term timeframe than the late long-term timeframe.

An additional project not considered in Chapter 11 of the Draft EIR/EIS for the No Action LLT and included in this analysis of the actions covered by the Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan (Bureau of Reclamation and California Department of Water Resources 2012). These actions are intended to address two of the Reasonable and Prudent Alternative (RPA) actions outlined in the NMFS (2009) BiOp: RPA Action I.6.1 and RPA Action 1.7. RPA Action I.6.1 (Restoration of Floodplain Rearing Habitat) requires increased seasonal inundation in the lower Sacramento River Basin, and RPA Action I.7 (Reduce Migratory Delays and Loss of Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in the Yolo Bypass) requires multispecies fish passage improvements and assessment of their performance.

CEQA Conclusion: The effects of the No Action Alternative (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 11, *Fish and Aquatic Resources*, Section 11.3.4.1 of the Draft EIR/EIS. However, implementation of RPA Action I.7 (Reduce Migratory Delays and Loss of Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in the Yolo Bypass) under the No Action Alternative (ELT) would provide improved connectivity and migration for Sacramento splittail, salmonids, and green and white sturgeon. Average Delta outflow would be similar to Existing Conditions, which would have limited effects on migration and survival of covered fish species migrating downstream in the spring. There would be a beneficial effect to these species in the No Action Alternative (ELT) as a result. There would be little effect on delta smelt and longfin smelt migration conditions, and therefore any impacts would be less than significant.

4.2.11 Terrestrial Biological Resources

Effects of the No Action Alternative (ELT) as considered for the purposes of Alternative 4A, 2D, and 5A would be similar to the effects described for the No Action Alternative (LLT), except that the shorter time frame would reduce the effects of many projects and programs listed in Table 12-7 in Chapter 12, *Terrestrial Biological Resources*, of the Draft EIR/EIS. The reduced time frame would also lessen the potential effects of sea level rise and would reduce, but not eliminate, the risks to biological resources from flood- or seismic-related failure of Delta levees.

Implementation of the on-going habitat expansion projects are likely to show significant progress in the ELT time period as efforts are made to counteract the terrestrial habitat losses associated with land conversion (primarily agricultural) and urban and infrastructure development in a timely fashion. These expansions would be expected to counteract any transportation- or water-related infrastructure development or urban development in the study area because of the tight controls on these developments in the Delta. Management of the state and federal wildlife areas and the private wetlands would continue to emphasize a balance of protection for sensitive plant and wildlife species and the need for recreation opportunities and long-term agricultural viability. The number of habitat enhancement projects and the acreage of natural habitats restored and protected would likely be lower than what would be expected over a 50-year time frame. Ongoing water management activities under the No Action Alternative (ELT) would not be likely to substantially modify the natural communities of the study area during the ELT time period. Most water management strategies being developed by state and federal water management agencies are designed to improve the conditions for special-status fish, wildlife and plants in the study area.

The potential for adverse effects on biological resources from gradual sea level rise and from levee system failures due to major flooding episodes or seismic activity would be significantly reduced under No Action Alternative (ELT), compared to the 50-year time frame under No Action Alternative (LLT). The extent of marsh habitat conversion would be lessened on the periphery of Suisun Marsh and the Yolo Basin, and along the Delta waterways with a lower rise in sea level. The long-term risk of habitat destruction from levee failure and subsequent flooding of riparian and cropland areas on Delta islands due to major flood events or seismic shaking would be reduced. However, the risk would remain that major areas of cropland and adjacent natural habitats could be lost due to the poor condition of many Delta levees.

Even though the No Action Alternative (ELT) time period is significantly reduced from the No Action Alternative (LLT) time period, the overall direction of existing and ongoing programs and policies that influence land conversion and land management in the study area would continue to be toward maintaining the mix of agricultural, recreational, water management, and wildlife uses in the Delta, Yolo Bypass and Suisun Marsh. Some actions that will occur under the No Action Alternative (ELT) will expand natural and manmade terrestrial and wetland habitats that will benefit the special-status and common plants and wildlife with expanded and enhanced habitat in the study area. The potential will remain, however, for long-term trends in levee deterioration, global climate change, and seismic activity that could damage levees and result in significant changes in natural communities and cultivated lands. Major reductions in tidal and nontidal wetland, riparian, and managed wetland sensitive natural communities and cultivated land habitats and their associated special-status plant and animal species would be an adverse effect on terrestrial biological resources.

CEQA Conclusion: Under the No Action Alternative (ELT) existing plans, programs and policies would affect terrestrial biological resources in the study area in a positive way. Many plans and programs call for expanded development and management of wetland and riparian habitats and increased management of cultivated lands for joint benefit to the farmer and wildlife. There would be a beneficial impact on terrestrial biological resources.

Risks associated with natural processes that could damage or destroy Delta levees that protect both natural habitats and agricultural lands will continue, only over a shorter time period. The risks include flood-related levee deterioration, potential for seismically induced levee collapse, and to a lesser extent, sea level rise associated with climate change. These risks, even over the shorter time period, if unchecked, could result in a net reduction in sensitive natural communities and special-status species, causing a significant impact on the terrestrial biological resources of the study area.

4.2.12 Land Use

The effects of the No Action Alternative as considered for the purposes of Alternatives 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 13, *Land Use*, Section 13.3.3.1 of the Draft EIR/EIS. Statewide and federal programs to preserve open space and agricultural lands would continue to be implemented. Additionally, projects and programs related to land development, habitat restoration, and flood control are also considered part of the No Action Alternative (ELT). As is the case in the late long-term timeframe, the land uses in the Delta in the early long-term would be anticipated to be generally similar to those of today because only limited types of development are allowed in the Primary Zone of the Delta. However, land use patterns and agricultural uses may experience change related to continued development pressure in areas outside the primary zone. Due to the shorter time frame, the magnitude of agricultural conversion and other changes in land use associated with development and habitat restoration activities within the Delta would be less than that considered in 2060. Similarly, risks associated with other factors that may affect land use conditions in the study area, including subsidence, levee instability, and sea level rise would be anticipated to be lower than the risks associated with those factors when considered in the late long-term.

Land use changes under the No Action Alternative (ELT) would not be anticipated to result in the physical division of any existing communities within the study area. While habitat restoration and urban development projects may result in localized conflicts with existing land uses and incompatibilities with policies and plans (depending on their locations and other characteristics), overall, the effects of plans, policies, programs, and other reasonably foreseeable circumstances included as part of the No Action Alternative (ELT) would not be anticipated to result in adverse effects on land use within the study area.

CEQA Conclusion: Under the No Action Alternative (ELT), existing land use designations, goals, and policies would guide land use in the Delta in a similar way as it exists today. Physical impacts on land use are anticipated to be less than significant under this alternative.

4.2.13 Agricultural Resources

The effects of the No Action Alternative as considered for the purposes of Alternatives 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 14, *Agricultural Resources*, Section 14.3.3.1 of the Draft EIR/EIS. Agricultural production would continue largely as it has under Existing Conditions and would include continued implementation of SWP/CVP operations, maintenance, enforcement, and protection programs by federal, state, and local agencies and non-profit groups, as well as projects that are permitted or assumed to be constructed by in the early long-term period. However, due to the shorter time frame, the magnitude of agricultural conversion including development and habitat restoration activities within the Plan Area would be less than that considered in 2060. Similarly, agricultural effects associated with climate change (including water quality and flooding risks) would be anticipated to be lower than consideration of the No Action Alternative (LLT). Continuing activities related to operation of SWP and CVP facilities, changes in water quality, and other indirect effects are not changes in the existing environment that would result in the conversion of substantial amounts of Important Farmland to nonagricultural use. However, because Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones in the study area would be converted to nonagricultural uses under existing plans and programs, direct and adverse effects upon agricultural resources in the study area would occur under the No Action Alternative.

CEQA Conclusion: Continuing activities related to operation of SWP and CVP facilities, changes in water quality, and other indirect effects are not changes in the existing environment that would result in the conversion of substantial amounts of Important Farmland to nonagricultural use. However, because Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones would be converted to nonagricultural uses under existing plans and programs, the No Action Alternative considered in the early long-term would have significant impacts upon agricultural resources in the study area.

4.2.14 Recreation

The effects of the No Action Alternative (ELT) considered for the purposes of Alternatives 4A, 2D, and 5A would be expected to be similar to the effects described for the No Action Alternative (LLT) in Chapter 15, *Recreation,* of the Draft EIR/EIS 15.3.3.1 of the Draft EIR/EIS. Recreation opportunities occurring under the No Action Alternative (ELT) would continue largely as described for Existing Conditions and would include continued implementation of SWP and CVP operations, maintenance, enforcement, and protection programs by federal, state, and local agencies and non-profit groups, as well as projects that are permitted or assumed to be constructed by in the early long-term period. This includes restoration actions occurring within the Yolo Bypass being driven by the 2008 and 2009 USFWS and NMFS BiOps and the restoration of 8,000 acres of intertidal habitat in the Delta and Suisun Marsh.

Land and water-based recreation opportunities and activities occurring within the Delta and at upstream reservoirs under the No Action Alternative (ELT) would be similar to those described under the No Action Alternative during the late long-term timeframe. Because the No Action Alternative (ELT) implementation period would be shorter, the magnitude of land-disturbing activities occurring within the Delta that could disrupt access to land-based recreation sites and disrupt access to Delta channels used for recreation would be expected to be less than the No Action Alternative (LLT). Similarly, changes in water-based recreation opportunities associated with changes in upstream reservoir storage, streamflow, and the abundance of sport fish would also be similar to the No Action Alternative (LLT), but the magnitude of these changes would also be less because of the shorter time period of the No Action Alternative (ELT).

Similar to the No Action Alternative (LLT), CALSIM II output was used to help evaluate the potential changes in north-of-Delta and south-of-Delta reservoirs where recreation opportunities could be affected by the alternatives, including the No Action Alternative (ELT). As shown in Table 4.2.11-1 and Table 4.2.11-2 the No Action Alternative (ELT) conditions would have more years in which reservoir levels fall below the recreation threshold relative to the existing condition with the exception of New Melones Reservoir. Under the No Action Alternative (ELT) conditions, the reservoirs would fall below the thresholds from 5 to 11 additional years than under Existing Conditions whereas New Melones Reservoir would be above the threshold for one additional year. The changes in the SWP and CVP reservoir elevations are attributable to change in demand and other external factors such as climate change. It is not possible to specifically define the exact extent of the changes attributable to future no action operations using these model simulation results. Thus, the precise contributions of sea level rise and climate change to the total differences between Existing Conditions and No Action Alternative (ELT) cannot be isolated in this comparison.

Table 4.2.11-1. Summary of SWP and CVP Reservoir Recreation Opportunities (years below end-of-September recreation threshold) for Existing Conditions and No Action Alternative (ELT)

	Recreation Threshold[a]					
	Trinity Lake		Shasta Lake		Lake Oroville	
	<2,270 ft Elevation		<967 ft Elevation		<700 ft Elevation	
Scenario	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Years[b]	Change Relative to Existing Condition (CEQA)[c]
Existing Conditions (CEQA)	21		17		17	
No Action (ELT)	32	11	22	5	26	9

[a] Recreation thresholds selected for the analysis represent the reservoir surface water elevation at which recreation opportunities become diminished due to restricted access to boat ramps, exposure of previously submerged islands or shoals that affect boater safety, and shoreline degradation.

[b] The number of years out of the 82 simulated when the September end-of-month elevation is less than the recreation elevation threshold for the selected scenario. An elevation less than the recreation threshold indicates years during which recreation opportunities may be diminished (see note a, above).

[c] The change values are the number of years of the simulated conditions that the selected alternative differs from the comparison condition (i.e., Existing Conditions). A positive change indicates more years with reduced recreation opportunities relative to the comparison condition. A negative change indicates fewer years with reduced recreation opportunities relative to the comparison condition.

Table 4.2.11-2. Summary of SWP and CVP Reservoir Recreation Opportunities (years below end-of-September recreation threshold) for Existing Conditions and the No Action Alternative (ELT)

	Recreation Threshold[a]					
	Folsom Lake		New Melones Lake		San Luis Reservoir	
	<405 ft Elevation		<900 ft Elevation		<360 ft Elevation	
Scenario	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Years[b]	Change Relative to Existing Condition (CEQA)[c]
Existing Conditions (CEQA)	22		9		3	
No Action (ELT)	33	11	8	-1	9	6

[a] Recreation thresholds selected for the analysis represent the reservoir surface water elevation at which recreation opportunities become diminished due to restricted access to boat ramps, exposure of previously submerged islands or shoals that affect boater safety, and shoreline degradation.

[b] The number of years out of the 82 simulated when the September end-of-month elevation is less than the recreation elevation threshold for the selected scenario. An elevation less than the recreation threshold indicates years during which recreation opportunities may be diminished (see note a, above).

[c] The change values are the number of years of the simulated conditions that the selected alternative differs from the comparison condition (i.e., Existing Conditions). A positive change indicates more years with reduced recreation opportunities relative to the comparison condition. A negative change indicates fewer years with reduced recreation opportunities relative to the comparison condition.

As described for the No Action Alternative (LLT) in Chapter 3, *Description of Alternatives* in the Draft EIR/EIS, many of the ongoing programs under No Action Alternative (ELT) would also include development of future projects that would require additional project-level environmental review. Future federal actions would be required to comply with NEPA, the federal Endangered Species Act (ESA), and other federal laws and regulations. Future state and local actions would be required to comply with CEQA, the California Endangered Species Act (CESA), and other state and local laws and regulations. Compliance and permit requirements would be implemented on a case-by-case basis.

The potential for catastrophic seismic events and potential effects on recreation opportunities in the Delta under the No Action Alternative (ELT) would be the same as described under the No Action Alternative (LLT). The change in water quality resulting from a seismic event in which Delta levees fail could result in permanent displacement of existing, well-established public use or private commercial recreation facilities as well as result in long-term reduction of recreation opportunities, recreational navigation opportunities and recreational fishing opportunities. To reclaim land or rebuild levees after a catastrophic event due to climate change or a seismic event would potentially also result in adverse impacts to recreational resources.

CEQA Conclusion: Overall, the ongoing projects, programs, and plans under the No Action Alternative (ELT) would result in the potential for temporary and permanent effects that are not expected to substantially change recreation opportunities or experiences in the Delta region. Adverse effects on recreation would occur as a result of short-term disruptions that would result in less-than-significant impacts. Beneficial impacts on recreation could occur as programs are implemented. Overall, the impact of the No Action Alternative (ELT) on recreation resource is considered less than significant.

4.2.15 Socioeconomics

Under the No Action Alternative (ELT) socioeconomic conditions would continue largely as under Existing Conditions. This alternative includes continued SWP/CVP operations, maintenance, enforcement, and protection programs by federal, state, and local agencies, as well as projects that are permitted or under construction. When compared with conditions at the late long-term, Delta communities and socioeconomic conditions in the Delta would be subject to lower level of risks associated with climate change, seismic activity, and other phenomena, as discussed in Appendix 3E, *Potential Seismic and Climate Change Risks to SWP/CVP Water Supplies*, of the Draft EIR/EIS.

Population and housing effects in the Delta under the No Action Alternative (ELT) would be anticipated to follow the trends identified in Chapter 16, *Socioeconomics,* Section 16.1 *Environmental Setting/Affected Environment*, of the Draft EIR/EIS, but a smaller increment of growth would be anticipated when compared to conditions in the late long-term. Similarly, the regional economy of the Delta region is expected to be similar in structure to that described for Existing Conditions. Potential changes in expenditures related to recreation and municipal and industrial water uses as well as potential changes in the value of agricultural production could result in changes to regional employment and income in the Delta region under the No Action Alternative (ELT). The scale of the economy would change with population growth; however, the structure of the economy would not. It is possible that some of the projects, programs, and plans considered part of the No Action Alternative (ELT) would reduce the total acreage and value of agricultural production in the Delta region. For example, under the 2008 and 2009 NMFS and USFWS BiOp, up to 8,000 acres of agricultural land could be converted to tidal habitat. Similarly, agricultural land uses in the Yolo Bypass or Suisun Marsh could be periodically or permanently disrupted by other habitat restoration efforts. While local government fiscal conditions in Delta region would be anticipated to be similar to existing conditions, programs resulting in public acquisition of privately-held land, in addition to the population and economic changes described above, could affect property and sales tax revenue.

CEQA Conclusion**:** The ongoing programs and plans under the No Action Alternative (ELT), along with anticipated population growth, would not be anticipated to substantially alter the character of Delta communities, the structure of the regional economy, or local government fiscal conditions, when compared with Existing Conditions and therefore would not be anticipated to result in any physical change to the environment, significant or otherwise.

Effects in South-of-Delta Hydrologic Regions

Under the No Action Alternative (ELT), several assumptions would create a deviation from Existing Conditions. First, an increase in M&I water rights demands is assumed north of the Delta, increasing overall system demands and reducing the availability of CVP water for export south of the Delta. Secondly, the No Action Alternative (ELT) includes the effects of implementation of the Fall X2 standard, which requires additional water releases through the Delta and would therefore reduce the availability of water for export to SWP and CVP facilities. The No Action Alternative (ELT) also includes effects of sea level rise and climate change, factors that would also reduce the amount of water available for SWP and CVP supplies (but not as much of a reduction as estimated for the No Action Alternative (LLT). These factors result in a decrease in deliveries under the No Action Alternative (ELT), when compared to Existing Conditions. A detailed explanation of factors influencing deliveries under the No Action Alternative (LLT) is provided in Section 5.3.3.1 in Appendix A of this RDEIR/SDEIS.

Changes in deliveries would result in similar effects to hydrologic regions as described for the No Action Alternative (LLT), but to a smaller magnitude. Where there are reduced deliveries to agricultural contractors, it is reasonable to expect that agricultural production in affected areas would also decline, with potential resultant changes in employment, labor income, community character, and local government fiscal conditions. Where M&I deliveries increase and accommodate population growth, such growth could stimulate economic activity resulting from increased demand for goods and services. As with estimating changes in agricultural production, the location and extent of population growth would depend largely on local factors. Where M&I deliveries under the No Action Alternative (ELT) would be reduced compared to Existing Conditions to the extent that they would, in the long run, constrain population growth, their implementation could reinforce a socioeconomic status quo or limit potential economic and employment growth in hydrologic regions. Further discussion of these potential effects is included in Section 4.2.27, *Environmental Justice*, and in Section 4.2.29, *Growth Inducement and Other Indirect Effects,* of this RDEIR/SDEIS.

CEQA Conclusion: Operation of water conveyance facilities under the No Action Alternative could affect socioeconomic conditions in the hydrologic regions receiving water from the SWP and CVP However, because these impacts are social and economic in nature, rather than physical, they are not considered environmental impacts under CEQA. To the extent that changes in socioeconomic conditions in the hydrologic regions would lead to physical impacts, such impacts are described in Section 4.2.29, *Growth Inducement and Other Indirect Effects*, of this RDEIR/SDEIS.

4.2.16 Aesthetics and Visual Resources

The effects of the No Action Alternative as considered for the purposes of Alternatives 4A, 2D, and 5A (at the early long-term timeframe) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 17, Aesthetic and Visual Resources, Section 17.3.3.1 of the Draft EIR/EIS.

Projects that are planned or currently under way that involve construction, operation and maintenance activities may result in potential to affect visual resources and viewer groups. The land uses in the Delta would be similar to those of today because only limited types of development are allowed in the Primary Zone of the Delta. However, some changes in the study area could occur as a result of localized population growth, continued land subsidence on Delta islands, levee instability and potential flood risk, sea level rise, and restoration activities. These changes could result in the conversion of additional agricultural land uses and would consequently affect the visual landscape. However, due to the shorter time frame for the No Action Alternative (ELT), the magnitude of visual effects associated with development and habitat restoration activities within the Plan Area would likely be less than that considered in 2060.

Many of the ongoing programs include development of future projects that would require additional project-level environmental review. Future federal actions would be required to comply with NEPA, the federal Endangered Species Act, and other federal laws and regulations. Compliance and permit requirements would be implemented on a case-by-case basis. Overall, implementing on-going programs and projects under the No Action Alternative (ELT), including changes in farmland are not expected to result in adverse changes to the visual environment because development in much of the study area is restricted by the primary zone designation and city and county ordinances.

CEQA Conclusion: In total, the ongoing programs and plans under the No Action Alternative (ELT) would result in the potential for temporary and permanent effects on the study area visual environment that are not expected to substantially change visual resource elements in the Delta because of the current restrictions on development in the primary zone and city and county ordinances to preserve the visual quality of the Delta. Future state and local actions would be required to comply with CEQA, the California Endangered Species Act, and other state and/or local laws and regulations. Therefore, this potential impact is considered less than significant.

4.2.17 Cultural Resources

The effects of the No Action Alternative (ELT) would be similar to the effects described for the No Action Alternative (LLT) in Chapter 18, *Cultural Resources,* Section 18.3.5.1 of the Draft EIR/EIS. Activities occurring within the Plan Area under the No Action Alternative (ELT) that could affect prehistoric and historic archaeological sites, buried human remains, and built-environment resources would be similar to those described under Existing Conditions. These activities include ongoing programs implemented by federal, state, and local agencies and non-profit groups, as well as projects that are permitted or assumed to be completed during the early long-term period. This includes restoration actions occurring within the Yolo Bypass and the restoration of 8,000 acres of intertidal habitat in the Delta and Suisun Marsh being driven by the 2008 and 2009 USFWS and NMFS BiOps.

Because the No Action Alternative (ELT) implementation period would be shorter, the magnitude of the ground disturbing activities that could adversely affect prehistoric and historic archaeological sites, buried human remains, and built-environment resources would be less than those expected under the No Action Alternative (LLT). However, adverse impacts on these cultural resources could still occur over the early long-term period as a result of ground disturbing activities within the Plan Area due to the planned restoration activities described above, and other actions such as flood control and roadway improvements.

***CEQA Conclusion*:** Under the No Action Alternative (ELT) activities will occur within the Plan Area that include disturbing lands that could contain prehistoric and historic archaeological sites, buried human remains, and built-environment resources. Land use changes within the Plan Area, including habitat restoration projects, could result in loss of these cultural resources, although to a lesser degree than under the No Action Alternative (LLT) because fewer acres would be disturbed. Because prehistoric and historic archaeological sites, buried human remains, and built-environment resources are known to occur within the Plan Area, actions occurring under the No Action Alternative (ELT) could result in disturbance to and potentially significant impacts on these cultural resources. These potential impacts are considered significant.

4.2.18 Transportation

The effects of the No Action Alternative as considered for the purposes of Alternatives 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 19, *Transportation*, Section 19.3.3.1 of the Draft EIR/EIS.

Under the No Action Alternative (ELT), any currently underway or planned project within the study area that involves construction and operation and maintenance activities may result in potential effects on transportation facilities from movement of personnel, delivery of construction equipment, and delivery of goods and services. The effects could include increased delays on already congested roadways or accelerated deterioration of roadway surfaces. Roadways currently experiencing congestion and delays would continue to experience level of service impacts unless capacity enhancements are undertaken.

Construction of the Yolo Bypass Improvements and 8,000 acres of tidal marsh habit restoration implemented under the No Action Alternative (ELT) may add additional trips to affected roadways, which could potentially create localized transportation effects and could affect access to farmland. However, in general, traffic volumes on roadway segments in the Plan Area would likely be less under the ELT timeframe than those considered in 2060 due to less population and employment growth in the region. Similarly, due to the shorter time frame, the magnitude of total construction traffic impacts associated with development and habitat restoration activities within the Plan Area would be less than that considered in 2060.

Under the No Action Alternative (ELT) that amount of growth that could occur would not be expected to substantially affect study area traffic volumes. Accordingly, there would be no adverse changes in the characteristics of the transportation systems over state highways, local roadways, or navigation through Delta channels. Other transportation modes such as bicycle, marine, rail, bus, and air traffic are also not expected to be adversely affected because of the minimal traffic volume growth expected under the No Action Alternative (ELT).

CEQA Conclusion**:** None of the projects or programs assumed through the ELT time period would create new growth that would be expected to substantially affect study area traffic volumes in the Study Area. Moreover, traffic generated under the No Action Alternative (ELT) is not projected to substantially increase delays or deterioration of pavement conditions that are substantial in relation to the existing level of service and pavement conditions. The impacts on other transportation modes such as bicycle, marine, rail, bus, and air traffic are also not expected to be substantially affected because of the minimal traffic volume growth expected under the No Action Alternative (ELT). This impact would be less than significant.

4.2.19 Public Services and Utilities

The effects of the No Action Alternative as considered for the purposes of Alternatives 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 20, *Public Services and Utilities*, Section 20.3.3.1 of the Draft EIR/EIS. Due to the shorter time frame, the magnitude of total impacts to public services and utilities resulting from construction associated with development and habitat restoration activities within the Plan Area would be less under the ELT timeframe than that considered in 2060 due to less development in the region.

Public services such as law enforcement, fire protection, emergency response services, public medical services, public schools, libraries, or other services would operate and expand as needed to appropriately serve the study area in accordance to their respective general plans and applicable local, state, and federal laws pertaining to service levels. Although some changes would be likely, the potential for public services and utilities effects under the No Action Alternative (ELT) would be minor because of the limited development allowed in the Delta primary zone. While development in the secondary zone would be anticipated to occur, required services and infrastructure will keep pace with it based on local general plan requirements.

It is assumed that projects included in the No Action Alternative (ELT) would include typical design and construction practices to avoid or minimize potential impacts on public services and utility systems, and would be subject to a project-level environmental review process to identify potential effects and to include feasible mitigation measures to avoid or substantially reduce potential effects. Public services and utilities effects under the No Action Alternative (ELT) would not be adverse.

CEQA Conclusion: In total, the ongoing programs and plans under the No Action Alternative (ELT) would include activities that will generate impacts on public services such as law enforcement, fire protection, emergency response services, public medical services, public schools, libraries, or other services would operate and expand as needed to appropriately serve the Plan Area in accordance with applicable general plans and local, state, and federal laws pertaining to service levels. However, because these projects have undergone or will undergo separate environmental review, it is assumed that potential public services and utilities effects have been or will be adequately addressed. Therefore, the effects of these plans, policies, and programs are considered less than significant.

4.2.20 Energy

The effects of the No Action Alternative as considered for the purposes of Alternatives 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 21, *Energy*, Section 21.3.3.1 of the Draft EIR/EIS.

The CALSIM-II simulation of No Action Alternative (ELT) upstream reservoir operations and river flows was used to estimate the energy generation at the upstream CVP and SWP facilities. The energy use for south of Delta pumping and delivery of water to CVP and SWP contractors was estimated from the CALSIM-II simulations of CVP and SWP pumping and deliveries for 1922–2003. The combined SWP/CVP energy factor would be about 1.5 gigawatt hours (GWh) per TAF. Accordingly, the No Action Alternative (ELT) would not increase the existing energy use factor and would not result in an adverse effect on energy resources.

CEQA Conclusion: The energy use factor (1.5 GWh per TAF) under the No Action Alternative (ELT) and Existing Conditions would be identical. Because the No Action Alternative (ELT) would not increase the energy use factor, it would not result in a significant impact on energy resources.

4.2.21 Air Quality and Greenhouse Gases

The effects of the No Action Alternative as considered for the purposes of Alternatives 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 22, *Air Quality and Greenhouse Gases*, Section 22.3.3.1 of the Draft EIR/EIS.

Facilities that are planned or currently under construction would result in short-term criteria pollutant and greenhouse gas (GHG) emissions from land disturbance and the use of heavy-duty equipment. Pollutant emissions are highly dependent on the total amount of disturbed area, the duration of construction, and the intensity of construction activity. In addition, the number and types of heavy-duty equipment significantly affect emissions generated by vehicle exhaust. Construction impacts can thus vary depending on the type of construction project implemented under the No Action Alternative (ELT). Due to the shorter time frame, the magnitude of total construction emissions associated with development and habitat restoration activities within the Plan Area would be less than that considered in 2060.

Restoration and conservation activities would take place under the No Action Alternative (ELT) and as part of planned and ongoing programs. These activities could result in temporary air quality effects from earthmoving and use of construction equipment. Due to the addition of the Yolo Bypass Improvements and 8,000 acres of tidal marsh habit restoration under the No Action Alternative (ELT), the magnitude of short-term emissions associated with restoration and conservation activities would be slightly greater than that considered in 2060 for the No Action Alternative as described in the Draft EIR/EIS.

Emissions from construction and restoration and conservation activities under the No Action Alternative (ELT) would result in an adverse effect if the incremental difference, or increase, relative to Existing Conditions exceeds applicable air district or federal *de minimis* thresholds. Future federal actions would be required to comply with NEPA and other federal laws and regulations. Mitigation and permit requirements would be implemented on a case-by-case basis.

There would be no changes attributable to the No Action Alternative (ELT) that would adversely affect long-term operations and maintenance (O&M) criteria pollutant emissions. GHG emissions generated by electricity consumption and distribution at the ELT timeframe are presented in Table 4.2.21-1. Because emissions rates are expected to decrease in the future due to state mandates for renewable energy production, the magnitude of electricity-related emissions would be slightly higher than considered in 2060, but still less than Existing Conditions.

Table 4.2.21-1. Total Criteria Pollutant and GHG Emissions from Electricity Consumption during Operation of the No Action Alternative (ELT) (tons/year)[a,b,c]

Condition	ROG	CO	NO_X	PM10	PM2.5[d]	SO_2	CO_2e[e]
Existing	9	88	1,212	102	102	512	1,672,965
No Action Alternative (ELT)	8	72	992	84	84	418	1,368,527

[a] Emissions assume implementation of RPS (see Appendix 22A, *Air Quality Analysis Methodology*, of the Draft EIR/EIS).

[b] Because GHG emissions are cumulative and not evaluated at the local air basin or air district level. The GHG analysis for SWP power utilizes actual and forecasted GHG emissions rates for the SWP system, which differs slightly from the above analysis. Statewide grid average emission factors were utilized for the above analysis as criteria pollutant emission factors for SWP were unavailable.

[c] Power plants located throughout the state supply the grid with power, which will be distributed to the study area to meet project demand. Power supplied by statewide power plants will generate criteria pollutants. Because these power plants are located throughout the state, criteria pollutant emissions associated with the No Action Alternative electricity demand cannot be ascribed to a specific air basin or air district within the study area.

[d] Emission factors for PM2.5 are currently unavailable. Consequently, PM2.5 emissions were assumed to equal PM10 emissions. Because PM2.5 represents a fraction of PM10, this approach represents a conservative assessment of PM2.5 emissions from electricity consumption.

[e] Emissions presented in metric tons of CO_2e.

CEQA Conclusion: Construction and operation of ongoing projects, programs, and plans under the No Action Alternative (ELT) would generate criteria pollutant and GHG emissions that could affect regional and local air quality. These projects would be required to comply with air district rules and regulations to reduce construction-related criteria pollutant and GHG emissions. Mitigation and permit requirements would be implemented on a case-by-case basis to help reduce construction- and operational-related impacts. Emissions would be considered significant if they exceed local air district thresholds, even with mitigation.

Energy required for long-term operation of the no project will be supplied by the California electrical grid. As shown in Table 4.2.21-1, operation of the No Action Alternative (ELT) would result in a net decrease in GHG emissions, relative to Existing Conditions. Consequently, a long-term GHG benefit would be realized under the No Action Alternative (ELT). Overall, the effect of the No Action Alternative (ELT) on air quality and GHG emissions is considered less than significant.

4.2.22 Noise

The effects of the No Action Alternative as considered for the purposes of Alternative 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 23, *Noise*, Section 23.3.3.1 of the Draft EIR/EIS.

Future noise conditions in the Delta are not expected to change substantially as existing repair, maintenance, habitat protection, and flood management activities would continue. Emergency repair of levees could create higher than normal levels of noise and vibration levels, although the timing and duration of equipment use and associated noise impacts would be unpredictable, as with any emergency event. In general, background noise levels in the Plan Area would likely be less under the ELT timeframe than those considered in 2060 due to less development in the region.

Construction activities and the operation of heavy equipment required for the Yolo Bypass Improvements and tidal habitat restoration would be a source of localized and temporary noise. In general, effects would be avoided through adherence to City and County noise construction ordinances. Equipment needed to implement ongoing programs, plans, and projects in Plan Area would also temporarily increase ambient noise levels. These projects have undergone or will undergo separate environmental review, in which noise reducing measures would be outlined, as necessary. Noise levels would be considered adverse if they exceed local standards, even with mitigation.

CEQA Conclusion: In total, the ongoing programs and plans under the No Action Alternative (ELT) would include activities that will generate temporary and localized noise. These projects have undergone or will undergo separate environmental review, in which noise reducing measures would be outlined, as necessary. Noise levels would be considered significant if they exceed local standards, even with mitigation.

4.2.23 Hazards and Hazardous Materials

The effects of the No Action Alternative as considered for the purposes of Alternatives 4A, 2D, and 5A (ELT) would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 24, *Hazards and Hazardous Materials*, Section 24.3.3.1 of the Draft EIR/EIS.

Projects that are planned or currently under way that involve construction, operation and maintenance activities may result in potential hazards to the environment or public including the potential for encountering contaminated soils and groundwater, release of hazardous materials (including flammable gases) from disturbance of regional fuel pipelines, accidental releases of hazardous materials (e.g., fuels, solvents, and lubricants) and improper disposal of hazardous materials and release of oils, solvents, and fuels from maintaining and cleaning equipment or vehicles. However, due to the shorter time frame, the magnitude of hazards and hazardous materials effects associated with development and habitat restoration activities within the Plan Area would be less than that considered in 2060. Similarly, hazards and hazardous materials effects associated with climate change (levee failure and flooding risks) would be anticipated to be less than under the No Action Alternative (LLT). Generally, impacts would be avoided through adherence to applicable federal, state, and local regulations; project-specific design; and implementation of best management practices (BMPs), environmental commitments, and/or mitigation, including HMMPs, SWPPPs, and SPCCPs. These practices/measures are intended to avoid, prevent, or minimize hazardous spills and construction-related hazards and/or mitigate for such occurrences. However, because the potential exists for hazards and hazardous materials effects to occur under existing plans and programs, adverse effects are expected to occur in the study area under the No Action Alternative.

CEQA Conclusion: Implementation of programs, policies, and projects under the No Action Alternative (ELT) in the study area would have the potential for significant impacts on the public or the environment related to hazards and/or hazardous materials (e.g., through the inadvertent release of fuels or lubricants during construction). However, these impacts would be smaller in scale and more confined in geographic scope relative to the No Action Alternative (LLT). Projects implemented under the No Action Alternative (ELT) would require their own separate environmental compliance processes; would be required to adhere to applicable federal, state, and local regulations; and would incorporate applicable BMPs, environmental commitments, and/or mitigation intended to avoid, prevent, or minimize hazardous spills and construction-related hazards and/or mitigate for such occurrences, which would help ensure that these types of impacts are mitigated to a less-than- significant level.

4.2.24 Public Health

The effects of the No Action Alternative (ELT) as considered for the purposes of Alternatives 4A, 2D, and 5A would be expected to be similar to those effects described for the No Action Alternative (LLT) in Chapter 25, *Public Health*, Section 25.3.3.1 of the Draft EIR/EIS.

New water supply facilities would be constructed under the No Action Alternative (ELT) as listed in Table 25-10 in Chapter 25, *Public Health*, of the Draft EIR/EIS; therefore, there could be a disruption to existing sources of methylmercury associated with this type of construction. Water supply operations under the No Action Alternative (ELT) likely would not involve the operation of solids lagoons or sedimentation basins; therefore, there would be no increase in the public's risk of exposure to vector-borne diseases. Under the No Action Alternative (ELT), there would be a change in various source waters throughout the Delta (i.e., upstream water, Bay water, agricultural return flow), due to potential changes in inflows, particularly from the Sacramento River watershed because of increased water demands or changes to climate and precipitation levels. Water supply operations under the No Action Alternative (ELT) would continue to use the existing source(s) of drinking water from the study area. These sources generally meet regulatory standards for most constituents. However, under the No Action Alternative (ELT), existing exceedances would not increase above baseline conditions (see Section 4.2.7, *Water Quality*, of the RDEIR/SDEIS) to levels that adversely affect any beneficial uses or substantially degrade water quality. Furthermore, drinking water from the study area would continue to be treated prior to distribution into the drinking water system.

Any modified reservoir operations under the No Action Alternative (ELT) are not expected to promote *Microcystis* production upstream of the Delta since large reservoirs upstream of the Delta are typically low in nutrient concentrations and phytoplankton outcompete cyanobacteria, including *Microcystis*. As described in Section 4.2.7 (*Water Quality*) above, hydrodynamic changes due to enhancements to the Yolo Bypass and 8,000 acres of tidal habitat would increase hydraulic residence times in the Delta, which would create conditions conducive to the formation of *Microcystis* blooms. Projected future water temperature changes in the Delta under the No Action Alternative (ELT) indicate that water temperatures would increase due to climate change. These temperature increases could lead to earlier attainment of the water temperature threshold of 19°C required to initiate *Microcystis* bloom formation, and thus earlier occurrences of *Microcystis* blooms in the Delta.

Therefore, the combination of increased water residence times in the Delta, due to assumed restoration activities, and increased water temperatures, due to climate change could result in increases in the frequency, magnitude, and geographic extent of *Microcystis* blooms in the Delta under the No Action Alternative (ELT). As such, impacts on beneficial uses, including drinking water and recreational waters, could occur and public health could be affected. Accordingly, this would be considered an adverse effect.

The No Action Alternative (ELT) may involve the operation of new transmission lines should additional sources of electricity be needed by either the water supply projects or as part of a general plan buildout. It is likely that with population growth projected by various general plans and regional plans would also result in an additional need for electricity and the construction and operation of new transmission lines. Furthermore, as more renewable energy sources such as solar power are developed, new transmission lines will likely be needed to convey power from the renewable energy source to users. Although, it is unknown where new transmission lines would be and if they would be located within close proximity to sensitive receptors (e.g., hospitals, schools, parks), it is likely some of them would be within close proximity to sensitive receptors and present new sources of EMFs. However, the utilities will implement the CPUC design criteria and guidelines regarding EMFs, and CPUC reviews proposals for transmission lines if feasible. Investor-owned utilities are required to obtain a permit from CPUC for construction of certain specified infrastructure (including transmission lines) listed under Public Utilities Code Section 1001 (California Public Utilities Commission 2011). CPUC reviews permit applications under two concurrent processes: (1) an environmental review pursuant to CEQA, and (2) the review of project need and costs pursuant to Public Utilities Code Sections 1001 et seq. and General Order 131-D (CPCN or PTC) (California Public Utilities Commission 2011). Therefore, the No Action Alternative (ELT) is not likely to result in adverse effects on public health with respect to EMFs.

Habitat restoration activities in the study area already approved, such as those associated with the Suisun Marsh Habitat Management, Preservation, and Restoration Plan, could be implemented under the No Action Alternative (ELT) time frame. These habitat restoration activities would generally be located in areas that are already potential sources of vectors, such as existing channels or agricultural areas. Furthermore, activities would be designed to maximize water exchange and flow, thereby minimize stagnant water and the production of mosquitoes. Finally, all of the restoration activities would occur in consultation with existing MVCDs. Therefore, it is not expected that habitat restoration under the No Action Alternative (ELT) would result in a substantial increase in the public's risk of exposure to vector-borne diseases.

Under the No Action Alternative (ELT), as described in Appendix 3D, *Defining Existing Conditions, No Action Alternative, No Project Alternative, and Cumulative Impact Conditions*, of the Draft EIR/EIS, there would be some change in inflows from the Sacramento River due to climate change-related changes in precipitation patterns; therefore, the amount of Delta waters consisting of agricultural return flow would increase slightly. Approximately 5% of the in-Delta agricultural use is livestock, the primary type of agricultural use that generates pathogens. The relatively small increase in the percentage of Delta waters consisting of agricultural return flow is not expected to cause a measureable change in the pathogen concentrations in the Delta waters because livestock is a small percentage of the overall agricultural use and none of the assumed No Action Alternative (ELT) conditions would substantially change the amount of livestock in the study area. Therefore, under the No Action Alternative (ELT), the concentrations of pathogens would remain relatively similar to existing concentrations and recreationists would not experience a substantial increase in exposure.

Construction of habitat restoration projects that are reasonably foreseeable or approved and/or under construction under the No Action Alternative (ELT) would likely temporarily mobilize existing constituents within sediments known to bioaccumulate, such as methylmercury or pesticides. This potential effect is expected in varying degrees depending on the location of restoration projects because the study area is generally known to be out of compliance with methylmercury levels. Construction effects would not be adverse because the mobilization would occur during a limited time and would be localized around the area of construction. Once operational, other habitat restoration projects could result in an increase of methylmercury as a result of biogeochemical processes and sediment conditions established in tidal wetlands. However, it is expected these projects either have, or would evaluate the potential for, methylmercury production and would implement measures to monitor and adaptively manage methylmercury production. For example, the Suisun Marsh Plan EIR/EIS evaluated the potential for methylmercury production due to tidal restoration and determined it would result in less than significant impacts and that monitoring and other measures would be incorporated into the adaptive management plan to manage methylmercury concerns. Therefore, the habitat restoration projects that would occur under the No Action Alternative (ELT) are not likely to adversely affect public health.

***CEQA Conclusion*:** It is expected that implementation of existing plans, or existing and reasonably foreseeable habitat restoration projects, would not result in a substantial increase in the public's risk of exposure to vector-borne diseases because of the location of existing vector habitat, restoration design, and consultation with MVCDs. This is because habitat restoration would be located in areas that are already potential sources of vectors, such as existing channels or agricultural areas. Furthermore, activities would be designed to maximize water exchange and flow, thereby minimizing stagnant water and the production of mosquitoes. Finally, all of the restoration activities would occur in consultation with existing MVCDs. Therefore, it is not expected that habitat restoration under the No Action Alternative (ELT) would result in a substantial increase in the public's risk of exposure to vector-borne diseases. As such, this impact is less than significant.

Construction impacts associated with No Action Alternative (ELT) habitat restoration projects would be less than significant because the mobilization of existing sediment-bound contaminants (e.g., methylmercury) would occur during a limited time and would be localized around the area of construction. Once operational, other habitat restoration projects could result in an increase of methylmercury as a result of biogeochemical processes and sediment conditions established in tidal wetlands. However, it is expected these projects either have, or would evaluate the potential for, methylmercury production and would implement measures to monitor and adaptively manage methylmercury production.

Water supply operations under the No Action Alternative (ELT) would continue to use the existing source(s) of drinking water from the study area. These sources generally meet regulatory standards for most constituents or experience some exceedances for constituents such as arsenic (see Chapter 8, *Water Quality*, of the Draft EIR/EIS. Under the No Action Alternative (ELT), existing exceedances would not increase above baseline conditions and, therefore, this impact would be less than significant.

It is unknown where new transmission lines would be in the ELT period and if they would be located in close proximity to sensitive receptors (e.g., hospitals, schools, parks); however, it is likely some of them would be within close proximity to sensitive receptors and present new sources of EMFs. Utilities will implement the CPUC design criteria and guidelines regarding EMFs, and CPUC reviews proposals for transmission lines if feasible. Accordingly, this impact would be less than significant

Because it is possible that under the No Action Alternative (ELT) increases in the frequency, magnitude, and geographic extent of *Microcystis* blooms in the Delta would occur due to increased water temperatures associated with climate change, as well as increased water residence times related to restoration activities, long-term water quality degradation may occur in the Delta and water exported from the Delta to the SWP/CVP Export Service Areas. Thus, impacts on beneficial uses could occur, and therefore this impact would be significant.

4.2.25 Minerals

The effects of the No Action Alternative (ELT) considered for the purposes of Alternative 4A, 2D, and 5A would be expected to be similar to the effects described for the No Action Alternative (LLT) in Chapter 26, *Minerals,* Section 26.3.3.1 of the Draft EIR/EIS. Access to natural gas wells and fields and aggregate resources and resulting production rates would be expected to be similar to those described under Existing Conditions and would include continued programs by federal, state, and local agencies and non-profit groups as well as projects that are permitted or assumed to be constructed in the ELT period. Because of the shorter implementation period, the magnitude of activities that could adversely affect access to natural gas wells and fields and aggregate resources in the Plan Area would be less than those considered under in 060. In addition, impacts on mineral resources attributable to climate change and sea level rise, (increased flooding risk) would be expected to be less when compared to conditions under the No Action Alternative (ELT). There could be adverse impacts on mineral resources in the ELT period as a result of changes in land uses within the Plan Area, primarily as a result of planned restoration activities.

Under the No Action Alternative (ELT), DOGGR regulatory programs that have jurisdiction over natural gas well development and abandonment would continue with no substantive changes. Similarly, programs that regulate mineral resources and programs to identify and conserve mineral resources would be implemented with no substantive changes in the future. CGS and SMGB programs would continue to classify and designate important mineral resource zones (MRZs) and DOC would continue to regulate mineral extraction under SMARA and continue to ensure that mining areas are reclaimed to adequately support future end uses following completion of regulated activities.

CEQA Conclusion: Under the No Action Alternative (ELT), some projects could occur in the Plan Area that could reduce access to natural gas and mineral resources. Land use changes within the Plan Area, including habitat restoration projects, could result in loss of access to mineral resources, although to a lesser degree than under the No Action Alternative (LLT). Access to these resources could be offset by implementing mitigation actions such as directional drilling. Other actions that would consume mineral resources (i.e., restoration actions, flood control improvements, roadway improvements, etc.) would occur within Plan Area, but would be supplied through existing permitted sites. As such, there would be no significant impacts on access to natural gas resources or the availability of aggregate resources within study area under the No Action Alternative (ELT).

4.2.26 Paleontological Resources

The effects of the No Action Alternative (ELT) considered for the purposes of Alternative 4A, 2D, and 5A would be expected to be similar to the effects described for the No Action Alternative (LLT) in Chapter 27, *Paleontological Resources*, Section 27.3.3.1 of the Draft EIR/EIS. Activities within the Plan Area that under the No Action Alternative (ELT) could affect paleontological resources would be expected to be similar to those described under Existing Conditions and would include continued programs by federal, state, and local agencies and non-profit groups as well as projects that are permitted or assumed to be constructed in the ELT period. This includes expected restoration actions within the Yolo Bypass being driven by the 2008 and 2009 USFWS and NMFS BiOps and the restoration of 8,000 acres intertidal habitat in the Delta and Suisun Marsh.

Because of the shorter implementation period, the magnitude of ground disturbing activities that could adversely affect paleontological resources would be less than those expected under the No Action Alternative (LLT). However, there could be adverse impacts on paleontological resources in the ELT period as a result of ground disturbing activities occurring within the Plan Area, as a result of the planned restoration activities described above and other activities such as flood control and roadway improvements.

CEQA Conclusion: Under the No Action Alternative (ELT), activities will occur within the Plan Area that include disturbing land that could impact paleontological resources. Land use changes within the Plan Area, including habitat restoration projects, could result in loss of paleontological resources, although to a lesser degree than under the No Action Alternative (LLT) because fewer acres would be disturbed. Because the region is sensitive for paleontological resources, these actions could collectively result in disturbance of paleontological resources and a potentially significant impact.

4.2.27 Environmental Justice

The effects of the No Action Alternative (ELT) on low income and minority populations would be similar to the effects described for the No Action Alternative in Chapter 28 *Environmental Justice*, Section 28.5.4 of the Draft EIR/EIS. Activities occurring within the Plan Area under the No Action Alternative (ELT) that could result in a disproportionate effect on low income and minority communities would be similar to those described under Existing Conditions. These activities include ongoing programs implemented by federal, state, and local agencies, and non-profit groups, as well as projects that are permitted or assumed to be completed during the early long-term period. This includes restoration actions occurring within the Yolo Bypass and the restoration of 8,000 acres of intertidal habitat in the Delta and Suisun Marsh being driven by the 2008 and 2009 USFWS and NMFS BiOps.

Because the No Action Alternative (ELT) implementation period would be shorter, the magnitude of activities that could adversely affect low income and minority populations would be less than those described for the No Action Alternative. Disproportionate adverse effects on these populations could occur directly as result of constructing a facility within or adjacent to a community or indirectly by alternating land uses in such a fashion that the economic activity that benefits these communities (i.e., agricultural, recreation, etc.) is reduced or eliminated during the early long-term period.

4.2.28 Climate Change

As described in Chapter 29, *Climate Change,* of the Draft EIR/EIS, climate change would be anticipated to change the conditions under which alternatives would be implemented. Under discussion of the No Action Alternative (LLT)[4], the impact analysis associated with each resource includes an evaluation of how the alternatives would affect the specific resource in question. In each of these analyses, where the effects of the alternatives are analyzed at the ELT and the LLT, climate change is integrated into the analysis. In these analyses, the alternatives are evaluated using a projection of future climate that includes changes in temperature, precipitation, humidity, hydrology, and sea level rise (SLR). Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS provides detailed information about the development of the climate change projections. Effects related to climate change would be anticipated to be smaller in magnitude in the ELT timeframe than in the late long-term.

4.2.29 Growth Inducement and Other Indirect Effects

As it relates to this document, growth will occur between the present and the year 2025, with or without the proposed action alternatives. Table 4.2.29-1 summarizes SWP and CVP deliveries under existing conditions (the CEQA baseline) and the No Action Alternative (ELT). Under the No Action Alternative ELT scenario, the facilities and operations of the SWP and CVP would continue to be similar to existing conditions. However, the No Action Alternative (ELT) includes two additional assumptions. First, the No Action Alternative (ELT) assumes that there would be an increase in M&I water rights demands north of the Delta, which would increase overall system demands and reduce the amount of CVP water available for export south of the Delta. Second, the No Action Alternative (ELT) includes effects of implementation of the Fall X2 standard, which requires additional water releases through the Delta and would result in decreased availability of water for export to SWP and CVP facilities. The No Action Alternative (ELT) also includes the effects of sea level rise and climate change, which would reduce the amount of water available for SWP and CVP water supplies, as described in Chapter 5, *Water Supply*, of the Draft EIR/EIS. These factors lead to an overall decrease in SWP and CVP deliveries under the No Action Alternative (ELT) as compared to existing conditions. For a more detailed explanation of factors influencing deliveries under the No Action Alternative (ELT), see Chapter 5, *Water Supply*, of the Draft EIR/EIS.

[4] Late-long term is modeled at 2060 whereas early-long term is modeled at 2025.

Table 4.2.29-1. Existing Conditions and No Action Alternative (ELT): Summary of Annual SWP and CVP Deliveries (thousand acre-feet)

	Existing Conditions		No Action Alternative (ELT)	
	Table A	Table A + Article 21	Table A	Table A + Article 21
M&I[a]	1,852	1,889	1,863	1,888
Agriculture	665	706	626	653
Total SWP	2,517	2,595	2,489	2,541
CVP M&I[a]	125		118	

Sources: Based on projected water deliveries as reported in BDCP modeling results for SWP contractors (SWP_TableA_Art21_delivery_by_contractor_newAlt1A2B_tables_110211.xls, November 2011; SWP_TableA_Art21_delivery_by_contractor_Alt2A_tables_021412.xls, February 2012; and SWP_TableA_Art21_ delivery_by_contractor_tables_110111(031412).xls, March 2012) and CVP contractors (BDCP_Alternatives CVP_M&I_Deliveries_020212.xls, February 2012; BDCP_Alternatives_CVP_M&I_Deliveries_with_Alt8_050112.xls, May 2012; and BDCP_Alternatives_CVP_M&I_Deliveries_ELT_052112, May 2012). [a] M&I – Municipal and Industrial (urban) customers.

Deliveries to the Hydrologic Regions

SWP. Under the No Action Alternative (ELT), deliveries would be decreased to all regions in the early long-term relative to existing conditions. In the early long-term, overall deliveries to the San Francisco Bay, South Coast and Colorado River regions would increase slightly to meet projected increases in demands in those areas, while overall deliveries to other regions would decrease. The South Coast Region would experience the largest increase (between 5 and 19 TAF) while the South Lahontan region would experience the largest decrease (approximately 5 TAF). Table A deliveries to M&I contractors overall would increase slightly by 95.7 TAF relative to existing conditions, while total (Table A and Article 21) deliveries to both M&I and agricultural contractors overall would decrease slightly relative to existing conditions.

CVP. Under the No Action Alternative (ELT), deliveries to all M&I contractors and all hydrologic regions would decrease by a total of 6.7 TAF relative to existing conditions.

No Action Alternative ELT Compared to Existing Conditions

SWP. Table A deliveries to all (M&I and agricultural) SWP contractors overall are projected to decrease by 1% relative to existing conditions, while total (Table A plus Article 21) deliveries to all SWP contractors are projected to decrease by 2%. Table A and total deliveries to M&I contractors are projected to increase by 0.6% and decrease by 0.1%, respectively.

CVP. Deliveries to all CVP M&I contractors are projected to decrease by 5% relative to Existing Conditions.

CEQA Conclusion: Under the No Action Alternative (ELT), overall deliveries to SWP and CVP contractors would decrease relative to existing conditions. To the extent that deliveries could remove a barrier to growth in the delivery areas, the No Action Alternative (ELT) would not contribute to growth in areas served by the SWP and CVP. Therefore, this potential impact is considered less than significant.

4.3 Impacts of Alternative 4A

4.3.1 Water Supply

Facilities construction under Alternative 4A would be identical to that described under Alternative 4. Alternative 4A water conveyance operations would be similar to the range of possible operations for the spring Delta outflow requirements that would occur under Alternative 4 H3 and Alternative 4 H4.

Model simulation results for Alternative 4A Early Long-term (ELT), which are represented by the range of Alternative 4 H3 (ELT) and Alternative 4 H4 (ELT), are summarized in Tables B.1-1 through B.1-3 in Appendix B of the RDEIR/SDEIS. Model simulation results for Alternative 4A at Late Long-term (LLT) which are similar to the range of Alternative 4 H3 (LLT) and Alternative 4 H4 (LLT) are summarized in Tables 5-7 through 5-9 in the Draft EIR/EIS.

As indicated in Section 5.3.2, *Determination of Effects*, of the Draft EIR/EIS, NEPA adverse effect and CEQA significant impact conclusions are not provided for the impacts discussed in this water supply sections.

4.3.1.1 Summary of Water Supply Operations under Alternative 4A

Change in Delta Outflow

Changes in long-term average Delta outflow under Alternative 4A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Figures 4.3.1-1 through 4.3.1-3 in this RDEIR/SDEIS and Tables B.1-1 through B.1-3 in Appendix B of this RDEIR/SDEIS.

Changes in long-term average Delta outflow under Alternative 4A (LLT) (similar to range of Alternative 4 H3 [LLT] and Alternative 4 H4 [LLT]) as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-3 through 5-5 and Tables 5-7 through 5-9 of the Draft EIR/EIS.

Late-fall and winter outflows remain similar or show minor reductions in Alternative 4A compared to No Action Alternative. In the spring months, outflow would increase under Alternative 4A as compared to No Action Alternative. SWP and CVP exports in summer months would increase and result in lower outflow as compared to No Action Alternative. In the fall months, outflow under Alternative 4A as compared to No Action Alternative would be similar because of the Fall X2 requirement in wet and above-normal years, and increased or similar outflow in September and October months of all year types due to OMR flow requirements and export reductions.

Long-term average and wet year peak outflows would increase in winter months with a corresponding decrease in spring months because of the shift in system inflows caused by climate change and increased Delta exports as compared to Existing Conditions. In other year types, Alternative 4A would result in higher or similar outflow because of the spring outflow requirements. In summer and fall months, Alternative 4A would result in similar or higher outflow because of changes in export patterns and OMR flow requirements and export reductions in fall months, and also because of the Fall X2 requirements in wet and above normal years. The incremental changes in Delta outflow between Alternative 4A and Existing Conditions would be a function of both the facility and operations assumptions (including north Delta intakes capacity of 9,000 cfs, less negative OMR flow requirements, enhanced spring outflow and/or Fall X2 requirements) and the reduction in water supply availability due to increased north of Delta urban demands, sea level rise and climate change.

Delta outflow under Alternative 4A would likely decrease in winter and summer months, or remain similar or increase in other months, compared to the conditions without the project.

Results for the range of changes in Delta Outflow under Alternative 4A (LLT), which is similar to range of Alternative 4 H3 (LLT) and Alternative 4 H4 (LLT), are presented in more detail in Appendix 5A, *BDCP EIR/S Modeling Technical Appendix*, of the Draft EIR/EIS.

Change in SWP and CVP Reservoir Storage

Changes in May and September reservoir storage under Alternative 4A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Figures 4.3.1-4 through 4.3.1-10 and Tables B.1-1 through B.1-3 in Appendix B of this RDEIR/SDEIS for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. SWP and CVP San Luis Reservoir storages are presented in Figures 4.3.1-11 through 4.3.1-14 for completeness.

Changes in May and September reservoir storage under Alternative 4A (LLT) as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-6 through 5-12 and Tables 5-7 through 5-9 of the Draft EIR/EIS for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. SWP and CVP San Luis Reservoir storages are presented in Figures 5-13 through 5-16 of the Draft EIR/EIS for completeness.

Results for changes in SWP and CVP reservoir storages under Alternative 4A (LLT), which is similar to range of Alternative 4 H3 (LLT) and Alternative 4 H4 (LLT), are presented in more detail in Appendix 5A, *BDCP EIR/S Modeling Technical Appendix*, of the Draft EIR/EIS.

Trinity Lake

Under Alternative 4A, average annual end of September Trinity Lake storage as compared to No Action Alternative would increase or remain similar in most years.

Under Alternative 4A, average annual end of September Trinity Lake storage as compared to Existing Conditions would decrease or remain similar. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 4A and the results show that average annual end of September Trinity Lake storage could increase or remain similar under Alternative 4A as compared to the conditions without the project.

Shasta Lake

Under Alternative 4A, average annual end of September Shasta Lake storage as compared to No Action Alternative would remain similar at ELT and decrease (up to 3%) at LLT.

Under Alternative 4A, average annual end of September Shasta Lake storage as compared to Existing Conditions would decrease. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 4A and the results show that average annual end of September Shasta Lake storage could remain similar or decrease under Alternative 4A as compared to the conditions without the project.

Lake Oroville

Under Alternative 4A, average annual end of September Lake Oroville storage as compared to No Action Alternative would increase.

Under Alternative 4A, average annual end of September Lake Oroville storage as compared to Existing Conditions would decrease in all years. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 4A and the results show that average annual end of September Lake Oroville storage would increase under Alternative 4A as compared to the conditions without the project.

Folsom Lake

Under Alternative 4A, average annual end of September Folsom Lake storage as compared to No Action Alternative would remain similar at ELT and decrease (2%) at LLT.

Under Alternative 4A, average annual end of September Folsom Lake storage as compared to Existing Conditions decrease. This decrease primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 4A and the results show that average annual end of September Folsom Lake storage could decrease or remain similar under Alternative 4A as compared to the conditions without the project.

San Luis Reservoir

Under Alternative 4A, average annual end of September San Luis Reservoir storage as compared to the No Action Alternative would mostly decrease, due to changes in export patterns.

Under Alternative 4A, average annual end of September San Luis Reservoir storage as compared to Existing Conditions would decrease. This decrease primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 4A and the results show that average annual end of September San Luis Reservoir storage would generally decrease under Alternative 4A as compared to the conditions without the project.

Change in Delta Exports

Changes in average annual Delta exports under Alternative 4A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.1-1 through B.1-3 in Appendix B and Figures 4.3.1-15 through 4.3.1-18 of this RDEIR/SDEIS.

Changes in average annual Delta exports under Alternative 4A (LLT) (similar to range of Alternative 4 H3 [LLT] and Alternative 4 H4 [LLT]) as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-17 through 5-20 and Tables 5-7 through 5-9 of the Draft EIR/EIS.

The addition of the north Delta intakes and changes to Delta regulatory requirements under Alternative 4A change SWP and CVP Delta exports as compared to Delta exports under Existing Conditions and the No Action Alternative.

Delta exports would either remain similar or increase in wetter years and decrease in drier years under Alternative 4A as compared to exports under No Action Alternative depending on the capability to divert water at the north Delta intakes during winter and spring months.

Total long-term average annual Delta exports under Alternative 4A would decrease as compared to exports under Existing Conditions reflecting changes in operations due to less negative OMR flows, implementation of Fall X2 and/or spring outflow under Alternative 4A, and sea level rise and climate change.

The incremental change in Delta exports under Alternative 4A as compared to No Action Alternative would be caused by the facility and operations assumptions of Alternative 4A. Delta exports would either remain similar or increase in wetter years and remain similar or decrease in the drier years under Alternative 4A as compared to the conditions without the project.

Change in SWP and CVP Deliveries

Impact WS-1: Changes in SWP CVP Water Deliveries during Construction

NEPA Effects: During construction of water conveyance facilities associated with Alternative 4A, operation of existing SWP and CVP water conveyance would continue. Construction would not affect the timing or amount of water exported from the Delta through SWP and CVP facilities.

CEQA Conclusion**:** Constructing Alternative 4A water conveyance facilities would not impact operation of existing SWP or CVP facilities.

Impact WS-2: Change in SWP and CVP Deliveries

The addition of the north Delta intakes under Alternative 4A provides operational flexibility compared to deliveries under Existing Conditions and the No Action Alternative.

Changes in SWP and CVP Deliveries under Alternative 4A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.1-1 through B.1-3 in Appendix B and Figures 4.3.1-22 through 4.3.1-28 of this RDEIR/SDEIS.

Changes in SWP and CVP Deliveries under Alternative 4A (LLT) (similar to range of Alternative 4 H3 [LLT] and Alternative 4 H4 [LLT]) as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-6 through 5-12 and Tables 5-7 through 5-9 of the Draft EIR/EIS.

Results for SWP and CVP deliveries at LLT are presented in more detail in Appendix 5A, *BDCP EIR/S Modeling Technical Appendix*, of the Draft EIR/EIS.

Total CVP Deliveries

Under Alternative 4A, average annual total CVP deliveries as compared to No Action Alternative, would increase by up to 3% at ELT and by up to 2% at LLT. Under Alternative 4A, average annual total south of Delta CVP deliveries as compared to No Action Alternative, would increase by about 5%.

Under Alternative 4A, average annual total CVP deliveries as compared to Existing Conditions, would increase by up to 3% at ELT and decrease by up to 2% at LLT. Under Alternative 4A, average annual total south of Delta CVP deliveries as compared to Existing Conditions, would decrease by up to 4% at ELT and by up to 9% at LLT. However, the decrease would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A in the absence of the effects of increased north of delta demands and sea level rise and climate change, and the results show that average annual total CVP deliveries and average annual total CVP south of Delta deliveries would increase or remain similar under Alternative 4A as compared to the conditions without the project.

CVP North of Delta Agricultural Deliveries

Under Alternative 4A, average annual CVP north of Delta agricultural deliveries would increase by up to 4% at ELT and by up to 2% at LLT as compared to No Action Alternative.

Under Alternative 4A, average annual CVP north of Delta agricultural deliveries as compared to Existing Conditions, would decrease by up to 18% at ELT and by up to 31% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A in, the absence of the effects of increased north of delta demands and sea level rise and climate change, and the results show that average annual CVP north of Delta agricultural deliveries as compared to No Action Alternative would generally increase. Therefore, average annual CVP north of Delta agricultural deliveries would generally increase or remain similar under Alternative 4A as compared to the conditions without the project.

CVP South of Delta Agricultural Deliveries

Under Alternative 4A, average annual CVP south of Delta agricultural deliveries as compared to No Action Alternative would increase by up to 12% at ELT and by up to 13% at LLT.

Under Alternative 4A, average annual CVP south of Delta agricultural deliveries as compared to Existing Conditions would decrease by up to 6% at ELT and 18% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP south of Delta agricultural deliveries as compared to No Action Alternative would generally increase. Therefore, average annual CVP south of Delta agricultural deliveries would increase or remain similar under Alternative 4A as compared to the conditions without the project.

CVP Settlement and Exchange Contract Deliveries

There would be negligible change to CVP Settlement Contract deliveries during dry and critical years under Alternative 4A as compared to deliveries under the No Action Alternative.

There would be negligible change to CVP Settlement Contract deliveries during dry and critical years under Alternative 4A at ELT as compared to deliveries under the Existing Conditions. Under Alternative 4A at LLT, CVP Settlement Contract deliveries during dry and critical years as compared to Existing Conditions would decrease. This is due to Shasta Lake storage declining to dead pool more frequently, as described previously, under increased north-of Delta demands and climate change and sea level rise conditions. As described in the methods section of Chapter 5, *Water Supply*, in the Draft EIR/EIS, model results and potential changes under these extreme reservoir storage conditions may not be representative of actual future conditions because changes in assumed operations may be implemented to avoid these conditions.

There would be no changes in deliveries to CVP Exchange Contractors under Alternative 4A.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that CVP Settlement Contract and CVP Exchange Contractors deliveries during dry and critical years would remain similar. Therefore, CVP Settlement Contract and CVP Exchange Contractors deliveries during dry and critical years under Alternative 4A would be similar to the deliveries under the conditions without the project.

CVP North of Delta Municipal and Industrial Deliveries

Under Alternative 4A, average CVP north of Delta M&I deliveries as compared to No Action Alternative would remain similar of result in minor increase.

Under Alternative 4A, average annual CVP north of Delta M&I deliveries as compared to Existing Conditions would increase by up to 88% at ELT and 82% at LLT. However, this increase primarily would occur because there would be an increase in north of Delta M&I water rights demands under Alternative 4A and No Action Alternative as compared to demands under Existing Conditions.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP north of Delta M&I deliveries would remain similar or show minor increase under Alternative 4A as compared to the deliveries under the No Action Alternative. Therefore, average annual CVP north of Delta M&I deliveries would remain similar or increase under Alternative 4A as compared to the conditions without the project.

CVP South of Delta Municipal and Industrial Deliveries

Under Alternative 4A, average CVP south of Delta M&I deliveries as compared to No Action Alternative, would increase by about 4%.

Under Alternative 4A, average annual CVP south of Delta M&I deliveries as compared to Existing Conditions would decrease by up to 2% at ELT and by up to 7% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP south of Delta M&I deliveries would remain similar or increase under Alternative 4A as compared to the deliveries under the No Action Alternative. Therefore, average annual CVP south of Delta M&I deliveries would increase or remain similar under Alternative 4A as compared to the conditions without the project.

Total SWP Deliveries

Under Alternative 4A, average annual total SWP deliveries as compared to No Action Alternative, would decrease (by about 3%) or increase (by about 12%) depending upon range of spring outflow requirements. Under Alternative 4A, average annual total south of Delta SWP deliveries as compared to No Action Alternative, would decrease (by about 4%) or increase (by about 16%) depending upon range of spring outflow requirements.

Under Alternative 4A, average annual total SWP deliveries as compared to Existing Conditions, would decrease (9%)or increase (5%) at ELT and remain similar or decrease (13%) at LLT depending upon range of spring outflow requirements. Under Alternative 4A, average annual total south of Delta SWP deliveries as compared to Existing Conditions, would decrease (12%) or increase (7%) at ELT and would decrease (17%) or remain similar at LLT depending upon range of spring outflow requirements. However, the decrease in deliveries primarily would occur due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that under Alternative 4A average annual total SWP deliveries would decrease and increase. Therefore, average annual total SWP deliveries and average annual total SWP south of Delta deliveries under Alternative 4A would show a decrease or an increase as compared to the conditions without the project depending upon the range of spring Delta outflow requirements.

SWP Table A Deliveries

Under Alternative 4A, average annual total SWP Table A deliveries with Article 56 (without Article 21) as compared to No Action Alternative, would decrease (by about 7%) or increase (by about 13%) depending upon range of spring outflow requirements. Under Alternative 4A scenarios, average annual total south of Delta SWP Table A deliveries with Article 56 (without Article 21) as compared to No Action Alternative, would decrease (by about 7%) or increase (by about 13%) depending upon range of spring outflow requirements.

Under Alternative 4A, average annual total SWP Table A deliveries with Article 56 (without Article 21) as compared to Existing Conditions, would decrease (11%) and increase (8%) at ELT and would decrease (17%) and increase (3%) at LLT depending upon range of spring outflow requirements. Under Alternative 4A, average annual total south of Delta SWP Table A deliveries with Article 56 (without Article 21) as compared to Existing Conditions, would decrease (12%) and increase (8%) at ELT and would decrease (17%) and increase (2%) at LLT depending upon range of spring outflow requirements. However, the decrease in deliveries primarily would occur due to sea level rise and climate change.

Deliveries under the No Action Alternative are an indication of the potential change due to Alternative 4A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that under Alternative 4A average annual total SWP Table A deliveries with Article 56 (without Article 21) would decrease or increase depending upon range of spring outflow requirements.

SWP Article 21 Deliveries

Under Alternative 4A, average annual total SWP Article 21 deliveries as compared to No Action Alternative, would increase by about 164%.

Under Alternative 4A, average annual total SWP Article 21 deliveries as compared to Existing Conditions, would decrease by up to 20% at ELT and by up to 32% at LLT. However, this decrease primarily would occur due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual Article 21 deliveries would increase under Alternative 4A as compared to the deliveries under the No Action Alternative. Therefore, average annual Article 21 deliveries would increase under Alternative 4A as compared to the conditions without the project.

SWP Feather River Service Area

Under Alternative 4A, average annual total SWP Feather River Service Area deliveries during dry and critical years as compared to No Action Alternative would increase or remain similar.

Under Alternative 4A, average annual total SWP Feather River Service Area deliveries during dry and critical years as compared to Existing Conditions, would decrease by up to 4% at ELT and by up to 6% at LLT. The primary cause of this reduction would be change in SWP operations due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 4A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual SWP Feather River Service Area deliveries would increase or remain similar under Alternative 4A as compared to the deliveries under No Action Alternative. Therefore, average annual SWP Feather River Service Area deliveries would remain similar under Alternative 4A as compared to the conditions without the project.

NEPA Effects: SWP and CVP deliveries under Alternative 4A as compared to deliveries under No Action Alternative would increase or remain similar. Indirect effects of changes in water deliveries in addition to potential effects on urban areas caused by changes in SWP and CVP water supply deliveries under Alternative 4A, are addressed in Section 4.3.26, *Growth Inducement and Other Indirect Effects,* and other sections of this RDEIR/SDEIS addressing specific resources.

CEQA Conclusion: SWP and CVP deliveries under Alternative 4A would decline as compared to deliveries under Existing Conditions. The primary cause of the reduction is increased north of Delta water demands that would occur under No Action Alternative and Alternative 4A and changes in SWP and CVP operations due to sea level rise and climate change. As shown above in the NEPA analysis, SWP and CVP deliveries would generally increase or remain similar under Alternative 4A as compared to deliveries under conditions in 2025 and 2060 without Alternative 4A if sea level rise and climate change conditions are considered the same under both scenarios (Alternative 4A and No Action Alternative). SWP and CVP deliveries under Alternative 4A would generally increase or remain similar as compared to deliveries under Existing Conditions without the effects of increased north of Delta water demands, sea level rise, and climate change. Some reductions in the SWP south of Delta deliveries could occur under Alternative 4A with higher spring outflow requirements. Indirect effects of changes in water deliveries including potential effects on urban areas caused by changes in SWP and CVP water supply deliveries are addressed in Section 4.3.26, *Growth Inducement and Other Indirect Effects,* and other sections of this RDEIR/SDEIS addressing specific resources.

Impact WS-3: Effects of Water Transfers on Water Supply

Alternative 4A increases project water supply allocations as compared to the No Action Alternative, and consequently will decrease cross-Delta water transfer demand compared to the No Action Alternative. Alternative 4A would change the combined SWP Table A and CVP south-of-Delta agricultural water supply allocations as compared to Existing Conditions, and the frequency of years in which cross-Delta transfers are assumed to be triggered would change as well, assuming an estimated cross-Delta transfer supply of 600,000 acre-feet in any one year.

Under Alternative 4A as compared to Existing Conditions, the frequency of years in which cross-Delta transfers would increase, and the average annual volume of those transfers would increase. Under Alternative 4A as compared to the No Action Alternative, the frequency of years in which cross-Delta transfers would occur would decrease.

Alternative 4A provides a separate cross-Delta facility with additional capacity to move transfer water from areas upstream of the Delta to export service areas and provides a longer transfer window than allowed under current regulatory constraints. In addition, the facility provides conveyance that would not be restricted by Delta reverse flow concerns or south Delta water level concerns. As a result of avoiding those restrictions, transfer water could be moved at any time of the year that capacity exists in the combined cross-Delta channels, the new cross-Delta facility, and the export pumps, depending on operational and regulatory constraints, including criteria guiding the operation of water conveyance facilities under Alternative 4A.

NEPA Effects: Alternative 4A would decrease water transfer demand compared to existing conditions. Alternative 4A would decrease conveyance capacity, enabling additional cross-Delta water transfers that could lead to increases in Delta exports when compared to No Action Alternative. Prior to approval, each transfer must go through NEPA review and be evaluated by the export facility agency, and may also be subject to CEQA review and/or SWRCB process. Indirect effects of changes in Delta exports or water deliveries are addressed in Section 4.2.29, *Growth Inducement and Other Indirect Effects*, and other sections addressing specific resources.

CEQA Conclusion: Alternative 4A would increase water transfer demand compared to existing conditions. Alternative 4A would increase conveyance capacity, enabling additional cross-Delta water transfers that could lead to increases in Delta exports when compared to existing conditions. Prior to approval, each transfer must go through the CEQA and/or SWRCB process and be evaluated by the export facility agency, and may also be subject to NEPA review. Indirect effects of changes in Delta exports or water deliveries are addressed in Section 4.2.29, *Growth Inducement and Other Indirect Effects,* and other sections addressing specific resources.

4.3.2 Surface Water

Facilities construction under Alternative 4A would be identical to those described under Alternative 4.

Alternative 4A water conveyance operations would be similar to the range of possible operations for the spring Delta outflow requirements that would occur under Alternative 4 H3 and Alternative 4 H4.

Model simulation results for Alternative 4A Early Long-term (ELT), which are represented by the range of Alternative 4 H3 (ELT) and Alternative 4 H4 (ELT), are summarized in Tables B.2-1 through B.2-6 in Appendix B of the RDEIR/SDEIS. Model simulation results for Alternative 4A at Late Long-term (LLT) which are similar to the range of Alternative 4 H3 (LLT) and Alternative 4 H4 (LLT) are summarized in Tables 6-2 through 6-9 in the Draft EIR/EIS.

Section 6.3.2, *Determination of Effects*, of the Draft EIR/EIS describes criteria used for the NEPA adverse effect and CEQA significant impact determinations.

SWP CVP Reservoir Storage and Related Changes to Flood Potential

Impact SW-1: Changes in SWP or CVP Reservoir Flood Storage Capacity

Reservoir storage in Shasta Lake, Folsom Lake, and Lake Oroville during the October through June period is compared to the flood storage capacity of each reservoir to identify the number of months where the reservoir storage is close to the flood storage capacity.

Changes in the number of months where the reservoir storage is close to the flood storage capacity under Alternative 4A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-1 through B.2-6 in Appendix B of this RDEIR/SDEIS.

Changes in the number of months where the reservoir storage is close to the flood storage capacity under Alternative 4A (LLT) (similar to range of Alternative 4 H3 [LLT] and Alternative 4 H4 [LLT]) as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Tables 6-2 through 6-7 of the Draft EIR/EIS.

NEPA Effects: Under Alternative 4A, the number of months where the reservoir storage is close to the flood storage capacity in Shasta Lake, Folsom Lake, and Lake Oroville would be similar (or show no more than 10% increase) under the No Action Alternative.

A comparison with storage conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that reservoir storages would not be consistently high during October through June under Alternative 4A as compared to the conditions under the No Action Alternative. Therefore, Alternative 4A would not result in adverse effects on reservoir flood storage capacity as compared to the conditions without the project.

CEQA Conclusion: Under Alternative 4A, the number of months where the reservoir storage is close to the flood storage capacity in Shasta Lake, Folsom Lake, and Lake Oroville would be less than under Existing Conditions. These differences represent changes under Alternative 4A, increased demands from Existing Conditions to No Action Alternative, and changes due to sea level rise and climate change.

Alternative 4A would not cause consistently higher storages in the upper Sacramento River watershed during the October through June period. Accordingly, Alternative 4A would result in a less-than-significant impact on flood management. No mitigation is required.

Highest Monthly Flows in Sacramento and San Joaquin Rivers and Related Changes to Flood Potential

Impact SW-2: Changes in Sacramento and San Joaquin River Flood Flows

Changes in highest monthly flows under Alternative 4A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-1 through B.2-3 in Appendix B and Figures 4.3.2-1 through 4.3.2-15 of this RDEIR/SDEIS.

Changes in highest monthly flows under Alternative 4A (LLT) (similar to range of Alternative 4 H3 [LLT] and Alternative 4 H4 [LLT]) as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 6-8 through 6-22 and Tables 6-2 through 6-4 of the Draft EIR/EIS.

Sacramento River at Bend Bridge

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would remain similar to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would increase by about 2% of the channel capacity (100,000 cfs) as compared to the flows under Existing Conditions. The increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 4A as compared to the No Action Alternative. Therefore, Alternative 4A would not result in adverse impacts on flow conditions in the Sacramento River at Bend Bridge as compared to the conditions without the project.

Sacramento River at Freeport

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would decrease by about 1% of the channel capacity (110,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would remain similar as compared to the flows under Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that there would not increase in high flow conditions under Alternative 4A as compared to the No Action Alternative. Therefore, Alternative 4A would not result in adverse impacts on flow conditions in the Sacramento River at Freeport as compared to the conditions without the project.

San Joaquin River at Vernalis

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would remain similar to (or show less than 1% change with respect to the channel capacity: 52,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would remain similar (or show less than 1% change with respect to the channel capacity: 52,000 cfs) as compared to the flows under Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 4A as compared to the No Action Alternative. Therefore, Alternative 4A would not result in adverse impacts on flow conditions in the San Joaquin River at Vernalis as compared to the conditions without the project.

Sacramento River at Locations Upstream of Walnut Grove (downstream of north Delta intakes)

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would decrease by about 9% of channel capacity (110,000 cfs) as compared to the flows under the No Action Alternative. This decrease primarily would occur due to the diversion of Sacramento River flow at the north Delta intakes under Alternative 4A.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would decrease by about 8% of channel capacity (110,000 cfs) as compared to the flows under Existing Conditions. This decrease primarily would occur due to the diversion of Sacramento River flow at the north Delta intakes under Alternative 4A.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 4A as compared to the No Action Alternative. Therefore, Alternative 4A would not result in adverse impacts on flow conditions in the Sacramento River upstream of Walnut Grove as compared to the conditions without the project.

Trinity River Downstream of Lewiston Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would remain similar as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would increase by about 4% of channel capacity (6,000 cfs) as compared to the flows under Existing Conditions. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 4A as compared to the No Action Alternative. Therefore, Alternative 4A would not result in adverse impacts on flow conditions in the Trinity River downstream of Lewiston Lake as compared to the conditions without the project.

American River Downstream of Nimbus Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would remain similar to (or show less than 1% change with respect to the channel capacity: 152,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would increase by no more than approximately 1% of the channel capacity (152,000 cfs) as compared to the flows under Existing Conditions. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 4A as compared to the No Action Alternative. Therefore, Alternative 4A would not result in adverse impacts on flow conditions in the American River at Nimbus Dam as compared to the conditions without the project.

Feather River Downstream of Thermalito Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would increase by about 1% of channel capacity (210,000 cfs) or remain similar as compared to the flows under the No Action Alternative depending on the range of spring Delta outflow requirements.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would increase by about 1% of channel capacity (210,000 cfs) or remain similar as compared to the flows under Existing Conditions depending on the range of spring Delta outflow requirements.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 4A as compared to the No Action Alternative. Therefore, Alternative 4A would not result in adverse impacts on flow conditions in the Feather River at Thermalito Dam as compared to the conditions without the project.

Yolo Bypass at Fremont Weir

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A would increase no more than approximately 1% of the channel capacity (343,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 4A at ELT would increase no more than 1% of the channel capacity (343,000 cfs) and at LLT would increase no more than 2% of the channel capacity (343,000 cfs) as compared to the flows under the Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 4A as compared to the No Action Alternative. Therefore, Alternative 4A would not result in adverse impacts on flow conditions in the Yolo Bypass at Fremont Weir as compared to the conditions without the project.

NEPA Effects: Overall, Alternative 4A would not result in an increase in potential risk for flood management compared to the No Action Alternative. Highest monthly flows under Alternative 4A in the locations considered in this analysis either were similar to or less than highest monthly flows that would occur under the No Action Alternative; or the increase in the highest monthly flows would be less than the flood capacity for the channels at these locations.

Therefore, Alternative 4A would not result in adverse effects on flood management.

***CEQA Conclusion*:** Alternative 4A would not result in an increase in potential risk for flood management compared to Existing Conditions when the changes due to sea level rise and climate change are eliminated from the analysis. Highest monthly flows under Alternative 4A in the locations considered in this analysis either were similar to or less than those that would occur under Existing Conditions without the changes in sea level rise and climate change; or the increased highest monthly flows would not exceed the flood capacity of the channels at these locations. Accordingly, Alternative 4A would result in a less-than-significant impact on flood management. No mitigation is required.

Reverse Flows in Old and Middle River

Impact SW-3: Change in Reverse Flow Conditions in Old and Middle Rivers

Changes in average monthly reverse flow conditions for Old and Middle River flows under Alternative 4A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-1 through B.2-3 in Appendix B and Figure 4.3.2-16 in this RDEIR/SDEIS.

Changes in average monthly reverse flow conditions for Old and Middle River flows under Alternative 4A (LLT) (similar to range of Alternative 4 H3 [LLT] and Alternative 4 H4 [LLT]) as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figure 6-23 and Tables 6-2 through 6-4 of the Draft EIR/EIS.

Reverse flow conditions for Old and Middle River flows would be reduced in all months under Alternative 4A on a long-term average basis except in April and May, compared to reverse flows under both Existing Conditions and the No Action Alternative. Compared to flows under the No Action Alternative, Old and Middle River flows would be generally less positive in April and May.

NEPA Effects: A comparison with reverse flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 4A without the effects of sea level rise and climate change. The results show that reverse flow conditions under Alternative 4A would be reduced in all months on a long-term average basis except in April and May as compared to No Action Alternative. In April and May the reverse flow conditions would be generally greater than 1% under Alternative 4A as compared to No Action Alternative. The effects to beneficial use of the surface water for water supplies and aquatic resources, is described in Section 4.3.4, *Water Quality* and Section 4.3.7, *Fish and Aquatic Resources*, of this RDEIR/SDEIS.

***CEQA Conclusion*:** Alternative 4A would provide positive changes related to reducing reverse flows in Old and Middle Rivers in June through March and negative changes in the form of increased reverse flow conditions in April and May, compared to Existing Conditions. The increase (more negative) in reverse flow conditions in April and May is generally greater than 1% as compared to

Existing Conditions. The significance of the impact to beneficial use of the surface water for water supplies and aquatic resources, and appropriate Mitigation Measures for those impacts to beneficial uses is described in Section 4.3.4, *Water Quality* and Section 4.3.7, *Fish and Aquatic Resources*, of this RDEIR/SDEIS.

Impact SW-4: Substantially Alter the Existing Drainage Pattern or Substantially Increase the Rate or Amount of Surface Runoff in a Manner That Would Result in Flooding during Construction of Conveyance Facilities

NEPA Effects: Effects associated with construction and operations of facilities under Alternative 4A would be similar to those described under Alternative 1A with the exception of two fewer intakes, elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 4A as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A. However, the measures included in Alternative 1A to avoid adverse effects would be included in Alternative 4A.

Alternative 4A would involve excavation, grading, stockpiling, soil compaction, and dewatering that would result in temporary and long-term changes to drainage patterns, drainage paths, and facilities that would in turn, cause changes in drainage flow rates, directions, and velocities. Although intakes have been designed and located on-bank to minimize changes to river flow characteristics, some localized water elevation changes would occur upstream and adjacent to each cofferdam at the intake sites due to facility location within the river. These localized surface elevation changes would not exceed an increase of 0.10 feet at any intake location even under flood flow conditions. Although minimal localized effects could occur, construction of cofferdams could impede river flows at the location of the intakes but would not increase water surface elevations upstream by more than 0.10 feet during flood events. Potential adverse effects could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages; and changes in sediment accumulation near the intakes. Mitigation Measure SW-4 is available to address effects of runoff and sedimentation.

***CEQA Conclusion*:** Alternative 4A could result in alterations to drainage patterns, stream courses, and runoff; and potential for slightly increased surface water elevations near the intakes in the rivers and streams during construction and operations of facilities located within the waterway. Although intakes have been designed and located on-bank to minimize changes to river flow characteristics, some localized water elevation changes would occur upstream and adjacent to each cofferdam at the intake sites due to facility location within the river. These localized surface elevation changes would not exceed an increase of 0.10 feet at any intake location even under flood flow conditions. Potential impacts could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages, and from changes in sediment accumulation near the intakes. These impacts are considered significant. Mitigation Measure SW-4 would reduce this impact to a less-than-significant level by implementing a number of measures which would prevent an increase in runoff volume and rate from land-side construction areas; and which would prevent an increase in sedimentation in the runoff from the construction areas.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A.

Impact SW-5: Substantially Alter the Existing Drainage Pattern or Substantially Increase the Rate or Amount of Surface Runoff in a Manner That Would Result in Flooding during Construction of Environmental Commitments 3, 4, and 6–11

NEPA Effects: Alternative 4A would include construction of the restoration area facilities under Environmental Commitments 3, 4, and 6–11.

Riparian habitat restoration is anticipated to occur primarily in association with the restoration of tidal marsh habitat, and channel margin habitat. The restored vegetation has the potential of increasing channel roughness, which could result in increases in channel water surface elevations, including under flood flow conditions, and in decreased velocities. Modified channel geometries could increase or decrease channel velocities and/or channel water surface elevations, including under flood flow conditions. Under existing regulations, the USACE, CVFPB, and DWR would require the habitat restoration projects to be flood neutral. The specific permits/decisions/approvals required are included in Table 1-1 of this RDEIR/SDEIS, and in Table 1-2 of the Draft EIR/EIS. Measures to reduce flood potential could include channel dredging to increase channel capacities and decrease channel velocities and/or water surface elevations.

***CEQA Conclusion*:** Alternative 4A would include construction of the restoration area facilities under Environmental Commitments 3, 4, and 6–11. Alternative 4A could result in alterations to drainage patterns, stream courses, and runoff; and potential for increased surface water elevations in the rivers and streams during construction and operations of facilities located within the waterway. These impacts are considered significant. Under existing regulations, the USACE, CVFPB, and DWR would require the habitat restoration projects to be flood neutral. The specific permits/decisions/approvals required are included in Table 1-1 of this RDEIR/SDEIS, and in Table 1-2 of the Draft EIR/EIS. Measures to reduce flood potential could include channel dredging to increase channel capacities and decrease channel velocities and/or water surface elevations. Mitigation Measure SW-4 would reduce this impact to a less-than-significant level by implementing a number of measures which would prevent an increase in runoff volume and rate from land-side construction areas; and which would prevent an increase in sedimentation in the runoff from the construction areas.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A

Impact SW-6: Create or Contribute Runoff Water Which Would Exceed the Capacity of Existing or Planned Stormwater Drainage Systems or Provide Substantial Additional Sources of Polluted Runoff

Effects associated with construction and operations of facilities under Alternative 4A would be similar to those described under Alternative 1A with the exception of two fewer intakes, elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 4A as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A because there would be fewer construction sites under this alternative.

NEPA Effects: Paving, soil compaction, and other activities would increase runoff during facilities construction and operations. Construction and operation of dewatering facilities and associated discharge of water would result in localized increases in flows and water surface elevations in receiving channels. These activities could result in adverse effects if the runoff volume exceeds the capacities of local drainages. As noted below in the CEQA Conclusion section, compliance with permit design requirements would avoid adverse effects on surface water quality and flows from dewatering activities. The use of dispersion facilities would reduce the potential for channel erosion. Mitigation Measure SW-4 is available to address adverse effects.

***CEQA Conclusion*:** Alternative 4A actions would include installation of dewatering facilities in accordance with permits issued by the Regional Water Quality Control Board and CVFPB (See Section 6.2.2.4 in Chapter 6, *Surface Water*, of the Draft EIR/EIS). Alternative 4A would include provisions to design the dewatering system in accordance with these permits to avoid significant impacts on surface water quality and flows. However, increased runoff could occur from facilities sites during construction or operations and could result in significant impacts if the runoff volume exceeds the capacities of local drainages. These impacts are considered significant. Mitigation Measure SW-4 would reduce this potential impact to a less-than-significant level.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A

Impact SW-7: Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding Due to the Construction of New Conveyance Facilities

NEPA Effects: Effects associated with construction of conveyance facilities under Alternative 4A would be identical to those described under Alternative 1A with the exception of two fewer intakes, elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 4A as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A.

Alternative 4A would not result in an increase to exposure of people or structures to flooding due to construction of the conveyance facilities because the project proponents would be required to comply with USACE, CVFPB, and DWR requirements to avoid increased flood potential and levee failure due to construction and operation of the facilities as described in Section 6.2.2.4 in Chapter 6, *Surface Water*, of the Draft EIR/EIS. Additionally, DWR would consult with local reclamation districts to ensure that construction activities would not conflict with reclamation district flood protection measures. Determination of design flood elevations would need to consider sea level rise to reduce impacts.

***CEQA Conclusion*:** Alternative 4A would not result in an increase to exposure of people or structures to flooding due to construction of the conveyance facilities because the project proponents would be required to comply with the requirements of USACE CVFPB, and DWR to avoid increased flood potential and levee failure due to construction and operation of the facilities as described in Section 6.2.2.4 in Chapter 6, *Surface Water*, of the Draft EIR/EIS. If the design flood elevations did not consider sea level rise to reduce impacts, these impacts are considered significant. Mitigation Measure SW-7 would reduce this impact to a less-than-significant level.

Mitigation Measure SW-7: Implement Measures to Reduce Flood Damage

Please see Mitigation Measure SW-7 under Impact SW-7 in the discussion of Alternative 1A

Impact SW-8: Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding Due to Environmental Commitments 3, 4, and 6–11

Tidal marsh habitat, and channel margin habitat could increase flood potential due to impacts on adjacent levees. The newly flooded areas would have larger wind fetch lengths (unobstructed distance which wind can travel over water and potentially develop large waves caused by wind force not tidal force) compared to the existing fetch lengths of the adjacent leveed channels. An increase in fetch length would result in increases in wave height and velocities that reach the existing levees along adjacent islands and floodplains. These potential increases in wave action could also reach the land-side of the remaining existing levees around the restoration area. In accordance with existing requirements of the USACE, CVFPB, and DWR, Alternative 4A would be designed to avoid increased flood potential as compared to Existing Conditions or No Action Alternative.

NEPA Effects: Alternative 4A would not result in an increase to exposure of people or structures to flooding due to the operation of the Environmental Commitments because the facilities would be required to comply with the requirements of the USACE, CVFPB, and DWR to avoid increased flood potential. However, increased wind fetch near open water areas of habitat restoration could cause potential damage to adjacent levees, which would be considered an adverse effect. This impact could become more substantial with sea level rise and climate change. Mitigation Measure SW-8 would reduce this potential adverse effect.

***CEQA Conclusion*:** Alternative 4A would not result in an increase to exposure of people or structures to flooding due to the construction or operations of Environmental Commitments because the facilities would be required to comply with the requirements of the USACE, CVFPB, and DWR to avoid increased flood potential. However, increased wind fetch near open water areas of habitat restoration could cause potential damage to adjacent levees. These impacts are considered significant. Mitigation Measure SW-8 would reduce this potential impact to a level of less than significant.

Mitigation Measure SW-8: Implement Measures to Address Potential Wind Fetch Issues

Please see Mitigation Measure SW-8 under Impact SW-8 in the discussion of Alternative 1A

Impact SW-9: Place within a 100-Year Flood Hazard Area Structures Which Would Impede or Redirect Flood Flows, or Be Subject to Inundation by Mudflow

Effects associated with construction and operations of facilities under Alternative 4A would be identical those described under Alternative 1A with the exception of two fewer intakes, elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 4A as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A. The measures included in Alternative 1A to avoid adverse effects would be included in Alternative 4A. As described under Impact SW-1, Alternative 4A would not increase flood potential on the Sacramento River, San Joaquin River, Trinity River, American

River, or Feather River, or Yolo Bypass as described under Impact SW-2. Alternative 4A would include measures, including Mitigation Measure SW-4, to address potential issues associated with alterations to drainage patterns, stream courses, and runoff and potential for increased surface water elevations in the rivers and streams during construction and operations of facilities.

NEPA Effects: Potential adverse effects could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages; and changes in sediment accumulation near the intakes. These effects are considered adverse. Mitigation Measure SW-4 is available to address these potential effects.

***CEQA Conclusion*:** Alternative 4A would not result in an impedance or redirection of flood flows or conditions that would cause inundation by mudflow due to construction or operations of the conveyance facilities or construction of the Environmental Commitments because the project proponents would be required to comply with the requirements of USACE, CVFPB, and DWR to avoid increased flood potential as described in Section 6.2.2.4 of Chapter 6, *Surface Water*, in the Draft EIR/EIS. Potential adverse impacts could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages, as well as changes in sediment accumulation near the intakes. These impacts are considered significant. Mitigation Measure SW-4 would reduce this potential impact to a less-than-significant level by implementing a number of measures which would prevent an increase in runoff volume and rate from land-side construction areas; and which would prevent an increase in sedimentation in the runoff from the construction areas.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A.

4.3.3 Groundwater

4.3.3.1 Delta Region

The conveyance facilities included under Alternative 4A are identical to those included under Alternative 4 and the footprint of the Alternative 4A conveyance facilities in the Delta is identical to the Alternative 4 footprint as described in Section 7.3.3.9 in Appendix A of this RDEIR/SDEIS. Therefore, impacts due to construction of the water conveyance facilities in the Delta would be identical to those described for Alternative 4, as they would occur in the same timeframe.

The effects of the operations under Alternative 4A compared to the No Action Alternative (ELT) are similar to the effects of operations under Alternative 4 as compared to the No Action Alternative (LLT) and described in the Draft EIR/EIS Chapter 7, *Groundwater*. Therefore, the effects on the Delta groundwater resources based on the comparison to each of the No Action Alternatives are similar.

Impact GW-1: During Construction, Deplete Groundwater Supplies or Interfere with Groundwater Recharge, Alter Local Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

See Impact GW-1 under Alternative 4; construction activities and potential impacts under Alternative 4A would be identical to those under Alternative 4 because both alternatives have the same footprint in the Delta.

NEPA Effects: Dewatering would temporarily lower groundwater levels in the vicinity of the dewatering sites. Three areas could be subject to substantial lowering of groundwater levels: (1) In the vicinity of intake pump stations 2, 3, and 5; (2) in the vicinity of the Intermediate Forebay; and (3) in the vicinity of the expanded Clifton Court Forebay portion that includes the Byron Tract area. Groundwater-level lowering from construction dewatering activities is forecasted to be less than 10 feet in the vicinity of the intakes and the Intermediate Forebay and less than 20 feet in the vicinity of the Byron Tract Forebay. Groundwater levels within 2,600 feet of the areas to be dewatered are anticipated to experience groundwater level reductions of less than 20 feet for the duration of the dewatering activities and up to 2 months after dewatering is completed. The sustainable yield of some wells might temporarily be affected by the lower water levels such that they are not able to support existing land uses. The construction of conveyance features would result in effects on groundwater levels and associated well yields that would be temporary. These effects are considered adverse. It should be noted that the forecasted impacts described above reflect a worst-case scenario as the option of installing seepage cutoff walls during dewatering was not considered in the analysis.

CEQA Conclusion: Construction activities associated with conveyance facilities under Alternative 4A including temporary dewatering and associated reduced groundwater levels have the potential to temporarily affect the productivity of existing nearby water supply wells. Groundwater levels within 2,600 feet of the areas to be dewatered are anticipated to experience groundwater level reductions of less than 20 feet for the duration of the dewatering activities and up to 2 months after dewatering is completed. Nearby wells could experience significant reductions in well yield, if they are shallow wells and may not be able to support existing land uses. The temporary impact on groundwater levels and associated well yields is considered significant because construction-related dewatering might affect the amount of water supplied by shallow wells located near the construction sites.

Mitigation Measure GW-1 identifies a monitoring procedure and options for maintaining an adequate water supply for land owners that experience a reduction in groundwater production from wells within 2,600 feet of construction-related dewatering activities. It should be noted that the forecasted impacts described above reflect a worst-case scenario as the option of installing seepage cutoff walls during dewatering was not considered in the analysis. Implementing Mitigation Measure GW-1 would help address these effects; however, the impact may remain significant because replacement water supplies may not meet the preexisting demands or planned land use demands of the affected party. In some cases this impact might temporarily be significant and unavoidable until groundwater elevations recover to pre-construction conditions which could require several months after dewatering operations cease.

Mitigation Measure GW-1: Maintain Water Supplies in Areas Affected by Construction Dewatering

Please see Mitigation Measure GW-1 under Impact GW-1 in the discussion of Alternative 1A.

Impact GW-2: During Operations, Deplete Groundwater Supplies or Interfere with Groundwater Recharge, Alter Local Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

See Impact GW-2 under Alternative 4; operations under Alternative 4A fall within the range of operations scenarios analyzed for Alternative 4.

NEPA Effects: The new Intermediate Forebay and the expanded Clifton Court Forebay would be constructed to comply with the requirements of the Division of Safety of Dams (DSD) which include design features intended to minimize seepage under the embankments. In addition, the forebays will include a seepage cutoff wall installed to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. Any potential vertical seepage under the smaller Intermediate Forebay would also be captured by the toe drain. However, operation of Alternative 4A would result in groundwater level increases in the vicinity of the expanded Clifton Court Forebay portion at Byron Tract due to groundwater recharge, similar to Alternative 1A.

Operation of the tunnel would have no impact on existing wells or yields given the facilities would be located more than 100 feet underground and would not substantially alter groundwater levels in the vicinity.

CEQA Conclusion: The new Intermediate Forebay and the expanded Clifton Court Forebay will include design features intended to minimize seepage under the embankments and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. Any potential vertical seepage under the smaller Intermediate Forebay would also be captured by the toe drain. However, operation of Alternative 4A would result in groundwater level increases in the vicinity of the expanded Clifton Court Forebay portion at Byron Tract due to groundwater recharge, similar to Alternative 1A, which would not reduce the yields of nearby wells.

Operation of the tunnel would have no impact on existing wells or yields given these facilities would be located over 100 feet underground and would not substantially alter groundwater levels in the vicinity.

Therefore, this impact would be less than significant. No mitigation is required.

Impact GW-3: Degrade Groundwater Quality during Construction and Operation of Conveyance Facilities

See Impact GW-3 under Alternative 4; the construction activities under Alternative 4A would be identical to those under Alternative 4, which would be similar to those under Alternative 1A with a lesser magnitude, because only three intakes would be constructed (instead of five). The operations under Alternative 4A fall within the range of operations scenarios analyzed for Alternative 4.

NEPA Effects: Dewatering would temporarily lower groundwater levels and cause small changes in groundwater flow patterns near the intake pump stations along the Sacramento River, Intermediate Forebay, and Byron Tract Forebay. Since no significant regional changes in groundwater flow directions are forecasted, and the inducement of poor-quality groundwater into areas of better quality is unlikely, it is anticipated that there would be no change in groundwater quality for Alternative 4A. Further, the planned treatment of extracted groundwater prior to discharge into adjacent surface waters would prevent significant impacts on groundwater quality. There would be no adverse effect.

CEQA Conclusion: No significant groundwater quality impacts are anticipated during construction activities. Because of the temporary and localized nature of construction dewatering, the potential for the inducement of the migration of poor-quality groundwater into areas of higher quality groundwater will be low. Further, the planned treatment of extracted groundwater prior to discharge into adjacent surface waters would prevent significant impacts on groundwater quality.

No significant groundwater quality impacts are anticipated in most areas of the Delta during the implementation of Alternative 4A, because changes to regional patterns of groundwater flow are not anticipated. However, degradation of groundwater quality near the Suisun Marsh area are likely, due to the effects of saline water intrusion caused by slightly rising sea levels. Effects due to climate change are provided for informational purposes only and do not lead to mitigation. This impact would be less than significant. No mitigation is required.

Impact GW-4: During Construction of Conveyance Facilities, Interfere with Agricultural Drainage in the Delta

See Impact GW-4 under Alternative 4; construction activities under Alternative 4A would be identical to those under Alternative 4, which would be similar to those under Alternative 1A with a lesser magnitude, because only three intakes would be constructed (instead of five).

NEPA Effects: In the absence of seepage cutoff walls intended to minimize local changes to groundwater flow, the lowering of groundwater levels due to construction dewatering would temporarily affect localized shallow groundwater flow patterns during and immediately after the construction dewatering period. For the Byron Tract Forebay site, only a portion of the shallow groundwater flow will be directed inward toward the dewatering operations. Forecasted temporary changes in shallow groundwater flow directions and areas of impacts are minor near the intakes. Therefore, agricultural drainage during construction of conveyance features is not forecasted to result in adverse effects under Alternative 4A. In some instances, the lowering of groundwater levels in areas that experience near-surface water level conditions (or near-saturated root zones) would be beneficial. There would be no adverse effect.

CEQA Conclusion: The forecasted changes in shallow groundwater flow patterns due to construction dewatering activities in the Delta are localized and temporary and are not anticipated to cause significant impacts on agricultural drainage. This impact would be less than significant. No mitigation is required.

Impact GW-5: During Operations of New Facilities, Interfere with Agricultural Drainage in the Delta

See Impact GW-5 under Alternative 4; operations under Alternative 4A would be similar to those under Alternative 4 from a footprint perspective in the Delta Region.

NEPA Effects: The Intermediate Forebay and the expanded Clifton Court Forebay will include a seepage cutoff wall to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. These design measures will greatly reduce any potential for seepage onto adjacent lands and avoid interference with agricultural drainage in the vicinity of the Intermediate Forebay. Once constructed, the operation of the forebay would be monitored to ensure seepage does not exceed performance requirements.

However, operation of Alternative 4A would result in local changes in shallow groundwater flow patterns adjacent to the expanded Clifton Court Forebay portion at Byron Tract, where groundwater recharge from surface water would result in groundwater level increases, similar to Alternative 4 and 1A. If existing agricultural drainage systems adjacent to the forebay are not adequate to accommodate the additional drainage requirements, operation of the forebay could interfere with agricultural drainage in the Delta. This effect would be considered adverse.

CEQA Conclusion: The Intermediate Forebay and the expanded Clifton Court Forebay will include a seepage cutoff wall to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. These design measures will greatly reduce any potential for seepage onto adjacent lands and avoid interference with agricultural drainage in the vicinity of the Intermediate Forebay. Once constructed, the operation of the forebay would be monitored to ensure seepage does not exceed performance requirements.

However, operation of Alternative 4A would result in local changes in shallow groundwater flow patterns adjacent to the expanded Clifton Court Forebay portion at Byron Tract, caused by groundwater recharge from surface water, and could cause significant impacts to agricultural drainage where existing systems are not adequate to accommodate the additional drainage requirements, similar to Alternative 4 and 1A. Implementation of Mitigation Measure GW-5 is anticipated to reduce this impact to a less-than-significant level in most instances, though in some instances mitigation may be infeasible due to factors such as costs that would be imprudent to bear in light of the fair market value of the affected land. The impact is therefore significant and unavoidable as applied to such latter properties.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A.

Impact GW-6: Deplete Groundwater Supplies or Interfere with Groundwater Recharge Alter Local Groundwater Levels Reduce the Production Capacity of Preexisting Nearby Wells, or Interfere with Agricultural Drainage as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementation of the environmental commitments under Alternative 4A could result in additional increased frequency of inundation of areas associated with the proposed tidal habitat, channel margin habitat, and seasonally inundated floodplain restoration actions, which would result in increased groundwater recharge. Such increased recharge could result in groundwater level rises in some areas. More frequent inundation would also increase seepage, which is already difficult and expensive to control in most agricultural lands in the Delta (see Chapter 14, *Agricultural Resources*, of the Draft EIR/EIS). Effects associated with the implementation of those environmental commitments are considered adverse. The implementation of Mitigation Measure GW-5 would help address these effects by identifying areas where seepage conditions have worsened and installing additional subsurface drainage measures, as needed.

CEQA Conclusion: Implementation of the environmental commitments under Alternative 4A could result in additional increased frequency of inundation of areas associated with the proposed tidal habitat, channel margin habitat, and seasonally inundated floodplain restoration actions, which would result in increased groundwater recharge. Such increased recharge could result in groundwater level rises in some areas. More frequent inundation would also increase seepage, which is already difficult and expensive to control in most agricultural lands in the Delta (see Chapter 14, *Agricultural Resources*, of the Draft EIR/EIS). Impacts associated with the implementation of those environmental commitments would result in significant impacts. This impact would be reduced to a less-than-significant level in most instances, with the implementation of Mitigation Measure GW-5 by identifying areas where seepage conditions have worsened and installing additional subsurface drainage measures, as needed. However, this impact is still considered significant and unavoidable.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A.

Impact GW-7: Degrade Groundwater Quality as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: The increased inundation frequency in restoration areas from the environmental commitments under Alternative 4A would increase the localized areas exposed to saline and brackish surface water, which would result in increased groundwater salinity beneath such areas. The flooding of large areas with saline or brackish water would result in an adverse effect on groundwater quality beneath or adjacent to flooded areas. It would not be possible to completely avoid this effect. However, if water supply wells in the vicinity of these areas are not useable because of water quality issues, Mitigation Measure GW-7 would help reduce this impact, but the impact would remain significant and unavoidable.

CEQA Conclusion: The increased inundation frequency in restoration areas from the environmental commitments under Alternative 4A would increase the localized areas exposed to saline and brackish surface water, which would result in increased groundwater salinity beneath such areas. The flooding of large areas with saline or brackish water would result in significant impacts on groundwater quality beneath or adjacent to flooded areas. It would not be possible to completely avoid this effect. However, if water supply wells in the vicinity of these areas are not useable because of water quality issues, Mitigation Measure GW-7 is available to address this effect.

Mitigation Measure GW-7: Provide an Alternate Source of Water

Please see Mitigation Measure GW-7 under Impact GW-7 in the discussion of Alternative 1A.

4.3.3.2 SWP CVP Export Service Areas

Impact GW-8: During Operations, Deplete Groundwater Supplies or Interfere with Groundwater Recharge Alter Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

As described in Chapter 7 in the Draft EIR/EIS, Alternative 4 includes 4 operational scenarios, H1, H2, H3, and H4. Alternative 4A would include total long-term average annual surface water deliveries to the CVP and SWP Service Areas that range between scenarios H3 and H4 deliveries at the early long-term simulation period (see Section 4.3.1, *Water Supply*, of this RDEIR/SDEIS).

Table 4.3.3-1 below shows the long-term average SWP and CVP deliveries for Alternative 4A (ranges of deliveries represent estimates for Alternative 4 scenarios H3 and H4 at early long-term) compared to existing conditions and the No Action Alternative at early long-term.

Table 4.3.3-1. Long-Term State Water Project and Central Valley Project Deliveries to Hydrologic Regions Located South of the Delta at Early Long-Term

	Long-Term Average State Water Project and Central Valley Project Deliveries at Early Long Term(TAF/year)		
Alternative	San Joaquin and Tulare Hydrologic Region	Central Coast Hydrologic Region	Southern California Hydrologic Region
Existing Conditions	2,964	47	1,647
No Action Alternative (ELT)	2,682	43	1,580
Alternative 4A ELT	2,765–2,960	40–50	1,468–1,766

The groundwater resource impacts of Alternative 4A will be similar to those under Alternative 4 compared to the No Action Alternative LLT; but the magnitude of the impacts would be proportional to the change in the quantity of CVP and SWP surface water supplies delivered to the SWP/CVP Export Service Areas compared to the No Action Alternative at ELT. See Table 7-7, in Chapter 7, *Groundwater*, of the Draft EIR/EIS for long-term average SWP and CVP surface water deliveries at LLT.

NEPA Effects: In the San Joaquin and Tulare Hydrologic Region, total long-term average annual water deliveries to the CVP and SWP Service Areas under Alternative 4A ELT are expected to be higher than the exports under the No Action Alternative at early long-term. Increases in surface water deliveries attributable to project operations from the implementation of Alternative 4A are anticipated to result in a corresponding decrease in groundwater use in the San Joaquin and Tulare Export Service Areas as compared to the No Action Alternative (ELT), as discussed in Section 4.2.4, *Water Supply*, of this RDEIR/SDEIS. Higher groundwater levels associated with reduced overall groundwater use would result in a beneficial effect on groundwater levels. Similarly, total long-term average annual water deliveries to the CVP and SWP Service Areas under Alternative 4A at LLT are expected to be higher than the exports under the No Action Alternative at late long-term.

The total long-term average annual SWP deliveries to Southern California areas under Alternative 4A would increase by approximately 186 TAF per year or would decrease by approximately 112 TAF per year depending on the range of spring Delta outflow requirements (see Section 4.1.2, *Description of Alternative 4A*, of this RDEIR/SDEIS) as compared to the No Action Alternative (ELT). A decrease in surface water deliveries could result in an increase in groundwater pumping and a decrease in groundwater levels, depending on the total water portfolio of the site specific areas. Therefore, decreases in surface water deliveries would result in adverse effects on groundwater levels.

When comparing the total long-term average annual SWP deliveries to Southern California areas under Alternative 4A at LLT with the No Action Alternative (LLT), deliveries would increase by approximately 184 TAF per year or would decrease by approximately 114 TAF per year depending on the range of spring Delta outflow requirements, similar to the comparison at ELT (see Table 7-7 in Chapter 7, *Groundwater*, of the Draft EIR/EIS). Therefore, the effects on groundwater resources would be similar at ELT and at LLT.

However, opportunities for additional pumping might be limited by basin adjudications and other groundwater management programs. Additionally, as discussed in Appendix 5B of the Draft EIR/EIS, *Responses to Reduced South of Delta Water Supplies*, adverse effects might be avoided due to the existence of various other water management options that could be undertaken in response to reduced exports from the Delta. These options include wastewater recycling and reuse, increased water conservation, water transfers, construction of new local reservoirs that could retain Southern California rainfall during wet years, and desalination.

Even if the effect is adverse, feasible mitigation would not be available to diminish this effect due to a number of factors. First, State Water Contractors currently and traditionally have received variable water supplies under their contracts with DWR due to variations in hydrology and regulatory constraints and are accustomed to responding accordingly. Any reductions associated with this impact would be subject to these contractual limitations. Under standard state water contracts, the risk of shortfalls in exports is borne by the contractors rather than DWR. As a result of this variability, many Southern California water districts have complex water management strategies that include numerous options, as described above, to supplement SWP surface water supplies. These water districts are in the best position to determine the appropriate response to reduced imports from the Delta. Second, as noted above, it may be legally impossible to extract additional groundwater in adjudicated basins without gaining the permission of watermasters and accounting for groundwater pumping entitlements and various parties under their adjudicated rights.

CEQA Conclusion*:* For the San Joaquin and Tulare Service Areas, total long-term average surface water deliveries under Alternative 4A at ELT and at LLT would be lower compared to Existing Conditions, largely because of effects due to climate change, sea level rise, and increased water demand north of the Delta. Groundwater pumping under Alternative 4A at ELT is anticipated to be greater than under Existing Conditions, and that groundwater levels in some areas would be lower than under Existing Conditions.

As shown above in the NEPA analysis, SWP and CVP deliveries would increase under Alternative 4A as compared to deliveries under conditions in 2025 without Alternative 4A if sea level rise and climate change conditions are considered the same. For reasons discussed in Chapter 7, *Groundwater*, Section 7.3.1, Methods for Analysis, in the Draft EIR/EIS, DWR has identified effects of action alternatives under CEQA separately from the effects of increased water demands, sea level rise, and climate change, which would occur without and independent of the Alternative 4A. Absent these factors, the impacts of Alternative 4A with respect to groundwater levels are anticipated to be less than significant because groundwater pumping is not anticipated to increase due to Alternative 4A.

Similarly to the NEPA analysis, in Southern California, long-term average surface water supplies would increase by approximately 119 TAF per year or would decrease by approximately 179 TAF per year depending on the range of spring Delta outflow requirements compared to Existing Conditions. A decrease in surface water deliveries could result in an increase in groundwater pumping and a decrease in groundwater levels, depending on the total water portfolio of the site specific areas. Therefore, decreases in surface water deliveries would result in significant impacts on groundwater resources under Alternative 4A. As discussed above in the NEPA conclusion, Southern California water districts may be able to avoid this impact due to various water management options. For reasons also discussed above, no feasible mitigation would be available to mitigate this impact if it is significant. Due to these uncertainties, the overall impact for Alternative 4A considered significant and unavoidable. When comparing the total long-term average annual SWP deliveries to Southern California areas under Alternative 4A at LLT with Existing Conditions, deliveries would increase by approximately 21 TAF per year or would decrease by approximately 277 TAF per year depending on the range of spring Delta outflow requirements, similar to the comparison at ELT (see Table 7-7 in Chapter 7, *Groundwater*, of the Draft EIR/EIS).

Impact GW-9: Degrade Groundwater Quality

NEPA Effects: As discussed under Impact GW-8, surface water deliveries to the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin under Alternative 4A are expected to increase as compared to the No Action Alternative (ELT) as well as at LLT. Increased surface water deliveries could result in a decrease in groundwater use. The decreased groundwater use is not anticipated to alter regional patterns of groundwater flow in these service areas. Therefore, it is not anticipated this would result in an adverse effect on groundwater quality in these areas because similar groundwater flow patterns would not cause poor quality groundwater migration into areas of better quality groundwater as might occur with increased pumping.

Long-term average annual SWP surface water supplies to Southern California could decrease depending on the range of spring Delta outflow requirements compared to the No Action Alternative at ELT and at LLT.

It is unclear, however, whether such reductions would lead to increased groundwater pumping for reasons discussed in connection to Impact GW-8. If groundwater pumping is increased, there could be resulting changes in regional patterns of groundwater flow and a change in groundwater quality. Due to the uncertainty associated with these effects, this effect is considered adverse. For the same reasons discussed earlier in connection with the possibility of increased groundwater pumping in Southern California, there is no feasible mitigation available to mitigate any changes in regional groundwater quality.

CEQA Conclusion: As discussed under Impact GW-8 above, the impacts of Alternative 4A with respect to groundwater levels are considered to be less than significant in the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin. Therefore, no significant groundwater quality impacts are anticipated in these areas during the implementation of Alternative 4A because it is not anticipated to alter regional groundwater flow patterns. Therefore, this impact is considered less than significant because groundwater levels and flow patterns would not change compared to Existing Conditions, and similar groundwater flow patterns would not cause poor quality groundwater migration into areas of better quality groundwater.

However, implementation of Alternative 4A at ELT and at LLT could degrade groundwater quality in portions of the Southern California SWP Export Service Areas; this impact is considered significant due to the possibility of increased groundwater pumping and the resulting effects on regional groundwater flow patterns. As discussed above, there is no feasible mitigation available to address this significant impact. The impact would be considered significant and unavoidable in these areas.

Due to the uncertainties identified in connection with the potential response to Impact GW-8 under Alternative 4A in Southern California, the overall impact for Impact GW-9 Alternative 4A is considered significant and unavoidable.

Impact GW-10: Result in Groundwater Level–Induced Land Subsidence

Groundwater level-induced land subsidence has the highest potential to occur in the San Joaquin and Tulare Export Service Areas, based on historical data, if groundwater pumping substantially increases due to the Alternatives.

NEPA Effects: As discussed under Impact GW-8, surface water deliveries to the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin under Alternative 4A are expected to increase as compared to the No Action Alternative (ELT) as well as at LLT. Increased surface water deliveries could result in a decrease in groundwater pumping. The decreased groundwater pumping would result in higher groundwater levels, and therefore, the potential for groundwater level-induced land subsidence is reduced under Alternative 4A. Operations under Alternative 4A would not result in an adverse effect on the potential for groundwater level-induced land subsidence in these areas because groundwater levels would not decline such that compaction of unconsolidated materials in the unconfined aquifer would occur.

CEQA Conclusion: As discussed under Impact GW-8 above, the impacts of Alternative 4A with respect to groundwater levels are considered to be less than significant in the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin. Therefore, the potential for groundwater level-induced land subsidence is anticipated to be less than significant in these areas during the implementation of Alternative 4A because it is not anticipated to result in a decline in groundwater levels such that compaction of unconsolidated materials in the unconfined aquifer would occur.

4.3.4 Water Quality

The water quality changes described for Alternative 4A reflect assumed water conveyance facilities operations. Alternative 4A includes water conveyance operational criteria similar to Alternative 4 (Operational Scenario H), but would be limited to operations within the range of Scenarios H3 and H4, as fully described in Chapter 3, *Description of Alternatives*, in Appendix A of the RDEIR/SDEIS. Alternative 4A operations are represented by the Scenarios H3 and H4 as follows:

- Scenario H3 – Includes spring outflow consistent with D-1641 and fall outflow consistent with Fall X2 requirements of the FWS 2008 BiOp.
- Scenario H4 – Includes higher spring outflow requirements than D-1641, and Fall X2 requirements of the FWS 2008 BiOp.

H3 and H4 operational criteria differ in the spring outflow that is assumed, and represent the range of operational effects of Alternative 4A. The facilities operations and maintenance impact analysis compares Alternative 4A results over the range of outcomes from the operational sub-scenarios to Existing Conditions (CEQA) and the No Action Alternative (NEPA).

The water quality changes described for Alternative 4A are also affected by assumptions regarding the extent of habitat restoration to be implemented. As described in Section 4.1.2, *Description of Alternative 4A*, of this RDEIR/SDEIS, Alternative 4A does not include the full suite of conservation actions included in Alternative 4. Aside from the water conveyance facilities, the most important differences from a water quality perspective are:

- CM2 – Yolo Bypass Improvements: this is included in Alternative 4, but not included in Alternative 4A; and
- CM4 – Tidal Natural Communities Restoration: includes 65,000 acres in Alternative 4, but would be significantly less under Alternative 4A.

This results in somewhat different patterns of water withdrawals from the Delta, and potentially somewhat different effects on water quality and aquatic habitat conditions in the Plan Area than analyzed for Alternative 4. As described in Section 4.1.2, *Description of Alternative 4A*, of this RDEIR/SDEIS, actions associated with Alternative 4 that are not proposed to be implemented under Alternative 4A would continue to be pursued as part of existing, but separate, projects and programs associated with the 2008 USFWS and 2009 NMFS BiOps (e.g., 8,000 acres of tidal habitat restoration and Yolo Bypass improvements), California EcoRestore, and the 2014 California Water Action Plan.

The analysis of boron, bromide, chloride, Dissolved organic carbon (DOC), electrical conductivity (EC), and nitrate under Alternative 4A in the ELT is based on modeling conducted for Alternative 4 in the ELT, which assumes implementation of Yolo Bypass Improvements and 25,000 acres of tidal natural communities restoration. As described above, Yolo Bypass Improvements are not a component of Alternative 4A and the amount of tidal habitat restoration (i.e. Environmental Commitment 4) would be significantly less than that represented in the modeling. In general, the significance of this difference is that the assessment of bromide, chloride, and EC for Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT), likely overestimates increases in bromide, EC, and chloride that could occur, particularly in the west Delta. Nevertheless, there is notable uncertainty in the results of all quantitative assessments that refer to modeling results, due to the differing assumptions used in the modeling and the description of Alternative 4A and the No Action Alternative (ELT).

Due to the reduced suite of environmental commitments in Alternative 4A compared to Alternative 4 (in particular, significantly less tidal restoration), there generally are fewer significant impacts identified for Alternative 4A than for Alternative 4.

Impact WQ-1: Effects on Ammonia Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), substantial point and non-point sources of ammonia-N do not exist upstream of the SRWTP at Freeport in the Sacramento River watershed, in the watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), or upstream of the Delta in the San Joaquin River watershed. Thus, like Alternative 4, operation of the water conveyance facilities under Alternative 4A would have negligible, if any, effect on ammonia concentrations in the rivers and reservoirs upstream of the Delta relative to Existing Conditions and the No Action Alternative (ELT and LLT). Any negligible increases in ammonia-N concentrations that could occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies, with regard to ammonia.

Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), a substantial decrease in Sacramento River ammonia concentrations is expected under Alternative 4A relative to Existing Conditions, due to planned lowering of ammonia in the SRWTP effluent discharge, and this is expected to decrease ammonia concentrations for all areas of the Delta that are influenced by Sacramento River water. Concentrations of ammonia at locations not influenced notably by Sacramento River water would change little relative to Existing Conditions, due to the similarity in San Joaquin River and San Francisco Bay concentrations and the lack of expected changes in either of these concentrations. Thus, Alternative 4A would not result in substantial increases in ammonia concentrations in the Plan Area, relative to Existing Conditions.

Relative to the No Action Alternative (ELT and LLT), the primary mechanism that could potentially alter ammonia concentrations under Alternative 4A is decreased flows in the Sacramento River, which would lower dilution available to the SRWTP discharge. This flow change would be attributable only to operations of the water conveyance facilities, since the same assumptions regarding SRWTP discharge ammonia concentrations, water demands, climate change, and sea level rise apply to both Alternative 4A and the No Action Alternative (ELT and LLT). A simple mass balance calculation was performed to calculate ammonia concentrations downstream of the SRWTP discharge (i.e., downstream of Freeport) under Alternative 4A and the No Action Alternative (ELT) to assess the effects of the flow changes. Monthly average CALSIM II flows at Freeport and the upstream ammonia concentration (0.04 mg/L-N; Central Valley Water Board 2010a:5) were used, together with the SRWTP permitted average dry weather flow (181 mgd) and seasonal ammonia limitations (1.5 mg/L-N in Apr–Oct, 2.4 mg/L-N in Nov–Mar), to estimate the average change in ammonia concentrations downstream of the SRWTP. Table 4.3.4-1 shows monthly average and long-term annual average predicted concentrations under the H3 and H4 operations scenarios. As

Table 4.3.4-1 shows, average monthly ammonia concentrations in the Sacramento River downstream of Freeport (upon full mixing of the SRWTP discharge with river water) under Alternative 4A and the No Action Alternative (ELT) are expected to be similar. In comparison to the No Action Alternative (ELT), minor increases in monthly average ammonia concentrations would occur during January through March, July through September, and during November for both operations scenarios (H3 and H4). Minor decreases in ammonia concentrations are expected for scenarios H3 and H4 in April and May. A minor increase in the annual average concentration would occur under Alternative 4A, compared to the No Action Alternative (ELT). Relative to the No Action Alternative (LLT), Alternative 4A is expected to result in similar minor increases in Sacramento River ammonia concentration, because the increased water demands, climate change, and sea level rise in the LLT would occur under both alternatives, and neither would affect ammonia sources or loading. The estimated ammonia concentrations in the Sacramento River downstream of Freeport under Alternative 4A would be similar to existing source water concentrations for the San Francisco Bay and San Joaquin River. Consequently, changes in source water fraction anticipated under Alternative 4A, relative to the No Action Alternative (ELT and LLT), are not expected to substantially increase ammonia concentrations at any Delta locations.

Ammonia concentrations downstream of Freeport in the Sacramento River under Alternative 4A would be similar to those under Alternative 4 (see Table 8-67 in Appendix A of the RDEIR/SDEIS). As stated for Alternative 4, any negligible increases in ammonia concentrations that could occur at certain locations in the Delta under Alternative 4A would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the water quality at these locations, with regard to ammonia.

Table 4.3.4-1. Estimated Ammonia (mg/L as N) Concentrations in the Sacramento River Downstream of the Sacramento Regional Wastewater Treatment Plant for the No Action Alternative Early Long-term (ELT) and Alternative 4A

	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Annual Average
No Action Alternative (ELT)	0.076	0.082	0.068	0.060	0.057	0.060	0.058	0.062	0.067	0.060	0.067	0.063	0.065
Alternative 4A, Scenario H3	0.076	0.086	0.068	0.061	0.058	0.061	0.057	0.060	0.067	0.063	0.071	0.075	0.067
Alternative 4A, Scenario H4	0.076	0.086	0.068	0.061	0.058	0.061	0.057	0.060	0.067	0.063	0.071	0.066	0.066

SWP/CVP Export Service Areas

As discussed above, for areas of the Delta that are influenced by Sacramento River water, including Banks and Jones pumping plants, ammonia-N concentrations are expected to decrease under Alternative 4A, relative to Existing Conditions (in association with less diversion of water influenced by the SRWTP). Like Alternative 4, this decrease in ammonia-N concentrations for water exported via the south Delta pumps is not expected to result in an adverse effect on beneficial uses or substantially degrade water quality of exported water, with regard to ammonia. Furthermore, as discussed above, for all areas of the Delta, including Banks and Jones pumping plants, ammonia concentrations are not expected to be substantially different under Alternative 4A relative to the No Action Alternative (ELT and LLT). Thus, any negligible increases in ammonia concentrations that could occur at Banks and Jones pumping plants would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade water quality at these locations, with regard to ammonia.

NEPA Effects: In summary, ammonia concentrations in water bodies upstream of the Delta, in the Plan Area, and the waters exported to the SWP/CVP Export Service Areas are not expected to be substantially different under Alternative 4A relative to the No Action Alternative (ELT and LLT). Thus, effects of the water conveyance facilities on ammonia are considered to be not adverse.

CEQA Conclusion: The magnitude and direction of changes in ammonia concentrations in water bodies upstream of the Delta, in the Plan Area, or the waters exported to the SWP/CVP Export Service Areas would be approximately the same as expected under Alternative 4, relative to Existing Conditions. There would be no substantial, long-term increase in ammonia concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the waters exported to the CVP and SWP service areas under Alternative 4A relative to Existing Conditions. As such, Alternative 4A is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because ammonia concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects on beneficial uses would occur. Ammonia is not CWA Section 303(d) listed within the affected environment and thus any minor increases that could occur in some areas would not make any existing ammonia-related impairment measurably worse because no such impairments currently exist. Because ammonia is not bioaccumulative, minor increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-2: Effects on Ammonia Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Some habitat restoration activities included in Environmental Commitments 3, 4, and 6–11 would occur on lands in the Delta formerly used for irrigated agriculture. Although this may decrease ammonia loading to the Delta from agriculture, increased biota in those areas as a result of restored habitat may increase ammonia loading originating from flora and fauna. Ammonia loaded from organisms is expected to be converted rapidly to nitrate by established microbial communities. Thus, these land use changes would not be expected to substantially increase ammonia concentrations in the Delta. Implementation of Environmental Commitments 12, 15, and 16 do not include actions that would affect ammonia sources or loading. Based on these findings, the effects on ammonia from the implementation Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 4A are determined to not be adverse.

***CEQA Conclusion*:** Land use changes that would occur from the environmental commitments are not expected to substantially increase ammonia concentrations, because the amount of area to be converted would be small relative to existing habitat, and any resulting ammonia would likely be rapidly converted to nitrate. Thus, it is expected there would be no substantial, long-term increase in ammonia concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the waters exported to the SWP/CVP Export Service Areas due to implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 relative to Existing Conditions. As such, implementation of these environmental commitments would not be expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. Because ammonia concentrations would not be expected to increase substantially from implementation of these environmental commitments, no long-term water quality degradation would be expected to occur and, thus, no significant impact on beneficial uses would occur. Ammonia is not CWA Section 303(d) listed within the affected environment and thus any minor increases that could occur in some areas would not make any existing ammonia-related impairment measurably worse because no such impairments currently exist. Because ammonia is not bioaccumulative, minor increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered less than significant. No mitigation is required.

Impact WQ-3: Effects on Boron Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), under Alternative 4A there would be no expected change to the sources of boron in the Sacramento River and east-side tributary watersheds and, thus, resultant changes in flows from altered system-wide operations would have negligible, if any, effects on the concentration of boron in the rivers and reservoirs of these watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease by 1%, relative to Existing Conditions (in association with the different operational components of Alternative 4A in the ELT, climate change, and increased water demands) (Table Bo-1 in Appendix B of this RDEIR/SDEIS). The reduced flow relative to Existing Conditions would result in possible increases in long-term average boron concentrations of up to about 0.5% relative to the Existing Conditions. Flows would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial boron increases relative to the No Action Alternative (ELT). The increased boron concentrations, relative to Existing Conditions, under Alternative 4A in the ELT would not increase the frequency of exceedances of any applicable objectives or criteria and would not be expected to cause further degradation at measurable levels in the lower San Joaquin River, and thus would not cause the existing impairment there to be discernibly worse. Consequently, Alternative 4A in the ELT would not be expected to cause exceedance of boron objectives/criteria or substantially degrade water quality with respect to boron, and thus would not adversely affect any beneficial uses of the Sacramento River, the east-side tributaries, associated reservoirs upstream of the Delta, or the San Joaquin River.

Effects of Alternative 4A in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect boron sources in these areas.

Delta

Effects of water conveyance facilities on boron under Alternative 4A in the Delta would be similar to the effects discussed for Alternative 4. To the extent that habitat restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. However, there would be less potential for increased boron concentrations at western Delta locations associated with restoration environmental commitments under Alternative

4A because very little would occur relative to Alternative 4. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-4. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

The effects of Alternative 4A relative to Existing Conditions and the No Action Alternative (ELT) are discussed together because the direction and magnitude of predicted change are similar. Relative to the Existing Conditions and No Action Alternative (ELT), Alternative 4A would result in increased long-term average boron concentrations for the 16-year period modeled at most of the interior Delta locations (increases up to 8% at the S. Fork Mokelumne River at Staten Island, 11% at Franks Tract, and 15% at Old River at Rock Slough) (Tables Bo-4 and Bo-5 in Appendix B of this RDEIR/SDEIS). The long-term average boron concentrations at most of the western Delta assessment locations would not change measurably. The long-term annual average and monthly average boron concentrations, for either the 16-year period or drought period modeled, would never exceed the 2,000 μg/L human health advisory objective (i.e., for children) or the 500 μg/L agricultural objective at the majority of assessment locations, which represents no change from the Existing Conditions and No Action Alternative (ELT) (Table Bo-3 in Appendix B of this RDEIR/SDEIS). A small increase in the frequency of exceedances 500 μg/L agricultural objective at the Sacramento River at Mallard Island (i.e., as much as 7% in the drought period relative to the No Action Alternative [ELT]) would not be anticipated to substantially affect agricultural diversions which occur primarily at interior Delta locations. Minor reductions in long-term average assimilative capacity of up to 9% at interior Delta locations (i.e., Old River at Rock Slough) would occur with respect to the 500 μg/L agricultural objective (Tables Bo-6 and Bo-7 in Appendix B of this RDEIR/SDEIS). However, because the absolute boron concentrations would still be well below the lowest 500 μg/L objective for the protection of the agricultural beneficial use under Alternative 4A, the levels of boron degradation would not be of sufficient magnitude to substantially increase the risk of exceeding objectives or cause adverse effects to municipal and agricultural water supply beneficial uses, or any other beneficial uses, in the Delta (Figure Bo-1 in Appendix B of this RDEIR/SDEIS).

Effects of Alternative 4A in the Delta in the LLT, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to those described above for the ELT. Boron concentrations may be higher at western Delta locations due to greater effects of climate change on sea level rise that would occur in the LLT; however, these effects are independent of the alternative. Further, boron is of concern in waters diverted for agricultural use, which primarily occurs in the interior Delta, and based on Delta source water characteristics (see Table 8-42 in Appendix A of the RDEIR/SDEIS), boron concentrations in the interior Delta would be expected to remain suitable for agricultural use.

SWP/CVP Export Service Areas

Under the Alternative 4A, long-term average boron concentrations would decrease at the Banks pumping plant (as much as 25%) and at Jones pumping plant (as much as 22%) relative to Existing Conditions, and the reductions would be similar compared to No Action Alternative (ELT) (Tables Bo-4 and Bo-5 in Appendix B of this RDEIR/SDEIS) as a result of export of a greater proportion of low-boron Sacramento River water. Commensurate with the decrease in exported boron concentrations, boron concentrations in the lower San Joaquin River may be reduced and would likely alleviate or lessen any expected increase in boron concentrations at Vernalis associated with flow reductions (see discussion of Upstream of the Delta), as well as locations in the Delta receiving a large fraction of San Joaquin River water. Reduced export boron concentrations also may contribute to reducing the existing CWA Section 303(d) impairment in the lower San Joaquin River and associated TMDL actions for reducing boron loading. These same effects on boron at the Banks and Jones pumping plants would be expected in the LLT, because the primary effect of climate change on sea level rise and boron concentrations is expected in the western Delta.

Maintenance of SWP and CVP facilities under Alternative 4A would not be expected to create new sources of boron or contribute towards a substantial change in existing sources of boron in the affected environment.

NEPA Effects: In summary, relative to the No Action Alternative (ELT and LLT), Alternative 4A would result in relatively small increases in long-term average boron concentrations in the Delta, not measurably increase boron levels in the lower San Joaquin River, and reduce boron levels in water exported to the SWP/CVP export service areas. However, the predicted changes would not be expected to cause exceedances of applicable objectives or further measurable water quality degradation, and thus would not constitute an adverse effect on water quality.

CEQA Conclusion: Based on the above assessment, any modified reservoir operations and subsequent changes in river flows under Alternative 4A, relative to Existing Conditions, would not be expected to result in a substantial adverse change in boron levels upstream of the Delta. Small increases in boron levels predicted for interior Delta locations in response to a shift in the Delta source water percentages would not be expected to cause exceedances of objectives, or substantial degradation of these water bodies. Alternative 4A maintenance also would not result in any substantial increases in boron concentrations in the affected environment. Boron concentrations would be reduced in water exported from the Delta to the CVP/SWP Export Service Areas, thus reflecting a potential improvement to boron loading in the lower San Joaquin River.

Boron is not a bioaccumulative constituent, thus any increased concentrations under Alternative 4A would not result in adverse boron bioaccumulation effects to aquatic life or humans. Relative to Existing Conditions, Alternative 4A would not result in substantially increased boron concentrations such that frequency of exceedances of municipal and agricultural water supply objectives would increase. The levels of boron degradation that may occur under Alternative 4 would not be of sufficient magnitude to cause substantially increased risk for adverse effects to municipal or agricultural beneficial uses within the affected environment. Long-term average boron concentrations would decrease in Delta water exports to the SWP and CVP service area, which may contribute to reducing the existing CWA Section 303(d) impairment of agricultural beneficial uses in the lower San Joaquin River. Based on these findings, this impact is determined to be less than significant. No mitigation is required.

Impact WQ-4: Effects on Boron Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: The implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 for Alternative 4A present no new direct sources of boron to the affected environment, including areas upstream of the Delta, within the Delta region, and in the SWP/CVP Export Service Areas. Habitat restoration activities in the Delta, while involving increased land and water interaction within these habitats, would not be anticipated to contribute boron which is primarily associated with source water inflows to the Delta (i.e., San Joaquin River, agricultural drainage, and Bay source water). Moreover, some habitat restoration would occur on lands within the Delta currently used for irrigated agriculture, thus replacing agricultural land uses with restored habitats. The potential reduction in irrigated lands within the Delta may result in reduced discharges of agricultural field drainage with elevated boron concentrations, which would be considered an improvement compared to the No Action Alternative (ELT and LLT). Consequently, as they pertain to boron, implementation of the environmental commitments would not be expected to adversely affect any of the beneficial uses of the affected environment.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 for Alternative 4A would not present new or substantially changed sources of boron to the affected environment upstream of the Delta, within Delta, or in the SWP/CVP Export Service Areas. As such, their implementation would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or other criteria would be exceeded in water bodies of the affected environment located upstream of the Delta, within the Delta, or in the SWP/CVP Export Service Areas or substantially degrade the quality of these water bodies, with regard to boron. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-5: Effects on Bromide Concentrations Resulting from Facilities Operations and Maintenance Upstream of the Delta

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), under Alternative 4A in the ELT there would be no expected change to the sources of bromide in the Sacramento River and east-side tributary watersheds. Thus, changes in the magnitude and timing of reservoir releases north and east of the Delta would have negligible, if any, effect on the sources, and ultimately the concentration of bromide in the Sacramento River, the eastside tributaries, and the various reservoirs of the related watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly (1%) compared to Existing Conditions and would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial bromide increases. Moreover, there are no existing municipal intakes on the lower San Joaquin River, which is the beneficial use most sensitive to elevated bromide concentrations. Consequently, Alternative 4A in the ELT would not be expected to adversely affect the MUN beneficial use, or any other beneficial uses, of the Sacramento River, the San Joaquin River, the eastside tributaries, or their associated reservoirs upstream of the Delta due to changes in bromide concentrations.

Effects of Alternative 4A in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect bromide sources in these areas.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-6. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the modeling methodology.

Estimates of bromide concentrations at Delta assessment locations were generated using a mass balance approach, and using relationships between EC and chloride and between chloride and bromide and DSM2 EC output. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding these modeling approaches. The assessment below identifies changes in bromide at Delta assessment locations based on both approaches.

Based on the mass balance modeling approach for bromide, relative to Existing Conditions, Alternative 4A long-term average bromide concentrations would increase in the S. Fork Mokelumne River at Staten Island, and decrease at all other assessment locations (Table Br-1 in Appendix B of this RDEIR/SDEIS). Average bromide concentrations at Staten Island would increase from 50 µg/L under Existing Conditions to 63–64 µg/L (26–28% increase depending on operations scenario) for the modeled 16-year hydrologic period (1976–1991). However, multiple interior and western Delta assessment locations would have an increased frequency of exceedance of 50 µg/L, which is the CALFED Drinking Water Program goal for bromide as a long-term average applied to drinking water intakes (Table Br-1 in Appendix B of this RDEIR/SDEIS). These locations are the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. The greatest increase in frequency of exceedance of the CALFED Drinking Water Program long-term goal of 50 µg/L would occur in the S. Fork Mokelumne River (24–25% increase depending on operations scenario) and Sacramento River at Emmaton (2–4% increase depending on operations scenario). The increase in frequency of exceedance of the 50 µg/L threshold at the other locations would be 2% or less. Similarly, these locations would have an increased frequency of exceedance of 100 µg/L, which is the concentration believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts (Table Br-1 in Appendix B of this RDEIR/SDEIS). The greatest increase in frequency of exceedance of 100 µg/L would occur at Franks Tract (6% increase) and San Joaquin River at Antioch (4–5% increase depending on operations scenario). The increase in frequency of exceedance of the 100 µg/L threshold at the other locations would be 3% or less.

Changes in long-term average bromide concentrations and changes in threshold exceedance frequencies relative to the No Action Alternative (ELT) are generally of similar magnitude to those previously described relative to Existing Conditions (Table Br-1 in Appendix B of this RDEIR/SDEIS). However, unlike the Existing Conditions comparison, relative to the No Action Alternative (ELT), long-term average bromide concentrations at Buckley Cove would increase under Alternative 4A, although the increases would be relatively small (<1%).

Results of the modeling approach which used relationships between EC and chloride and between chloride and bromide were consistent with the discussion above, and assessment of bromide using these modeling results leads to the same conclusions as are presented above for the mass balance approach (Tables Br-2 in Appendix B of this RDEIR/SDEIS).

Unlike Alternative 4, there would be no increased bromide concentration or frequency of exceedance of bromide thresholds in Barker Slough at the North Bay Aqueduct under Alternative 4A relative to Existing Conditions and the No Action Alternative (ELT). Also, the magnitude of bromide concentration increases at Mallard Slough and in the San Joaquin River at Antioch during their historical months of use, relative to Existing Conditions and the No Action Alternative (ELT) would be generally similar to those described for Alternative 4 (Tables Br-5 and Br-6 in Appendix B of this RDEIR/SDEIS), and the frequency of exceedance of bromide thresholds would be similar (Tables Br-3 and Br-4 in Appendix B of this RDEIR/SDEIS). As described for Alternative 4, the use of seasonal intakes at these locations is largely driven by acceptable water quality, and thus has historically been opportunistic. Opportunity to use these intakes would remain, and the predicted increases in bromide concentrations at Antioch and Mallard Slough would not be expected to adversely affect MUN beneficial uses, or any other beneficial use, at these locations.

The effects of Alternative 4A in the LLT in the Delta region, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to that described above. There may be higher bromide concentrations in the LLT in the western Delta, but this would be associated with sea level rise, not the project alternative, because the primary source of bromide to the Delta is sea water intrusion.

SWP/CVP Export Service Areas

Under Alternative 4A, long-term average bromide concentrations at the Banks and Jones pumping plants, based on the mass balance modeling approach, would decrease. Long-term average bromide concentrations for the modeled 16-year hydrologic period at the pumping plants would decrease by as much as 48% relative to Existing Conditions and 44% relative to the No Action Alternative (ELT) (Table Br-1 in Appendix B of this RDEIR/SDEIS). As a result, less frequent exceedances of the 50 μg/L and 100 μg/L assessment thresholds would occur and an overall improvement in SWP/CVP Export Service Areas water quality would occur respective to bromide. Commensurate with the decrease in exported bromide, an improvement in lower San Joaquin River bromide would also occur since bromide in the lower San Joaquin River is principally related to irrigation water deliveries from the Delta. Results of the modeling approach which used relationships between EC and chloride and between chloride and bromide are consistent with the mass balance results, and assessment of bromide using these modeling results leads to the same conclusions as are presented for the mass balance approach (Table Br-2 in Appendix B of this RDEIR/SDEIS).

The effects of Alternative 4A in the LLT in the SWP/CVP Export Service Areas, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to that described above, because the sea level rise that could occur in the LLT would not be expected to result in substantial bromide contributions to the water exported at Banks and Jones pumping plants.

Maintenance of SWP and CVP facilities under Alternative 4A would not be expected to create new sources of bromide or contribute towards a substantial change in existing sources of bromide in the affected environment. Maintenance activities would not be expected to cause any substantial change in bromide such that MUN beneficial uses, or any other beneficial use, would be adversely affected anywhere in the affected environment.

***NEPA Effects*:** In summary, the operations and maintenance activities under Alternative 4A, relative to the No Action Alternative (ELT and LLT) would result in an increased frequency of exceedance of the 50 μg/L and 100 μg/L bromide thresholds for protecting against the formation of disinfection byproducts in treated drinking water at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. However, long-term average bromide concentrations would increase only in the S. Fork Mokelumne River at Staten Island and San Joaquin River at Buckley Cove; there would be decreases in long-term average bromide concentrations at the other assessment locations. The long-term bromide concentration in the S. Fork Mokelumne River at Staten Island would be less than the concentration believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts, and the increase in the San Joaquin River at Buckley Cove would be minimal (<1%). Thus, these increased bromide concentrations are not expected to result in adverse affects to MUN beneficial uses, or any other beneficial use, at these locations. Based on these findings, this effect is determined to not be adverse.

CEQA Conclusion: While greater water demands under Alternative 4A would alter the magnitude and timing of reservoir releases north and east of the Delta, these activities would have negligible, if any, effect on the sources of bromide, and ultimately the concentration of bromide in the Sacramento River, the San Joaquin River, the eastside tributaries, and the various reservoirs of the related watersheds, as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS).

Under Alternative 4A there would be an increased frequency of exceedance of the 50 µg/L and 100 µg/L bromide thresholds for protecting against the formation of disinfection byproducts in treated drinking water at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. However, long-term average bromide concentrations would increase only in the S. Fork Mokelumne River at Staten Island and decrease at all other assessment locations. The long-term bromide concentration in the S. Fork Mokelumne River at Staten Island (63–64 µg/L) would be less than the 100 µg/L believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts. Further, as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), the use of seasonal intakes at Antioch and Mallard Island is largely driven by acceptable water quality, and thus has historically been opportunistic and opportunity to use these intakes would remain. Thus, these increased bromide concentrations would not be expected to adversely affect MUN beneficial uses, or any other beneficial use, at these locations.

The assessment of effects on bromide in the SWP/CVP Export Service Areas is based on assessment of changes in bromide concentrations at Banks and Jones pumping plants. Long-term average bromide concentrations at the Banks and Jones pumping plants are predicted to decrease by as much as 48% relative to Existing Conditions and there would be less frequent exceedance of bromide concentration thresholds.

Based on the above, Alternative 4A would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria because none exist for bromide. Alternative 4A would not result in any substantial change in long-term average bromide concentration or exceed 50 and 100 µg/L assessment threshold concentrations by frequency, magnitude, and geographic extent that would result in adverse effects on any beneficial uses within affected water bodies. Bromide is not a bioaccumulative constituent and thus concentrations under this alternative would not result in bromide bioaccumulating in aquatic organisms. Increases in exceedances of the 100 µg/L assessment threshold concentration would be 6% or less at all locations assessed, which is considered to be less than substantial long-term degradation of water quality. The levels of bromide degradation that may occur under the Alternative 4A would not be of sufficient magnitude to cause substantially increased risk for adverse effects on any beneficial uses of water bodies within the affected environment. Bromide is not CWA Section 303(d) listed and thus the minor increases in long-term average bromide concentrations would not affect existing beneficial use impairment because no such use impairment currently exists for bromide. Based on these findings, this impact is less than significant. No mitigation is required.

Impact WQ-6: Effects on Bromide Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would present no new sources of bromide to the affected environment, including areas Upstream of the Delta, within the Plan Area, and the SWP/CVP Export Service Areas. Some habitat restoration activities would occur on lands in the Delta formerly used for irrigated agriculture. Such replacement or substitution of land use activity would not be expected to result in new or increased sources of bromide to the Delta. Therefore, as they pertain to bromide, implementation of these environmental commitments would not be expected to adversely affect MUN beneficial use, or any other beneficial uses, of the affected environment.

Environmental Commitment 4 would result in some tidal habitat restoration, however, the areal extent would be small relative to the existing and No Action Alternative tidal area and, thus not expected to appreciably affect the magnitude of daily tidal water exchange at the restoration areas or alter other hydrodynamic conditions in adjacent Delta channels that would result in measurable bromide concentration changes.

In summary, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 4A relative to the No Action Alternative (ELT and LLT), would have negligible, if any, effects on bromide concentrations. Therefore, the effects on bromide from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 4A would not present new or substantially changed sources of bromide to the affected environment. Some environmental commitments may replace or substitute for existing irrigated agriculture in the Delta. This replacement or substitution would not be expected to substantially increase or present new sources of bromide. Thus, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would have negligible, if any, effects on bromide concentrations throughout the affected environment, would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria because none exist for bromide, and would not cause changes in bromide concentrations that would result in significant impacts on any beneficial uses within affected water bodies. Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause significant long-term water quality degradation such that there would be greater risk of significant impacts on beneficial uses, would not cause greater bioaccumulation of bromide, and would not further impair any beneficial uses due to bromide concentrations because no uses are currently impaired due to bromide levels. Based on these findings, this impact is considered less than significant. No mitigation is required.

Impact WQ-7: Effects on Chloride Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 4A on chloride concentrations in reservoirs and rivers upstream of the Delta would be the similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). Chloride loading in these watersheds would remain unchanged and resultant changes in flows from altered system-wide operations would have negligible, if any, effects on the concentration of chloride in the rivers and reservoirs of these watersheds. There would be no expected change to the sources of chloride in the Sacramento River and east-side tributary watersheds, and changes in the magnitude and timing of reservoir releases north and east of the Delta would have negligible, if any, effect on the sources, and ultimately the concentration of chloride in the Sacramento River, the eastside tributaries, and the various reservoirs of the related watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly (1%) compared to Existing Conditions and would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial chloride increases. Moreover, there are no existing municipal intakes on the lower San Joaquin River. Consequently, Alternative 4A in the ELT would not be expected to cause exceedances of chloride objectives/criteria or substantially degrade water quality with respect to chloride, and thus would not adversely affect any beneficial uses of the Sacramento River, the eastside tributaries, associated reservoirs upstream of the Delta, or the San Joaquin River.

Effects of Alternative 4A in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect chloride sources in these areas.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 4A would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-8. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Estimates of chloride concentrations at Delta assessment locations were generated using a mass balance approach and EC-chloride relationships and DSM2 EC output. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding these modeling approaches. The assessment below identifies changes in chloride at Delta assessment locations based on both approaches.

Modeling of chloride using both the mass balance approach and EC-chloride relationship predicts that Alternative 4A in the ELT would result in similar or reduced long-term average chloride concentrations, relative to Existing Conditions, for the 16-year period modeled at all assessment locations except for the S. Fork Mokelumne River at Staten Island. The increase in long-term average chloride concentration at Staten Island would be 4 mg/L (25%) based on the mass balance modeling and 2 mg/L (9%) based on the EC-chloride relationship (Tables Cl-6 though Cl-9 in Appendix B of this RDEIR/SDEIS). These increases are extremely small in absolute terms and relative to applicable water quality objectives, and are within the estimated modeling uncertainty. The results differ from Alternative 4, under which there would be increased long-term average chloride concentrations also at the North Bay Aqueduct at Barker Slough. The change in long-term average chloride concentrations relative to the No Action Alternative (ELT) would be similar to those relative to Existing Conditions.

The following outlines the modeled chloride changes relative to the applicable objectives and beneficial uses of Delta waters.

Municipal Beneficial Uses Relative to Existing Conditions

Estimates of chloride concentrations generated using EC-chloride relationships were used to evaluate the 150 mg/L Bay-Delta WQCP objective for municipal and industrial beneficial uses on a basis of the percent of years the chloride objective is exceeded for the modeled 16-year period. The objective is exceeded if chloride concentrations exceed 150 mg/L for a specified number of days in a given water year at Antioch and Contra Costa Pumping Plant #1. For Alternative 4A, the modeled frequency of objective exceedance would decrease at the Contra Costa Pumping Plant #1 from 6.7% of years under Existing Conditions, to 0% of years under operations scenario H3 and H4 (Table Cl-1 in Appendix B of this RDEIR/SDEIS).

Evaluation of the 250 mg/L Bay-Delta WQCP objective for chloride utilized results from both the mass balance approach and EC-chloride relationship. The basis for the evaluation was the predicted number of days the objective would be exceeded for the modeled 16-year period.

Based on the mass balance approach, there would be a decreased frequency of exceedance of the 250 mg/L objective under Alternative 4A, relative to Existing Conditions, at all locations except in the Sacramento River at Mallard Island and the Sacramento River at Emmaton. In the Sacramento River at Mallard Island, the frequency of objective exceedance would increase from 85% under Existing Conditions to 86% under Alternative 4A for the entire period modeled under both operations scenarios (Table Cl-2 in Appendix B of this RDEIR/SDEIS). In the Sacramento River at Emmaton, there would be an increase in chloride objective exceedance during the drought period modeled, from 55% to 57% under operations scenario H3, although these changes are within the uncertainty of the modeling approach; there would be no increase in objective exceedances under operations scenario H4.

The mass balance results also indicate reduced assimilative capacity with respect to the 250 mg/L objective during certain months and at certain locations. In the San Joaquin River at Antioch, there would be a reduction in assimilative capacity in March and April of up to 18% for the 16-year period modeled, and 61% for the drought period modeled (Tables Cl-12 and Cl-14 in Appendix B of this RDEIR/SDEIS). Assimilative capacity at the Contra Costa Pumping Plant #1 also would be reduced, in February through June by up to 5% for the entire period modeled and 7% for the drought period modeled. These estimates include the effect of climate change and sea level rise, as well as the alternative. Comparisons to the No Action Alternative (ELT) below provide an assessment of the effect of the alternative alone.

When utilizing the EC-chloride relationship to model chloride concentrations for the 16-year period, trends in frequency of exceedance and use of assimilative capacity would be similar to that discussed when utilizing the mass balance modeling approach (Tables Cl-3, Cl-13, and Cl-15 in Appendix B of this RDEIR/SDEIS). However, the EC-chloride relationships predicted changes of lesser magnitude, where predictions of change utilizing the mass balance approach were generally of greater magnitude, and thus more conservative. As discussed in Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS, in cases of such disagreement, the approach that yielded the more conservative predictions was used as the basis for determining adverse impacts.

CWA Section 303(d) Listed Water Bodies–Relative to Existing Conditions

Tom Paine Slough in the southern Delta is on the state's CWA Section 303(d) list for chloride with respect to the secondary MCL of 250 mg/L. Monthly average chloride concentrations at the Old River at Tracy Road for the 16-year period modeled, which represents the nearest DSM2-modeled location to Tom Paine Slough, would be generally similar under Alternative 4A in the ELT relative to Existing Conditions, and thus, would not be further degraded on a long-term basis and Alternative 4A in the ELT would thus not make this impairment discernibly worse (Figure Cl-1 in Appendix B of this RDEIR/SDEIS).

Suisun Marsh also is on the state's CWA Section 303(d) list for chloride in association with the Bay-Delta WQCP objectives for maximum allowable salinity during the months of October through May, which establish appropriate seasonal salinity conditions for fish and wildlife beneficial uses. With respect to Suisun Marsh the monthly average chloride concentrations for the 16-year period modeled would generally increase under Alternative 4A in the ELT relative to Existing Conditions in March through May at the Sacramento River at Mallard Island (Figure Cl-2 in Appendix B of this RDEIR/SDEIS) and at Collinsville (Figure Cl-3 in Appendix B of this RDEIR/SDEIS), and increase substantially in October through May at Montezuma Slough at Beldon's Landing (i.e., over a doubling of concentration in December through February) (Figure Cl-4 in Appendix B of this RDEIR/SDEIS). However, modeling of Alternative 4A assumed no operation of the Montezuma Slough Salinity Control Gates, but the project description assumes continued operation of the Salinity Control Gates, consistent with assumptions included in the No Action Alternative. A sensitivity analysis modeling run conducted for Alternative 4 scenario H3 at the LLT with the gates operational consistent with the No Action Alternative resulted in substantially lower EC levels than indicated in the original Alternative 4 modeling results for Suisun Marsh, but EC levels were still somewhat higher than EC levels under Existing Conditions for several locations and months. Although chloride was not specifically modeled in these sensitivity analyses, it is expected that chloride concentrations would be nearly proportional to EC levels in Suisun Marsh. Additionally, although these analyses were only conducted at the LLT, they are expected to generally also apply to the ELT. Another modeling run with the gates operational and restoration areas removed resulted in EC levels nearly equivalent to Existing Conditions (see Appendix 8H Attachment 1 in Appendix A of the RDEIR/SDEIS for more information on these sensitivity analyses). Since Alternative 4A in the ELT includes operation of the gates, and includes very little tidal restoration area, it is anticipated that chloride increases in Suisun Marsh predicted via the modeling would not occur, and that chloride in Suisun Marsh under Alternative 4A in the ELT would be very similar to Existing Conditions. For these reasons, any changes in chloride in Suisun Marsh are expected to have no adverse effect on marsh beneficial uses.

Municipal Beneficial Uses Relative to No Action Alternative (ELT)

Similar to the assessment conducted for Existing Conditions, estimates of chloride concentrations generated from EC-chloride relationships were used to evaluate the 150 mg/L Bay-Delta WQCP objective for municipal and industrial beneficial uses. For Alternative 4A in the ELT, the modeled frequency of objective exceedance would not change at the Contra Costa Pumping Plant #1--the No Action Alternative (ELT) and Scenarios H3 and H4 all would have 0% exceedance (Table Cl-1 in Appendix B of this RDEIR/SDEIS).

Based on the mass balance approach, the frequency of exceedance of the 250 mg/L objective under Alternative 4A in the ELT would be the same, or would decrease, at all locations relative to the No Action Alternative (ELT) (Table Cl-2 in Appendix B of this RDEIR/SDEIS). Estimates of long-term use of assimilative capacity using the mass balance results indicated the potential for reduced assimilative capacity with respect to the 250 mg/L objective for certain months and locations. Calculations using the long-term monthly average concentrations showed that in the San Joaquin River at Antioch, there would be a reduction in assimilative capacity in April of 2% for the entire period modeled and 32% for the drought period modeled under operations scenario H3, but an increase in assimilative capacity under operations scenario H4 for both the entire period modeled and the drought period (Tables Cl-12 and Cl-14 in Appendix B of this RDEIR/SDEIS). The same approach showed that assimilative capacity at the Contra Costa Pumping Plant #1 also would be reduced in March through June, by up to 5%, and in October by up to 21% for the entire period modeled. During the drought period modeled, there would be similar reductions of assimilative capacity in April through June by up to 3% and a reduction in assimilative capacity of up to 88% in September (Tables Cl-12 and Cl-14 in Appendix B of this RDEIR/SDEIS). However, this approach used long-term average chloride concentrations, which can be heavily influenced by changes in a small number of years when chloride concentrations would already be very high. Additionally, when long term averages are just below the objective, very small changes in chloride that are within the modeling uncertainty can result in very high estimates of use of assimilative capacity. To further investigate the potential for water quality degradation with respect to chloride, the concentrations of chloride during individual water years was examined.

This further examination was limited to the mass balance approach, since when utilizing the EC-chloride relationship to model monthly average chloride concentrations for the 16-year period, trends in frequency of exceedance and use of assimilative capacity were similar to that discussed for the mass balance modeling approach (Tables Cl-3, Cl-13, and Cl-15 in Appendix B of this RDEIR/SDEIS). However, utilizing the EC-chloride relationships predicted changes of lesser magnitude, where predictions of change utilizing the mass balance approach were generally of greater magnitude, and thus more conservative. As discussed in Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS, in cases of such disagreement, the approach that yielded the more conservative predictions was used as the basis for determining adverse impacts.

Figure Cl-9 shows chloride concentrations in April during the five-year drought period (1987–1991) at Antioch, where Tables Cl-12 and Cl-14 in Appendix B of this RDEIR/SDEIS indicated up to 32% use of assimilative capacity. The figure shows that during three of the five years, chloride concentrations increased relative to the No Action Alternative (ELT) and decreased in the other two years. The absolute differences estimated are fairly small and may be within modeling uncertainty. Figures Cl-10 and Cl-11 show a box and whisker plot and exceedance plot for April at Antioch for all dry and critical water years modeled (not just the 1987–1991 drought period). These graphs show that while the median chloride concentration is slightly increased relative to the No Action Alternative (ELT) under both scenarios, the maximums, 25th percentile, and 75th percentile values are all decreased. Based on this analysis, long-term degradation is not expected at Antioch in April during drought years.

Figure Cl-12 shows chloride levels in September at Contra Costa Pumping Plant #1 during the drought period (1987–1991), where Tables Cl-12 and Cl-14 in Appendix B of this RDEIR/SDEIS indicated 88% use of assimilative capacity. In general, changes in chloride concentrations relative to the No Action Alternative (ELT) are fairly small, and may be within modeling uncertainty. Figures Cl-13 and Cl-14 show a box and whisker plot and exceedance plot for September at Contra Costa Pumping Plant #1 for all dry and critical water years modeled (not just the 1987–1991 drought period). These graphs show that the median chloride concentration is slightly decreased relative to the No Action Alternative (ELT) under both scenarios, and chloride concentrations are generally similar to the No Action Alternative (ELT) throughout the range seen. The 88% use of assimilative capacity was shown because long term averages were just below the criterion, so a very small increase in chloride (that is probably within the modeling uncertainty) resulted in a very high estimate of use of assimilative capacity. Similar results are shown in Figure Cl-15, Cl-16, and Cl-17 for October at Contra Costa Pumping Plant #1. Median concentrations decreased slightly, and the exceedance plot shows generally similar concentrations throughout the range seen. Figure Cl-15 shows that while some years see increased concentrations (e.g., 1978, 1989), other years see decreased concentrations (e.g., 1980, 1982). Based on this analysis, long-term degradation is not expected at Contra Costa Pumping Plant #1 in September during drought years, or October on a long-term average basis.

Furthermore, sensitivity analyses conducted of Alternative 4 Scenario H3 without restoration areas indicated lower chloride levels in the western Delta than with the restoration areas. It is thus likely that modeling of Alternative 4A that does not include restoration areas would show lower levels of chloride at Antioch in April, and at Contra Costa Pumping Plant #1 in September and October than is shown herein using the Alternative 4 (ELT) modeling.

Based on the low level of water quality degradation estimated for the western Delta, and the lack of exceedance of water quality objectives, Alternative 4A is not expected to have substantial adverse effects on municipal and industrial beneficial uses in the western Delta.

CWA Section 303(d) Listed Water Bodies–Relative to No Action Alternative (ELT)

With respect to the state's CWA Section 303(d) listing for chloride, Alternative 4A would generally result in similar changes to those discussed for the comparison to Existing Conditions. Monthly average chloride concentrations at Tom Paine Slough would not be further degraded on a long-term basis, based on changes that would occur in Old River at Tracy Road (Figure Cl-1 in Appendix B of this RDEIR/SDEIS). Modeling indicated that monthly average chloride concentrations at source water channel locations for the Suisun Marsh would increase substantially in some months during October through May relative to the No Action Alternative (ELT) (Figures Cl-2, Cl-3, and Cl-4 in Appendix B of this RDEIR/SDEIS), but the results of sensitivity analyses performed indicate that chloride increases in Suisun Marsh predicted via the modeling would not occur, and that chloride in Suisun Marsh under Alternative 4A in the ELT would be very similar to the No Action Alternative (ELT). Depending on where tidal restoration areas assumed to be included in the No Action Alternative are located, chloride concentrations under Alternative 4A could be less than under the No Action Alternative (ELT). For these reasons, any changes in chloride in Suisun Marsh are expected to have no adverse effect on marsh beneficial uses.

The effects of Alternative 4A in the LLT in the Delta region, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to effects in the ELT. With greater climate change and sea level rise, additional outflow may be required at certain times to prevent increases in chloride in the west Delta. Small increases in chloride concentrations may occur in some areas, but it is not expected that these increases would cause exceedance of Bay-Delta WQCP objectives of cause substantial long-term degradation that would impact municipal and industrial beneficial uses.

SWP/CVP Export Service Areas

Under Alternative 4A in the ELT, long-term average chloride concentrations at the Banks and Jones pumping plants, based on the mass balance analysis of modeling results for the 16-year period, would decrease relative to Existing Conditions. Chloride concentrations would be reduced by 42–47% at Banks pumping plant, depending on operations scenario (Tables Cl-6 and Cl-8 in Appendix B of this RDEIR/SDEIS). At Jones pumping plant, chloride concentrations would be reduced 41–43%, depending on operations scenario (Tables Cl-6 and Cl-8 in Appendix B of this RDEIR/SDEIS). The frequency of exceedances of applicable water quality objectives would decrease relative to Existing

Conditions, for both the 16-year period and the drought period modeled (Table Cl-2 in Appendix B of this RDEIR/SDEIS). The chloride concentration changes relative to the No Action Alternative (ELT) would be similar. Consequently, water exported into the SWP/CVP Export Service Areas would generally be of similar or better quality with regard to chloride relative to Existing Conditions and the No Action Alternative (ELT). Results of the modeling approach which utilized a EC-chloride relationship are consistent these results, and assessment of chloride using these modeling output results in the same conclusions as for the mass balance approach (Tables Cl-3, Cl-7, and Cl-9 in Appendix B of this RDEIR/SDEIS).

Commensurate with the reduced chloride concentrations in water exported to the SWP/CVP Export Service Area, reduced chloride loading in the lower San Joaquin River would be anticipated which would likely reduce chloride concentrations at Vernalis.

The effects of Alternative 4A in the LLT in the SWP/CVP Export Service Areas, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be very similar to effects in the ELT.

Maintenance of SWP and CVP facilities would not be expected to create new sources of chloride or contribute towards a substantial change in existing sources of chloride in the affected environment. Maintenance activities would not be expected to cause any substantial change in chloride such that any long-term water quality degradation would occur, thus, beneficial uses would not be adversely affected anywhere in the affected environment.

***NEPA Effects*:** In summary, relative to the No Action Alternative (ELT and LLT), Alternative 4A would not result in substantially increased chloride concentrations upstream of the Delta, in the Delta, or in the SWP/CVP Export Service Area on a long-term average basis that would result in adverse effects on the municipal and industrial water supply beneficial use, or any other beneficial use. Additional exceedance of the 150 mg/L and 250 mg/L objectives is not expected, and substantial long-term degradation is not expected that would result in adverse effects on the municipal and industrial water supply beneficial use, or any other beneficial use. Based on these findings, this effect is determined to not be adverse.

***CEQA Conclusion*:** Chloride is not a constituent of concern in the Sacramento River watershed upstream of the Delta, thus river flow rate and reservoir storage reductions that would occur under Alternative 4A relative to Existing Conditions, would not be expected to result in a substantial adverse change in chloride levels. Additionally, relative to Existing Conditions, Alternative 4A would not result in reductions in river flow rates (i.e., less dilution) or increased chloride loading such that there would be any substantial increase in chloride concentrations upstream of the Delta in the San Joaquin River watershed.

Relative to Existing Conditions, Alternative 4A would not result in substantially increased chloride concentrations in the Delta on a long-term average basis that would result in adverse effects on the municipal and industrial water supply beneficial use. Additional exceedance of the 150 mg/L and 250 mg/L objectives is not expected, and substantial long-term degradation is not expected that would result in adverse effects on the municipal and industrial water supply beneficial use.

Chloride concentrations would be reduced under Alternative 4A in water exported from the Delta to the SWP/CVP Export Service Areas thus reflecting a potential improvement to chloride loading in the lower San Joaquin River.

Chloride is not a bioaccumulative constituent, thus any increased concentrations under the Alternative 4A would not result in substantial chloride bioaccumulation impacts on aquatic life or humans. Alternative 4A maintenance would not result in any substantial changes in chloride concentration upstream of the Delta or in the SWP/CVP Export Service Areas

Based on these findings, this impact is determined to be less than significant. No mitigation is required.

Impact WQ-8: Effects on Chloride Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects**:** The implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 4A would present no new direct sources of chloride to the affected environment, including areas Upstream of the Delta, within the Plan Area, and the SWP/CVP Export Service Areas. Consequently, as they pertain to chloride, implementation of these environmental commitments would not be expected to adversely affect any of the beneficial uses of the affected environment. Moreover, some habitat restoration activities would occur on lands within the Delta currently used for irrigated agriculture. The potential reduction in irrigated lands within the Delta may result in reduced discharges of agricultural field drainage with elevated chloride concentrations, which would be considered an improvement relative to the No Action Alternative (ELT and LLT). Therefore, the effects on chloride from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

CEQA Conclusion**:** Implementation of the Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 4A would not present new or substantially changed sources of chloride to the affected environment upstream of the Delta, within Delta, or in the SWP/CVP Export Service Areas. Replacement of irrigated agricultural land uses in the Delta with habitat restoration may result in some reduction in discharge of agricultural field drainage with elevated chloride concentrations, thus resulting in improved water quality conditions. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-9: Effects on Dissolved Oxygen Resulting from Facilities Operations and Maintenance

As described in detail for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), DO levels are primarily affected by water temperature, flow velocity, turbulence, amounts of oxygen demanding substances present (e.g., ammonia, organics), and rates of photosynthesis (which is influenced by nutrient levels), respiration, and decomposition. Water temperature and salinity affect the maximum DO saturation level (i.e., the highest amount of oxygen the water can dissolve). Flow velocity affects the turbulence and re-aeration of the water (i.e., the rate at which oxygen from the atmosphere can be dissolved in water). High nutrient content can support aquatic plant and algae growth, which in turn generates oxygen through photosynthesis and consumes oxygen through respiration and decomposition.

As described for Alternative 4, amounts of oxygen demanding substances present (e.g., ammonia, organics) in the reservoirs and rivers upstream of the Delta, rates of photosynthesis (which is influenced by nutrient levels/loading), and respiration and decomposition of aquatic life is not expected to change sufficiently under Alternative 4A to substantially alter DO levels relative to Existing Conditions or the No Action Alternative (ELT and LLT). Further, the rivers upstream of the Delta are well oxygenated and experience periods of supersaturation (i.e., when DO level exceeds the saturation concentration). Because these are large, turbulent rivers, any reduced DO saturation level that would be caused by an increase in temperature under Alternative 4A would not be expected to cause DO levels to be outside of the range seen historically. Flow changes that would occur under Alternative 4A would not be expected to have substantial effects on river DO levels; likely, the changes would be immeasurable. This is because sufficient turbulence and interaction of river water with the atmosphere would continue to occur to maintain water saturation levels (due to these factors) at levels similar to that of Existing Conditions and the No Action Alternative (ELT and LLT).

Also as described for Alternative 4, salinity changes would generally have relatively minor effects on Delta DO levels. Further, the relative degree of tidal exchange of flows and turbulence, which contributes to exposure of Delta waters to the atmosphere for reaeration, would not be expected to substantially change relative to Existing Conditions or the No Action Alternative (ELT and LLT), such that these factors would reduce Delta DO levels below objectives or levels that protect beneficial uses. Similarly, increased temperature under Alternative 4A would generally have relatively minor effects on Delta DO levels, relative to Existing Conditions.

Similar to Alternative 4, flows in the San Joaquin River at Stockton were evaluated, and are shown in Figure DO-1 in Appendix B of this RDEIR/SDEIS. The figure shows that while flows would change somewhat, they would generally be within the range of flows seen under Existing Conditions and the No Action Alternative. Reports indicate that the aeration facility performs adequately under the range of flows from 250-1,000 cfs (ICF International 2010). Based on the above, the expected changes in flows in the San Joaquin River at Stockton are not expected to substantially move the point of minimum DO, and therefore the aeration facility would likely still be located appropriately to keep DO levels above Basin Plan objectives. Overall, assuming continued operation of the aerators, the alternative is not expected to have a substantial adverse effect on DO in the Deep Water Ship Channel. It is expected that DO levels in the Deep Water Ship Channel, which is CWA Section 303(d) listed as impaired due to low DO, would remain similar to those under Existing Conditions and the No Action Alternative (ELT and LLT) or improve as TMDL-required studies are completed and actions are implemented to improve DO levels. DO levels in other Clean Water Act Section 303(d)-listed waterways would not be expected to change relative to Existing Conditions or the No Action Alternative (ELT and LLT), as the circulation of flows, tidal flow exchange, and re-aeration would continue to occur.

In the SWP/CVP Export Service Areas, the primary factor that would affect DO in the conveyance channels and ultimately the receiving reservoirs would be changes in the levels of nutrients and oxygen-demanding substances and DO levels in the exported water. As described above and for Alternative 4, exported water could potentially be warmer and have higher salinity relative to Existing Conditions and the No Action Alternative (ELT and LLT). Nevertheless, because the biochemical oxygen demand of the exported water would not be expected to substantially differ from that under Existing Conditions or the No Action Alternative (ELT and LLT) due to water quality regulations, canal turbulence, exposure of the water to the atmosphere, and the algal communities that exist within the canals that would establish an equilibrium for DO levels within the canals. The same would occur in downstream reservoirs.

NEPA Effects: Because DO levels are not expected to change substantially relative to the No Action Alternative (ELT and LLT), the effects on DO from implementing Alternative 4A are determined to not be adverse.

CEQA Conclusion: The effects of Alternative 4A on DO levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). Reservoir storage reductions that would occur under Alternative 4A, relative to Existing Conditions, would not be expected to result in a substantial adverse change in DO levels in the reservoirs, because oxygen sources (surface water aeration, aerated inflows, vertical mixing) would remain. Similarly, river flow rate reductions would not be expected to result in a substantial adverse change in DO levels in the rivers upstream of the Delta, given that mean monthly flows would remain within the ranges historically seen under Existing Conditions and the affected river are large and turbulent. Any reduced DO saturation level that may be caused by increased water temperature would not be expected to cause DO levels to be outside of the range seen historically. Finally, amounts of oxygen demanding substances and salinity would not be expected to change sufficiently to affect DO levels.

It is expected there would be no substantial change in Delta DO levels in response to a shift in the Delta source water percentages under this alternative or substantial degradation of these water bodies, with regard to DO. DO levels would be affected by nutrient loading, which the state regulates the discharges of, and this loading would not be expected to lower DO levels relative to Existing Conditions based on historical DO levels. Further, the anticipated changes in salinity would have relatively minor effects on DO levels, and tidal exchange, which contribute to the reaeration of Delta waters would not be expected to change substantially.

There is not expected to be substantial, if even measurable, changes in DO levels in the SWP/CVP Export Service Areas waters, relative to Existing Conditions, because the biochemical oxygen demand of the exported water would not be expected to substantially differ from that under Existing Conditions (due to water quality regulations), canal turbulence and exposure of the water to the atmosphere and the algal communities that exist within the canals that would establish an equilibrium for DO levels within the canals. The same would occur in downstream reservoirs.

Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would result in significant impacts on any beneficial uses within affected water bodies. Because no substantial changes in DO levels are expected, long-term water quality degradation would not be expected to occur, and, thus, beneficial uses would not be adversely affected. Various Delta waterways are CWA Section 303(d)-listed for low DO, but because no substantial decreases in DO levels would be expected, greater degradation and DO-related impairment of these areas would not be expected. Based on these findings, this impact would be less than significant. No mitigation is required.

Impact WQ-10: Effects on Dissolved Oxygen Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects**:** Environmental Commitments 3, 4, and 6–11 would involve habitat restoration actions. The increased habitat provided by these environmental commitments could contribute to an increased biochemical or sediment demand, through contribution of organic carbon and plants decaying, though the areal extent of the effects would be less than under Alternative 4, because less land would be converted under Alternative 4A. The areal extent of new habitat implemented for the Environmental Commitments would be small relative to the existing and No Action Alternative tidal area, and similar habitat exists currently in the Delta and is not identified as contributing to adverse DO conditions. Although additional DOC loading to the Delta may occur (see impact WQ-18), the amount expected would be minimal and only a fraction of the DOC is available to microorganisms that would consume oxygen as part of the decay and mineralization process. Since decreases in dissolved organic carbon are not typically observed in Delta waterways due to these processes, any increase in DOC is unlikely to contribute to adverse DO levels in the Delta.

CM14, which under Alternative 4 would fund improvements to the oxygen aeration facility in the Stockton Deep Water Ship Channel to meet TMDL objectives established by the Central Valley Water Board, would not be implemented under Alternative 4A. However, the existing aeration facility would continue to be operated to enhance DO levels in the channel. Thus, DO levels would be expected similar those under the No Action Alternative (ELT and LLT).

CM19, which under Alternative 4 would fund projects to contribute to reducing pollutant discharges in stormwater, also would not be implemented under Alternative 4A. Thus, the potential for reduced biochemical oxygen demand load described for Alternative 4 would not occur in the near-term and loading of these constituents and, thus DO levels, would be expected to be similar to that which would occur under the No Action Alternative (ELT and LLT).

The remaining environmental commitments would not affect DO levels because they are actions that do not affect the presence of oxygen-demanding substances.

Based on the above findings, the effects on DO from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

***CEQA Conclusion*:** It is expected that DO levels in the Upstream of the Delta Region, in the Plan Area, or in the SWP/CVP Export Service Areas following implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 4A would not be substantially different from existing DO conditions, because these would contribute to a minimal, localized change in oxygen-demanding substances associated with habitat restoration, if at all. Therefore, these environmental commitments are not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would result in significant impacts on any beneficial uses within affected water bodies. Because no substantial changes in DO levels would be expected, long-term water quality degradation would not be expected, and, thus, beneficial uses would not be adversely affected. Various Delta waterways are CWA Section 303(d)-listed for low DO, but because no substantial decreases in DO levels would be expected, greater degradation and impairment of these areas would not be expected. Based on these findings, this impact would be less than significant. No mitigation is required.

Impact WQ-11: Effects on Electrical Conductivity Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 4A on EC levels in reservoirs and rivers upstream of the Delta would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). The extent of new urban growth would be less in the ELT, thus discharges of EC-elevating parameters in runoff and wastewater discharges to water bodies upstream of the Delta would be expected to be less than in the LLT. However, the state is regulating point source discharges of EC-related parameters and implementing a program to further decrease loading of EC-related parameters to tributaries. Based on these considerations, and those described in Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS, EC levels (highs, lows, typical conditions) in the

Sacramento River and its tributaries, the eastside tributaries, or their associated reservoirs upstream of the Delta would not be expected to be outside the ranges occurring under Existing Conditions.

For the San Joaquin River, increases in EC levels under Alternative 4A could occur, but would be slightly less than those described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). This is because the effects of climate change and increase water demands on flows, which could effect dilution of high EC discharges, would be less in the ELT. The implementation of the adopted TMDL for the San Joaquin River at Vernalis and the ongoing development of the TMDL for the San Joaquin River upstream of Vernalis are expected to contribute to improved EC levels. Based on these considerations, substantial changes in EC levels in the San Joaquin River relative to Existing Conditions would not be expected to be of sufficient magnitude and geographic extent that would result in adverse effects on any beneficial uses, or substantially degrade the quality of these water bodies, with regard to EC.

Delta

As mentioned at the beginning of Section 4.3.4, the analysis of EC under Alternative 4A is based on modeling conducted for Alternative 4 in the ELT, which assumes implementation of Yolo Bypass Improvements and 25,000 acres of tidal natural communities restoration. Also, the modeling was originally performed assuming the Emmaton compliance point shifted to Threemile Slough. However, Yolo Bypass Improvements are not a component of Alternative 4A and the amount of tidal habitat restoration (i.e., Environmental Commitment 4) would be significantly less than that represented in the Alternative 4A modeling. Also, Alternative 4A does not include a change in compliance point from Emmaton to Threemile Slough. Furthermore, there are several factors related to the modeling approach that may result in modeling artifacts that show objective exceedance, when in reality no such exceedance would occur. The result of all of these factors is that the quantitative modeling results presented in this assessment is not entirely predictive of actual effects under Alternative 4A, and the results should be interpreted with caution. In order to understand the significance of all of these factors on the results, sensitivity analyses and other analyses were performed to evaluate the impact of maintaining the compliance point at Emmaton, the impact of having substantially less restoration than included in the modeling that was analyzed, and whether exceedances were indeed modeling artifacts or were potential alternative-related effects that may actually occur. For more information on these sensitivity analyses, refer to Chapter 8, Section 8.3.1.7, *Electrical Conductivity*, and Appendix 8H Attachment 1, both in Appendix A of the RDEIR/SDEIS.

In this assessment, the modeling results are described and then in most cases are qualified in light of findings from the sensitivity analyses. Conclusions thus represent assessment of the combination of the modeling results and sensitivity analysis findings.

The modeling of EC under Alternative 4A included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 4A would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of operations-related water quality changes (i.e., water conveyance facilities). Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-12. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Relative to Existing Conditions and the No Action Alternative (ELT), initial review of modeling results indicated that Alternative 4A would potentially result in an increase in the number of days the Bay-Delta WQCP EC objectives would be exceeded in the Sacramento River at Emmaton, and San Joaquin River at San Andreas Landing and Prisoners Point (Table EC-1 in Appendix B of this RDEIR/SDEIS). Additionally, the modeling results indicated potentially large increases in EC in Suisun Marsh. However, to understand and interpret these results, considerations must be made regarding uncertainty in the modeling, differing assumptions between the modeling and the alternative, and sensitivity analyses. These objectives and locations are addressed in the context of these considerations in detail below. At all other locations, the level of exceedance and EC in the modeling results was approximately equivalent or lower than under Existing Conditions and the No Action Alternative (ELT).

Sacramento River at Emmaton

Modeling results indicated that the Emmaton EC objective would be exceeded more often under Alternative 4A than under Existing Conditions and the No Action Alternative (ELT), and that increases in EC could cause substantial water quality degradation in summer months of dry and critical water years. However, sensitivity analyses have shown that the level of effect would be less than presented in the modeling. Remaining increases in exceedance of the objective and degradation are expected to be addressed via real-time operations, including real time management of the north Delta and south Delta intakes, as well as Delta Cross Channel operation. Further discussion is provided below.

Modeling results indicated that the percent of days the Emmaton EC objective would be exceeded for the entire period modeled (1976–1991) would increase from 6% under Existing Conditions, or 13% under the No Action Alternative (ELT), to 17–18% and the percent of days out of compliance would increase from 11% under Existing Conditions, or 21% under the No Action Alternative (ELT), to 26–28%, depending on the operations scenario. Although these results are for modeling that was originally performed for Alternative 4 at the ELT assuming the Emmaton compliance point shifted to Threemile Slough, Alternative 4A does not include a change in compliance point from Emmaton to Threemile Slough.

Sensitivity analyses were performed that modeled Alternative 4 scenario H3 at the LLT with Emmaton as the compliance point. These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT, because the factors affecting salinity findings in the sensitivity analysis (e.g., modeling assumptions, physical hydrodynamic mechanisms) are similar between the ELT and LLT (see Appendix 8H Attachment 1, in Appendix A of the RDEIR/SDEIS). Assuming the compliance location at Emmaton instead of Threemile Slough in the CALSIM II modeling decreased exceedances at Emmaton from 28% to 15% under Alternative 4, operations scenario H3 at the LLT (see Appendix 8H, Attachment 1, of the RDEIR/SDEIS for more discussion of these sensitivity analyses), which would still be greater than Existing Conditions, but is very close to the No Action Alternative (ELT). Table 2 of Appendix 8H, Attachment 1, in Appendix A of the RDEIR/SDEIS indicates that most of these exceedances are a result of modeling artifacts, but some exceedances are due to deadpool conditions that occurred in 1977, 1981, and 1990 under Alternative 4 scenario H3 at the LLT and not under Existing Conditions. As discussed in Chapter 5, *Water Supply*, Section 5.3.1, *Methods for Analysis*, of this RDEIR/SDEIS, under extreme hydrologic and operational conditions where there is not enough water supply to meet all requirements, CALSIM II uses a series of operating rules to reach a solution that is a simplified version of the very complex decision processes that SWP and CVP operators would use in actual extreme conditions. Thus, it is unlikely that the Emmaton objective would actually be violated due to dead pool conditions. However, these results indicate that water supply could be either under greater stress or under stress earlier in the year, and EC levels at Emmaton and in the western Delta may increase as a result, leading to EC degradation and increased possibility of adverse effects to agricultural beneficial uses.

This is evidenced in the modeling results, which indicated that long-term monthly average EC levels at Emmaton would increase 1–22% for the entire period modeled (1976–1991) and 4–44% during the drought period modeled (1987–1991), relative to the No Action Alternative (ELT) (Tables EC-8A and EC-8B in Appendix B of this RDEIR/SDEIS). The largest increases in EC would occur during the summer months of the drought period, and more generally in dry and critical water year types. During these periods, additional flow in the Sacramento River at Emmaton would reduce or eliminate increases in EC. It is expected that for May–September of dry and critical water years, less pumping from the north Delta intakes and greater reliance on south Delta intakes would allow for enough flow in the Sacramento River at Emmaton to reduce water quality degradation to levels closer to the No Action Alternative that would be considered not adverse.

San Joaquin River at San Andreas Landing

Alternative 4A is not expected to have adverse effects on EC in the San Joaquin River at San Andreas Landing, relative to Existing Conditions and the No Action Alternative (ELT). Modeling results estimated that the percent of days the San Andreas Landing EC objective would be exceeded would increase from 1% under Existing Conditions to 2% under operations scenario H3, and would decrease to 0% under operations scenario H4 (Table EC-1 in Appendix B of this RDEIR/SDEIS). The percent of days out of compliance with the EC objective for San Andreas Landing would increase from 1% under Existing Conditions to 4% for operations scenario H3, and would decrease to 0% under operations scenario H4. San Andreas Landing average EC would decrease 6% for the entire period modeled, but would increase 1–3% during the drought period modeled, relative to Existing Conditions (Tables EC-8A and EC-8B in Appendix B of this RDEIR/SDEIS). Results relative to the No Action Alternative (ELT) were similar (Tables EC-8A and EC-8B in Appendix B of this RDEIR/SDEIS). However, sensitivity analyses performed for Alternative 4 scenario H3 at the LLT indicate that many of these exceedances are likely modeling artifacts, and the small number of remaining exceedances would be small in magnitude, lasting only a few days, and could be addressed with real time operations of the SWP and CVP (see Chapter 8, Section 8.3.1.1, *Models Used and Their Linkages*, in Appendix A of this RDEIR/SDEIS for a description of real time operations of the SWP and CVP). These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT, because the factors affecting salinity findings in the sensitivity analysis (e.g., modeling assumptions, physical hydrodynamic mechanisms) are similar between the ELT and LLT (see Appendix 8H Attachment 1, in Appendix A of the RDEIR/SDEIS).

San Joaquin River at Prisoners Point

Modeling results indicated that the EC objective that applies between the San Joaquin River at Jersey Point and Prisoners Point would be exceeded at Prisoners Point more often under Alternative 4A than under Existing Conditions and the No Action Alternative (ELT). However, modeling results without restoration areas would be expected to show a lesser effect, and remaining exceedances are expected to be able to be addressed via real-time operations, including real time management of the north Delta and south Delta intakes, as well as Head of Old River Barrier management. Further discussion is provided below.

Modeling results estimated that the percent of days the Prisoners Point EC objective would be exceeded would increase from 6% under Existing Conditions, or 1% under the No Action Alternative (ELT), to 17–20% and the percent of days out of compliance with the EC objective would increase from 10% under Existing Conditions, or 1% under the No Action Alternative (ELT), to 20–23%, depending on the operations scenario (Table EC-1 in Appendix B of this RDEIR/SDEIS). The magnitude of the exceedances is estimated to be very small—the objective is 440 µmhos/cm, and the EC during times of exceedance was generally between 440 and 550 µmhos/cm. The exceedances generally occurred in drier water years, when flows are lower. During these times, the EC in the San Joaquin River at Vernalis is greater than in the Sacramento River entering the Delta, and is high enough on its own to cause an exceedance.

There are two main drivers of the increase in exceedances under the alternative: an increase in San Joaquin River flow at Prisoners Point during April and May under the alternative, relative to Existing Conditions and the No Action Alternative (ELT), and a reduction in the amount of Sacramento River water moving past Prisoners Point under the alternative. The result is increased San Joaquin River water at Prisoners Point, and a reduction in the dilution that the Sacramento River provides the higher EC San Joaquin River. The increase in San Joaquin River flow at Prisoners Point is due to a reduction in pumping from the south Delta under the alternative, as well as due to the presence of the Head of Old River Barrier, which increases flow in the San Joaquin River downstream of Old River by preventing flow from entering Old River. The reduction in Sacramento River water influence is due to less pumping at the south Delta pumping plants (i.e., greater pumping draws more Sacramento River water through the Delta).

Sensitivity analyses conducted for Alternative 4 scenario H3 at the LLT indicated that removing all tidal restoration areas (such as is largely the case in Alternative 4A at the ELT) would reduce the number of exceedances by about 9 percentage points, but there would still be more exceedances than under Existing Conditions or the No Action Alternative. Sensitivity analyses also indicated that if the Head of Old River Barrier was open in April and May, exceedances would be reduced by about 5 percentage points. Both of these analyses also showed lower EC during April and May, including during times when modeling showed the objective to be exceeded. These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT. Results of the sensitivity analyses indicate that the exceedances are partially a function of the restoration that was assumed in the Alternative 4A modeling, but partly due also to operations of the alternative itself, due to Head of Old River Barrier assumptions and south Delta export differences (see Appendix 8H, Attachment 1, in Appendix A of the RDEIR/SDEIS for more discussion of these sensitivity analyses). Appendix 8H, Attachment 2, in Appendix A of the RDEIS/SDEIS contains a more detailed assessment of the likelihood of exceedances estimated via modeling for Alternatives 1–9 impacting aquatic life beneficial uses. Specifically, Appendix 8H, Attachment 2, in Appendix A of the RDEIR/SDEIS discusses whether these exceedances might have indirect effects on striped bass spawning in the Delta, and concludes that the high level of uncertainty precludes making a definitive determination for those alternatives. However, based on the sensitivity analyses conducted, modeling of Alternative 4A that did not contain restoration areas would likely show a lesser level of effects than presented herein (using the Alternative 4 ELT modeling), both in terms of frequency and magnitude of exceedance. Additionally, by adaptively managing the Head of Old River Barrier and the fraction of south Delta versus north Delta diversions, EC levels at Prisoners Point would likely be decreased to a level that would not adversely affect aquatic life beneficial uses.

Suisun Marsh

For Suisun Marsh October–May is the period when Bay-Delta WQCP EC objectives for protection of fish and wildlife apply. Modeling results indicate that average EC for the entire period modeled would increase in the Sacramento River at Collinsville during the months of March through May relative to Existing Conditions, by 0.1–0.2 mS/cm (Table EC-3 in Appendix B of this RDEIR/SDEIS). In Montezuma Slough at National Steel, average EC levels would increase in December through March by 0.1–0.4 mS/cm (Table EC-4 in Appendix B of this RDEIR/SDEIS). The most substantial EC increase would occur in Montezuma Slough near Beldon Landing, with long-term average EC levels increasing by 1.1–5.3 mS/cm, depending on the month and operations scenario, at least doubling during some months the long-term average EC relative to Existing Conditions (Table EC-5 in Appendix B of this RDEIR/SDEIS). Sunrise Duck Club and Volanti Slough also would have long-term average EC increases during October–May ranging 0.7–3.1 mS/cm (Tables EC-6 and EC-7 in Appendix B of this RDEIR/SDEIS). Modeled long-term average EC increases in Suisun Marsh under Alternative 4A relative to the No Action Alternative (ELT) are similar to the increases relative to Existing Conditions.

However, modeling used in the assessment of Alternative 4A assumed no operation of the Montezuma Slough Salinity Control Gates, but the project description assumes continued operation of the Salinity Control Gates, consistent with assumptions included in the No Action Alternative. A sensitivity analysis modeling run conducted for Alternative 4 scenario H3 at the LLT with the gates operational consistent with the No Action Alternative resulted in substantially lower EC levels than indicated in the original Alternative 4 modeling results discussed above, but EC levels were still somewhat higher than EC levels under Existing Conditions and the No Action Alternative for several locations and months. Another modeling run with the gates operational and restoration areas removed resulted in EC levels nearly equivalent to Existing Conditions and the No Action Alternative (see Appendix 8H, Attachment 1, of the Draft EIR/EIS for more information on these sensitivity analyses). Since Alternative 4A at the ELT includes operation of the gates, and includes very little tidal restoration areas, it is anticipated that EC increases in Suisun Marsh predicted via the modeling would not occur, and that EC in Suisun Marsh under Alternative 4A would be very similar to Existing Conditions and No Action Alternative (ELT). Depending on where tidal restoration areas assumed to be included in the No Action Alternative are located, EC under Alternative 4A could be less than under the No Action Alternative (ELT). For these reasons, any changes in EC in Suisun Marsh are expected to have no adverse effect on marsh beneficial uses.

SWP/CVP Export Service Areas

Under Alternative 4A, at the Banks pumping plant, there would be no exceedance of the Bay-Delta WQCP's 1,000 µmhos/cm EC objective for the entire period modeled under operations scenario H4 (Table EC-2 in Appendix B of this RDEIR/SDEIS). However, under operations scenario H3, the frequency of exceedance of the EC objective would be 1% for the entire period modeled and 2% for the drought period modeled. This differs from Alternative 4, under which there would be no exceedance of the EC objective under either operations scenario. Relative to Existing Conditions, average EC levels under Alternative 4A would decrease 25–28% for the entire period modeled and 21–27% during the drought period modeled, depending on the operations scenario. Relative to the No Action Alternative (ELT), average EC levels would similarly decrease, by 21–25% for the entire period modeled and 18–25% during the drought period modeled (Tables EC-8A and EC-8B in Appendix B of this RDEIR/SDEIS).

At the Jones pumping plant, there would be no exceedance of the Bay-Delta WQCP s 1,000 μmhos/cm EC objective for the entire period modeled under operations scenario H3 (Table EC-2 in Appendix B of this RDEIR/SDEIS). However, under operations scenario H4, the frequency of exceedance of the EC objective would be 1% for the entire period modeled and 0% for the drought period modeled. This differs from Alternative 4, under which there would be no exceedance of the EC objective under either operations scenario. Relative to Existing Conditions, average EC levels under Alternative 4A would decrease 25% for the entire period modeled and 22–23% during the drought period modeled, depending on the operations scenario. Relative to the No Action Alternative (ELT), average EC levels would similarly decrease, by 22% for the entire period modeled and 19–20% during the drought period modeled, depending on the operations scenario (Tables EC-8A and EC-8B in Appendix B of this RDEIR/SDEIS).

Based on the decreases in long-term average EC levels that would occur at the Banks and Jones pumping plants, Alternative 4A would not cause degradation of water quality with respect to EC in the SWP/CVP Export Service Areas rather, Alternative 4A would improve long-term average EC conditions in the SWP/CVP Export Service Areas.

Commensurate with the EC decrease in exported waters, an improvement in lower San Joaquin River average EC levels would be expected since EC in the lower San Joaquin River is, in part, related to irrigation water deliveries from the Delta. While the magnitude of this expected lower San Joaquin River improvement in EC is difficult to predict, the relative decrease in overall loading of EC-elevating constituents to the Export Service Areas would likely alleviate or lessen any expected increase in EC at Vernalis related to decreased annual average San Joaquin River flows.

The export area of the Delta is listed on the state's CWA Section 303(d) list as impaired due to elevated EC Alternative 4A would result in lower average EC levels relative to Existing Conditions and the No Action Alternative (ELT) and, thus, would not contribute to additional beneficial use impairment related to elevated EC in the SWP/CVP Export Service Areas waters.

NEPA Effects: In summary, based on the results of the modeling and sensitivity analyses conducted, it is unlikely that there would be increased frequency of exceedance of agricultural EC objectives in the western, interior, or southern Delta. However, modeling results indicate that there could be increased long-term and drought period average EC levels during the summer months that would occur in the western Delta (i.e., in the Sacramento River at Emmaton) under Alternative 4A relative to the No Action Alternative (ELT), that could contribute to adverse effects on the agricultural beneficial uses. In addition, the increased frequency of exceedance of the San Joaquin River at Prisoners Point EC objective could contribute to adverse effects on fish and wildlife beneficial uses (specifically, indirect adverse effects on striped bass spawning), though there is a high degree of uncertainty associated with this impact. Suisun Marsh is CWA Section 303(d) listed as impaired due to elevated EC, but EC levels are not expected to change substantially under Alternative 4A, relative to the No Action Alternative (ELT), and thus it is not expected that they would contribute to additional beneficial use impairment. The increases in EC in the Sacramento River at Emmaton, particularly during summer months of dry and critical water years, and the additional exceedances of water quality objectives in the San Joaquin River at Prisoners Point constitute an adverse effect on water quality. Mitigation Measure WQ-11 would be available to reduce these effects.

CEQA Conclusion: River flow rate and reservoir storage reductions that would occur under Alternative 4A, relative to Existing Conditions, would not be expected to result in a substantial adverse change in EC levels in the reservoirs and rivers upstream of the Delta, given that: changes in the quality of watershed runoff and reservoir inflows would not be expected to occur in the future; the state's regulation of point-source discharge effects on Delta salinity-elevating parameters and the expected further regulation as salt management plans are developed; the salt-related TMDLs adopted and being developed for the San Joaquin River; and the expected improvement in lower San Joaquin River average EC levels commensurate with the lower EC of the irrigation water deliveries from the Delta.

Relative to Existing Conditions, Alternative 4A would not result in any substantial increases in long-term average EC levels in the SWP/CVP Export Service Areas, and exceedance of the Bay-Delta WQCP EC objective would be infrequent. Average EC levels for the entire period modeled would decrease at both the Banks and Jones pumping plants and, thus, this alternative would not contribute to additional beneficial use impairment related to elevated EC in the SWP/CVP Export Service Areas waters. Rather, this alternative would improve long-term EC levels in the SWP/CVP Export Service Areas, relative to Existing Conditions.

Further, relative to Existing Conditions, Alternative 4A would not result in substantial increases in long-term average EC in Suisun Marsh. Thus, EC levels in Suisun Marsh are not expected to further degrade existing EC levels and thus would not contribute additionally to adverse effects on the fish and wildlife beneficial uses. Because EC is not bioaccumulative, any changes in long-term average EC levels would not directly cause bioaccumulative problems in fish and wildlife. Suisun Marsh is CWA Section 303(d) listed as impaired due to elevated EC, but EC levels are not expected to change substantially under Alternative 4A, relative to Existing Conditions, and thus it is not expected that they would contribute to additional beneficial use impairment.

In the Plan Area, Alternative 4A is not expected to result in an increase in the frequency with which Bay-Delta WQCP EC objectives are exceeded, except for at the San Joaquin River at Prisoners Point (fish and wildlife objective; 11–14% increase). The increased frequency of exceedance of the fish and wildlife objective at Prisoners Point could contribute to adverse effects on aquatic life (specifically, indirect adverse effects on striped bass spawning), though there is a high degree of uncertainty associated with this impact. However, modeling of Alternative 4A that did not contain restoration areas would likely show a lesser level of effects than presented herein (using the Alternative 4 ELT modeling), both in terms of frequency and magnitude of exceedance. Additionally, by adaptively managing the Head of Old River Barrier and the fraction of south Delta versus north Delta diversions, EC levels at Prisoners Point would likely be decreased to a level that would not adversely affect aquatic life beneficial uses.

Average EC levels at Emmaton would increase by 4–5% during the drought period modeled. The largest monthly average increases in EC would occur during the summer months of the drought period, and more generally in dry and critical water year types. The increases in drought period average EC levels could cause substantial water quality degradation that would potentially contribute to adverse effects on the agricultural beneficial uses in the western Delta. The comparison to Existing Conditions reflects changes in EC due to both Alternative 4A operations and climate change/sea level rise. The adverse effects expected to occur at Emmaton would be due in part to the effects of climate change/sea level rise, and in part due to Alternative 4A operations. This is evidenced by the significant effects expected in the No Action Alternative (ELT) at Emmaton relative to Existing Conditions, as well as the fact that a lesser level of adverse effects is expected at

Emmaton under Alternative 4A relative to the No Action Alternative (ELT). During summer of dry and critical water years, additional flow in the Sacramento River at Emmaton would reduce or eliminate increases in EC. It is expected that for May–September of dry and critical water years, less pumping from the north Delta intakes and greater reliance on south Delta intakes would allow for enough flow in the Sacramento River at Emmaton to reduce water quality degradation to levels closer to the No Action Alternative that would not be expected to adversely affect beneficial uses. Because EC is not bioaccumulative, the increases in long-term average EC levels would not directly cause bioaccumulative problems in aquatic life or humans. The western Delta is CWA Section 303(d) listed for elevated EC and the increased EC degradation that could occur in the western Delta could make beneficial use impairment measurably worse.

Based on these findings, this impact in the Plan Area is considered to be significant. Implementation of Mitigation Measure WQ-11 would be expected to reduce these effects to a less-than-significant level.

Mitigation Measure WQ-11: Avoid or Minimize Reduced Water Quality Conditions

The implementation of mitigation actions shall be focused on avoiding or minimizing those incremental effects attributable to implementation of Alternative 4A operations only. Mitigation actions to avoid or minimize the incremental EC effects attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 4A. The goal of specific actions is to reduce/avoid additional exceedances of Delta EC objectives and reduce long-term average concentration increases to levels that would not adversely affect beneficial uses within the Delta. Implementation of Mitigation Measure WQ-11 would be expected to reduce effects on EC to a less-than-significant level.

Mitigation Measure WQ-11a: Adaptively Manage Diversions at the North and South Delta Intakes to Reduce or Eliminate Water Quality Degradation in Western Delta

Modeling results for Alternative 4A indicated water quality degradation in the Sacramento River at Emmaton during May-September of dry and critical water year types, relative to the No Action Alternative (ELT). Additional flow in the Sacramento River at Emmaton would be expected to reduce EC levels under Alternative 4A to levels closer to the No Action Alternative (ELT) that would not be expected to adversely affect beneficial uses. By reducing diversions from the north Delta intakes during these periods (and consequently increasing diversions from the south Delta intakes), additional flow would be available in the Sacramento River to reduce water quality degradation with respect to EC. The BDCP proponents shall adaptively manage the split between north and south Delta diversions during May-September of dry and critical water years to limit EC in the Sacramento River at Emmaton to levels consistent with the No Action Alternative.

Mitigation Measure WQ-11b: Adaptively Manage Head of Old River Barrier and Diversions at the North and South Delta Intakes to Reduce or Eliminate Exceedances of the Bay-Delta WQCP Objective at Prisoners Point

Modeling results for Alternative 4A indicated additional exceedances of the Bay-Delta WQCP objective for protection of striped bass between Jersey Point and Prisoners Point at Prisoners Point. It is expected that by adaptively managing the Head of Old River Barrier and the fraction of south Delta versus north Delta diversions, exceedances of the EC objective at Prisoners Point could be avoided, and EC levels at Prisoners Point would be decreased to a level that would not adversely affect aquatic life beneficial uses. The BDCP proponents shall adaptively manage the Head of Old River Barrier and the split between north and south Delta diversions during April-May to avoid exceedances of the objective at Prisoners Point. These actions would not be required in critical water years, when the objective does not apply. The BDCP proponents will consult with CDFW, USFWS, and NMFS to ensure that such actions are warranted to avoid adverse impacts of salinity on striped bass spawning in the San Joaquin River, and to minimize adverse effects these mitigation actions may have on other species.

Impact WQ-12: Effects on Electrical Conductivity Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15 and 16.

***NEPA Effects*:** The implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would present no new direct sources of EC to the affected environment, including areas upstream of the Delta, within the Delta region, and in the SWP/CVP Export Service Areas. As they pertain to EC, implementation of these environmental commitments would not be expected to adversely affect any of the beneficial uses of the affected environment. Moreover, some habitat restoration activities would occur on lands within the Delta currently used for irrigated agriculture. Such replacement or substitution of land use activity is not expected to result in new or increased sources of EC to the Delta and, in fact, could decrease EC through elimination of high EC agricultural runoff.

Environmental Commitment 4 would result in some tidal habitat restoration, however, the areal extent would be small relative to the existing and No Action Alternative tidal area and, thus not expected to appreciably affect the magnitude of daily tidal water exchange at the restoration areas or alter other hydrodynamic conditions in adjacent Delta channels that would result in measurable EC changes.

In summary, implementation of the environmental commitments would not be expected to adversely affect EC levels in the affected environment and thus would not adversely affect beneficial uses or substantially degrade water quality with regard to EC within the affected environment. Therefore, the effects on EC from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 4A would not present new or substantially changed sources of EC to the affected environment. Some environmental commitments may replace or substitute for existing irrigated agriculture in the Delta. This replacement or substitution is not expected to substantially increase or present new sources of EC, and could actually decrease EC loads to Delta waters, because agricultural drainage can be a source of elevated EC. Thus, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would have negligible, if any, adverse effects on EC levels throughout the affected environment and would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria that would result in adverse effects on any beneficial uses within affected water bodies. Further, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause significant long-term water quality degradation such that there would be greater risk of adverse effects on beneficial uses. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-13: Effects on Mercury Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the Alternative 4A on mercury levels in surface waters upstream of the Delta relative to Existing Conditions and the No Action Alternative (ELT) would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). This is because factors which affect mercury concentrations in surface waters upstream of the Delta are similar under Alternatives 4 and 4A. The changes in flow in the Sacramento River under Alternative 4A relative to Existing Conditions and the No Action Alternative (ELT) would not be of the magnitude of storm flows, in which substantial sediment-associated mercury is mobilized. Therefore, mercury loading should not be substantially different due to changes in flow. In addition, even though it may be flow-affected, total mercury concentrations remain well below criteria at upstream locations. Any negligible changes in mercury concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to mercury. Both waterborne methylmercury concentrations and largemouth bass fillet mercury concentrations are expected to remain above guidance levels at upstream of Delta locations, but would not change substantially because the anticipated changes in flow are not expected to substantially change mercury loading relative to Existing Conditions or the No Action Alternative (ELT).

The upstream of Delta areas in the north will benefit from the implementation of the Cache Creek, Sulfur Creek, Harley Gulch, and Clear Lake Mercury TMDLs and the American River methylmercury TMDL. These projects will target specific sources of mercury and methylation upstream of the Delta and could result in net improvement to Delta mercury loading in the future. The implementation of these projects could help to ensure that upstream of Delta environments will not be substantially degraded for water quality with respect to mercury or methylmercury.

In the LLT, the primary difference will be changes in flow regime due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on mercury are expected to be similar to those described above.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 4A would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-14. See Chapter 8, Section 8.3.1.3, *Plan Area,* in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

The effects of Alternative 4A on waterborne concentrations of mercury (Table Hg-1 in Appendix B of this RDEIR/SDEIS) and methylmercury (Table Hg-2 in Appendix B of this RDEIR/SDEIS), and fish tissue mercury concentrations for largemouth bass fillet (Tables Hg-3 through Hg-8 in Appendix B of this RDEIR/SDEIS) were evaluated for nine Delta locations.

Similar to Alternative 4, increases in long-term average mercury concentrations relative to Existing Conditions and the No Action Alternative (ELT) would be very small, 0.4 ng/L or less. Also, use of assimilative capacity for mercury relative to the 25 ng/L ecological threshold under Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT), would be very low, approximately 2% or less for all Delta locations (Tables Hg-9 and Hg-10 in Appendix B of this RDEIR/SDEIS). These concentration changes and small changes in assimilative capacity for mercury are not expected to result in adverse (or positive) effects to beneficial uses.

Changes in methylmercury concentrations in water also are expected to be very small. The greatest annual average methylmercury concentration under Alternative 4A would be 0.166 ng/L for the San Joaquin River at Buckley Cove (all scenarios), for the drought period modeled, which would be slightly higher than Existing Conditions (0.161 ng/L) and slightly lower than the No Action Alternative (ELT) (0.168 ng/L) (Table Hg-2 in Appendix B of this RDEIR/SDEIS). All methylmercury concentrations in water were estimated to exceed the TMDL guidance objective of 0.06 ng/L under Existing Conditions and, therefore, no assimilative capacity exists.

Fish tissue estimates for largemouth bass fillet show small or no increases in mercury concentrations under Alternative 4A relative to Existing Conditions and the No Action Alternative (ELT) based on long-term annual average concentrations for mercury at the Delta locations (Tables Hg-5 and Hg-8 in Appendix B of this RDEIR/SDEIS). Concentrations expected for scenario H3 with Equation 2 would increase by 10 percent to 12 percent in Mokelumne River (South Fork) at Staten Island, Franks Tract, Old River at Rock Slough, and San Joaquin River at Antioch relative to Existing Conditions in all years and by 11 percent to 12 percent at Staten Island and Rock Slough relative to the No Action Alternative (ELT) in all years (Table Hg-6 in Appendix B of this RDEIR/SDEIS). Concentrations expected for scenario H4 show decreases (11%) with Equation 2 in the North Bay Aqueduct at Barker Slough relative to Existing Conditions in all years and for the drought period modeled, and a decrease of 11 percent relative to the No Action Alternative (ELT) for the drought period (Table Hg-8 in Appendix B of this RDEIR/SDEIS). Because the increases are relatively small, and it is not evident that substantive increases are expected at numerous locations throughout the Delta, these changes are expected to be within the uncertainty inherent in the modeling approach, and would likely not be measurable in the environment. See Appendix 8I, *Mercury*, of the Draft EIR/EIS for a complete discussion of the uncertainty associated with the fish tissue estimates.

Briefly, the bioaccumulation models contain multiple sources of uncertainty associated with their development. These are related to: analytical variability; temporal and/or seasonal variability in Delta source water concentrations of methylmercury; interconversion of mercury species (i.e., the non-conservative nature of methylmercury as a modeled constituent); and limited sample size (both in number of fish and time span over which the measurements were made), among others. Although there is considerable uncertainty in the models used, the results serve as a reasonable approximations of a very complex process. Considering the uncertainty, small (i.e., < 20–25%) increases or decreases in modeled fish tissue mercury concentrations at a low number of Delta locations (i.e., 2–3) should be interpreted to be within the uncertainty of the overall approach, and not predictive of actual adverse effects. Larger increases, or increases evident throughout the Delta, can be interpreted as more reliable indicators of potential adverse effects.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on mercury are expected to be similar to those described above.

SWP/CVP Export Service Areas

The analysis of mercury and methylmercury in the SWP/CVP Export Service Areas was based on concentrations estimated at the Banks and Jones pumping plants. Both waterborne total and methylmercury concentrations for Alternative 4A, all scenarios, at the Jones and Banks pumping plants, would be lower than Existing Conditions and the No Action Alternative (ELT) (Tables Hg-1 and Hg-2 in Appendix B of this RDEIR/SDEIS). Therefore, mercury shows an increased assimilative capacity at these locations (Tables Hg-9 and Hg-10 in Appendix B of this RDEIR/SDEIS).

The largest improvements in bass tissue mercury concentrations and exceedance quotients ([EQs]; modeled tissue divided by TMDL guidance concentration) for Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT) at any location within the Delta are expected for the Banks and Jones pumping plant export pump locations. The greatest improvement in largemouth bass tissue mercury concentration are expected for scenario H4 at the Banks and Jones pumping plants (-14% and -16%, respectively) relative to the No Action Alternative (ELT) (Tables Hg-5 through Hg-8 in Appendix B of this RDEIR/SDEIS).

In the LLT, the primary difference will be changes in the Delta source water fractions to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on mercury are expected to be similar to those described above.

***NEPA Effects*:** Based on the above discussion, Alternative 4A would not cause concentrations of mercury and methylmercury in water and fish tissue in the affected environment to be substantially different from the No Action Alternative (ELT and LLT) and, thus, would not cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because mercury concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Because any increases in mercury or methylmercury concentrations are not likely to be measurable, changes in mercury concentrations or fish tissue mercury concentrations would not make any existing mercury-related impairment measurably worse. In comparison to the No Action Alternative (ELT and LLT), Alternative 4A would not be expected to increase levels of mercury by frequency, magnitude, and geographic extent such that the affected environment would be expected to have measurably higher body burdens of mercury in aquatic organisms, thereby substantially increasing the health risks to wildlife (including fish) or humans consuming those organisms. Based on these findings, the effects of Alternative 4A on mercury in the affected environment are considered to be not adverse.

***CEQA Conclusion*:** Under Alternative 4A, greater water demands and climate change would alter the magnitude and timing of reservoir releases and river flows upstream of the Delta in the Sacramento River watershed and east-side tributaries, relative to Existing Conditions. Concentrations of mercury and methylmercury upstream of the Delta would not be substantially different relative to Existing Conditions due to the lack of important relationships between mercury/methylmercury concentrations and flow for the major rivers.

Methylmercury concentrations exceed criteria at all locations in the Delta and no assimilative capacity exists. However, monthly average waterborne concentrations of total and methylmercury, over the period of record, under Alternative 4A would be very similar to Existing Conditions.

Similarly, estimates of fish tissue mercury concentrations show small differences would occur among sites for Alternative 4A as compared to Existing Conditions for Delta sites.

Assessment of effects of mercury in the SWP/CVP Export Service Areas were based on effects on mercury concentrations and fish tissue mercury concentrations at the Banks and Jones pumping plants. The Banks and Jones pumping plants are expected to show increased assimilative capacity for waterborne mercury and decreased fish tissue concentrations of mercury for Alternative 4A, all scenarios, as compared to Existing Conditions.

As such, Alternative 4A is expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because mercury concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Because any increases in mercury or methylmercury concentrations are not likely to be measurable, changes in mercury concentrations or fish tissue mercury concentrations would not make any existing mercury-related impairment measurably worse. In comparison to Existing Conditions, Alternative 4A would not increase levels of mercury by frequency, magnitude, and geographic extent such that the affected environment would be expected to have measurably higher body burdens of mercury in aquatic organisms, thereby substantially increasing the health risks to wildlife (including fish) or humans consuming those organisms. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-14: Effects on Mercury Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects**:** The potential types of effects on mercury resulting from implementation of the environmental commitments under Alternative 4A would be generally similar to those described under Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). However, the magnitude of effects on mercury and methylmercury at locations upstream of the Delta, in the Delta, and the SWP/CVP Export Service Areas related to habitat restoration would be considerably lower than described for Alternative 4. This is because the amount of habitat restoration to be implemented under Alternative 4A would be very low compared to the total proposed restoration area that would be implemented under Alternative 4. The small amount of habitat restoration to be implemented under Alternative 4A may occur on lands in the Delta formerly used for irrigated agriculture. Habitat restoration proposed under Alternative 4A has the potential to increase water residence times and increase accumulation of organic sediments that are known to enhance methylmercury bioaccumulation in biota in the vicinity of the restored habitat areas. Design of restoration sites would be guided by Environmental Commitment 12, which requires development of site-specific mercury management plans as restoration actions are implemented. The effectiveness of minimization and mitigation actions implemented according to the mercury management plans is not known at this time, although the potential to reduce methylmercury concentrations exists based on current research. Although Environmental Commitment 12 would be implemented with the goal to reduce this potential effect, there remain uncertainties related to site-specific restoration conditions and the potential for increases in methylmercury concentrations in the Delta in the vicinity of the restored areas. Therefore, the effect of Environmental Commitments 3, 4, 6–12, 15, and 16 on mercury and methylmercury is considered to be adverse.

CEQA Conclusion**:** There would be no substantial, long-term increase in mercury or methylmercury concentrations or loads in the rivers and reservoirs upstream of the Delta or the waters exported to the SWP/CVP Export Service Areas due to implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 relative to Existing Conditions. However, in the Delta, due to the small amount of tidal restoration areas proposed, relative to Existing Conditions, uptake of mercury from water and/or methylation of inorganic mercury may increase in localized areas as part of the creation of new, marshy, shallow, or organic-rich restoration areas. Although not quantifiable, on a local level, increases in methylmercury concentrations may be measurable. Methylmercury is CWA Section 303(d)-listed within the affected environment, and therefore any potential measurable increase in methylmercury concentrations would make existing mercury-related impairment measurably worse. Because mercury is bioaccumulative, increases in water-borne mercury or methylmercury that could occur in some areas could bioaccumulate to somewhat greater levels in aquatic organisms and would, in turn, pose health risks to fish, wildlife, or humans. Design of restoration sites would be guided by Environmental Commitment 12, which requires development of site-specific mercury management plans as restoration actions are implemented. The effectiveness of minimization and mitigation actions implemented according to the mercury management plans is not known at this time, although the potential to reduce methylmercury concentrations exists based on current research. Although Environmental Commitment 12 would be implemented with the goal to reduce this potential effect, the uncertainties related to site specific restoration conditions and the potential for increases in methylmercury concentrations in the Delta result in this potential impact being considered significant because, as described above, any potential measurable increase in methylmercury concentrations would make existing mercury-related impairment measurably worse. No mitigation measures would be available until specific restoration actions are proposed. Therefore, this impact is considered significant and unavoidable.

Impact WQ-15: Effects on Nitrate Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

As described for Alternative 4 (in Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), nitrate levels in the major rivers (Sacramento, Feather, American) are low, generally due to ample dilution available in the reservoirs and rivers relative to the magnitude of the point and non-point source discharges, and there is no correlation between historical water year average nitrate concentrations and water year average flow in the Sacramento River at Freeport. Consequently, any modified reservoir operations and subsequent changes in river flows under Alternative 4A, relative to Existing Conditions or the No Action Alternative (ELT), are expected to have negligible, if any, effects on average reservoir and river nitrate-N concentrations in the Sacramento River watershed upstream of the Delta.

In the San Joaquin River watershed, nitrate concentrations are higher than in the Sacramento River watershed, owing to use of nitrate based fertilizers throughout the lower watershed. The correlation between historical water year average nitrate concentrations and water year average flow in the San Joaquin River at Vernalis is a weak inverse relationship—that is, generally higher flows result in lower nitrate concentrations, while low flows result in higher nitrate concentrations (linear regression r^2=0.49; Figure 2 in Appendix 8J, *Nitrate*, of the Draft EIR/EIS). Under Alternative 4A, long-term average flows at Vernalis would decrease an estimated 1% relative to Existing Conditions and would remain virtually the same relative to the No Action Alternative (ELT). Given the relatively small decreases in flows and the weak correlation between nitrate and flows in the San Joaquin

River, it is expected that nitrate concentrations in the San Joaquin River would be minimally affected, if at all, by anticipated changes in flow rates under the No Action Alternative (ELT).

In the LLT, the primary difference will be changes in flow regime due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on nitrate are expected to be similar to those described above.

Any negligible changes in nitrate concentrations that may occur under Alternative 4A in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies, with regard to nitrate.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-16. See section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Mass balance calculations indicate that under Alternative 4A relative to Existing Conditions and the No Action Alternative (ELT), nitrate concentrations throughout the Delta are anticipated to remain low (<1.4 mg/L-N) relative to adopted objectives (Table N-1 in Appendix B of this RDEIR/SDEIS). Although changes at specific Delta locations and for specific months may be substantial on a relative basis (Tables N-4 and N-5 in Appendix B of this RDEIR/SDEIS), the absolute concentration of nitrate in Delta waters would remain low (<1.4 mg/L-N) in relation to the drinking water MCL of 10 mg/L-N, as well as all other thresholds (see *Nitrate* within Chapter 8, Section 8.3.17, *Constituent-Specific Considerations Used in the Assessment*, in Appendix A of the RDEIR/SDEIS). Long-term average nitrate concentrations are anticipated to remain below 1 mg/L-N at all 11 Delta assessment locations except the San Joaquin River at Buckley Cove, where long-term average concentrations would be somewhat above 1 mg/L-N. Nevertheless, at this location, long-term average nitrate concentrations would be somewhat reduced under Alternative 4A relative to Existing Conditions, and slightly increased relative to the No Action Alternative (ELT). Overall, the difference in long-term average nitrate concentrations at various locations throughout the Delta under Alternative 4A compared to Alternative 4 would be negligible (i.e., <0.1 mg/L). As was similarly concluded for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), no additional exceedances of the MCL are anticipated at any location under Alternative 4A, regardless of operations scenario (Table N-1 in Appendix B of this RDEIR/SDEIS).

Use of assimilative capacity relative to the drinking water MCL of 10 mg/L-N under Alternative 4A would be low or negligible (i.e., <4%) in comparison to both Existing Conditions and the No Action Alternative (ELT), for all locations and months, for all modeled years (1976–1991), and for the drought period (1987–1991) (Tables N-6 and N-7 in Appendix B of this RDEIR/SDEIS). One exception is for Buckley Cove on the San Joaquin River in August, where use of assimilative capacity available during the drought period relative to the No Action Alternative (ELT) would range from 6.3% to 6.5%. Changes in use of assimilative capacity relative to Existing Conditions and the No

Action Alternative (ELT) under Alternative 4A would be approximately the same as described for Alternative 4.

As described for Alternative 4, actual nitrate concentrations would likely be higher than the modeling results indicate in certain locations under Alternative 4A. This is the mass balance modeling does not account for contributions from the SRWTP, which would be implementing nitrification/partial denitrification, or Delta wastewater treatment plant dischargers that practice nitrification, but not denitrification. However, as described for Alternative 4, any increases in nitrate concentrations that may occur at certain locations within the Delta under Alternative 4A would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the water quality at these locations, with regard to nitrate.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on nitrate are expected to be similar to those described above.

SWP/CVP Export Service Areas

Assessment of effects of Alternative 4A on nitrate in the SWP/CVP Export Service Areas is based on effects on nitrate at the Banks and Jones pumping plants.

Results of the mass balance calculations indicate that the change in nitrate concentrations and use of assimilative capacity would be similar for the two operations scenarios of Alternative 4A (Tables N-4 through N-7 in Appendix B of this RDEIR/SDEIS). Relative to Existing Conditions and the No Action Alternative (ELT), nitrate concentrations at Banks and Jones pumping plants under Alternative 4A are anticipated to decrease on a long-term average annual basis (Tables N-4 and N-5 in Appendix B of this RDEIR/SDEIS). During the late summer, particularly in the drought period assessed, concentrations are expected to increase substantially on a relative basis (i.e., >50%), but the absolute value of these changes (i.e., in mg/L-N) would be small. Additionally, given the many factors that contribute to potential algal blooms in the SWP and CVP canals within the Export Service Areas, and the lack of studies that have shown a direct relationship between nutrient concentrations in the canals and reservoirs and problematic algal blooms in these water bodies, there is no basis to conclude that these small (i.e., generally <0.3 mg/L-N), seasonal increases in nitrate concentrations would increase the potential for problem algal blooms in the SWP/CVP Export Service Areas. Overall, the difference in long-term average nitrate concentrations at Banks and Jones pumping plants under Alternative 4A compared to Alternative 4 would be negligible (i.e., <0.1 mg/L). As was similarly concluded for Alternative 4, no additional exceedances of the MCL are anticipated under Alternative 4A (Table N-1 in Appendix B of this RDEIR/SDEIS). On a monthly average basis and on a long-term annual average basis, for all modeled years and for the drought period only, use of assimilative capacity available under Existing Conditions and the No Action Alternative (ELT), relative to the 10 mg/L-N MCL, would be negligible (<3%) for both Banks and Jones pumping plants (Tables N-4 and N-5 in Appendix B of this RDEIR/SDEIS). Use of assimilative capacity relative to Existing Conditions and the No Action Alternative (ELT) for Alternative 4A would be slightly less than expected to occur under Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS).

In the LLT, the primary difference will be changes in the Delta source water fractions to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on nitrate are expected to be similar to those described above.

Any increases in nitrate concentrations that may occur in water exported via Banks and Jones pumping plants are not expected to result in adverse effects to beneficial uses or substantially degrade the quality of exported water, with regard to nitrate.

NEPA Effects**:** Modified reservoir operations and subsequent changes in river flows under Alternative 4A, relative to the No Action Alternative (ELT and LLT), are expected to have negligible, if any, effects on reservoir and river nitrate concentrations upstream of Freeport in the Sacramento River watershed and upstream of the Delta in the San Joaquin River watershed. In the Delta, nitrate concentrations throughout the Delta are anticipated to remain low (<1.4 mg/L-N) relative to adopted objectives. No additional exceedances of the 10 mg/L-N MCL are anticipated at any Delta location, and use of assimilative capacity available under the No Action Alternative, relative to the drinking water MCL of 10 mg/L-N, would be low. Long-term average nitrate concentrations at Banks and Jones pumping plants are anticipated to differ negligibly relative to the No Action Alternative (ELT and LLT) and no additional exceedances of the 10 mg/L-N MCL are anticipated. Therefore, the effects on nitrate from implementing water conveyance facilities are considered to be not adverse.

CEQA Conclusion: Nitrate concentrations are generally low in the reservoirs and rivers of the watersheds, owing to substantial dilution available for point sources and the lack of substantial nonpoint sources of nitrate upstream of the SRWTP in the Sacramento River watershed, and in the watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers).Although higher in the San Joaquin River watershed, nitrate concentrations are not well-correlated with flow rates. Consequently, any modified reservoir operations and subsequent changes in river flows under Alternative 4A, relative to Existing Conditions, are expected to have negligible, if any, effects on reservoir and river nitrate concentrations upstream of Freeport in the Sacramento River watershed and upstream of the Delta in the San Joaquin River watershed.

In the Delta, results of the mass balance calculations indicate that under Alternative 4A, relative to Existing Conditions, nitrate concentrations throughout the Delta are anticipated to remain low (<1.4 mg/L-N) relative to adopted objectives. No additional exceedances of the 10 mg/L-N MCL are anticipated at any location, and use of assimilative capacity available under Existing Conditions, relative to the drinking water MCL of 10 mg/L-N, would be low or negligible (i.e., <4%) for all for virtually all locations and months.

Assessment of effects of nitrate in the SWP/CVP Export Service Areas is based on effects on nitrate concentrations at the Banks and Jones pumping plants. Results of the mass balance calculations indicate that under Alternative 4A relative to Existing Conditions, long-term average nitrate concentrations at Banks and Jones pumping plants are anticipated to change negligibly. No additional exceedances of the 10 mg/L-N MCL are anticipated, and use of assimilative capacity available under Existing Conditions, relative to the MCL would be negligible (i.e., <3%) for both Banks and Jones pumping plants for all months.

Based on the above, there would be no substantial, long-term increase in nitrate concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the SWP/CVP Export Service Areas under Alternative 4A relative to Existing Conditions. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because nitrate concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Nitrate is not CWA Section 303(d) listed within the affected environment and thus any increases that may occur in some areas and months would not make any existing nitrate-related impairment measurably worse because no such impairments currently exist. Because nitrate is not bioaccumulative, increases that may occur in some areas and months would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-16: Effects on Nitrate Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Some habitat restoration activities included in Environmental Commitments 3, 4, and 6–11 would occur on lands within the Delta formerly used for agriculture. As discussed for Impact WQ-2, increased biota that may result in those areas may increase ammonia, which in turn may be converted to nitrate by established microbial communities. However, the areal extent of new habitat implemented for the Environmental Commitments would be less than the existing and No Action Alternative habitat areas, and similar habitat exists currently in the Delta and is not identified as contributing to adverse nitrate conditions. Thus, these land use changes would not be expected to substantially increase nitrate concentrations in the Delta. Implementation of Environmental Commitments 12, 15, and 16 do not include actions that would affect nitrate sources or loading. Based on these findings, the effects on nitrate from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

CEQA Conclusion: Land use changes that would occur from the environmental commitments are not expected to substantially increase nitrate concentrations, because the amount of area to be converted would be small relative to existing habitat, and existing habitats are not known for contributing to adverse nitrate conditions. Thus, it is expected that implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because nitrate concentrations are not expected to increase substantially due to these environmental commitments, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Nitrate is not CWA Section 303(d) listed within the affected environment and thus any minor increases that may occur in some areas would not make any existing nitrate-related impairment measurably worse because no such impairments currently exist. Because nitrate is not bioaccumulative, minor increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-17: Effects on Dissolved Organic Carbon Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 4A on DOC concentrations in reservoirs and rivers upstream of the Delta would be similar to those effects described for Alternative 4 because factors affecting DOC concentrations (e.g., source and non-point source inputs) in these water bodies would be similar.

Moreover, long-term average flow and DOC levels in the Sacramento River at Hood and San Joaquin River at Vernalis are poorly correlated. Thus changes in system operations and resulting reservoir storage levels and river flows under Alternative 4A would not be expected to cause substantial long-term changes in DOC concentrations in the water bodies upstream of the Delta. Any changes in DOC levels in water bodies upstream of the Delta under Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would not be of sufficient frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies.

Delta

Effects of water conveyance facilities on long-term average DOC concentrations under Alternative 4A in the Delta would be similar to the effects discussed for Alternative 4. To the extent that habitat restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. However, there would be less potential for increased DOC concentrations at western Delta locations associated with habitat restoration under Alternative 4A because very little would occur relative to Alternative 4. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-18. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Under Alternative 4A, the geographic extent of effects pertaining to long-term average DOC concentrations in the Delta would be similar to that described for Alternative 4, although the magnitude of predicted long-term change and relative frequency of concentration threshold exceedances would be lower. The effects of Alternative 4A relative to Existing Conditions and the No Action Alternative (ELT) are discussed together because the direction and magnitude of predicted change are similar. Relative to the Existing Conditions and No Action Alternative (ELT), Alternative 4A would result in small increases in long-term average DOC concentrations for both the modeled 16-year period (1976–1991) and drought period (1987–1991) at several interior Delta locations (increases up to 0.3 mg/L at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, and Contra Costa Pumping Plant #1) (Table DOC-1 in Appendix B of this RDEIR/SDEIS). The increases in average DOC concentrations would correspond to more frequent concentration threshold exceedances, with the greatest change occurring at the Contra Costa Pumping Plant #1 locations exceeding the 3 mg/L (i.e., increase from 52% under Existing Conditions to 72% under Alternative 4A for the modeled 16-year period). The change in frequency of threshold concentration exceedances at other assessment locations would be similar or lower.

While Alternative 4A would lead to slightly higher long-term average DOC concentrations at some municipal water intakes and Delta interior locations, the predicted change would not be expected to adversely affect MUN beneficial uses, or any other beneficial use. As discussed for Alternative 4, substantial changes in ambient DOC concentrations would need to occur before significant changes in drinking water treatment plant design or operations are triggered. The increases in long-term average DOC concentrations estimated to occur at various Delta locations under Alternative 4A are of sufficiently small magnitude that they would not require existing drinking water treatment plants to substantially upgrade treatment for DOC removal above levels currently employed.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on DOC are expected to be similar to those described above.

Relative to Existing Conditions and the No Action Alternative (ELT and LLT), Alternative 4A would lead to predicted improvements in long-term average DOC concentrations at Barker Slough, as well as Banks and Jones pumping plants (discussed below).

SWP/CVP Export Service Areas

Under the Alternative 4A, long-term average DOC concentrations would decrease at Barker Slough (as much as 0.1–0.2 mg/L) and at both the Banks and Jones pumping plants (as much as 0.4 mg/L) relative to Existing Conditions and depending on operational scenario, and the reductions would be similar compared to No Action Alternative (ELT) (Table DOC-1 in Appendix B of this RDEIR/SDEIS). Decreases in long-term average DOC would result in generally lower exceedance frequencies for concentration thresholds, although the frequency of exceedances of the 3 mg/L threshold during the modeled drought period would increase at the Banks and Jones pumping plants (i.e., increase from 57% under Existing Conditions to 77% under Alternative 4A). Comparisons to the No Action Alternative (ELT) yield similar trends, but with slightly smaller magnitude drought period changes.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on DOC are expected to be similar to those described above.

Maintenance of SWP and CVP facilities under Alternative 4A would not be expected to create new sources of DOC or contribute towards a substantial change in existing sources of DOC in the affected area.

NEPA Effects: In summary, the operations and maintenance activities under Alternative 4A, relative to the No Action Alternative (ELT and LLT), would not cause a substantial long-term change in DOC concentrations in the water bodies upstream of the Delta, in the Delta, or in the SWP/CVP Export Service Areas. The long-term average DOC concentrations at Banks and Jones pumping plants are predicted to decrease by about 0.4 mg/L, while long-term average DOC concentrations for some Delta interior locations are predicted to increase by as much as 0.3 mg/L. Regardless of operational scenario, the increase in long-term average DOC concentration that could occur within the Delta interior would not be of sufficient magnitude to adversely affect the MUN beneficial use, or any other beneficial uses, of Delta waters. Based on these findings, the effect of operations and maintenance activities on DOC under Alternative 4A is determined to be not adverse.

CEQA Conclusion: For the same reasons described for Alternative 4, the operations and maintenance activities under Alternative 4A, relative to the Existing Conditions, would not cause a substantial long-term change in DOC concentrations in the water bodies upstream of the Delta, in the Delta, or in the SWP/CVP Export Service Areas. Any modified reservoir operations and subsequent changes in river flows under Alternative 4A, relative to Existing Conditions, would not be expected to result in a substantial adverse change in DOC levels upstream of the Delta. Moreover, long-term average flow and DOC at Sacramento River at Hood and San Joaquin River at Vernalis are poorly correlated; therefore, changes in river flows would not be expected to cause a substantial long-term change in DOC concentrations upstream of the Delta.

Relative to Existing Conditions, the Alternative 4A would result in relatively small increases (i.e., ≤0.3 mg/L) in long-term average DOC concentrations at some interior Delta locations. The predicted increases under the operational scenarios modeled would not substantially increase the frequency with which long-term average DOC concentrations exceeds 2, 3, or 4 mg/L. While the operational scenarios would lead to slightly higher long-term average DOC concentrations at the interior Delta locations and some municipal water intakes, the predicted changes would not be expected to adversely affect MUN beneficial uses, or any other beneficial use.

Relative to Existing Conditions, the Alternative 4A would result in reduced long-term average DOC concentrations at the Banks and Jones pumping plants and Barker Slough. However, Alternative 4A would result in slightly greater frequency of exceedance of the 3 mg/L DOC concentration threshold during the modeled drought period. Nevertheless, under any operational scenario, an overall improvement in DOC-related water quality would be predicted in the SWP/CVP Export Service Areas.

Based on the above, the operations and maintenance activities of Alternative 4A Scenarios H3–H4 would not result in any substantial change in long-term average DOC concentration. The increases in long-term average DOC concentration that could occur within the Delta would not be of sufficient magnitude to adversely affect the MUN beneficial use, or any other beneficial uses, of Delta waters or waters of the SWP/CVP Service Area. Because DOC is not bioaccumulative, the increases in long-term average DOC concentrations would not directly cause bioaccumulative problems in aquatic life or humans. Finally, DOC is not causing beneficial use impairments and thus is not CWA Section 303(d) listed for any water body within the affected environment. Because long-term average DOC concentrations are not expected to increase substantially, no long-term water quality degradation with respect to DOC is expected to occur and, thus, no adverse effects on beneficial uses would occur. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-18: Effects on Dissolved Organic Carbon Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

The potential types of effects on DOC resulting from implementation of the environmental commitments under Alternative 4A would be generally similar to those described under Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). However, the magnitude of effects on DOC at locations upstream of the Delta, in the Delta, and the SWP/CVP export service areas would be considerably lower than described for Alternative 4.

As described for Alternative 4, Environmental Commitments 3, 9, 11, 12, 15, and 16 would present no major sources of DOC to the affected environment, including areas Upstream of the Delta, within the Plan Area, and the SWP/CVP Export Service Area that would adversely affect beneficial uses. Environmental Commitments 4, 6, 7, and 10 include habitat restoration activities known to be sources of DOC. However, the amount of new habitat restoration to be implemented would be very small compared to the areal extent of existing habitat and that proposed for the No Action Alternative. Based on the amount of habitat restoration proposed, DOC loading from these areas would be very low in these water bodies. Consequently, relative to the Existing Conditions and No Action Alternative (ELT and LLT), the potential DOC loading to the Delta would be minimal, and thus not contribute substantially to the amounts of DOC in raw drinking water supplies.

NEPA Effects: Relative to existing habitat and that to be developed under the No Action Alternative (ELT and LLT), the area of new habitat restoration implemented for the environmental commitments would be very small. Implementation of non-habitat restoration environmental commitments would not be expected to have substantial, if even measurable, effect on DOC concentrations upstream of the Delta, within the Delta, and in the SWP/CVP Export Service Areas, because they would present no major sources of DOC to the affected environment. Consequently, any increases in average DOC levels in the affected environment are not expected to be of sufficient frequency, magnitude and geographic extent that would adversely affect the MUN beneficial use, or any other beneficial uses, of the affected environment, nor would potential increases substantially degrade water quality with regard to DOC. Based on these findings, the effect of the environmental commitments on DOC is determined to be not adverse.

CEQA Conclusion: Implementation of habitat restoration environmental commitments is not expected to cause a substantial long-term change in DOC concentrations in the water bodies upstream of the Delta, in the Delta, or in the SWP/CVP Export Service Areas, relative to the Existing Conditions, because the land area proposed for restoration would be relatively small compared to existing land area and sources of DOC. Implementation of other environmental commitments also would not be expected to have substantial, if even measurable, effect on DOC concentrations upstream of the Delta, within the Delta, and in the SWP/CVP Export Service Areas, because they would present no major sources of DOC to the affected environment. Consequently, increases in average DOC levels in the affected environment are not expected to be of sufficient frequency, magnitude and geographic extent that would adversely affect the MUN beneficial use, or any other beneficial uses, of the affected environment, nor would potential increases substantially degrade water quality with regard to DOC. Furthermore, DOC is not bioaccumulative, therefore changes in DOC concentrations would not cause bioaccumulative problems in aquatic life or humans. Finally, DOC is not causing beneficial use impairments and thus is not CWA Section 303(d) listed for any water body within the affected environment. Because long-term average DOC concentrations are not expected to increase substantially, no long-term water quality degradation with respect to DOC is expected to occur and, thus, no adverse effects on beneficial uses would occur. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-19: Effects on Pathogens Resulting from Facilities Operations and Maintenance

The effects of operation of the water conveyance facilities under Alternative 4A on pathogen levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). As described for Alternative 4, pathogen concentrations in the Sacramento and San Joaquin Rivers have a minimal relationship to flow rate in these rivers. Further, urban runoff contributions during the dry season would be expected to be a relatively small fraction of the rivers' total flow rates. During wet weather events, when urban runoff contributions would be higher, the flows in the rivers also would be higher. Given the small magnitude of urban runoff contributions relative to the magnitude of river flows and that pathogen concentrations in the rivers have a minimal relationship to river flow rate, river flow rate and reservoir storage reductions that would occur under Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would not be expected to result in a substantial adverse change in pathogen concentrations in the reservoirs and rivers upstream of the Delta.

The effects of Alternative 4A relative to Existing Conditions and the No Action Alternative (ELT and LLT) would be changes in the relative percentage of water throughout the Delta being comprised of various source waters (i.e., water from the Sacramento River, San Joaquin River, Bay water, eastside tributaries, and agricultural return flow), due to potential changes in inflows particularly from the Sacramento River watershed. However, as described for Alternative 4, it is expected there would be no substantial change in Delta pathogen concentrations in response to a shift in the Delta source water percentages under this alternative or substantial degradation of these water bodies, with regard to pathogens, because it is expected that pathogen sources in close proximity to Delta sites would have a greater influence on pathogen levels at the site, rather than the primary source(s) of water to the site. In-Delta potential pathogen sources, including water-based recreation, tidal habitat, wildlife, and livestock-related uses, would continue under this alternative. As such, there is not expected to be substantial, if even measurable, changes in pathogen concentrations in the SWP/CVP Export Service Area waters.

As such, Alternative 4A would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or U.S. EPA-recommended pathogen criteria would be exceeded in water bodies of the affected environment located upstream of the Delta or substantially degrade the quality of these water bodies, with regard to pathogens.

NEPA Effects: Because pathogen levels are expected to be minimally affected relative to the No Action Alternative (ELT and LLT), the effects on pathogens from implementing Alternative 4A are determined to be not adverse.

CEQA Conclusion: The effects of Alternative 4A on pathogen levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because the factors that would affect pathogen levels in the surface waters of these areas would be similar. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because pathogen concentrations are not expected to increase substantially, no long-term water quality degradation for pathogens is expected to occur and, thus, no adverse effects on beneficial uses would occur. The San Joaquin River in the Stockton Deep Water Ship Channel is CWA Section 303(d) listed for pathogens. Because no measurable increase in Deep Water Ship Channel pathogen concentrations are expected to occur on a long-term basis, further degradation and impairment of this area is not expected to occur. Finally, pathogens are not bioaccumulative constituents. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-20: Effects on Pathogens Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** Environmental Commitments 3, 4, and 6–11 would involve habitat restoration actions. Tidal wetlands are known to be sources of coliforms originating from aquatic, terrestrial, and avian wildlife that inhabit these areas (Desmarais et al. 2001, Grant et al. 2001, Evanson and Ambrose 2006, Tetra Tech 2007). Specific locations of restoration areas for this alternative have not yet been established. However, most low-lying land suitable for restoration is unsuitable for livestock. Therefore, it is likely that the majority of land to be converted to wetlands would be crop-based agriculture or fallow/idle land. Because of a great deal of scientific uncertainty in the loading of coliforms from these various sources, the resulting change in coliform loading is uncertain, but it is anticipated that coliform loading to Delta waters would increase. Based on findings from the Pathogens Conceptual Model that pathogen concentrations are greatly influenced by the proximity to the source, this could result in localized increases in wildlife-related coliforms relative to the No Action Alternative (ELT and LLT). The geographic extent of the potential increases would be less than under Alternative 4, because less land would be converted under Alternative 4A. The Delta currently supports similar habitat types and, with the exception of the CWA Section 303(d) listing for the Stockton Deep Water Ship Channel, is not recognized as exhibiting pathogen concentrations that rise to the level of adversely affecting beneficial uses. As such, the potential increase in wildlife-related coliform concentrations due to tidal habitat creation is not expected to adversely affect beneficial uses.

The remaining environmental commitments would not be expected to affect pathogen levels, because they are actions that do not affect the presence of pathogen sources.

Based on these findings, the effects on pathogens from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

CEQA Conclusion: Based on findings from the Pathogens Conceptual Model that pathogen concentrations are greatly influenced by the proximity to the source, implementation of Environmental Commitments 3, 4, and 6–11 could result in localized increases in wildlife-related coliforms relative to Existing Conditions. The geographic extent of the increase would be less than under Alternative 4, because less land would be converted under Alternative 4A. The Delta currently supports similar habitat types and, with the exception of the CWA Section 303(d) listing for the Stockton Deep Water Ship Channel, is not recognized as exhibiting pathogen concentrations that rise to the level of adversely affecting beneficial uses. As such, the potential increase in wildlife-related coliform concentrations due to tidal habitat creation is not expected to adversely affect beneficial uses. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because pathogen concentrations are not expected to increase substantially, no long-term water quality degradation for pathogens is expected to occur and, thus, no adverse effects on beneficial uses would occur. The San Joaquin River in the Stockton Deep Water Ship Channel is CWA Section 303(d) listed for pathogens. Because no measurable increase in Deep Water Ship Channel pathogen concentrations are expected to occur on a long-term basis, further degradation and impairment of this area is not expected to occur. Finally, pathogens are not bioaccumulative constituents. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-21: Effects on Pesticide Concentrations Resulting from Facilities Operations and Maintenance

The effects of Alternative 4A on pesticide levels in surface waters upstream of the Delta, relative to Existing Conditions and the No Action Alternative (ELT), would be similar to those expected to occur under Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because under Alternative 4A, the primary factor that would influence pesticide concentrations in surface waters upstream of the Delta—the effect of timing and magnitude of reservoir releases on dilution capacity—is expected to change by a similar degree. As shown in Tables P-1 through P-4 in Appendix B of this RDEIR/SDEIS, changes in average winter and summer flow rates, relative to Existing Conditions and the No Action Alternative (ELT), are expected to be similar to or less than changes in flow rates expected under Alternative 4 in the Sacramento River at Freeport, American River at Nimbus, Feather River at Thermalito and the San Joaquin River at Vernalis (shown in Tables 1–4 in Appendix 8L, *Pesticides*, of the Draft EIR/EIS). Similarly, the primary factor that would influence pesticide concentrations in surface waters of the Delta and in the SWP/CVP Export Service Areas (i.e., changes in San Joaquin River, Sacramento River and Delta Agriculture source water fractions at various Delta locations, including Banks and Jones pumping plants) is expected to change by a similar degree. As shown for the two operational scenarios of Alternative 4A (Figures B.4-23 through B.4-66 in Appendix B of this RDEIR/SDEIS), the percent change in monthly average source water fractions would be similar to changes expected under Alternative 4 (Figures 133–175 in Appendix 8D, *Source Water Fingerprinting Results*, of the Draft EIR/EIS).

It was concluded for Alternative 4, and thus for Alternative 4A based on similar flow changes, that the potential average summer flow reductions would not be of sufficient magnitude to substantially increase in-river pesticide concentrations or alter the long-term risk of pesticide-related effects on aquatic life beneficial uses upstream of the Delta. Greater long-term average flow reductions, and corresponding reductions in dilution/assimilative capacity, would be necessary before long-term risk of pesticide related effects on aquatic life beneficial uses would be adversely altered. Similarly, the modeled changes in the source water fractions of Sacramento River, San Joaquin River, and Delta agriculture water under Alternative 4A would not be of sufficient magnitude to substantially alter the long-term risk of pesticide-related toxicity to aquatic life, nor adversely affect other beneficial uses of the Delta. Based on the general observation that San Joaquin River, in comparison to the Sacramento River, is a greater contributor of organophosphate insecticides in terms of greater frequency of incidence and presence at concentrations exceeding water quality benchmarks, modeled increases in Sacramento River fraction at Banks and Jones would generally represent an improvement in export water quality respective to pesticides.

The flow changes in the LLT would be expected in the ranges of that described above for Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT), and that described for Alternative 4 relative to the No Action Alternative (LLT) in Chapter 8, Section 8.3.3.9, in Appendix A of this RDEIR/SDEIS. Thus, similar to above and Alternative 4, the flow changes that would occur in the LLT under Alternative 4A, relative to Existing Conditions and the No Action Alternative (LLT), would not be expected to result in changes in dilution of pesticides of sufficient magnitude to substantially alter the long-term risk of pesticide-related toxicity to aquatic life, nor adversely affect other beneficial uses upstream of the Delta, in the Delta, or the SWP/CVP Export Service Areas.

NEPA Effects: In summary, the changes in long-term average flows on the Sacramento, Feather, American, and San Joaquin Rivers under Alternative 4A relative to the No Action Alternative (ELT and LLT) would be of insufficient magnitude to substantially increase the long-term risk of pesticide-related water quality degradation and related toxicity to aquatic life in these water bodies upstream of the Delta. Similarly, changes in source water fractions to the Delta would be of insufficient magnitude to substantially alter the long-term risk of pesticide-related water quality degradation and related toxicity to aquatic life in the Delta or CVP/SWP Export Service Areas. Therefore, the effects on pesticides from the water conveyance facilities are determined not to be adverse.

***CEQA Conclusion*:** Based on the discussion above, the effects of Alternative 4A on pesticide levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to or slightly less than those described for the Alternative 4. The considered operational scenarios of Alternative 4A would not result in any substantial change in long-term average pesticide concentration or result in substantial increase in the anticipated frequency with which long-term average pesticide concentrations would exceed aquatic life toxicity thresholds or other beneficial use effect thresholds upstream of the Delta, at the 11 assessment locations analyzed for the Delta, or the SWP/CVP service area. Numerous pesticides are currently used throughout the affected environment, and while some of these pesticides may be bioaccumulative, those present-use pesticides for which there is sufficient evidence for their presence in waters affected by SWP and CVP operations (i.e., diazinon, chlorpyrifos, diuron, and pyrethroids) are not considered bioaccumulative, and thus changes in their concentrations would not directly cause bioaccumulative problems in aquatic life or humans. Furthermore, while there are numerous CWA Section 303(d) listings throughout the affected environment that name pesticides as the cause for beneficial use impairment, the modeled changes in upstream river flows and Delta source water fractions under Scenarios H3–H4 would not be expected to make any of these beneficial use impairments measurably worse. Because long-term average pesticide concentrations are not expected to increase substantially, no long-term water quality degradation with respect to pesticides is expected to occur and, thus, no adverse effects on beneficial uses would occur. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-22: Effects on Pesticide Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), Environmental Commitments 3, 4, and 6–11 could involve the conversion of active or fallow agricultural lands to natural landscapes, such as wetlands, grasslands, floodplains, and vernal pools. In the long-term, conversion of agricultural land to natural landscapes could possibly result in a limited reduction in pesticide use throughout the Delta. In the short-term, tidal and non-tidal wetland restoration over former agricultural lands may include the contamination of water with pesticide residues contained in the soils. Present use pesticides typically degrade fairly rapidly, and in such cases where pesticide containing soils are flooded, dissipation of those pesticides would be expected to occur rapidly. Environmental Commitments 12, 15, and 16 do not include actions that would affect pesticide sources or loading. Unlike under Alternative 4, *CM13 Invasive Aquatic Vegetation Control* and *CM19 Urban Stormwater Treatment* would not be implemented. Because of this, benefits to water quality from treatment measures that would reduce pesticide loading from urban land uses, as well as adverse impacts to water quality from application of herbicides directly to waters in the plan area that would occur under Alternative 4 would not occur under Alternative 4A.

NEPA Effects: Environmental Commitments 3, 4, 6–12, 15, and 16 do not involve actions that would contribute long-term additional loading of pesticides, and the potential short-term loading from former agricultural lands would be expected to degrade and dissipate rapidly. Therefore, relative to the No Action Alternative (ELT and LLT), the effects on pesticides from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to be not adverse.

CEQA Conclusion: Environmental Commitments 3, 4, 6–12, 15, and 16 do not involve actions that would contribute long-term additional loading of pesticides, and the potential short-term loading from former agricultural lands would be expected to degrade and dissipate rapidly, such that pesticide levels would differ little from Existing Conditions. Therefore, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause substantial long-term increases in pesticide concentrations in the rivers and reservoirs upstream of the Delta, in the Delta Region, or the SWP/CVP Export Service Areas. As such, these environmental commitments are not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because pesticide concentrations are not expected to increase substantially, no long-term water quality degradation for pesticides is expected to occur and, thus, no adverse effects to beneficial uses would occur. Furthermore, any negligible changes in long-term pesticide concentrations that may occur throughout the affected environment would not be expected to make any existing beneficial use impairments measurably worse. Environmental Commitments 3, 4, 6–12, 15, 16 do not include the use of pesticides known to be bioaccumulative in animals or humans, nor do the environmental commitments propose the use of any pesticide currently named in a CWA Section 303(d) listing of the affected environment. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-23: Effects on Phosphorus Concentrations Resulting from Facilities Operations and Maintenance

The effects of Alternative 4A on phosphorus concentrations in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because factors which affect phosphorus concentrations in surface waters of these areas are the same under Alternative 4 and Alternative 4A. As described for Alternative 4, phosphorus loading to waters upstream of the Delta is not anticipated to change, and because changes in flows do not necessarily result in changes in concentrations or loading of phosphorus to these water bodies, substantial changes in phosphorus concentration are not anticipated under Alternative 4A, relative to Existing Conditions or the No Action Alternative (ELT and LLT), upstream of the Delta. Phosphorus concentrations may increase during January through March at locations in the Delta where the source fraction of San Joaquin River water increases, due to the higher concentration of phosphorus in the San Joaquin River during these months compared to Sacramento River water or San Francisco Bay water. However, based on the DSM2 fingerprinting results (Figures B.4-1 through B.4-66 in Appendix B of this RDEIR/SDEIS), together with source water concentrations (in Figure 8-56 in Appendix A of the RDEIR/SDEIS), the magnitude of increases during these months is expected to be negligible to low (i.e., <0.02 mg/L) at all Delta locations relative to Existing Conditions and the No Action Alternative (ELT and LLT). Thus, phosphorus concentrations in the Delta and waters exported from Banks and Jones pumping plants to the SWP/CVP Export Service Areas are expected to be similar to Existing Conditions and the No Action Alternative (ELT and LLT).

NEPA Effects: In summary, operation of the water conveyance facilities would have little to no effect on phosphorus concentrations in water bodies upstream of the Delta, in the Plan Area, and the waters exported to the SWP/CVP Export Service Areas, relative to the No Action Alternative (ELT and LLT). Thus, effects of the water conveyance facilities on phosphorus are considered to be not adverse.

CEQA Conclusion**:** The effects of Alternative 4A on phosphorus levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the Alternative 4. There would be no substantial, long-term increase in phosphorus concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the waters exported to the CVP and SWP service areas under Alternative 4A relative to Existing Conditions. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because phosphorus concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Phosphorus is not CWA Section 303(d) listed within the affected environment and thus any minor increases that may occur in some areas would not make any existing phosphorus-related impairment measurably worse because no such impairments currently exist. Because phosphorus is not bioaccumulative, minor increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-24: Effects on Phosphorus Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS) Environmental Commitments 3, 4, and 6–11 would include activities that create additional aquatic habitat, which may affect phosphorus dynamics and speciation in localized areas where the restoration would occur, but would not contribute to additional phosphorus loading. Therefore, phosphorus concentrations are not expected to change substantially in the affected environment as a result of these restoration activities. Unlike under Alternative 4, *CM19 Urban Stormwater Treatment* would not be implemented under Alternative 4A. Because urban stormwater is a potential source of phosphorus in the affected environment, the slight decreases in phosphorus loading expected to occur as a result of implementation of CM19 under Alternative 4, relative to Existing Conditions and the No Action Alternative, would not occur under Alternative 4A. Environmental Commitments 12, 15, and 16 do not include actions that would affect phosphorus sources or loading.

NEPA Effects: Environmental Commitments 3, 4, 6–12, 15, and 16 do not involve actions that would contribute long-term additional loading of phosphorus. Therefore, relative to the No Action Alternative (ELT and LLT), the effects on phosphorus from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

CEQA Conclusion: Environmental Commitments 3, 4, 6–12, 15, and 16 do not involve actions that would contribute long-term additional loading of phosphorus. Therefore, there would be no substantial, long-term increase in phosphorus concentrations in the rivers and reservoirs upstream of the Delta, in the Delta Region, or the waters exported to the SWP/CVP Export Service Areas due to implementation of these environmental commitments relative to Existing Conditions. Because phosphorus concentrations are not expected to increase substantially due to these environmental commitments, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Phosphorus is not CWA Section 303(d) listed within the affected environment and, thus, the environmental commitments would not make any existing phosphorus-related impairment measurably worse because no such impairments currently exist. Because phosphorus is not bioaccumulative, any increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-25: Effects on Selenium Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 4A on selenium concentrations in reservoirs and rivers upstream of the Delta would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), because factors affecting selenium concentrations in these water bodies would be similar. Substantial point sources of selenium do not exist upstream in the Sacramento River watershed, in the watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), or upstream of the Delta in the San Joaquin River watershed. Nonpoint sources of selenium within the watersheds of the Sacramento River and the eastern tributaries also are relatively low, resulting in generally low selenium concentrations in the reservoirs and rivers of those watersheds. Consequently, any modified reservoir operations and subsequent changes in river flows under Alternative 4A, relative to Existing Conditions or the No Action Alternative (ELT and LLT), are expected to have negligible, if any, effects on reservoir and river selenium concentrations upstream of Freeport in the Sacramento River watershed or in the eastern tributaries upstream of the Delta. Similarly, it is expected that selenium concentrations in the San Joaquin River would be minimally affected, if at all, by anticipated changes in flow rates under Alternative 4A, given the relatively small decreases in flows and the considerable variability in the relationship between selenium concentrations and flows in the San Joaquin River. Any negligible changes in selenium concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to selenium.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 4A would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-26. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Alternative 4A would result in small changes in average selenium concentrations in water relative to Existing Conditions and No Action Alternative (ELT) at all modeled Delta assessment locations (Table Se-1 in Appendix B of this RDEIR/SDEIS). Long-term average concentrations at some interior and western Delta locations would increase by 0.01–0.04 μg/L for the entire period modeled (1976–1991), depending on operational scenario. These small increases in selenium concentrations in water would result in small reductions (4% or less) in available assimilative capacity for selenium, relative to USEPA's draft water quality criterion of 1.3 μg/L (Tables Se-8a and Se-8b in Appendix B of this RDEIR/SDEIS). The long-term average selenium concentrations in water under Alternative 4A (range 0.09–0.40 μg/L) would be similar to Existing Conditions (range 0.09–0.41 μg/L) and the No Action Alternative (ELT) (range 0.09–0.39 μg/L), and would be below the draft water quality criterion of 1.3 μg/L (Table Se-1 in Appendix B of this RDEIR/SDEIS). These changes would be nearly identical to those under Alternative 4.

Relative to Existing Conditions and the No Action Alternative (ELT), Alternative 4A would result in small changes (about 1% or less) in estimated selenium concentrations in most biota (whole-body fish, bird eggs [invertebrate diet or fish diet], and fish fillets) throughout the Delta, with little difference among locations (Tables Se-2a, Se-2b, Se-4a and Se-4b in Appendix B of this RDEIR/SDEIS). Level of Concern Exceedance Quotients (i.e., modeled tissue divided by Level of Concern benchmarks) for selenium concentrations in those biota for all years and for drought years are less than 1.0, indicating low probability of adverse effects. Similarly, Advisory Tissue Level Exceedance Quotients for selenium concentrations in fish fillets for all years and drought years are less than 1.0. Estimated selenium concentrations in sturgeon for the San Joaquin River at Antioch are predicted to increase by about 17 to 19 percent relative to Existing Conditions and to the No

Action Alternative (ELT) in all years (from about 4.7 to about 5.6 mg/kg dry weight [dw]), and those for sturgeon in the Sacramento River at Mallard Island are predicted to increase by about 12 percent in all years (from about 4.4 to 4.9 mg/kg dw) (Tables Se-5 and Se-6 in Appendix B of this RDEIR/SDEIS). Selenium concentrations in sturgeon during drought years are expected to increase by about 4 to 7 percent at those locations (Tables Se-5 and Se-6 in Appendix B of this RDEIR/SDEIS). Detection of small changes in whole-body sturgeon such as those estimated for the western Delta would require very large sample sizes because of the inherent variability in fish tissue selenium concentrations. Low Toxicity Threshold Exceedance Quotients for selenium concentrations in sturgeon in the western Delta would exceed 1.0 for drought years at both locations (as they do for Existing Conditions and the No Action Alternative (ELT) and for all years in the San Joaquin River at Antioch (where quotient increases from 0.94 to 1.1) (Table Se-7 in Appendix B of this RDEIR/SDEIS). The High Toxicity Threshold Quotient would be less than 1.0 at both locations for all years and drought years (Table Se-7 in Appendix B of this RDEIR/SDEIS).

The disparity between larger estimated changes for sturgeon and smaller changes for other biota is attributable largely to differences in modeling approaches, as described in Appendix 8M, *Selenium*, in Appendix A of this RDEIR/SDEIS. The model for most biota was calibrated to encompass the varying concentration-dependent uptake from waterborne selenium concentrations (expressed as the K_d, which is the ratio of selenium concentrations in particulates [as the lowest level of the food chain] relative to the waterborne concentration) that was exhibited in data for largemouth bass in 2000, 2005, and 2007 at various locations across the Delta. In contrast, the modeling for sturgeon could not be similarly calibrated at the two western Delta locations and used literature-derived uptake factors and trophic transfer factors for the estuary from Presser and Luoma (2013). As noted in Appendix 8M, there was a significant negative log-log relationship of K_d to waterborne selenium concentration that reflected the greater bioaccumulation rates for bass at low waterborne selenium than at higher concentrations. There was no difference in bass selenium concentrations in the Sacramento River at Rio Vista in comparison to the San Joaquin River at Vernalis in 2000, 2005, and 2007 [Foe 2010], despite a nearly 10-fold difference in waterborne selenium. Thus, there is more confidence in the site-specific modeling based on the Delta-wide model that was calibrated for bass data than in the estimates for sturgeon based on "fixed" K_ds for all years and for drought years without regard to waterborne selenium concentration at the two locations in different time periods.

Residence time of water in the Delta is expected to increase relative to Existing Conditions primarily as a result of habitat restoration (8,000 acres of tidal habitat restoration and enhancements to the Yolo Bypass) that is assumed to occur under the No Action Alternative (ELT) separate from Alternative 4A. Although estimates of the residence time increases are not available for Alternative 4A, estimates for Alternative 4 Scenario H3 at the Late Long Term (presented in Table 8-60a in Section 8.3.1.7 of Appendix A in the *Microcystis* subsection) which contained 65,000 acres of tidal restoration are available, and is expected that residence time increases under Alternative 4A would be substantially less than identified for Alternative 4 in the table.

If increases in fish tissue or bird egg selenium were to occur as a result of increased residence time, the increases would likely be of concern only where fish tissues or bird eggs are already elevated in selenium to near or above thresholds of concern. That is, where biota concentrations are currently low and not approaching thresholds of concern (which, as discussed above, is the case throughout the Delta, except for sturgeon in the western Delta), changes in residence time alone would not be expected to cause them to then approach or exceed thresholds of concern. Thus, the most likely area in which biota tissues would be at levels high enough that additional bioaccumulation due to increased residence time from restoration areas would be a concern is the western Delta and Suisun

Bay for sturgeon. Based on the expected minor increases in residence time in the western Delta and Suisun Bay, any increases are not expected to be of sufficient magnitude to substantially affect selenium bioaccumulation.

Relative to Existing Conditions and the No Action Alternative (ELT), Alternative 4A would result in essentially no change in selenium concentrations throughout the Delta for most biota (about 1% or less), although larger increases in selenium concentrations are predicted for sturgeon in the western Delta. Concentrations of selenium in sturgeon would exceed only the lower benchmark, indicating a low potential for effects. The modeling of bioaccumulation for sturgeon is less calibrated to site-specific conditions than that for other biota, which was calibrated on a robust dataset for modeling of bioaccumulation in largemouth bass as a representative species for the Delta. Overall, Alternative 4A would not be expected to substantially increase the frequency with which applicable water quality criterion, or toxicity and level of concern benchmarks would be exceeded in the Delta (there being only a small increase for sturgeon relative to the low benchmark and no exceedance of the high benchmark) or substantially degrade the quality of water in the Delta, with regard to selenium. These changes would be similar to those described for Alternative 4.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on selenium are expected to be similar to those described above.

SWP/CVP Export Service Areas

Alternative 4 would result in small (0.05–0.09 μg/L) decreases in long-term average selenium concentrations in water at the Banks and Jones pumping plants, relative to Existing Conditions and the No Action Alternative (ELT), for the entire period modeled (Table Se-1 in Appendix B of this RDEIR/SDEIS). These decreases in long-term average selenium concentrations in water would result in increases in available assimilative capacity for selenium at these pumping plants, relative to the USEPA's draft water quality criterion of 1.3 μg/L (Tables Se-8a and Se-8b in Appendix B of this RDEIR/SDEIS). The long-term average selenium concentrations in water for Alternative 4A (range 0.16–0.19 μg/L) would be well below the draft water quality criterion of 1.3 μg/L (Table Se-1 in Appendix B of this RDEIR/SDEIS).

Relative to Existing Conditions and the No Action Alternative (ELT), Alternative 4A would result in small changes (about 1% or less) in estimated selenium concentrations in biota (whole-body fish, bird eggs [invertebrate diet], bird eggs [fish diet], and fish fillets) (Tables Se-4a and Se-4b in Appendix B of this RDEIR/SDEIS). Concentrations in biota would not exceed any selenium toxicity or level of concern benchmarks for Alternative 4A (Tables Se-4a and Se-4b in Appendix B of this RDEIR/SDEIS).

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on selenium are expected to be similar to those described above.

NEPA Effects**:** Relative to the No Action Alternative (ELT and LLT), Alternative 4A would result in essentially negligible changes in selenium concentrations in water upstream of the Delta. Similarly, there would be negligible changes in selenium water and most biota concentrations in the Delta, with no exceedances of benchmarks for biological effects. For sturgeon in the Delta, there would be only a small increase of threshold exceedance relative to the low benchmark for sturgeon and no exceedance of the high benchmark. At the Banks and Jones pumping plants, Alternative 4A would cause no increases in the frequency with which applicable benchmarks would be exceeded and would slightly improve the quality of water in selenium concentrations. Therefore, the effects on selenium (both as waterborne and as bioaccumulated in biota) from Alternative 4A are considered to be not adverse.

***CEQA Conclusion*:** There are no substantial point sources of selenium in watersheds upstream of the Delta, and no substantial nonpoint sources of selenium in the watersheds of the Sacramento River and the eastern tributaries. Nonpoint sources in the San Joaquin Valley that contribute selenium to the Delta will be controlled through a TMDL developed by the Central Valley Water Board (2001) for the lower San Joaquin River, established limits for the Grassland Bypass Project, and Basin Plan objectives (Central Valley Water Board [2010d] and State Water Board [2010b, 2010c]) that are expected to result in decreasing discharges of selenium from the San Joaquin River to the Delta. Consequently, any modified reservoir operations and subsequent changes in river flows under Alternative 4A, relative to Existing Conditions, are expected to cause negligible changes in selenium concentrations in water. Any negligible changes in selenium concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to selenium.

Relative to Existing Conditions, modeling estimates indicate Alternative 4A would result in essentially no change in selenium concentrations in water or most biota throughout the Delta, with no exceedances of benchmarks for biological effects. The Low Toxicity Threshold Exceedance Quotient for selenium concentrations in sturgeon for all years in the San Joaquin River at Antioch would increase slightly, from 0.94 for Existing Conditions to 1.1 for Alternative 4A. Concentrations of selenium in sturgeon would exceed only the lower benchmark, indicating a low potential for effects. Overall, Alternative 4A would not be expected to substantially increase the frequency with which applicable benchmarks would be exceeded in the Delta (there being only a small increase for sturgeon exceedance relative to the low benchmark for sturgeon and no exceedance of the high benchmark) or substantially degrade the quality of water in the Delta, with regard to selenium.

Assessment of effects of selenium in the SWP/CVP Export Service Areas is based on effects on selenium concentrations at the Banks and Jones pumping plants. Relative to Existing Conditions, all Alternative 4A would cause no increases in the frequency with which applicable benchmarks would be exceeded, and would slightly improve the quality of water in selenium concentrations at the Banks and Jones pumping plants.

Based on the above, selenium concentrations that would occur in water under Alternative 4A would not cause additional exceedances of applicable state or federal numeric or narrative water quality objectives/criteria, or other relevant water quality effects thresholds identified for this assessment, by frequency, magnitude, and geographic extent that would result in adverse effects to one or more beneficial uses within affected water bodies. In comparison to Existing Conditions, water quality conditions under Alternative 4A would not increase levels of selenium by frequency, magnitude, and geographic extent such that the affected environment would be expected to have measurably higher body burdens of selenium in aquatic organisms, thereby substantially increasing the health risks to wildlife (including fish) or humans consuming those organisms. Water quality conditions under these alternative scenarios with respect to selenium would not cause long-term degradation of water quality in the affected environment, and therefore would not result in use of available assimilative capacity such that exceedances of water quality objectives/criteria would be likely and would result in substantially increased risk for adverse effects to one or more beneficial uses. This alternative would not further degrade water quality by measurable levels, on a long-term basis, for selenium and, thus, cause the CWA Section 303(d)-listed impairment of beneficial use to be made discernibly worse. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-26: Effects on Selenium Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS) Environmental Commitments 12, 15, and 16 do not involve actions that would increase selenium loading or otherwise alter selenium concentrations or residence time such that there would be a change in selenium concentrations in water or biota. Further, with the possible exception of changes in Delta hydrodynamics resulting from habitat restoration, Environmental Commitments 3, 4, and 6–11 would not substantially increase selenium concentrations in the water bodies of the affected environment. Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics, and thus such effects of these restoration measures were included in the assessment of facilities operations and maintenance (see Impact WQ-25).

While the implementation of Environmental Commitment 4 would create shallow backwater areas that could result in local increased water residence times, the extent of these areas would be minimal relative to the area of the Delta, and environmental changes associated with their development are unlikely to be of magnitude that would measurably change selenium concentrations in water or biota, relative to Existing Conditions. Further, although water residence times associated restoration could increase, they are not expected to increase without bound, and selenium concentrations in the water column would not continue to build up and be recycled in sediments and organisms as may be the case within a closed water system. However, because increases in bioavailable selenium in habitat restoration areas are uncertain, proposed avoidance and minimization measures would require evaluating risks of selenium exposure at a project level for each restoration area, minimizing to the extent practicable potential risk of additional bioaccumulation, and monitoring selenium levels in fish and/or wildlife to establish whether, or to what extent, additional bioaccumulation is occurring. See Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS for a description of the environmental commitment project proponents are making with respect to selenium management; and Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP for additional detail on this avoidance and minimization measure (AMM27).

NEPA Effects: Environmental Commitments 3, 4, 6–12, 15, and 16 would not increase selenium loading, and the amount of restoration that would occur would be minimal relative to the area of the Delta and implemented such that any localized changes in residence time are unlikely to measurably change selenium concentrations in water or biota relative to the No Action Alternative (ELT and LLT), under which more restoration would occur. Therefore, the effects on selenium from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to be not adverse.

***CEQA Conclusion*:** Environmental Commitments 3, 4, 6–12, 15, and 16 would not increase selenium loading, and the amount of restoration that would occur would be minimal relative to the area of the Delta and implemented such that any localized changes in residence time are unlikely to measurably change selenium concentrations in water or biota relative to Existing Conditions. Therefore, it is expected that with implementation of these environmental commitments there would be no substantial, long-term increase in selenium concentrations in water in the rivers and reservoirs upstream of the Delta, water in the Delta, or the waters exported to the SWP/CVP Export Service Areas, relative to Existing Conditions. As such, these environmental commitments would not cause additional exceedances of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Given the factors discussed in the assessment above and for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), any increases in bioaccumulation rates from waterborne selenium that could occur in some areas as a result of increased water residence times would not be of sufficient magnitude and geographic extent that any portion of the Delta would be expected to have measurably higher body burdens of selenium in aquatic organisms, and therefore would not substantially increase risk for adverse effects to beneficial uses. Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause long-term degradation of water quality resulting in sufficient use of available assimilative capacity such that occasionally exceeding water quality objectives/criteria would be likely. Also, these environmental commitments would not result in substantially increased risk for adverse effects to any beneficial uses. Furthermore, although the Delta is a CWA Section 303(d)-listed water body for selenium, given the discussion in the assessment above, it is unlikely that restoration areas would result in measurable increases in selenium in fish tissues or bird eggs such that the beneficial use impairment would be made discernibly worse.

Because it is unlikely that substantial increases in selenium in fish tissues or bird eggs would occur such that effects on aquatic life beneficial uses would be anticipated, and because of the avoidance and minimization measures that are designed to further minimize and evaluate the risk of such increases (see Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP for more detail on AMM27) as well as the Selenium Management environmental commitment (see Appendix 3B, *Environmental Commitments*, of the Draft EIR/EIS this impact is considered less than significant. No mitigation is required.

Impact WQ-27: Effects on Trace Metal Concentrations Resulting from Facilities Operations and Maintenance

The effects of operation of the water conveyance facilities under Alternative 4A on trace metal concentrations in surface waters upstream of the Delta, relative to Existing Conditions and the No Action Alternative (ELT and LLT) would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS).

Given the poor association of dissolved trace metal concentrations with flow, river flow rate and reservoir storage reductions that would occur under Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would not be expected to result in a substantial adverse change in trace metal concentrations in the reservoirs and rivers upstream of the Delta.

In the Delta, for metals of primarily aquatic life concern (copper, cadmium, chromium, lead, nickel, silver, and zinc), average and 95th percentile trace metal concentrations of the primary source waters to the Delta are very similar, and very large changes in source water fraction would be necessary to effect a relatively small change in trace metal concentration at a particular Delta location. Moreover, average and 95th percentile trace metal concentrations for these primary source waters are all below their respective water quality criteria, including those that are hardness-based (see Tables 8-51 and 8-52 in Appendix A of this RDEIR/SDEIS). No mixing of these three source waters could result in a metal concentration greater than the highest source water concentration, and given that the average and 95th percentile source water concentrations for copper, cadmium, chromium, led, nickel, silver, and zinc do not exceed their respective criteria, more frequent exceedances of criteria in the Delta would not occur. For metals of primarily human health and drinking water concern (arsenic, iron, manganese), average and 95th percentile concentrations are also very similar (see Tables 8–10 in Appendix 8N,*Trace Metals*, of the Draft EIR/EIS) and average concentrations are below human health criteria. No mixing of these three source waters could result in a metal concentration greater than the highest source water concentration, and given that the average water concentrations for arsenic, iron, and manganese do not exceed water quality criteria, more frequent exceedances of drinking water criteria in the Delta would not be expected to occur.

Because Alternative 4A would not result in substantial increases in trace metal concentrations in the water exported from the Delta or diverted from the Sacramento River through the proposed conveyance facilities, there is not expected to be substantial changes in trace metal concentrations in the SWP/CVP Export Service Areas, relative to Existing Conditions or the No Action Alternative (ELT and LLT).

As such, Alternative 4A would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or CTR criteria would be exceeded in the water bodies of the affected environment or substantially degrade the quality of these water bodies, with regard to trace metals.

NEPA Effects: Alternative 4A would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or CTR criteria would be exceeded in the water bodies of the affected environment or substantially degrade the quality of these water bodies, with regard to trace metals, relative to the No Action Alternative (ELT and LLT)., Therefore, the effects on trace metals from implementing Alternative 4A are determined to not be adverse.

CEQA Conclusion: While Alternative 4A would alter the magnitude and timing of reservoir releases north, south and east of the Delta, this would have no substantial effect on the various watershed sources of trace metals. Moreover, long-term average flow and trace metals at Sacramento River at Hood and San Joaquin River at Vernalis are poorly correlated; therefore, changes in river flows would not be expected to cause a substantial long-term change in trace metal concentrations upstream of the Delta.

Average and 95th percentile trace metal concentrations are very similar across the primary source waters to the Delta. Given this similarity, very large changes in source water fraction would be necessary to effect a relatively small change in trace metal concentration at a particular Delta location. Moreover, average and 95th percentile trace metal concentrations for these primary source waters are all below their respective water quality criteria. No mixing of these three source waters could result in a metal concentration greater than the highest source water concentration, and given that trace metals do not already exceed water quality criteria, more frequent exceedances of criteria in the Delta would not be expected to occur under Alternative 4A.

Because Alternative 4A is not expected to result in substantial changes in trace metal concentrations in Delta waters, which includes Banks and Jones pumping plants, effects on trace metal concentrations in the SWP/CVP Export Service Area are expected to be negligible.

As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because trace metal concentrations are not expected to increase substantially, no long-term water quality degradation for trace metals is expected to occur and, thus, no adverse effects to beneficial uses would occur. Furthermore, any negligible changes in long-term trace metal concentrations that may occur in water bodies of the affected environment would not be expected to make any existing beneficial use impairments measurably worse. The trace metals discussed in this assessment are not considered bioaccumulative, and thus would not directly cause bioaccumulative problems in aquatic life or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-28: Effects on Trace Metal Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 present no new sources of trace metals to the affected environment, including areas upstream of the Delta, within the Delta, or in the SWP/CVP Export Service Areas. CM19, which under Alternative 4 would fund projects to contribute to reducing pollutant discharges in urban stormwater, would not be implemented under Alternative 4A, thus the associated trace metal reduction described for Alternative 4 would not occur under this alternative. However, stormwater discharges would continue to be regulated by the state and contributions would be expected to be similar to Existing Conditions and the No Action Alternative (ELT and LLT). The remaining environmental commitments would not be expected to affect trace metal levels, because they are actions that do not affect the presence of trace metal sources. As they pertain to trace metals, implementation of these environmental commitments would not be expected to adversely affect beneficial uses of the affected environment or substantially degrade water quality with respect to trace metals.

NEPA Effects: Because Environmental Commitments 3, 4, 6–12, 15, and 16 present no new sources of trace metals to the affected environment, the effects on trace metal concentrations from implementing these environmental commitments are determined to be not adverse.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause substantial long-term increase in trace metal concentrations in the rivers and reservoirs upstream of the Delta, in the Delta Region, or the SWP/CVP Export Service Areas, because they present no new sources of trace metals to the affected environment. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because trace metal concentrations are not expected to increase substantially, no long-term water quality degradation for trace metals is expected to occur and, thus, no adverse effects to beneficial uses would occur. Furthermore, any negligible changes in long-term trace metal concentrations that may occur throughout the affected environment would not be expected to make any existing beneficial use impairments measurably worse. The trace metals discussed in this assessment are not considered bioaccumulative, and thus would not directly cause bioaccumulative problems in aquatic life or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-29: Effects on TSS and Turbidity Resulting from Facilities Operations and Maintenance

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), the operation of the water conveyance facilities under Alternative 4A is expected to have a minimal effect on TSS and turbidity levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions and the No Action Alternative (ELT and LLT). This is because the factors that would affect TSS and turbidity levels in the surface waters of these areas would be the same. TSS concentrations and turbidity levels in rivers upstream of the Delta are affected primarily by: 1) TSS concentrations and turbidity levels of the water released from the upstream reservoirs, 2) erosion occurring within the river channel beds, which is affected by river flow velocity and bank protection, 3) TSS concentrations and turbidity levels of tributary inflows, point-source inputs, and nonpoint runoff as influenced by surrounding land uses; and 4) phytoplankton, zooplankton and other biological material in the water. Within the Delta, TSS concentrations and turbidity levels in Delta waters are affected by TSS concentrations and turbidity levels of inflows (and associated sediment load), as well as fluctuation in flows within the channels due to the tides, with sediments depositing as flow velocities and turbulence are low at periods of slack tide, and sediments becoming suspended when flow velocities and turbulence increase when tides are near the maximum. TSS and turbidity variations can also be attributed to phytoplankton, zooplankton and other biological material in the water. These factors would be similar under Alternative 4A and Alternative 4, are expected to be minimally different from Existing Conditions and the No Action Alternative (ELT and LLT). Because Alternative 4A is expected to have minimal effect on TSS concentrations and turbidity levels in Delta waters, including water exported at the south Delta pumps, relative to Existing Conditions or the No Action Alternative (ELT and LLT), Alternative 4A also is expected to have minimal effect on TSS concentrations and turbidity levels in the SWP/CVP Export Service Areas waters.

NEPA Effects: Because TSS concentrations and turbidity levels are expected to be minimally affected relative to the No Action Alternative (ELT and LLT), the effects on TSS and turbidity from implementing Alternative 4A are determined to not be adverse.

CEQA Conclusion: As described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS) changes in river flow rate and reservoir storage that would occur under Alternative 4A, relative to Existing Conditions, would not be expected to result in a substantial adverse change in TSS concentrations and turbidity levels in the reservoirs and rivers upstream of the Delta, given that suspended sediment concentrations are more affected by season than flow. Within the Delta, geomorphic changes associated with sediment transport and deposition are usually gradual, occurring over years, and high storm event inflows would not be substantially affected. Thus, it is expected that the TSS concentrations and turbidity levels in the affected channels would not be substantially different from the levels under Existing Conditions. There is not expected to be substantial, if even measurable, changes in TSS concentrations and turbidity levels in the SWP/CVP Export Service Areas waters under Alternative 4A, relative to Existing Conditions, because this alternative is not expected to result in substantial changes in TSS concentrations and turbidity levels at the south Delta export pumps, relative to Existing Conditions. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives where such objectives are not exceeded under Existing Conditions. Because TSS concentrations and turbidity levels are not expected to be substantially different, long-term water quality degradation is not expected, and, thus, beneficial uses are not expected to be adversely affected. Finally, TSS and turbidity are neither bioaccumulative nor CWA Section 303(d) listed constituents. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-30: Effects on TSS and Turbidity Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Environmental Commitments 3, 4, and 6–11 would involve habitat restoration actions. Creation of habitat and open water through implementation of these environmental commitments could affect Delta hydrodynamics and, thus, erosion and deposition potential in certain Delta channels, though the geographic extent of the effects would be substantially less than under Alternative 4, because less land would be converted under Alternative 4A. The magnitude of increases in TSS concentrations and turbidity levels in the affected channels due to higher potential of erosion cannot be readily quantified. The increases in TSS concentrations and turbidity levels in the affected channels could be substantial in localized areas, depending on how rapidly the channels equilibrate with the new tidal flux regime, after implementation of this alternative. However, geomorphic changes associated with sediment transport and deposition are usually gradual, occurring over years. Within the reconfigured channels there could be localized increases in TSS concentrations and turbidity levels, but within the greater Plan Area it is expected that the TSS concentrations and turbidity levels would not be substantially different from the levels under Existing Conditions or the No Action Alternative (ELT and LLT).

CM19, which under Alternative 4 would fund projects to contribute to reducing pollutant discharges in stormwater, would not be implemented under Alternative 4A, thus the associated TSS and turbidity reduction described for Alternative 4 would not occur under this alternative. Nevertheless, stormwater discharges would still be subject to the state's NPDES program requirements to implement control measures, which would contribute to controlling TSS and turbidity in discharges.

The remaining environmental commitments would not be expected to affect TSS concentrations and turbidity levels, because they are actions that do not affect the presence of TSS and turbidity sources.

***NEPA Effects*:** Localized, temporary changes in TSS and turbidity could occur associated with the restoration actions of Environmental Commitments 3, 4, 6–12, 15, and 16. However, these changes would be gradual and not expected to substantially differ from No Action Alternative (ELT and LLT) conditions. Therefore, the effects on TSS and turbidity from implementing these environmental commitments are determined to be not adverse.

***CEQA Conclusion*:** It is expected that the TSS concentrations and turbidity levels Upstream of the Delta, in the Plan Area, and the SWP/CVP Export Service Areas due to implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not be substantially different relative to Existing Conditions, except within localized areas of the Delta modified through creation of habitat and open water. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives where such objectives are not exceeded under Existing Conditions. Because TSS concentrations and turbidity levels Upstream of the Delta, in the greater Plan Area, and in the SWP/CVP Export Service Areas are not expected to be substantially different, long-term water quality degradation is not expected relative to TSS and turbidity, and, thus, beneficial uses are not expected to be adversely affected. Finally, TSS and turbidity are neither bioaccumulative nor CWA Section 303(d) listed constituents. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-31: Water Quality Effects Resulting from Construction-Related Activities for the Water Conveyance Facilities and Environmental Commitments

The potential construction-related water quality effects that would occur under Alternative 4A would be of a lower magnitude compared to the effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because the size and number of construction activities for some environmental commitments under Alternative 4A would be reduced, or not occur, compared to Alternative 4. The construction-related activities for the water conveyance facilities under Alternative 4A would be the same as described for Alternative 4. However, there would be substantially less area of in-water habitat restoration activities implemented under Alternative 4A compared to Alternative 4. Therefore, the amount of construction activity under Alternative 4A would be lower than described for Alternative 4, thus resulting in less potential for construction-related disturbances and contaminant discharges to surface waters.

The construction-related activities for Alternative 4A would be most extensive for the new water conveyance facilities. Construction of water conveyance facilities would involve vegetation removal, material storage and handling, excavation, overexcavation for facility foundations, surface grading, trenching, road construction, levee construction, construction site dewatering, soil stockpiling, reusable tunnel material (RTM) dewatering basin construction and storage operations, and other general facility construction activities (i.e., concrete, steel, carpentry, and other building trades) over approximately 7,500 acres during the course of constructing the facilities. Vegetation would be removed (via grubbing and clearing) and grading and other earthwork would be conducted at the intakes, pumping plants, the intermediate forebay, the Byron Tract Forebay, canal and gates between the Byron Tract Forebay tunnel shafts and the approach canal to the Banks Pumping Plant, borrow areas, RTM and spoil storage areas, setback and transition levees, sedimentation basins, solids handling facilities, transition structures, surge shafts and towers, substations, transmission line footings, access roads, concrete batch plants, fuel stations, bridge abutments, barge unloading facilities, and laydown areas. Construction of each intake would take nearly four years to complete.

Habitat restoration environmental commitments in the Delta, including restored tidal wetlands, floodplain, and related channel margin and off-channel habitats, also would involve substantial in-water construction-related activities in localized areas of the Delta. Other non-habitat restoration environmental commitments are not anticipated to involve construction activities that would result in substantial discharges of any constituents of concern.

NEPA Effects: Potential construction-related water quality effects may include discharges of turbidity/TSS due to the erosion of disturbed soils and associated sedimentation entering surface water bodies or other construction-related wastes (e.g., concrete, asphalt, cleaning agents, paint, and trash). Construction activities also may result in temporary or permanent changes in stormwater generation or drainage and runoff patterns (i.e., velocity, volume, and direction) that may cause or contribute to soil erosion and offsite sedimentation, such as creation of additional impervious surfaces (e.g., pavement, buildings, compacted soils), blockage or restriction of existing drainage channels, or general surface drainage changes from grading and excavation activity. Additionally, the use of heavy earthmoving equipment may result in spills and leakage of oils, gasoline, diesel fuel, and related petroleum contaminants used in the fueling and operation of such construction equipment.

Land surface grading and excavation activities, or exposure of disturbed sites immediately following construction and prior to stabilization, could result in rainfall- and stormwater-related soil erosion, runoff, and offsite sedimentation in surface water bodies. The initial runoff following construction, or return of seasonal rains to previously disturbed sites, can result in runoff with peak pollutant levels and is referred to as "first flush" storm events. Soil erosion and runoff can also result in increased concentrations and loading of organic matter, nutrients (nitrogen and phosphorus), and other contaminants contained in the soil such as trace metals, pesticides, or animal-related pathogens. Graded and exposed soils also can be compacted by heavy machinery, resulting in reduced infiltration of rainfall and runoff, thus increasing the rate of runoff (and hence contaminants) to downstream water bodies.

Construction activities also would be anticipated to involve the transport, handling, and use of a variety of hazardous substances and non-hazardous materials that may adversely affect water quality if discharged inadvertently to construction sites or directly to water bodies. Typical construction-related contaminants include petroleum products for refueling and maintenance of machinery (e.g., fuel, oils, solvents), concrete, paints and other coatings, cleaning agents, debris and trash, and human wastes. Construction activities also would involve large material storage and laydown areas, and occasional accidental spills of hazardous materials stored and used for construction may occur. Contaminants released or spilled on bare soil also may result in groundwater contamination. Dewatering operations may contain elevated levels of suspended sediment or other constituents that may cause water quality degradation.

The intensity of construction activity along with the fate and transport characteristics of the chemicals used, would largely determine the magnitude, duration, and frequency of construction-related discharges and resulting concentrations and degradation associated with the specific constituents of concern. The potential water quality concerns associated with the major categories of contaminants that might be discharged as a result of construction activity include the following.

- Suspended sediment: May increase turbidity (i.e., reduce water clarity) that can affect aquatic organisms and increase the costs and effort of removal in municipal/industrial water supplies. Downstream sedimentation can affect aquatic habitat, or cause a nuisance if it affects functions of agricultural or municipal intakes, or boat navigation.
- Organic matter: May contribute turbidity and oxygen demanding substances (i.e., reduce dissolved oxygen levels) that can affect aquatic organisms. Organic carbon may increase the potential for disinfection byproduct formation in municipal drinking water supplies.
- Nutrients: May contribute nitrogen, phosphorus, and other key nutrients that can contribute to nuisance biostimulation of algae and vascular aquatic plants, which may affect municipal water supplies, recreation, aquatic life, and aesthetics.
- Petroleum hydrocarbons: May contribute toxic compounds to aquatic life, and oily sheens may reduce oxygen/gas transfer in water, foul aquatic habitats, and reduce water quality for municipal supplies, recreation, and aesthetics.
- Trace constituents (metals, pesticides, synthetic organic compounds): Compounds in eroded soil or construction-related materials (e.g., paints, coatings, cleaning agents) may be toxic to aquatic life.
- Pathogens: Bacteria, viruses, and protozoans may affect aquatic life and increase human health risks via municipal water supplies, reduced recreational water quality, or contaminated shellfish beds.

- Other inorganic compounds: Construction-related materials can contain inorganic compounds such as acidic/basic materials which can change pH and may adversely affect aquatic life and habitats. Concrete contains lime which can increase pH levels, and drilling fluids may alter pH.

Some construction-related contaminants, such as PAHs that may be in some fuel and oil petroleum byproducts, may be bioaccumulative in aquatic and terrestrial organisms. Construction activities also may disturb areas where bioaccumulative constituents are present in the soil (e.g., mercury, selenium, organochlorine pesticides, PCBs, and dioxin/furan compounds), or may disturb soils that contain constituents included on the Section 303(d) lists of impaired water bodies in the affected environment. While the 303(d)-listed Delta channels impaired by mercury are widespread, impairment by selenium, pesticides, PCBs, and dioxin/furan compounds is more limited, and there are no 303(d) listings for PAH impairment. Bioaccumulation of constituents in the aquatic foodchain, and 303(d)-related impaired water bodies, arise as a result of long-term loading of a constituent or a pervasive and widespread source of constituent discharge (e.g., mercury).However, as a result of the generally localized disturbances, and intermittent and temporary nature of construction-related activities, construction would not be anticipated to result in contaminant discharges of substantial magnitude or duration to contribute to long-term bioaccumulation processes, or cause measureable long-term degradation such that existing 303(d) impairments would be made discernibly worse or TMDL actions to reduce loading would be adversely affected.

The environmental commitments for construction-related water quality protection would be specifically designed as a part of the final design, included in construction contracts as a required element, and would be implemented to avoid, prevent, and minimize the potential discharges of constituents of concern to water bodies and associated adverse water quality effects and comply with state water quality regulations. Additionally, temporary and permanent changes in stormwater drainage and runoff would be minimized and avoided through construction of new or modified drainage facilities, as described in the Chapter 3, *Description of Alternatives*, in Appendix A of this RDEIR/SDEIS. This alternative would include installation of temporary drainage bypass facilities, long-term cross drainage, and replacement of existing drainage facilities that would be disrupted due to construction of new facilities.

Construction-related activities would be conducted in accordance with the environmental commitment to develop and implement BMPs for all activities that may result in discharge of soil, sediment, or other construction-related contaminants to surface water bodies, and obtain authorization for the construction activities under the State Water Board's NPDES Stormwater General Permit for Stormwater Discharges Associated with Construction and Land Disturbance Activities (Order No. 2009-0009-DWQ/NPDES Permit No. CAS000002). The General Construction NPDES Permit requires the preparation and implementation of SWPPPs, which are the principal plans within the required PRDs that identify the proposed erosion control and pollution prevention BMPs that would be used to avoid and minimize construction-related erosion and contaminant discharges. The development of the SWPPPs, and applicability of other provisions of this General Construction Permit depends on the "risk" classification for the construction which is determined based on the potential for erosion to occur as well as the susceptibility of the receiving water to potential adverse effects of construction. While the determination of project risk level, and planning and development of the SWPPPs and BMPs to be implemented, would be completed as a part of final design and contracting for the work, the responsibility for compliance with the provisions of the General Construction Permit necessitates that BMPs are applied to all disturbance activities. In addition to the BMPs, the SWPPPs would include BMP inspection and monitoring activities, and identify responsibilities of all parties, contingency measures, agency contacts, and training requirements and documentation for those personnel responsible for installation, inspection, maintenance, and repair of BMPs. The General Construction Permit contains NALs and for pH and turbidity, and specifies storm event water quality monitoring to determine if construction is resulting in elevated discharges of these constituents, and monitoring for any non-visible contaminants determined to have been potentially released. If an NAL is determined to have been exceeded, the General Construction Permit requires the discharger to conduct a construction site and run-on evaluation to determine whether contaminant sources associated with the site's construction activity may have caused or contributed to the exceedance and immediately implement corrective actions if they are needed.

The BMPs that are routinely implemented in the construction industry and have proven successful at reducing adverse water quality effects include, but are not limited to, the following broad categories of actions (letters refer to categories of specific BMPs identified in Appendix 3B, *Environmental Commitments*), for which Appendix 3B identifies specific BMPs within these categories:

- Waste Management and Spill Prevention and Response (BMP categories A.2 and A.3): Waste management BMPs are designed to minimize exposure of waste materials at all construction sites and staging areas such as waste collection and disposal practices, containment and protection of wastes from wind and rain, and equipment cleaning measures. Spill prevention and response BMPs involve planning, equipment, and training for personnel for emergency event response.
- Erosion and Sedimentation Control (BMP categories A.4 and A.5): Erosion control BMPs are designed to prevent erosion processes or events including scheduling work to avoid rain events, stabilizing exposed soils; minimize offsite sediment runoff; remove sediment from onsite runoff before it leaves the site; and slow runoff rates across construction sites. Identification of appropriate temporary and long-term seeding, mulching, and other erosion control measures as necessary. Sedimentation BMPs are designed to minimize offsite sediment runoff once erosion has occurred involving drainage controls, perimeter controls, detention/sedimentation basins, or other containment features.
- Good Housekeeping and Non-Stormwater Discharge Management (BMP category A.6 and A.7): Good housekeeping BMPs are designed to reduce exposure of construction sites and materials storage to stormwater runoff including truck tire tracking control facilities; equipment washing; litter and construction debris; and designated refueling and equipment inspection/maintenance practices Non-stormwater discharge management BMPs involve runoff measures for contaminants not directly associated with rain or wind including vehicle washing and street cleaning operations.
- Construction Site Dewatering and Pipeline Testing (BMP category A.8).Dewatering BMPs involve actions to prevent discharge of contaminants present in dewatering of groundwater during construction, discharges of water from testing of pipelines or other facilities, or the indirect erosion that may be caused by dewatering discharges.
- BMP Inspection and Monitoring (BMP category A.9): Identification of clear objectives for evaluating compliance with SWPPP provisions, and specific BMP inspection and monitoring procedures, environmental awareness training, contractor and agency roles and responsibilities, reporting procedures, and communication protocols.

In addition to the Category "A" BMPs for surface land disturbances identified in the environmental commitments (Appendix 3B, *Environmental Commitments*), BMPs implemented also would include the Category "B" BMPs for tunnel/pipeline construction that involves actions primarily to avoid and minimize sediment and contaminant discharges associated with RTM excavation, hauling, and RTM dewatering operations. Additionally, habitat restoration activities under CM2 and CM4–CM10 would be subject to implementation of the Category "C" BMPs (In-Water Construction BMPs) and Category "D" BMPs (Tidal and Wetland Restoration) designed to minimize disturbance and direct discharge of turbidity/suspended solids to the water during in-water construction activities. Category "E" BMPs identify general permanent post-construction actions that would be implemented for all terrestrial, in-water, and habitat restoration activities and would involve planning, design, and development of final site stabilization, revegetation, and drainage control features.

Finally, acquisition of applicable environmental permits may be required for specific conservation measures, which may include specific WDRs or CWA Section 401 water quality certifications from the appropriate Regional Water Boards, CDFW Streambed Alteration Agreements, and USACE CWA Section 404 dredge and fill permits. These other permit processes may include requirements to implement additional action-specific BMPs that may reduce potential adverse discharge effects of constituents of concern.

The potential construction-related contaminant discharges that could result from this alternative would not be anticipated to result in adverse water quality effects at a magnitude, frequency, or regional extent that would cause substantial adverse effects to aquatic life. Relative to Existing Conditions, this assessment indicates the following.

- Projects would be managed under state water quality regulations and project-defined actions to avoid and minimize contaminant discharges.
- Individual projects would generally be dispersed, and involve infrequent and temporary activities, thus not likely resulting in substantial exceedances of water quality standards or long-term degradation.
- Potential construction-related contaminant discharges would not cause additional exceedance of applicable water quality objectives where such objectives are not exceeded under Existing Conditions. Long-term water quality degradation is not anticipated, and hence would not be expected to adversely affect beneficial uses.
- By the intermittent and temporary frequency of construction-related activities and potential contaminant discharges, the constituent-specific effects would not be of substantial magnitude or duration to contribute to long-term bioaccumulation processes, or cause measureable long-term degradation such that existing 303(d) impairments would be made discernibly worse or TMDL actions to reduce loading would be adversely affected.

Consequently, because the construction-related activities for the conservation measures would be conducted with implementation of environmental commitments, including but not limited to those identified in Appendix 3B, with respect to the No Action Alternative conditions, this alternative would not be expected to cause constituent discharges of sufficient frequency and magnitude to result in a substantial increase of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern, and thus would not adversely affect any beneficial uses in the Delta.

In summary, with implementation of environmental commitments in Appendix 3B, the potential construction-related water quality effects are considered to be not adverse.

CEQA Conclusion: As explained above, water quality effects resulting from construction-related activities would be less under Alternative 4A compared to Alternative 4, which was determined to be less than significant. Moreover, because environmental commitments would be implemented under Alternative 4A for construction-related activities along with agency-issued permits that also contain construction requirements to protect water quality, the construction-related effects, relative to Existing Conditions, would not be expected to cause or contribute to substantial alteration of existing drainage patterns which would result in substantial erosion or siltation on- or off-site, substantial increased frequency of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern on a long-term average basis, and thus would not adversely affect any beneficial uses in water bodies upstream of the Delta, within the Delta, or in the SWP/CVP Export Service Areas. Moreover, because the construction-related activities would be temporary and intermittent in nature, the construction would involve negligible discharges, if any, of bioaccumulative or CWA Section 303(d) listed constituents to water bodies of the affected environment. As such, construction activities would not contribute measurably to bioaccumulation of contaminants in organisms or humans or cause CWA Section 303(d) impairments to be discernibly worse. Based on these findings, this impact is determined to be less than significant. No mitigation is required.

Impact WQ-32: Effects on *Microcystis* Bloom Formation Resulting from Facilities Operations and Maintenance

Upstream of the Delta

Adverse effects from *Microcystis* upstream of the Delta have only been documented in lakes such as Clear Lake, where eutrophic levels of nutrients give cyanobacteria a competitive advantage over other phytoplankton during the bloom season. Large reservoirs upstream of the Delta are typically characterized by low nutrient concentrations, where other phytoplankton outcompete cyanobacteria, including *Microcystis*. In the rivers and streams of the Sacramento River watershed, watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), and the San Joaquin River upstream of the Delta under Existing Conditions, bloom development is limited by high water velocity and low residence times. These conditions are not expected to change under Alternative 4A or the No Action Alternative (ELT and LLT). Consequently, any modified reservoir operations under Alternative 4A are not expected to promote *Microcystis* production upstream of the Delta, relative to Existing Conditions and the No Action Alternative (ELT and LLT).

Delta

Modeling that adequately accounted for the effects of water conveyance facilities operations and maintenance and the hydrodynamic impacts of the environmental commitments on long-term average residence times in the six Delta sub-areas was not available for Alternative 4A, so the hydrodynamic effects of this alternative on *Microcystis* were determined qualitatively. For the assessment of Alternative 4, modeling scenarios included assumptions regarding how certain habitat restoration activities of the project alternative would affect Delta hydrodynamics, so the impacts due solely to operations and maintenance of the water conveyance facilities under Alternative 4 could not be determined. Because the assessment for Alternative 4A is qualitative, the effects discussed for the Delta under water conveyance facilities are related solely to operations and maintenance, not the hydrodynamic effects of restoration actions, which are discussed in Impact WQ-33.

The effects of Alternative 4A on *Microcystis* levels, and thus microcystin concentrations in the Delta, relative to Existing Conditions, would be less than those described for Alternative 4 in Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS for the reasons discussed below.

Under the two operational scenarios of Alternative 4A, a portion of the Sacramento River water which would be conveyed through the Delta to the south Delta intakes under Existing Conditions would be replaced at various locations throughout the Delta by other source water due to diversion of Sacramento River water at the north Delta intake under Alternative 4A. The change in flow paths of water through the Delta that would occur under Alternative 4A could result in localized increases in residence time in various Delta sub-regions, and decreases in residence time in other areas. In general, there is substantial uncertainty regarding the extent that operations and maintenance of Alternative 4A would result in a net increase in water residence times at various locations throughout the Delta relative to Existing Conditions. In contrast to Alternative 4A, the combination of the habitat restoration and operations and maintenance assumptions included in the hydrodynamic modeling of Alternative 4 resulted in a substantial increase in water residence times, and thus a potential increase in *Microcystis* abundance, at numerous locations throughout the Delta at the late long-term timeframe relative to Existing Conditions.

Besides the effects of operations and maintenance described above, substantial increases in water residence times due to factors unrelated to the project alternative, including habitat restoration (8,000 acres of tidal habitat and enhancements to the Yolo Bypass), sea level rise and climate change, are expected to occur in the Delta, relative to Existing Conditions. Although there is uncertainty regarding the degree to which operations and maintenance of the project alternative would affect water residence times in the Delta, it is likely that such effects would be small in comparison to the combined effects of restoration activities, sea level rise and climate change. Slight increases in ambient water temperatures (1.3–2.5°F), due to climate change in the ELT, are expected to occur in the Delta under Alternative 4A, relative to Existing Conditions. However, due to the combination of the effects of restoration activities unrelated to the project alternative, climate change, and sea level rise on increased residence times, as well as the effects of climate change on increased ambient water temperatures, it is possible that increases in the frequency, magnitude, and geographic extent of *Microcystis* blooms in the Delta would occur, relative to Existing Conditions. The magnitude by which water temperatures and residence times would increase due to these factors would be less under Alternative 4A than under Alternative 4.

The effects of Alternative 4A on *Microcystis* levels, and thus microcystin concentrations in the Delta relative to the No Action Alternative (ELT and LLT) would be less than those described for Alternative 4 in Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS for the reasons discussed below.

As described relative to Existing Conditions, operations and maintenance of Alternative 4A could alter source water flow paths through the Delta, which could result in localized increases in residence time in various Delta sub-regions, and decreases in residence time in other areas. In general, there is substantial uncertainty regarding the extent that operations and maintenance of Alternative 4A would result in a net increase in water residence times at various locations throughout the Delta relative to the No Action Alternative (ELT and LLT).

The previously discussed influence of factors unrelated to implementation of the project alternative, including habitat restoration (8,000 acres of tidal habitat restoration and enhancements to the Yolo Bypass), climate change and sea level rise on increased water residence times, as well as the influence of climate change on increased ambient water temperatures in the Delta, would occur under both Alternative 4A and No Action Alternative (ELT and LLT). In summary, operations and maintenance of Alternative 4A is not expected to increase water residence times or ambient water temperatures throughout the Delta, and thus result in adverse effects on *Microcystis*, relative to No Action Alternative (ELT and LLT).

SWP/CVP Export Service Area

The effects of Alternative 4A on *Microcystis* levels, and thus microcystin concentrations, in the SWP/CVP Export Service Areas relative to Existing Conditions would be less than those described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). As described above for the Delta, source waters to the south Delta intakes could be adversely affected relative to Existing Conditions by *Microcystis* both from an increase in Delta water temperatures associated with climate change and from an increase in water residence times. The impacts from increased Delta water residence times would be primarily related to habitat restoration (8,000 acres of tidal habitat restoration and enhancements to the Yolo Bypass) that is assumed to occur separate from Alternative 4A. The combined effect of these factors on *Microcystis* in source waters to the south Delta intakes would likely be much greater than the influence of operations and maintenance of Alternative 4A, the effects of which are uncertain. In contrast to Alternative 4A, the combination of the habitat restoration and operations and maintenance assumptions included in the hydrodynamic modeling of Alternative 4 resulted in a substantial increase in water residence times, and thus a potential increase in *Microcystis* abundance, at numerous locations throughout the Delta relative to Existing Conditions. Increases in ambient air temperatures due to climate change relative to Existing Conditions are expected under this alternative. Increases in ambient air temperatures are expected to result in warmer ambient water temperatures, and thus conditions more suitable to *Microcystis* growth, in the water bodies of the SWP/CVP Export Service Areas. The incremental increase in long-term average air temperatures would be less at the ELT (2.0°F), compared to the LLT (4.0°F).

The effects of Alternative 4A on *Microcystis* levels, and thus microcystin concentrations, in the SWP/CVP Export Service Areas, relative to the No Action Alternative (ELT and LLT), are expected to be less than effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because effects of *Microcystis* on water exports from Banks and Jones pumping plants would be different between Alternative 4A and Alternative 4. Specifically, under Alternative 4A, the fraction of water flowing through the Delta that would reach the existing south Delta intakes is not expected to be adversely affected by *Microcystis* blooms, relative to the No Action Alternative (ELT and LLT), as discussed in the "Delta" section above; while under Alternative 4 this fraction of water is expected to be adversely affected by *Microcystis* blooms, relative to the No Action Alternative (LLT). Additionally, conditions in the SWP/CVP Export Service Areas under Alternative 4A are not expected to become more conducive to *Microcystis* bloom formation, relative to the No Action Alternative (ELT and LLT), because neither water residence time nor water temperatures are projected to increase in the SWP/CVP Export Service Areas.

NEPA Effects: Modified reservoir operations under Alternative 4A are not expected to promote *Microcystis* production upstream of the Delta, relative to the No Action Alternative (ELT and LLT). Similarly, operations and maintenance of Alternative 4A is not expected to increase water residence times or ambient water temperatures throughout the Delta, including at the Banks and Jones pumping plants, and thus result in adverse effects on *Microcystis* in the Delta, relative to No Action Alternative (ELT and LLT). Thus, the effects on *Microcystis* in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas from implementing water conveyance facilities are determined to be not adverse.

CEQA Conclusion: As with Alternative 4, modified reservoir operations under Alternative 4A are not expected to promote *Microcystis* production upstream of the Delta, relative to the Existing Conditions. The effects of operations and maintenance of water conveyance facilities under Alternative 4A on *Microcystis* in surface waters in the Delta and in the SWP/CVP Export Service Areas, relative to Existing Conditions, would be less than those described for the Alternative 4. Operations and maintenance of Alternative 4A is not expected to increase water residence times or ambient water temperatures throughout the Delta, including at the Banks and Jones pumping plants, and thus result in adverse effects on *Microcystis* in the Delta, relative to Existing Conditions. As such, this alternative would not be expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. *Microcystis* and microcystins are not CWA Section 303(d) listed within the affected environment and thus any increases that could occur in some areas would not make any existing *Microcystis* impairment measurably worse because no such impairments currently exist. Because *Microcystis* and microcystins are not bioaccumulative, increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. However, it is possible that increases in the frequency, magnitude, and geographic extent of *Microcystis* blooms in the Delta would occur under Alternative 4A for reasons unassociated with operations and maintenance of the project alternative, including tidal habitat restoration activities, climate change and sea level rise. While long-term water quality degradation may occur and, thus, impacts on beneficial uses could occur, these impacts are not related to implementation of Alternative 4A. Although there is considerable uncertainty regarding this impact, the effects on *Microcystis* from implementing water conveyance facilities are determined to be less than significant. No mitigation is required.

Impact WQ-33: Effects on *Microcystis* Bloom Formation Resulting from Environmental Commitments

Under Alternative 4A, Fisheries Enhancements to the Yolo Bypass would not be implemented, but under a plan separate and distinct from Alternative 4A, enhancements to the Yolo Bypass and 8,000 acres of tidal habitat restoration would be implemented in the ELT. These activities are assumed to occur under both Alternative 4A and the No Action Alternative. Implementation of Environmental Commitment 4 under Alternative 4A would result in a very small amount of tidal restoration within the Delta. In contrast, under Alternative 4, full implementation of Yolo Bypass enhancements would occur and 65,000 acres of tidal restoration would be developed. The implementation of Environmental Commitment 4 under Alternative 4A would have negligible effects compared to the development of 8,000 acres of tidal habitat and enhancements to the Yolo Bypass in the ELT that are unrelated to implementation of the alternative. These activities would create shallow backwater areas that could result in local warmer water and increased water residence time of magnitude and extent that would result in measurable changes on *Microcystis* levels in the Delta, relative to Existing Conditions.

The implementation of fisheries enhancements to the Yolo Bypass and the development of 65,000 acres of tidal restoration areas would be expected to result in widespread hydrodynamic effects that increase water residence times, and thus *Microcystis* levels, in the Delta under Alternative 4, relative to Existing Conditions and the No Action Alternative (LLT). Thus, the effects on *Microcystis* from implementing Environmental Commitment 4 under Alternative 4A, relative to Existing Conditions, would be substantially lower than expected under Alternative 4.

NEPA Effects: Based on the discussion above, the effects on *Microcystis* from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to be not adverse.

CEQA Conclusions: Based on the discussion above, Environmental Commitments 3, 4, 6–12, 15, and 16 would not be expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. *Microcystis* and microcystins are not CWA Section 303(d) listed within the affected environment and thus any increases that could occur in some areas would not make any existing *Microcystis* impairment measurably worse because no such impairments currently exist. Because *Microcystis* and microcystins are not bioaccumulative, increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. However, it is possible that increases in the frequency, magnitude, and geographic extent of *Microcystis* blooms in the Delta would occur at the early long-term for reasons unassociated with implementation of the Environmental Commitments, including tidal habitat restoration and enhancements to the Yolo Bypass. While long-term water quality degradation may occur and, thus, significant impacts on beneficial uses could occur, these impacts are not related to implementation of the Environmental Commitments. Therefore, the effects on *Microcystis* from implementing the Environmental Commitments are determined to be less than significant. No mitigation is required.

Impact WQ-34: Effects on San Francisco Bay Water Quality Resulting from Facilities Operations and Maintenance and Environmental Commitments

The effects analysis presented in the preceding impacts (Impact WQ-1 through WQ-33) concluded that Alternative 4A would have a less-than-significant impact/no adverse effect on the following constituents in the Delta:

- Boron
- Bromide
- Chloride
- DOC
- Dissolved oxygen
- Pathogens
- Pesticides
- Trace metals
- Turbidity and TSS
- *Microcystis*

Elevated concentrations of boron are of concern in drinking and agricultural water supplies. Chloride, DOC, and bromide concentrations also are of concern in drinking water supplies. However, waters in the San Francisco Bay are not designated to support municipal water supply (MUN) and agricultural supply (AGR) beneficial uses. Changes in Delta dissolved oxygen, pathogens, pesticides, trace metals, and turbidity and TSS are not anticipated to be of a frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of the Delta. Changes in *Microcystis* would be primarily due to factors unassociated with the project alternative. Thus, changes in boron, bromide, chloride, DOC, dissolved oxygen, pathogens, pesticides, trace metals, turbidity and TSS, and *Microcystis* in Delta outflow associated with implementation of Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT and LLT) are not anticipated to be of a frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of the of San Francisco Bay, as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of this RDEIR/SDEIS).

Elevated EC is of concern for its effects on the agricultural beneficial use (AGR) and fish and wildlife beneficial uses. San Francisco Bay does not have an AGR beneficial use designation. As described for Alternative 4, salinity throughout San Francisco Bay is largely a function of the tides, as well as to some extent the freshwater inflow from upstream. However, the changes in Delta outflow due to Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would be minor compared to tidal flows, and thus no substantial adverse effects on salinity, or fish and wildlife beneficial uses, downstream of the Delta are expected.

Also, as described for Alternative 4, changes in nutrient loading would not be expected to contribute to adverse effects to beneficial uses. Changes in nitrogen (ammonia and nitrate) loading to Suisun and San Pablo Bays under Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would not adversely impact primary productivity in these embayments because light limitation and grazing current limit algal production in these embayments. Nutrient levels and ratios are not considered a direct driver of *Microcystis* and cyanobacteria levels in the North Bay. The only postulated effect of changes in phosphorus loads to Suisun and San Pablo Bays is related to the influence of nutrient stoichiometry on primary productivity. However, there is uncertainty regarding the impact of nutrient ratios on phytoplankton community composition and abundance. As described for Alternative 4, any effect on phytoplankton community composition would likely be small compared to the effects of grazing from introduced clams and zooplankton in the estuary. Therefore, changes in total nitrogen and phosphorus loading that would occur in Delta outflow to San Francisco Bay, relative to Existing Conditions and the No Action Alternative (ELT and LLT), are not expected to result in degradation of water quality with regard to nutrients that would result in adverse effects to beneficial uses.

Similar to Alternative 4, loads of mercury, methylmercury, and selenium from the Delta to San Francisco Bay are estimated to change relatively little due to changes in source water fractions and net Delta outflow that would occur under Alternative 4A, relative to Existing Conditions and the No Action Alternative (ELT and LLT), because changes in Delta outflow would be similar.

NEPA Effects: Based on the discussion above, Alternative 4A, relative to the No Action Alternative (ELT and LLT), would not cause further degradation to water quality with respect to boron, bromide, chloride, dissolved oxygen, DOC, EC, mercury, pathogens, pesticides, selenium, nutrients (ammonia, nitrate, phosphorus), trace metals, turbidity and TSS, or *Microcystis* in the San Francisco Bay. Further, changes in these constituent concentrations in Delta outflow would not be expected to cause changes in Bay concentrations of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses. In summary, effects on the San Francisco Bay from implementation of water conveyance facilities and Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

CEQA Conclusion: As with Alternative 4, Alternative 4A would not be expected to cause long-term degradation of water quality in San Francisco Bay resulting in sufficient use of available assimilative capacity such that occasionally exceeding water quality objectives/criteria would be likely and would result in substantially increased risk for adverse effects to one or more beneficial uses. Further, this alternative would not be expected to cause additional exceedance of applicable water quality objectives/criteria in the San Francisco Bay by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. Any changes in boron, bromide, chloride, and DOC in the San Francisco Bay would not adversely affect beneficial uses, because the uses most affected by changes in these parameters, MUN and AGR, are not beneficial uses of the Bay. Further, no substantial changes in dissolved oxygen, pathogens, pesticides, trace metals, turbidity or TSS, and *Microcystis* are anticipated in the Delta due to the implementation of Alternative 4A, relative to Existing Conditions, therefore, no substantial changes to these constituents levels in the Bay are anticipated. Changes in Delta salinity would not contribute to measurable changes in Bay salinity, as the change in Delta outflow would be two to three orders of magnitude lower than (and thus minimal compared to) the Bay's tidal flow and thus, have minimal influence on salinity changes. Changes in nutrient load, relative to Existing Conditions, are expected to have minimal effect on water quality degradation, primary productivity, or phytoplankton community composition. As with Alternative 4, the change in mercury and methylmercury load (which is based on source water and Delta outflow), relative to Existing Conditions, would be within the level of uncertainty in the mass load estimate and not expected to contribute to water quality degradation, make the CWA Section 303(d) mercury impairment measurably worse or cause mercury/methylmercury to bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Similarly, based on Alternative 4 estimates, the increase in selenium load would be minimal, and total and dissolved selenium concentrations would be expected to be the same as Existing Conditions, and less than the target associated with white sturgeon whole-body fish tissue levels for the North Bay. Thus, the change in selenium load is not expected to contribute to water quality degradation, or make the CWA Section 303(d) selenium impairment measurably worse or cause selenium to bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

4.3.5 Geology and Seismicity

Impact GEO-1: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Strong Seismic Shaking of Water Conveyance Features during Construction

Earthquakes could be generated from local and regional seismic sources during construction of the Alternative 4A water conveyance facilities. Seismically induced ground shaking could cause injury of workers at the construction sites as a result of collapse of facilities.

As stated under Alternative 4, the results of the seismic study (California Department of Water Resources 2007a) show that the ground shakings in the Delta are not sensitive to the elapsed time since the last major earthquake (i.e., the projected shaking hazard results for 2005, 2050, 2100, and 2200 are similar).

The hazard of structural failure from seismic shaking under Alternative 4A resulting in loss of property, personal injury, or death during construction would be identical to Alternative 4.

NEPA Effects: Seismically-induced ground shaking could cause loss of property or personal injury at the Alternative 4A construction sites (including intake locations, pipelines from intakes to the intermediate forebay, the tunnels, the pumping plant, and the expanded Clifton Court Forebay) as a result of collapse of facilities. Facilities lying directly on or near active blind faults may have an increased likelihood of loss of property or personal injury in the event of seismically-induced ground shaking.

During construction, all active construction sites would be designed and managed to meet the safety and collapse-prevention requirements of the relevant state codes and standards listed under the Alternative 4 analysis, and discussed in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, for the anticipated seismic loads. Generally, the applicable codes require that facilities be built so that they incur minimal damage in the event of a foreseeable seismic event and that they remain functional following such an event and that the facility is able to perform without catastrophic failure in the event of a maximum design earthquake (the greatest earthquake reasonably expected to be generated by a specific source on the basis of seismological and geological evidence).

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment, practicing crane and scaffold safety measures).

Conformance with these health and safety requirements and the application of accepted, proven construction engineering practices would reduce any potential risk such that construction of Alternative 4A would not create an increased likelihood of loss of property, personal injury or death of individuals. Therefore, there would be no adverse effect.

***CEQA Conclusion*:** Seismically induced ground shaking that is estimated to occur and the resultant ground motion anticipated at Alternative 4A construction sites, including the intake locations, the tunnels, the pipelines and the forebays, could cause collapse or other failure of project facilities while under construction. As described under Alternative 4, DWR would conform to Cal-OSHA and other state code requirements, such as shoring, bracing, lighting, excavation depth restrictions, required slope angles, and other measures, to protect worker safety. Conformance with these standards and codes is an environmental commitment of the project (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS. Conformance with these health and safety requirements and the application of accepted, proven construction engineering practices would reduce this risk and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 4A. This impact would be less than significant. No mitigation is required.

Impact GEO-2: Loss of Property, Personal Injury, or Death from Settlement or Collapse Caused by Dewatering during Construction of Water Conveyance Features

As with Alternative 4, settlement of excavations could occur as a result of dewatering at Alternative 4A construction sites with shallow groundwater. Dewatering can stimulate settlement in excavation and tunneling sites. The settlement could cause the slopes of excavations to fail. Locations where dewatering would occur during construction of Alternative 4A water conveyance features would be identical to that under Alternative 4 and the potential impacts are identical under both alternatives.

NEPA Effects: This potential effect could be substantial because settlement or collapse during dewatering could cause injury of workers at the construction sites as a result of collapse of excavations.

The hazard of settlement and subsequent collapse of excavations would be evaluated by assessing site-specific geotechnical and hydrological conditions at intake locations, as well as where intake and forebay pipelines cross waterways and major irrigation canals. A California-registered civil engineer or California-certified engineering geologist would recommend measures in a geotechnical report to address these hazards, such as seepage cutoff walls and barriers, shoring, grouting of the bottom of the excavation, and strengthening of nearby structures, existing utilities, or buried structures. As described in Section 9.3.1, *Methods for Analysis*, the measures would conform to applicable design and building codes, guidelines, and standards, as described under Alternative 4.

DWR has made an environmental commitment to also conform to appropriate code and standard requirements to minimize potential risks (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Generally, the applicable codes require that facilities be built in such a way that settlement is minimized. Mandatory worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment, practicing crane and scaffold safety measures).

Conformance to these and other applicable design specifications and standards would ensure that construction of Alternative 4A would not create an increased likelihood of loss of property, personal injury or death of individuals from settlement or collapse caused by dewatering. Therefore, there would be no adverse effect.

***CEQA Conclusion*:** Settlement or failure of excavations during construction could result in loss of property or personal injury. However, DWR would conform to Cal-OSHA and other state code requirements to protect worker safety as described under Alternative 4. DWR has also made an environmental commitment to conform to appropriate codes and standards to minimize potential risks (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Additionally, DWR has made an environmental commitment that a geotechnical report be completed by a California-certified engineering geologist, that the report's geotechnical design recommendations be included in the design of project facilities, and that the report's design specifications are properly executed during construction to minimize the potential effects from settlement and failure of excavations. Proper execution of these environmental commitments to minimize potential risks would result in no increased likelihood of loss of property, personal injury or death due to construction of Alternative 4A. The impact would be less than significant. No mitigation is required.

Impact GEO-3: Loss of Property, Personal Injury, or Death from Ground Settlement during Construction of Water Conveyance Features

The potential for ground settlement under Alternative 4A would be identical to that under Alternative 4. The geologic units in the area of the Alternative 4A modified pipeline/tunnel alignment are the same as those shown for Alternative 4 in Figure 9-3 and summarized in Table 9-26 of the Draft EIR/EIS. The characteristics of each unit would affect the potential for settlement during geotechnical investigation and tunneling operations. Segments 1 and 3, located in the Clarksburg area and the area west of Locke, respectively, contain higher amounts of sand than the other segments, so they pose a greater risk of settlement.

Given the likely design depth of the tunnels, the potential for excessive systematic settlement expressed at the ground surface caused by tunnel installation is thought to be relatively low. Operator errors or highly unfavorable/unexpected ground conditions could result in larger settlement. Large ground settlements caused by tunnel construction are almost always the result of using inappropriate tunneling equipment (incompatible with the ground conditions), improperly operating the machine, or encountering sudden or unexpected changes in ground conditions.

NEPA Effects: The potential effect could be substantial because ground settlement could occur during geotechnical investigations and the tunneling operation. During detailed project design, a site-specific subsurface geotechnical evaluation would be conducted along the modified pipeline/tunnel alignment to verify or refine the findings of the preliminary geotechnical investigation. These effects would be reduced with implementation of DWR's Environmental Commitments and Avoidance and Minimization Measures (Appendix 3B in Appendix A of this RDEIR/SDEIS). As required by DWR's Environmental Commitments, the results of the site-specific evaluation and the California-registered civil engineer or California-certified engineering geologist's recommendations would be documented in a detailed geotechnical report prepared in accordance with state guidelines, in particular *Guidelines for Evaluating and Mitigating Seismic Hazards in California* (California Geological Survey 2008).

As described in Section 9.3.1*, Methods for Analysis,* the measures would conform to applicable design and building codes, guidelines, and standards, such as USACE design measures. See Alternative 4 for a specific list of applicable codes and standards DWR has made this conformance and monitoring process an environmental commitment (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

Generally, the applicable codes require that facilities be built so that they are designed for a landside slope stability and seepage/underseepage factors of safety greater than 1.0 (i.e., stable) and would therefore be less impacted in the event of ground settlement. The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment, practicing crane and scaffold safety measures). Conformance to these and other applicable design specifications and standards would ensure that construction of Alternative 4A would not create an increased likelihood of loss of property, personal injury or death of individuals from ground settlement. Therefore, there would be no adverse effect.

***CEQA Conclusion*:** Ground settlement above the tunneling operation could result in loss of property or personal injury during construction. However, DWR would conform to Cal-OSHA, USACE and other design requirements to protect worker safety as described under Alternative 4. DWR has made conformance to geotechnical design recommendations and monitoring an environmental commitment (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Hazards to workers and project structures would be controlled at safe levels and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 4A. The impact would be less than significant. No mitigation is required.

Impact GEO-4: Loss of Property, Personal Injury, or Death from Slope Failure during Construction of Water Conveyance Features

Excavation of borrow material could result in failure of cut slopes and application of temporary spoils and RTM at storage sites could cause excessive settlement in the spoils, potentially causing injury of workers at the construction sites. The potential for slope failure under Alternative 4A would be identical to that under Alternative 4.

NEPA Effects: The potential effect could be substantial because excavation of borrow material and the resultant cutslopes and potential failure of spoils/RTM fill slopes could cause injury of workers at the construction sites. The potential for slope failure under Alternative 4A would be identical to that under Alternative 4.

During design, the potential for native ground settlement below the spoils would be evaluated by a geotechnical engineer using site-specific geotechnical and hydrological information. The use of shoring, seepage cutoff walls, and ground modifications to prevent slope instability, soil boiling, or excessive settlement would be considered in the design. As described in Section 9.3.1, *Methods for Analysis,* the measures would conform to applicable design and building codes, guidelines, and standards.

In addition to the risk of slope failure at borrow sites and spoils and RTM sites, there are also potential impacts on levee stability resulting from construction of Alternative 4A water conveyance facilities. All levee reconstruction/building pad construction would conform to applicable state and federal flood management engineering and permitting requirements.

DWR would ensure that the geotechnical design recommendations are included in the design of project facilities and construction specifications and are properly executed during construction to minimize the potential effects from failure of excavations. Conformance with relevant codes and standards would reduce the potential risk for increased likelihood of loss of property or personal injury from settlement/failure of cutslopes of borrow sites and failure of soil or RTM fill slopes during construction. The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment, practicing crane and scaffold safety measures). The relevant codes and standards represent performance standards that must be met by contractors and these measures are subject to monitoring by state and local agencies. DWR has made this conformance and monitoring process an environmental commitment (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

Conformance to these and other applicable design specifications and standards would ensure that construction of Alternative 4A would not create an increased likelihood of loss of property, personal injury or death of individuals from slope failure at borrow sites and spoils and RTM storage sites.

The reconstruction of levees would improve levee stability over existing conditions due to improved side slopes, erosion countermeasures (geotextile fabrics, rock revetments, riprap, or other material), seepage reduction measures, and overall mass. Therefore, there would be no adverse effect.

CEQA Conclusion: Settlement/failure of cutslopes of borrow sites and failure of soil/RTM fill slopes could result in loss of property or personal injury during construction. However, because DWR would conform with Cal-OSHA and other state code requirements and conform to applicable geotechnical design guidelines and standards, such as USACE design measures, the hazard would be controlled to a safe level and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 4A at borrow sites and spoils and RTM storage sites. The reconstruction of levees would improve levee stability over existing conditions due to improved side slopes, erosion countermeasures, seepage reduction measures, and overall mass. The impact would be less than significant. No mitigation is required.

Impact GEO-5: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Construction-Related Ground Motions during Construction of Water Conveyance Features

Pile driving and other heavy equipment operations would cause vibrations that could initiate liquefaction and associated ground movements in places where soil and groundwater conditions are present to allow liquefaction to occur. The consequences of liquefaction could result in damage nearby structures and levees. The potential for liquefaction under Alternative 4A would be identical to that under Alternative 4.

NEPA Effects: The potential effect could be substantial because construction-related ground motions could initiate liquefaction, which could cause failure of structures during construction, which could result in injury of workers at the construction sites. The potential for liquefaction under Alternative 4A would be identical to that under Alternative 4.

During design, the facility-specific potential for liquefaction would be investigated by a geotechnical engineer. The investigations are an environmental commitment (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). In areas determined to have a potential for liquefaction, the California-registered civil engineer or California-certified engineering geologist would develop design strategies and construction methods to ensure that pile driving and heavy equipment operations do not cause liquefaction which otherwise could damage facilities under construction and surrounding structures, and could threaten the safety of workers at the site.

Design measures to avoid pile-driving induced levee failure may include predrilling or jetting, using open-ended pipe piles to reduce the energy needed for pile penetration, using CIDH piles/piers that do not require driving, using pile jacking to press piles into the ground by means of a hydraulic system, or driving piles during the drier summer months. Field data collected during design also would be evaluated to determine the need for and extent of strengthening levees, embankments, and structures to reduce the effect of vibrations. These construction methods would conform with current seismic design codes and requirements, as described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS. Such design standards include USACE's *Engineering and Design—Stability Analysis of Concrete Structures* and *Soil Liquefaction during Earthquakes,* by the Earthquake Engineering Research Institute.

DWR has made the environmental commitment (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), that the construction methods recommended by the geotechnical engineer are included in the design of project facilities and construction specifications to minimize the potential for construction-induced liquefaction. DWR also has committed to ensure that these methods are followed during construction.

Generally, the applicable codes require that facilities be built so that if soil in the foundation or surrounding area are subject to liquefaction, the removal or densification of the liquefiable material should be considered, along with alternative foundation designs. Additionally, any modification to a federal levee system would require USACE approval under 33 USC 408 (a 408 Permit).

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment, practicing crane and scaffold safety measures).

Conformance to construction method recommendations and other applicable specifications would ensure that construction of Alternative 4A would not create an increased likelihood of loss of property, personal injury or death of individuals due to construction-related ground motion and resulting potential liquefaction in the work area. Therefore, there would be no adverse effect.

***CEQA Conclusion*:** Construction-related ground motions could initiate liquefaction, which could cause failure of structures during construction. However, because DWR would conform to Cal-OSHA and other state code requirements and conform to applicable design guidelines and standards, such as USACE design measures, the hazard would be controlled to a level that would protect worker safety (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Further, DWR has made an environmental commitment (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) that the construction methods recommended by the geotechnical engineer are included in the design of project facilities and construction specifications to minimize the potential for construction-induced liquefaction. DWR also has committed to ensure that these methods are followed during construction. Proper execution of these environmental commitments would result in no increased likelihood of loss of property, personal injury or death due to construction of Alternative 4A. The impact would be less than significant. No mitigation is required.

Impact GEO-6: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Rupture of a Known Earthquake Fault during Operation of Water Conveyance Features

NEPA Effects: Alternative 4A would include the same physical/structural components as Alternative 4, and therefore, the effects of Alternative 4A would be the same as Alternative 4. The effect would not be adverse because like Alternative 4, no active faults extend into the Alternative 4A alignment. Additionally, although the Thornton Arch and West Tracy blind thrusts occur beneath the Alternative 4A alignment, they do not present a hazard of surface rupture based on available information, including the AP Earthquake Fault Zone Map showing faults capable of surface rupture (Figure 9-5 of the Draft EIR/EIS).

However, because there is limited information regarding the depths of the Thornton Arch and West Tracy blind thrusts, seismic surveys would be performed on the blind thrust during the design phase to determine the depths to the top of the faults. More broadly, design-level geotechnical studies would be prepared by a geotechnical engineer licensed in the state of California during project design. Consistent with the environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), DWR would ensure that the geotechnical engineer's recommended measures to address adverse conditions would conform to applicable design codes, guidelines, and standards, would be included in the project design and construction specifications, and would be properly executed during construction. Generally, the applicable codes require that facilities be built so that they incur minimal damage in the event of a foreseeable seismic event and that they remain functional following such an event and that the facility is able to perform without catastrophic failure in the event of a maximum design earthquake (the greatest earthquake reasonably expected to be generated by a specific source on the basis of seismological and geological evidence). As described in Section 9.3.1, *Methods for Analysis* in Chapter 9*, Geology and Seismicity*, of the Draft EIR/EIS*,* such conformance with design codes, guidelines, and standards are considered environmental commitments by DWR (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

DWR would ensure that the geotechnical design recommendations are included in the design of project facilities and construction specifications to minimize the potential effects from seismic events and the presence of adverse soil conditions. DWR would also ensure that the design specifications are properly executed during construction.

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment).

Conformance to these and other applicable design specifications and standards would ensure that operation of Alternative 4 would not create an increased likelihood of loss of property, personal injury or death of individuals in the event of ground movement in the vicinity of the project. There would be no adverse effect.

***CEQA Conclusion*:** There are no active faults capable of surface rupture that extend into the Alternative 4A modified pipeline/tunnel alignment. Design-level geotechnical studies would be prepared by a geotechnical engineer licensed in the state of California during project design. The studies would further assess site-specific conditions at and near all the project facility locations, including seismic activity, soil liquefaction, and other potential geologic and soil-related hazards. This information would be used to verify assumptions and conclusions included in the EIR/EIS. Consistent with the project's environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), DWR would ensure that the geotechnical engineer's recommended measures to address adverse conditions would conform to applicable design codes, guidelines, and standards, would be included in the project design and construction specifications, and would be properly executed during construction. Conformance to these and other applicable design specifications and standards would ensure that operation of Alternative 4 would not create an increased likelihood of loss of property, personal injury or death of individuals in the event of ground movement in the vicinity of the project. Therefore, such ground movements would not jeopardize the integrity of the surface and subsurface facilities along the Alternative 4A conveyance alignment or the proposed expanded Clifton Court Forebay and associated facilities adjacent to the existing Clifton Court Forebay. There would be no impact. No mitigation is required.

Impact GEO-7: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Strong Seismic Shaking during Operation of Water Conveyance Features

Earthquake events may occur on the local and regional seismic sources during operation of the Alternative 4A water conveyance facilities. The ground shaking could damage pipelines, tunnels, intake facilities, pumping plants, and other facilities disrupting the water supply through the conveyance system. In an extreme event of strong seismic shaking, uncontrolled release of water from damaged pipelines, tunnels, intake facilities, pumping plant, and other facilities could cause flooding, disruption of water supplies to the south, and inundation of structures. These effects are discussed more fully in Appendix 3E, *Potential Seismicity and Climate Change Risks to SWP/CVP Water Supplies*, of the Draft EIR/EIS.

NEPA Effects: This potential effect could be substantial because strong ground shaking could damage pipelines, tunnels, intake facilities, pumping plant, and other facilities and result in loss of property or personal injury. The effects of Alternative 4A would be identical to Alternative 4. The damage could disrupt the water supply through the conveyance system. In an extreme event, an uncontrolled release of water from the conveyance system could cause flooding and inundation of structures. Please refer to Chapter 6, *Surface Water*, and Appendix 3E, *Potential Seismicity and Climate Change Risks to SWP/CVP Water Supplies*, of the Draft EIR/EIS for a detailed discussion of potential flood effects.

The structure of the underground conveyance facility would decrease the likelihood of loss of property or personal injury of individuals from structural shaking of surface and subsurface facilities along the Alternative 4A conveyance alignment in the event of strong seismic shaking.

In accordance with the DWR's environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), design-level geotechnical studies would be conducted by a licensed civil engineer who practices in geotechnical engineering. The California-registered civil engineer or California-certified engineering geologist's recommended measures to address this hazard would conform to applicable design codes, guidelines, and standards.

DWR would ensure that the geotechnical design recommendations are included in the design of project facilities and construction specifications to minimize the potential effects from seismic events and the presence of adverse soil conditions. Generally, the applicable codes require that facilities be built so that they incur minimal damage in the event of a foreseeable seismic event and that they remain functional following such an event and that the facility is able to perform without catastrophic failure in the event of a maximum design earthquake (the greatest earthquake reasonably expected to be generated by a specific source on the basis of seismological and geological evidence). DWR would also ensure that the design specifications are properly executed during construction. See Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS.

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment).

Conformance to these and other applicable design specifications and standards would ensure that operation of Alternative 4A would not create an increased likelihood of loss of property, personal injury or death of individuals from structural shaking of surface and subsurface facilities along the Alternative 4A conveyance alignment in the event of strong seismic shaking. Therefore, there would be no adverse effect.

***CEQA Conclusion*:** The impacts of Alternative 4A would be identical to Alternative 4. Seismically induced strong ground shaking could damage pipelines, tunnels, intake facilities, pumping plant, and other facilities. The damage could disrupt the water supply through the conveyance system. In an extreme event, an uncontrolled release of water from the damaged conveyance system could cause flooding and inundation of structures. (Please refer to Chapter 6, *Surface Water*, of the Draft EIR/EIS for a detailed discussion of potential flood impacts.) However, through the final design process, which would be supported by geotechnical investigations required by DWR's environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), measures to address this hazard would be required to conform to applicable design codes, guidelines, and standards. Conformance with these codes and standards is an environmental commitment by DWR to ensure that ground shaking risks are minimized as the water conveyance features are operated. The hazard would be controlled to a safe level and there would be no increased likelihood of loss of property, personal injury or death due to operation of Alternative 4A. The impact would be less than significant. No mitigation is required.

Impact GEO-8: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Seismic-Related Ground Failure (Including Liquefaction during Operation of Water Conveyance Features

NEPA Effects: The potential effect could be substantial because seismically induced ground shaking could cause liquefaction, and damage pipelines, tunnels, intake facilities, pumping plant, and other facilities. The damage could disrupt the water supply through the conveyance system. In an extreme event, an uncontrolled release of water from the damaged conveyance system could cause flooding and inundation of structures. The effects of Alternative 4A would be identical to Alternative 4. Please refer to Appendix 3E, *Potential Seismicity and Climate Change Risks to SWP/CVP Water Supplies*, of the Draft EIR/EIS for a detailed discussion of potential flooding effects.

In the process of preparing final facility designs, site-specific geotechnical and groundwater investigations would be conducted to identify and characterize the vertical (depth) and horizontal (spatial) extents of liquefiable soil. During final design, site-specific potential for liquefaction would be investigated by a geotechnical engineer. In areas determined to have a potential for liquefaction, a California-registered civil engineer or California-certified engineering geologist would develop design measures and construction methods to meet design criteria established by building codes and construction standards to ensure that the design earthquake does not cause damage to or failure of the facility. Such measures and methods include removing and replacing potentially liquefiable soil, strengthening foundations (for example, using post-tensioned slab, reinforced mats, and piles) to resist excessive total and differential settlements, and using *in situ* ground improvement techniques (such as deep dynamic compaction, vibro-compaction, vibro-replacement, compaction grouting, and other similar methods). The results of the site-specific evaluation and California-registered civil engineer or California-certified engineering geologist's recommendations would be documented in a detailed geotechnical report prepared in accordance with state guidelines, in particular *Guidelines for Evaluating and Mitigating Seismic Hazards in California* (California Geological Survey 2008). Conformance with these design requirements is an environmental commitment by DWR to ensure that liquefaction risks are minimized as the water conveyance features are operated (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

DWR would ensure that the geotechnical design recommendations are included in the design of project facilities and construction specifications to minimize the potential effects from liquefaction and associated hazards. DWR would also ensure that the design specifications are properly executed during construction.

Additionally, any modification to a federal levee system would require USACE approval under 33 USC 408 (a 408 Permit).

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment). Conformance to these and other applicable design specifications and standards would ensure that the hazard of liquefaction and associated ground movements would not create an increased likelihood of loss of property, personal injury or death of individuals from structural failure resulting from seismic-related ground failure along the Alternative 4A conveyance alignment during operation of the water conveyance features. Therefore, the effect would not be adverse.

***CEQA Conclusion*:** The impacts of Alternative 4A would be identical to Alternative 4. Seismically induced ground shaking could cause liquefaction. Liquefaction could damage pipelines, tunnels, intake facilities, pumping plant, and other facilities, and thereby disrupt the water supply through the conveyance system. In an extreme event, flooding and inundation of structures could result from an uncontrolled release of water from the damaged conveyance system. (Please refer to Chapter 6, *Surface Water*, of the Draft EIR/EIS for a detailed discussion of potential flood impacts.) However, through the final design process, measures to address the liquefaction hazard would be required to conform to applicable design codes, guidelines, and standards. Conformance with these design standards is an environmental commitment by DWR to ensure that liquefaction risks are minimized as the water conveyance features are operated. See Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS. The hazard would be controlled to a safe level and there would be no increased likelihood of loss of property, personal injury or death due to operation of Alternative 4A. The impact would be less than significant. No mitigation is required.

Impact GEO-9: Loss of Property, Personal Injury, or Death from Landslides and Other Slope Instability during Operation of Water Conveyance Features

Alternative 4A would involve excavation that creates new cut-and-fill slopes and construction of new embankments and levees. As a result of ground shaking and high soil-water content during heavy rainfall, existing and new slopes that are not properly engineered and natural stream banks could fail and cause damage to facilities. The effects of Alternative 4A would be identical to Alternative 4.

NEPA Effects: The potential effect could be substantial because levee slopes and stream banks may fail, either from high pore-water pressure caused by high rainfall and weak soil, or from seismic shaking. Structures built on these slopes could be damaged or fail entirely as a result of slope instability. As discussed in Impact SW-2 in Chapter 6, *Surface Water*, of the Draft EIR/EIS, operation of the water conveyance features under Alternative 4A would not result in an increase in potential risk for flood management compared to existing conditions. Peak monthly flows under Alternative 4A in the locations considered were similar to or less than those that would occur under existing conditions. Since flows would not be substantially greater, the potential for increased rates of erosion or seepage are low. For additional discussion on the possible exposure of people or structures to impacts from flooding due to levee failure, please refer to Impact SW-6 in Chapter 6, *Surface Water*, of the Draft EIR/EIS.

During project design, a geotechnical engineer would develop slope stability design criteria (such as minimum slope safety factors and allowable slope deformation and settlement) for the various anticipated loading conditions. The design criteria would be documented in a detailed geotechnical report prepared in accordance with state guidelines, in particular *Guidelines for Evaluating and Mitigating Seismic Hazards in California* (California Geological Survey 2008).

Site-specific geotechnical and hydrological information would be used, and the design would conform with the current standards and construction practices. The design requirements would be presented in a detailed geotechnical report. Conformance with these design requirements is an environmental commitment by DWR to ensure that slope stability hazards would be avoided as the water conveyance features are operated. See Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS. DWR would ensure that the geotechnical design recommendations are included in the design of cut and fill slopes, embankments, and levees to minimize the potential effects from slope failure. DWR would also ensure that the design specifications are properly executed during construction.

Generally, the applicable codes require that facilities be built to certain factors of safety in order to ensure that facilities perform as designed for the life of the structure despite various soil parameters.

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment). Conformance to the above and other applicable design specifications and standards would ensure that the hazard of slope instability would not create an increased likelihood of loss of property, personal injury of individuals along the Alternative 4A conveyance alignment during operation of the water conveyance features. Therefore, the effect would not be adverse.

***CEQA Conclusion*:** Unstable levee slopes and natural stream banks may fail, either from high pore-water pressure caused by high rainfall and weak soil, or from seismic shaking. Structures constructed on these slopes could be damaged or fail entirely as a result of slope instability.

However, during the final project design process, as required by DWR's environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), a geotechnical engineer would develop slope stability design criteria (such as minimum slope safety factors and allowable slope deformation and settlement) for the various anticipated loading conditions during facility operations.

DWR would also ensure that measures to address this hazard would be required to conform to applicable design codes, guidelines, and standards. Conformance with these codes and standards is an environmental commitment by DWR to ensure cut and fill slopes and embankments will be stable as the water conveyance features are operated and there would be no increased likelihood of loss of property, personal injury or death due to operation of Alternative 4A. The impact would be less than significant. No mitigation is required.

Impact GEO-10: Loss of Property, Personal Injury, or Death from Seiche or Tsunami during Operation of Water Conveyance Features

The effects of Alternative 4A would be identical to Alternative 4.

NEPA Effects: The effect of a tsunami generated in the Pacific Ocean would not be adverse because the distance from the ocean and attenuating effect of the San Francisco Bay would likely allow only a low (i.e., less than 2 feet) tsunami wave height to reach the Delta (Contra Costa Transportation Agency 2009).

In most parts of the Plan Area, the effects of a seiche would not be adverse because the seismic hazard and the geometry of the water bodies (i.e., wide and shallow) near conveyance facilities are not favorable for a seiche to occur. However, assuming that the West Tracy fault is potentially active, a potential exists for a seiche to occur in the expanded Clifton Court Forebay. The effect could be adverse because the waves generated by a seiche could overtop the expanded Clifton Court Forebay embankments, causing erosion of the embankments and subsequent flooding in the vicinity.

However, design-level geotechnical studies would be conducted by a licensed civil engineer who practices in geotechnical engineering. The studies would determine the peak ground acceleration caused by movement of the West Tracy fault and the maximum probable seiche wave that could be generated by the ground shaking. The California-registered civil engineer or California-certified engineering geologist's recommended measures to address this hazard, as well as the hazard of a seiche overtopping the expanded Clifton Court Forebay embankment, would conform to applicable design codes, guidelines, and standards. Conformance with these codes and standards is an environmental commitment by DWR to ensure that the adverse effects of a seiche are controlled to an acceptable level while the forebay facility is operated. See Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS.

DWR would ensure that the geotechnical design recommendations are included in the design of project facilities and construction specifications to minimize the potential effects from seismic events and consequent seiche waves. DWR would also ensure that the design specifications are properly executed during construction.

Generally, the applicable codes provide guidance on estimating the effects of climate change and sea level rise and associated effects when designing a project and ensuring that a project is able to respond to these effects.

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment). Conformance to these and other applicable design specifications and standards would ensure that the embankment for the expanded portion of the Clifton Court Forebay would be designed and constructed to contain and withstand the anticipated maximum seiche wave height and would not create an increased likelihood of loss of property, personal injury or death of individuals along the Alternative 4A conveyance alignment during operation of the water conveyance features. Therefore, the effect would not be adverse.

CEQA Conclusion: The height of a tsunami wave reaching the Suisun Marsh and the Delta would be small because of the distance from the ocean and attenuating effect of the San Francisco Bay. Similarly, the potential for a significant seiche to occur in most parts of the Plan Area is considered low because the seismic hazard and the geometry of the water bodies (i.e., wide and shallow) near conveyance facilities are not favorable for a seiche to occur. However, assuming the West Tracy fault is potentially active, a potential exists for a seiche to occur in the expanded Clifton Court Forebay (Fugro Consultants 2011).

However, design-level geotechnical studies would be conducted by a licensed civil engineer who practices in geotechnical engineering. The studies would determine the peak ground acceleration caused by movement of the West Tracy fault and the maximum probable seiche wave that could be generated by the ground shaking. The California-registered civil engineer or California-certified engineering geologist's recommended measures to address this hazard, as well as the hazard of a seiche overtopping the expanded Clifton Court Forebay embankment, would conform to applicable design codes, guidelines, and standards. Conformance with these codes and standards is an environmental commitment by DWR to ensure that the adverse effects of a seiche are controlled to an acceptable level while the forebay facility is operated. DWR would ensure that the geotechnical design recommendations are included in the design of project facilities and construction specifications to minimize the potential effects from seismic events and consequent seiche waves. DWR would also ensure that the design specifications are properly executed during construction.

The effect would not be adverse because the expanded Clifton Court Forebay embankment would be designed and constructed according to applicable design codes, guidelines, and standards to contain and withstand the anticipated maximum seiche wave height, as required by DWR's environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). There would be no increased likelihood of loss of property, personal injury or death due to operation of Alternative 4A from seiche or tsunami. The impact would be less than significant. No additional mitigation is required.

Impact GEO-11: Ground Failure Caused by Increased Groundwater Surface Elevations from Unlined Canal Seepage as a Result of Operating the Water Conveyance Facilities

NEPA Effects: Alternative 4A would not involve construction of unlined canals; therefore, there would be no increase in groundwater surface elevations and consequently no effect caused by canal seepage. There would be no adverse effect.

***CEQA Conclusion*:** Alternative 4A would not involve construction of unlined canals; therefore, there would be no increase in groundwater surface elevations and consequently no impact caused by canal seepage. The impact would be less than significant. No mitigation is required.

Impact GEO-12: Loss of Property, Personal Injury, or Death Resulting from Structural Failure Caused by Rupture of a Known Earthquake Fault at Restoration Opportunity Areas

According to the available AP Earthquake Fault Zone Maps, only the Suisun Marsh ROA could be affected by rupture of an earthquake fault. The active Green Valley fault crosses the southwestern corner of the ROA. The active Cordelia fault extends approximately 1 mile into the northwestern corner of the ROA. Rupture of these faults could damage levees and berms constructed as part of the restoration, which could result in failure of the levees and flooding of otherwise protected areas. Under Alternative 4A, no Environmental Commitments would occur in the Suisun Marsh ROA.

Within the Delta, active or potentially active blind thrust faults were identified in the seismic study (California Department of Water Resources 2007a). The extreme southeastern corner of the Suisun Marsh is underlain by the Montezuma blind thrust zone. Parts of the Cache Slough and Yolo Bypass ROAs are underlain by part of the North Midland blind thrust zone. The Cosumnes/Mokelumne River and East Delta ROAs are underlain by the Thornton Arch zone. Although these blind thrusts are not expected to rupture to the ground surface during earthquake events, they may produce ground or near-ground shear zones, bulging, or both. In the seismic study (California Department of Water Resources 2007a), the Thornton Arch blind thrust was assigned a 20% probability of being active. The depth to the Thornton Arch blind fault is unknown. Based on limited geologic and seismic survey information, it appears that the potential of having any shear zones, bulging, or both at the sites of the habitat levees is low because the depth to the blind thrust faults is generally deep.

NEPA Effects: Effects related to rupture of a known earthquake fault within an ROA under Alternative 4A would be similar in mechanism to those described for Alternative 4, but to a substantially smaller magnitude based on the conservation activities proposed under Alternative 4A (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS).

Because there is limited information regarding the depths of the blind faults mentioned above, seismic surveys would be performed in the vicinity of the faults as part of final design. These surveys would be used to verify fault depths where levees and other features would be constructed. Collection of this depth information would be part of broader, design-level geotechnical studies conducted by a geotechnical engineer licensed in the state of California to support all aspects of site-specific project design. The studies would assess site-specific conditions at and near all the project facility locations, including the nature and engineering properties of all soils and underlying geologic strata, and groundwater conditions. The geotechnical engineers' information would be used to develop final engineering solutions to any hazardous condition, consistent with the code and standards requirements of federal, state and local oversight agencies. Conformance with these design standards is an environmental commitment by the project proponents to ensure that risks from a fault rupture are minimized as levees for habitat restoration areas are constructed and maintained (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). The hazard would be controlled to a safe level by following the proper design standards.

The project proponents would ensure that the geotechnical design recommendations are included in the design of project facilities and construction specifications to minimize the potential effects from seismic events and the presence of adverse soil conditions. The project proponents would also ensure that the design specifications are properly executed during implementation.

Generally, the applicable codes require that facilities be built so that they incur minimal damage in the event of a foreseeable seismic event and that they remain functional following such an event and that the facility is able to perform without catastrophic failure in the event of a maximum design earthquake (the greatest earthquake reasonably expected to be generated by a specific source on the basis of seismological and geological evidence).

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment, practicing crane and scaffold safety measures). Conformance to these and other applicable design specifications and standards would ensure that the hazard of ground movement in the vicinity of the blind thrusts underlying the ROAs would not jeopardize the integrity of the levees and other features constructed in the ROAs and would not create an increased likelihood of loss of property, personal injury or death of individuals in the ROAs. This effect would not be adverse.

***CEQA Conclusion*:** As noted above, effects related to rupture of a known earthquake fault within an ROA under Alternative 4A would be similar in mechanism to those described for Alternative 4, but to a substantially smaller magnitude based on the restoration activities proposed under Alternative 4A. Rupture of the Cordelia and Green Valley faults could occur at the Suisun Marsh ROA and damage ROA facilities, such as levees and berms. Damage to these features could result in their failure, causing flooding of otherwise protected areas. Environmental Commitments under Alternative 4A would not occur in the Suisun Marsh area.

However, through the final design process for conservation activities in the ROAs and because there is limited information regarding the depths of the blind faults mentioned above, seismic surveys would be performed in the vicinity of the faults as part of final designs. These surveys would be used to verify fault depths where levees and other features would be constructed. Collection of this depth information would be part of broader, design-level geotechnical studies conducted by a geotechnical engineer licensed in the state of California to support all aspects of site-specific project design. The studies would assess site-specific conditions at and near all the project facility locations, including the nature and engineering properties of all soils and underlying geologic strata, and groundwater conditions. The geotechnical engineer's information would be used to develop final engineering solutions and project designs to any hazardous condition, consistent with DWR's environmental commitments (see Appendix 3B, *Environmental Commitments,* in Appendix A of this RDEIR/SDEIS).

Additionally, measures to address the fault rupture hazard would be required to conform to applicable design codes, guidelines, and standards. Conformance with these design codes, guidelines, and standards is an environmental commitment by the project proponents to ensure that fault rupture risks are minimized as the conservation activities are implemented. The hazard would be controlled to a safe level and there would be no increased likelihood of loss of property, personal injury or death in the ROAs. The impact would be less than significant. No mitigation is required.

Impact GEO-13: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Strong Seismic Shaking at Restoration Opportunity Areas

Effects related to strong seismic shaking within an ROA under Alternative 4A would be similar in mechanism to those described for Alternative 4, but to a substantially smaller magnitude based on the conservation activities proposed under Alternative 4A (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS).

Earthquake events may occur on the local and regional seismic sources at or near the ROAs. Because of its proximity to these faults, the Suisun Marsh ROA would be especially subject to ground shaking caused by the Concord-Green Valley fault. The Cache Slough ROA would be subject to shaking from the Northern Midland fault zone, which underlies the ROA. Although more distant from these sources, the other ROAs would be subject to shaking from the San Andreas, Hayward–Rodgers Creek, Calaveras, Concord–Green Valley, San Gregorio, Greenville, and Mt. Diablo Thrust faults and the more proximate blind thrusts in the Delta.

Among all the ROAs, the Suisun Marsh ROA would be most subject to ground shaking because of its proximity to active faults. The Suisun Marsh ROA is subject to a PGA of approximately 0.31–0.35 g for 200-year return interval, while the PGA for the other ROAs ranges from approximately 0.11–0.26 g. The ground shaking could damage levees and other structures, and in an extreme event cause levees to fail such that protected areas flood. However, Environmental Commitments under Alternative 4A would not occur in the Suisun Marsh area.

NEPA Effects: All temporary facilities would be designed and built to meet the safety and collapse-prevention requirements for the above-anticipated seismic loads. Therefore, this effect is considered not adverse. No additional mitigation measures are required.

Site-specific geotechnical information would be used to further assess the effects of local soil on the OBE and MDE ground shaking and to develop design criteria that minimize the potential of damage. Design-level geotechnical studies would be prepared by a geotechnical engineer licensed in the state of California during project design. The studies would assess site-specific conditions at and near all the project facility locations and provide the basis for designing the levees and other features to withstand the peak ground acceleration caused by fault movement in the region. The geotechnical engineer's recommended measures to address this hazard would conform to applicable design codes, guidelines, and standards. Conformance with these design standards is an environmental commitment by the project proponents to ensure that strong seismic shaking risks are minimized as the conservation activities are implemented (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

The project proponents would ensure that the geotechnical design recommendations are included in the design of project features and construction specifications to minimize the potential effects from seismic events and the presence of adverse soil conditions. The project proponents would also ensure that the design specifications are properly executed during implementation.

Generally, the applicable codes require that facilities be built so that they incur minimal damage in the event of a foreseeable seismic event and that they remain functional following such an event and that the facility is able to perform without catastrophic failure in the event of a maximum design earthquake (the greatest earthquake reasonably expected to be generated by a specific source on the basis of seismological and geological evidence).

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment, practicing crane and scaffold safety measures). Conformance to these and other applicable design specifications and standards would ensure that the hazard of seismic shaking would not jeopardize the integrity of levees and other features at the ROAs and would not create an increased likelihood of loss of property, personal injury or death of individuals in the ROAs. This effect would not be adverse.

***CEQA Conclusion*:** Ground shaking could damage levees, berms, and other structures. Among all the ROAs, the Suisun Marsh ROA would be the most subject to ground shaking because of its proximity to active faults. However, Environmental Commitments under Alternative 4A would not occur in the Suisun Marsh area. Damage to these features could result in their failure, causing flooding of otherwise protected areas. Conformance with these design standards is an environmental commitment by the project proponents to ensure that strong seismic shaking risks are minimized as the conservation activities are operated and there would be no increased likelihood of loss of property, personal injury or death in the ROAs (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). The impact would be less than significant. No mitigation is required.

Impact GEO-14: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Seismic-Related Ground Failure (Including Liquefaction) Beneath Restoration Opportunity Areas

Effects related to seismic-related ground failure beneath an ROA under Alternative 4A would be similar in mechanism to those described for Alternative 4, but to a substantially smaller magnitude based on the conservation activities proposed under Alternative 4A (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS).

New structural features are proposed at the ROAs, such as levees as part of Environmental Commitment 4, setback levees as part of Environmental Commitment 6. However, the amount of restoration being proposed under Alternative 4A is much smaller in breadth than under Alternative 4. Earthquake induced ground shaking could cause liquefaction, resulting in damage to or failure of these levees and other features constructed at the restoration areas. The consequences of liquefaction are manifested in terms of compaction or settlement, loss of bearing capacity, lateral spreading (horizontal soil movement), and increased lateral soil pressure. Failure of levees and other structures could result in flooding of otherwise protected areas in Suisun Marsh and behind new setback levees along the Sacramento and San Joaquin Rivers and in the South Delta ROA

The ROAs vary with respect to their liquefaction hazard (Figure 9-6 of the Draft EIR/EIS). All of the levees in the Suisun Marsh ROA have a medium vulnerability to failure from seismic shaking and resultant liquefaction. The liquefaction vulnerability among the other ROAs in which seismically-induced levee failure vulnerability has been assessed (Figure 9-6 of the Draft EIR/EIS) (i.e., in parts or all the Cache Slough Complex and South Delta ROAs) is medium or high.

NEPA Effects: The potential effect could be substantial because earthquake-induced liquefaction could damage ROA facilities, such as levees and berms. Damage to these features could result in their failure, causing flooding of otherwise protected areas.

During final design of conservation facilities, site-specific geotechnical and groundwater investigations would be conducted by a geotechnical engineer to identify and characterize the vertical (depth) and horizontal (spatial) extent of liquefiable soil.

In areas determined to have a potential for liquefaction, the engineer would develop design parameters and construction methods to meet the design criteria established to ensure that design earthquake does not cause damage to or failure of the facility. Conformance with these design standards is an environmental commitment by the project proponents to ensure that liquefaction risks are minimized as the conservation activities are implemented.

Generally, the applicable codes require that facilities be built so that if soil in the foundation or surrounding area are subject to liquefaction, the removal or densification of the liquefiable material should be considered, along with alternative foundation designs. The hazard would be controlled to a safe level.

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment, practicing crane and scaffold safety measures). As required by the environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), the project proponents would ensure that the geotechnical design recommendations are included in the design of levees and construction specifications to minimize the potential effects from liquefaction and associated hazard. The project proponents would also ensure that the design specifications are properly executed during implementation and would not create an increased likelihood of loss of property, personal injury or death of individuals in the ROAs. This effect would not be adverse.

CEQA Conclusion**:** Earthquake induced ground shaking could cause liquefaction, resulting in damage to or failure of levees, berms, and other features constructed at the restoration areas. Failure of levees and other structures could result in flooding of otherwise protected areas. As required by the environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), site-specific geotechnical and groundwater investigations would be conducted to identify and characterize the vertical (depth) and horizontal (spatial) extent of liquefiable soil. The project proponents would ensure that the geotechnical design recommendations are included in the design of levees and construction specifications to minimize the potential effects from liquefaction and associated hazard. The project proponents would also ensure that the design specifications are properly executed during implementation and would not create an increased likelihood of loss of property, personal injury or death of individuals in the ROAs. Further, through the final design process, measures to address the liquefaction hazard would be required to conform to applicable design codes, guidelines, and standards. Conformance with these design standards is an environmental commitment by the project proponents to ensure that liquefaction risks are minimized as the water conservation features are implemented and there would be no increased likelihood of loss of property, personal injury or death in the ROAs. The impact would be less than significant. No mitigation is required.

Impact GEO-15: Loss of Property, Personal Injury, or Death from Landslides and Other Slope Instability at Restoration Opportunity Areas

Effects related to landslides and slope instability at an ROA under Alternative 4A would be similar in mechanism to those described for Alternative 4, but to a substantially smaller magnitude based on the conservation activities proposed under Alternative 4A (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS).

Implementation of Environmental Commitments 3, 4, 6, and 7 could involve breaching, modification or removal of existing levees and construction of new levees and embankments. Levee modifications, including levee breaching or lowering, may be performed to reintroduce tidal exchange, reconnect remnant sloughs, restore natural remnant meandering tidal channels, encourage development of dendritic channel networks, and improve floodwater conveyance.

Levee modifications could involve the removal of vegetation and excavation of levee materials. Excess earthen materials could be temporarily stockpiled, then re-spread on the surface of the new levee slopes where applicable or disposed of offsite. Any breaching or other modifications would be required to be designed and implemented to maintain the integrity of the levee system and to conform to flood management standards and permitting processes. This would be coordinated with the appropriate flood management agencies. Those agencies may include USACE, DWR, CVFPB, and other flood management agencies. For more detail on potential modifications to levees as a part of conservation activities, please refer to Chapter 3, *Conservation Strategy*, of the Draft BDCP, and Appendix D, *Substantive BDCP Revisions*, of this RDEIR/SDEIS

New and existing levee slopes and stream/channel banks could fail and could damage facilities as a result of seismic shaking and as a result of high soil-water content during heavy rainfall.

With the exception of levee slopes, natural stream banks, and part of the Suisun Marsh ROA the topography of ROAs is nearly level to gently sloping. The areas that may be susceptible to slope failure are along existing Sacramento and San Joaquin River and Delta island levees and stream/channel banks, particularly those levees that consist of non-engineered fill and those streambanks that are steep and consist of low strength soil.

The structures associated with conservation activities would not be constructed in, nor would they be adjacent to, areas that are subject to mudflows/debris flows from natural slopes.

NEPA Effects: The potential effect could be substantial because levee slopes and embankments may fail, either from high pore-water pressure caused by high rainfall and weak soil, or from seismic shaking. Failure of these features could result in loss, injury, and death as well as flooding of otherwise protected areas.

As outlined in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, erosion protection measures and protection against related failure of adjacent levees would be taken where levee breaches were developed. Erosion protection measures would also be taken where levee lowering is done for the purposes of allowing seasonal or periodic inundation of lands during high flows or high tides to improve habitat or to reduce velocities and elevations of floodwaters. Neighboring levees could require modification to accommodate increased flows or to reduce effects of changes in water elevation or velocities along channels following inundation of tidal marshes. Hydraulic modeling would be used during subsequent analyses to determine the need for such measures.

New levees would be constructed to separate lands to be inundated for tidal marsh from non-inundated lands, including lands with substantial subsidence. Levees could be constructed as described for the new levees at intake locations. Any new levees would be required to be designed and implemented to conform to applicable flood management standards and permitting processes.

Additionally, during project design, a geotechnical engineer would develop slope stability design criteria (such as minimum slope safety factors and allowable slope deformation and settlement) for the various anticipated loading conditions.

Site-specific geotechnical and hydrological information would be used, and the design would conform with the current standards and construction practices, as described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS.

The project proponents would ensure that the geotechnical design recommendations are included in the design of embankments and levees to minimize the potential effects from slope failure. The project proponents would also ensure that the design specifications are properly executed during implementation.

Generally, the applicable codes require that facilities be built to certain factors of safety in order to ensure that facilities perform as designed for the life of the structure despite various soil parameters.

The worker safety codes and standards specify protective measures that must be taken at construction sites to minimize the risk of injury or death from structural or earth failure (e.g., utilizing personal protective equipment). Conformance to the above and other applicable design specifications and standards would ensure that the hazard of slope instability would not jeopardize the integrity of levees and other features at the ROAs and would not create an increased likelihood of loss of property, personal injury or death of individuals in the ROAs. This effect would not be adverse.

CEQA Conclusion: Unstable new and existing levee and embankment slopes could fail as a result of seismic shaking and as a result of high soil-water content during heavy rainfall and cause flooding of otherwise protected areas. However, during project design and as required by the project proponents' environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), a geotechnical engineer would develop slope stability design criteria (such as minimum slope safety factors and allowable slope deformation and settlement) for the various anticipated loading conditions. The project proponents would ensure that the geotechnical design recommendations are included in the design of embankments and levees to minimize the potential effects from slope failure. The project proponents would also ensure that the design specifications are properly executed during implementation.

Additionally, as required by the project proponents' environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), site-specific geotechnical and hydrological information would be used to ensure conformance with applicable design guidelines and standards, such as USACE design measures. Through implementation of these environmental commitments, the hazard would be controlled to a safe level and there would be no increased likelihood of loss of property, personal injury or death in the ROAs. The impact would be less than significant. Therefore, no mitigation is required.

Impact GEO-16: Loss of Property, Personal Injury, or Death from Seiche or Tsunami at Restoration Opportunity Areas as a Result of Implementing the Conservation Actions

NEPA Effects: The distance from the ocean and attenuating effect of the San Francisco Bay would likely allow only a low tsunami wave height to reach the Suisun Marsh and the Delta. Conditions for a seiche to occur at the ROAs are not favorable. Therefore, the effect would not be adverse.

***CEQA Conclusion*:** Based on recorded tsunami heights at the Golden Gate, the height of a tsunami wave reaching the ROAs would be small because of the distance from the ocean and attenuating effect of the San Francisco Bay. Similarly, the potential for a significant seiche to occur in the Plan Area that would cause loss of property, personal injury, or death at the ROAs is considered low because conditions for a seiche to occur at the ROAs are not favorable. The impact would be less than significant. No mitigation is required.

4.3.6 Soils

Impact SOILS-1: Accelerated Erosion Caused by Vegetation Removal and Other Soil Disturbances as a Result of Constructing the Proposed Water Conveyance Facilities

Alternative 4A would include the same physical/structural components as Alternative 4. These locations would be where soils have similar erosion hazards and would not substantially change the project effects on water soil erosion. The effects of Alternative 4A would, therefore, be the same as under Alternative 4. See the discussion of Impact SOILS-1 under Alternative 4.

NEPA Effects: Construction of the proposed water conveyance facility under Alternative 4A could cause substantial accelerated erosion. However, as described in Section 10.3.1, *Methods for Analysis*, of the Draft EIR/EIS, and Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, DWR would be required to obtain coverage under the General Permit for Construction and Land Disturbance Activities, necessitating the preparation of a SWPPP and an erosion control plan. Proper implementation of the requisite SWPPP and compliance with the General Permit (as discussed in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) would ensure that there would not be substantial soil erosion resulting in daily site runoff turbidity in excess of 250 NTUs as a result of construction of the proposed water conveyance facility, and therefore, there would not be an adverse effect.

Additionally, implementation of the environmental commitment Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material would help reduce wind blowing of excavated soils, particularly peat soils, during transport and placement at spoils storage, disposal, and reuse areas.

CEQA Conclusion: Vegetation removal and other soil disturbances associated with construction of water conveyance facilities could cause accelerated water and wind erosion of soil. However, DWR would seek coverage under the state General Permit for Construction and Land Disturbance Activities, necessitating the preparation of a SWPPP and an erosion control plan. As a result of implementation of the requisite SWPPP, and compliance with the General Permit, there would not be substantial soil erosion resulting in daily site runoff turbidity in excess of 250 NTUs the effect would be less than significant. No mitigation is required.

Impact SOILS-2: Loss of Topsoil from Excavation, Overcovering and Inundation as a Result of Constructing the Proposed Water Conveyance Facilities

Alternative 4A would include the same physical/structural components as Alternative 4 and construction would be the same as under Alternative 4. Therefore, the effects on topsoil under Alternative 4A would be the same as Alternative 4. See the discussion of Impact SOILS-2 under Alternative 4.

NEPA Effects: Topsoil effectively would be lost as a resource as a result of its excavation (e.g., forebays, borrow areas, tunnel shafts, levee foundations, intake facilities, pumping plants): overcovering (e.g., levees and embankments, spoil storage, pumping plants); and water inundation (e.g., forebays, sedimentation basins, and solids lagoons). DWR has made an Environmental Commitment for Disposal Site Preparation which would require that a portion of the temporary sites selected for storage of spoils, RTM and dredged material will be set aside for topsoil storage and the topsoil would be saved for reapplication to disturbed areas, thereby lessening the effect.

However, this effect would be adverse because it would result in a substantial loss of topsoil. Mitigation Measures SOILS-2a and SOILS-2b would reduce the severity of this effect.

***CEQA Conclusion*:** Construction of the water conveyance facilities would involve excavation, overcovering, and inundation of topsoil over extensive areas, thereby resulting in a substantial loss of topsoil despite a commitment for Disposal Site Preparation. The impact on soils in the Plan Area would be significant. Mitigation Measures SOILS-2a and SOILS-2b would minimize and compensate for these impacts, but not to a less-than-significant level because topsoil would be permanently lost over extensive areas. Therefore, this impact is considered significant and unavoidable.

Mitigation Measure SOILS-2a: Minimize Extent of Excavation and Soil Disturbance

Please see Mitigation Measure SOILS-2a under Impact SOILS-2 in the discussion of Alternative 4.

Mitigation Measure SOILS-2b: Salvage, Stockpile, and Replace Topsoil and Prepare a Topsoil Storage and Handling Plan

Please see Mitigation Measure SOILS-2b under Impact SOILS-2 in the discussion of Alternative 4.

Impact SOILS-3: Property Loss, Personal Injury, or Death from Instability, Failure, and Damage from Construction on or in Soils Subject to Subsidence as a Result of Constructing the Proposed Water Conveyance Facilities

Alternative 4A would include the same physical/structural components as Alternative 4 and therefore the effects from potential soil subsidence under Alternative 4A would be the same as Alternative 4. See the discussion of Impact SOILS-3 under Alternative 4.

NEPA Effects: This potential effect could be substantial because the facilities could be located on unstable soils that are subject to subsidence. However, as described in Section 10.3.1, *Methods for Analysis*, of the Draft EIR/EIS, and Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, geotechnical studies (as described in the Geotechnical Exploration Plan—Phase 2 [California Department of Water Resources 2014]) would be conducted at all facilities to identify the types of soil avoidance or soil stabilization measures that should be implemented to ensure that the facilities are constructed to withstand subsidence and settlement and to conform to applicable state and federal standards. These investigations would build upon the geotechnical data reports (California Department of Water Resources 2001a, 2010b, 2011) and the CERs (California Department of Water Resources 2010a, 2010b). As discussed under Alternative 4, conforming to state and federal design standards, including conduct of site-specific geotechnical evaluations, would ensure that appropriate design measures are incorporated into the project and any subsidence that takes place under the project facilities would not jeopardize their integrity. Therefore, there would not be an adverse effect.

***CEQA Conclusion*:** Some of the conveyance facilities would be constructed on soils that are subject to subsidence. Subsidence occurring after the facility is constructed could result in damage to or failure of the facility. However, DWR would be required to design and construct the facilities according to state and federal design standards and guidelines (e.g., California Building Code, American Society of Civil Engineers Minimum Design Loads for Buildings and Other Structures, ASCE-7-10, 2010) (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Conforming to these codes would reduce the potential hazard of subsidence or settlement to acceptable levels by avoiding construction directly on or otherwise stabilizing the soil material that is prone to subsidence. Because these measures would reduce the potential hazard of subsidence or settlement to meet design standards, the impact would be less than significant. No mitigation is required.

Impact SOILS-4: Risk to Life and Property as a Result of Constructing the Proposed Water Conveyance Facilities in Areas of Expansive, Corrosive, and Compressible Soils

Alternative 4A would include the same physical/structural components as Alternative 4 and therefore the effects related to expansive, corrosive, and compressible soils under Alternative 4A would be the same as Alternative 4. See the discussion of Impact SOILS-4 under Alternative 4.

NEPA Effects: The integrity of the water conveyance facilities, including tunnels, pipelines, intake facilities, pumping plants, access roads and utilities, and other features could be adversely affected because they would be located on expansive, corrosive, and compressible soils. However, all facility design and construction would be executed in conformance with the CBC which specifies measures to mitigate effects of expansive soils, corrosive soils, and soils subject to compression and subsidence. By conforming to the CBC and other applicable design standards, potential effects associated with expansive and corrosive soils and soils subject to compression and subsidence would be offset (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). There would be no adverse effect.

CEQA Conclusion**:** Some of the project facilities would be constructed on soils that are subject to expansion, corrosion to concrete and uncoated steel, and compression under load. Expansive soils could cause foundations, underground utilities, and pavements to crack and fail. Corrosive soils could damage in-ground facilities or shorten their service life. Compression/settlement of soils after a facility is constructed could result in damage to or failure of the facility. However, because DWR would be required to design and construct the facilities in conformance with state and federal design standards, guidelines, and building codes (e.g., CBC and USACE design standards). Conforming to these codes and standards is an environmental commitment by DWR to ensure that potential adverse effects associated with expansive and corrosive soils and soils subject to compression and subsidence would be offset (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Therefore, this impact would be less than significant. No mitigation is required.

Impact SOILS-5: Accelerated Bank Erosion from Increased Channel Flow Rates as a Result of Operations

Alternative 4A have operations similar to those under Alternative 4 and therefore the potential effects on accelerated bank erosion because the flow from the north Delta under Alternative 4A would be the same as Alternative 4. See the discussion of Impact SOILS-5 under Alternative 4.

NEPA Effects: The effect of increased channel flow rates on channel bank scour would not be adverse because, as described in Section 3.6.2, *Conservation Components*, of Appendix A of this RDEIR/SDEIS, as part of the Environmental Commitment 4, major channels could be dredged to create a larger cross-section that would offset increased tidal velocities. The effect would not be adverse because there would be no net increase in river flow rates and therefore no net increase in channel bank scour.

CEQA Conclusion**:** Changes in operational flow regimes could cause increases in flow rates in channels and sloughs, potentially leading to increases in channel bank scour. However, where such changes are expected to occur (i.e., at the mouths of tidal marsh channels), the project would also entail expansion of the channel cross-section to increase the tidal prism at these locations as described in Section 3.6.2, *Conservation Components*, of Appendix A of this RDEIR/SDEIS. The net effect would be to reduce the channel flow rates by 10–20% compared to Existing Conditions. Consequently, no appreciable increase in scour is anticipated. The impact would be less than significant. No mitigation is required.

Impact SOILS-6: Accelerated Erosion Caused by Clearing, Grubbing, Grading, and Other Disturbances Associated with Implementation of Proposed Environmental Commitments 3, 4, 6-11

Effects under Alternative 4A on accelerated erosion would be similar in mechanism to those described for Alternative 4, but to a substantially lesser magnitude based on the Environmental Commitments proposed under Alternative 4A (and as described in Section 4.1.2, *Description of Alternative 4A*, in this RDEIR/SDEIS). See the discussion of Impact SOILS-6 under Alternative 4.

Implementation of some of the Environmental Commitments would involve ground disturbance and construction activities that could lead to accelerated soil erosion rates and consequent loss of topsoil. Implementation of Environmental Commitments 3, 4, and 6–11 could involve breaching, modification or removal of existing levees and construction of new levees and embankments. Levee modifications, including levee breaching or lowering, may be performed to reintroduce tidal exchange, reconnect remnant sloughs, restore natural remnant meandering tidal channels, encourage development of dendritic channel networks, and improve floodwater conveyance. Some of the environmental commitments would also require constructing setback levees and cross levees or berms; raising the land elevation by excavating relatively high areas to provide fill for subsided areas or by importing fill material; surface grading; deepening and/or widening tidal channels; excavating new channels; modifying channel banks; and other activities. These activities could lead to accelerated soil erosion rates and consequent loss of topsoil.

Construction of conservation hatcheries and implementation of urban stormwater treatment are not part of Alternative 4A.

NEPA Effects: These effects could potentially cause substantial accelerated erosion. However, as described in Section 10.3.1, *Methods for Analysis*, of the Draft EIR/EIS, and Appendix 3B, *Environmental Commitments,* in Appendix A of this RDEIR/SDEIS, the project proponents would be required to obtain coverage under the General Permit for Construction and Land Disturbance Activities, necessitating the preparation of a SWPPP and an erosion control plan. Proper implementation of the requisite SWPPP, site-specific BMPs, and compliance with the General Permit would ensure that accelerated water and wind erosion as a result of implementing conservation measures would not be an adverse effect.

***CEQA Conclusion*:** Vegetation removal and other soil disturbances associated with construction of restoration areas could cause accelerated water and wind erosion of soil. However, the project proponents would seek coverage under the state General Permit for Construction and Land Disturbance Activities (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Permit conditions would include erosion and sediment control BMPs (such as revegetation, runoff control, and sediment barriers) and compliance with water quality standards. As a result of implementation of permit conditions, the impact would be less than significant. No mitigation is required.

Impact SOILS-7: Loss of Topsoil from Excavation, Overcovering and Inundation Associated with Restoration Activities as a Result of Implementing the Proposed Environmental Commitments 3–4, 6–11

Effects from implementation of Environmental Commitments under Alternative 4A on loss of topsoil would be similar in mechanism to those described for Alternative 4, but to a substantially lesser magnitude based on the smaller acreages of restoration proposed by the Environmental Commitments under Alternative 4A (and as described in Section 4.1.2, *Description of Alternative 4A*, of this RDEIR/SDEIS). See the discussion of Impact SOILS-7 under Alternative 4.

NEPA Effects: Topsoil effectively would be lost as a resource as a result of its excavation (e.g., levee foundations, water control structures); overcovering (e.g., levees, embankments, application of fill material in subsided areas); and water inundation (e.g., aquatic habitat areas) over areas of the Plan Area. Based on ICF's calculations using a geographic information system, implementation of habitat restoration activities at the ROAs would result in excavation, overcovering, or inundation of a minimum of 1,176 acres of topsoil. This effect would be adverse because it would result in a substantial loss of topsoil. Mitigation Measures SOILS-2a and SOILS-2b would reduce the severity of this effect.

***CEQA Conclusion*:** Significant impacts could occur if there is loss of topsoil from excavation, overcovering, and inundation associated with restoration activities as a result of implementing the proposed Environmental Commitments. Implementation of the Environmental Commitments would involve excavation, overcovering, and inundation (to create aquatic habitat areas) of topsoil over extensive areas, thereby resulting in a substantial loss of topsoil. Therefore, the impact would be significant. Mitigation Measures SOILS-2a and SOILS-2b would minimize and compensate for these impacts to a degree by minimizing topsoil loss, but not to a less-than-significant level because topsoil would still be permanently lost over extensive areas. Therefore, this impact is considered significant and unavoidable.

Mitigation Measure SOILS-2a: Minimize Extent of Excavation and Soil Disturbance

Please see Mitigation Measure SOILS-2a under Impact SOILS-2 in the discussion of Alternative 4

Mitigation Measure SOILS-2b: Salvage, Stockpile, and Replace Topsoil and Prepare a Topsoil Storage and Handling Plan

Please see Mitigation Measure SOILS-2b under Impact SOILS-2 in the discussion of Alternative 4

Impact SOILS-8: Property Loss, Personal Injury, or Death from Instability, Failure, and Damage from Construction on Soils Subject to Subsidence as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–11

Effects from implementation of Environmental Commitments under Alternative 4A related to subsidence would be similar in mechanism to those described for Alternative 4, but to a substantially lesser magnitude based on the Environmental Commitments proposed under Alternative 4A (and as described in Section 4.1.2, *Description of Alternative 4A*, in RDEIR/SDEIS). Damage to or failure of the habitat levees could occur where these are constructed in soils and sediments that are subject to subsidence and differential settlement. These soil conditions have the potential to exist in the Suisun Marsh ROA Levee damage or failure could cause surface flooding in the vicinity. See the discussion of Impact SOILS-8 under Alternative 4.

NEPA Effects: This potential effect could be substantial because the facilities could be located on unstable soils that are subject to subsidence. However, as described in Section 10.3.1, *Methods for Analysis*, of the Draft EIR/EIS, and Appendix 3B, *Environmental Commitments,* in Appendix A of this RDEIR/SDEIS, geotechnical studies would be conducted at all the ROAs to identify the types of soil stabilization that should be implemented to ensure that levees, berms, and other features are constructed to withstand subsidence and settlement and to conform to applicable state and federal standards.

With construction of all levees, berms, and other conservation features designed and constructed to withstand subsidence and settlement and through conformance with applicable state and federal design standards, this effect would not be adverse.

CEQA Conclusion**:** Some of the restoration area facilities would be constructed on soils that are subject to subsidence. Subsidence occurring after the facility is constructed could result in damage to or failure of the facility. However, because the project proponents would be required to design and construct the facilities according to state and federal design standards and guidelines (which may involve, for example, replacement of the organic soil), the impact would be less than significant. No mitigation is required.

Impact SOILS-9: Risk to Life and Property from Construction in Areas of Expansive, Corrosive, and Compressible Soils as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–11

Effects from implementation of Environmental Commitments under Alternative 4A in areas of expansive, corrosive, or compressible soils would be similar in mechanism to those described for Alternative 4, but to a substantially lesser magnitude based on the environmental commitments proposed under Alternative 4A (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS). See the discussion of Impact SOILS-9 under Alternative 1A.

Seasonal shrinking and swelling of moderately or highly expansive soils could damage water control structures or cause them to fail, resulting in a release of water from the structure and consequent flooding, which would cause unplanned inundation of aquatic habitat areas. Soils in all the ROAs possess high potential for corrosion of uncoated steel, and the Suisun ROA and portions of the West Delta ROA possess soils with high corrosivity to concrete.

Highly compressible soils are in the Cache Slough, Yolo Bypass Cosumnes/Mokelumne, and South Delta ROAs.

NEPA Effects: The Environmental Commitments could be located on expansive, corrosive, and compressible soils. However, ROA-specific geotechnical studies and testing would be completed prior to construction within the ROAs. The site-specific studies and testing would identify specific areas where engineering soil properties, including soil compressibility, may require special consideration during construction of specific features within ROAs (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Conformity with USACE, CBC, and other design standards for construction on expansive, corrosive and/or compressible soils described in detail in Chapter 10, *Soils*, in the Draft EIR/EIS, would prevent adverse effects of such soils.

CEQA Conclusion**:** Some of the restoration facilities would be constructed on soils that are subject to expansion, corrosive to concrete and uncoated steel, and compress under load. Expansive soils could cause foundations, underground utilities, and pavements to crack and fail. Corrosive soils could damage in-ground facilities or shorten their service life. Compression or settlement of soils after a facility is constructed could result in damage to or failure of the facility. However, as outlined in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, because the project proponents would be required to design and construct the facilities according to state and federal design standards, guidelines, and building codes (which may involve, for example, soil lime stabilization, cathodic protection of steel, and soil replacement), this impact would be considered less than significant. No mitigation is required.

4.3.7 Fish and Aquatic Resources

As described in Section 4.1 of Section 4, Alternative 4A would result in the same potential construction impact mechanisms as Alternative 4. Alternative 4A includes water conveyance operational criteria similar to Alternative 4 (Operational Scenario H), but will be limited to operations within the range of Scenarios H3 and H4, as fully described in Section 4.1. In addition, Alternative 4A would be implemented over a shorter period of time, similar to the ELT time frame. This results in somewhat different patterns of water withdrawals from the Delta, and potentially somewhat different effects on water quality and aquatic habitat conditions in the Plan Area, than analyzed for Alternative 4. Alternative 4A operations are represented by the Scenarios H3 and H4 as follows:

- Scenario H3 – Includes spring outflow consistent with D-1641 and fall outflow consistent with Fall X2 requirements of the FWS 2008 BiOp.
- Scenario H4 – Includes higher spring outflow requirements than D-1641, and Fall X2 requirements of the FWS 2008 BiOp.

H3 and H4 operational criteria differ in the spring outflow that is assumed, and are concluded to represent the range of operational effects of Alternative 4A (Appendix B, *Supplemental Modeling for Alternative 4A*, Section B.7). The operations impact analysis compares ELT Alternative 4A results over the range of outcomes from the operational sub-scenarios with Existing Conditions (CEQA) or the No Action Alternative Action in the ELT (NEPA, with the modeling scenario referred to as NAA_ELT). The Alternative 4A sub-scenarios are referred to as H3_ELT and H4_ELT; and are also occasionally referred to as Evaluated Starting Operations (ESO_ELT) and High Outflow Scenario (HOS_ELT), respectively. The analysis concludes with a single impact statement for each issue. Additionally, the effects of Alternative 4A in the LLT are similar to the effects of the alternative in the ELT, except where noted.

As described in Section 4.1, Alternative 4A differs from Alternative 4 in that it is not an HCP (it focuses instead on ESA Section 7 and CESA Section 2081(b) compliance) and does not include the full suite of conservation actions included in Alternative 4. Aside from the water conveyance facilities, the following Environmental Commitments relevant to fish and aquatic resources are included in Alternative 4A:

- *Environmental Commitment 4, Tidal Natural Communities Restoration* is would include up to 59 acres of restoration
- *Environmental Commitment 6, Channel Margin Enhancement* is would include 4.6 levee miles of enhancement
- *Environmental Commitment 7, Riparian Natural Community Restoration* includes 251 acres of restoration
- *Environmental Commitment 12, Methylmercury Management* would be focused on restored tidal wetland areas
- *Environmental Commitment 15, Localized Reduction of Predatory Fishes* is focused on two of the locations proposed for Alternative 4: the vicinity of the north Delta intakes and Clifton Court Forebay

- *Environmental Commitment 16, Nonphysical Fish Barriers* is focused on one of the locations proposed for Alternative 4: the divergence between the Sacramento River and Georgiana Slough

Each of these environmental commitments (Environmental Commitments) is described in more detail in Section 4.1.2.3 of Section 4. As described in Section 4.1.2.3, many of the actions that are not proposed to be implemented under Alternative 4A would continue to be pursued as part of existing but separate projects and programs associated with the 2009 and 2009 USFWS and NMFS BiOps (e.g., Yolo Bypass improvements, 8,000 acres of tidal habitat restoration) and the 2014 California Water Action Plan. Those actions are separate from, and independent of, Alternative 4A. The analysis of Alternative 4A presented below assumes that modeling conducted for the various *BDCP Effects Analysis* scenarios in the ELT time frame (i.e., NAA_ELT, H3_ELT, and H4_ELT) is representative of operations and resulting Delta flow-related conditions under Alternative 4A. Because it is assumed that the NAA_ELT scenario would include actions such as Yolo Bypass improvements pursued under separate projects and programs, additional discussion is included where these additional actions are not explicitly captured in the modeling and could result in differences from modeling results.

Reflecting the reduced suite of environmental commitments in Alternative 4A compared to Alternative 4 conservation measures, generally fewer impacts are discussed for Alternative 4A than for Alternative 4.

Delta Smelt

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

The potential effects of construction of the water conveyance facilities on delta smelt or critical habitat would be the same as described for Alternative 4 and are outlined in the discussion below.

The construction and maintenance activities of the new intakes and screens would occur entirely within designated critical habitat. Small numbers of delta smelt eggs, larvae, and adults could be present in the north Delta in June during a portion of the in-water construction period for the intake facilities. Small numbers could also be present in June or July during construction of the barge landings in the east Delta and south Delta and during construction at Clifton Court Forebay and the operable barrier at the Head of Old River (see Table 11-8 in Chapter 11, Section 11.3.1.1, in Appendix A of this RDEIR/SDEIS, [hereafter, Table 11-8]). The types of construction impacts are identical to Alternative 4, which draws on the analysis of Alternative 1A. In summary, those potential impacts include temporary increases in turbidity; accidental spills; disturbance of contaminated sediments; underwater noise; fish stranding; in-water work activities; loss of spawning, rearing, or migration habitat; and predation. Effects related to these are summarized below.

Temporary Increases in Turbidity

The construction of Alternative 4A would unavoidably result in the generation and release of suspended sediments to the water column, temporarily increasing water column turbidity and altering habitat conditions for delta smelt and other fish species. However, as noted for Alternative 1A, species such as delta and longfin smelt have evolved and adapted to life in turbid waters to avoid predators and to successfully forage on prey organisms, so increases in turbidity are expected to generally improve habitat conditions for these species.

Turbidity-producing construction activities in the Sacramento River, Clifton Court Forebay, at the Head of Old River barrier location, and other locations include bed and bank disturbance during cofferdam placement and removal, channel dredging adjacent to the new intake locations and at the Head of Old River operable barrier location, excavation within Clifton Court Forebay, and the placement of bed and bank armoring. Propeller wash associated with barge traffic at the tunnel shaft construction sites would also be expected to produce localized turbidity pulses. These effects would occur periodically wherever in-water construction activities and/or associated vessel traffic are taking place.

Although the construction of Alternative 4A would result in unavoidable turbidity effects, these effects would be minimized to the extent possible to minimize effects on other species and water quality by limiting the duration of in-water construction activities and through implementing the environmental commitments described below and in Appendix 3B, *Environmental Commitments.* These environmental commitments include *Conduct Environmental Training*; *Develop and Implement a Stormwater Pollution Prevention Plan* (SWPPP); *Develop and Implement an Erosion and Sediment Control Plan*; *Develop and Implement a Hazardous Materials Management Plan* (HMMP) that includes a *Spill Prevention, Containment, and Countermeasure Plan* (SPCCP); *Dispose of Spoils, Reusable Tunnel Material, and Dredged Material*; *Develop and Implement a Fish Rescue and Salvage Plan*; and *Develop and Implement a Barge Operations Plan*. While delta smelt are not expected to be substantially exposed to any changes in turbidity during construction, and any exposure would not be adverse because of their preference for turbid conditions, construction activities would still need to comply with the standard terms and conditions for in-water work.

Accordingly, prior to the onset of construction activities, DWR and/or their contractors will conduct environmental training to inform field management and construction personnel of the need to avoid and protect sensitive resources during construction of the water conveyance facilities. Turbidity and sediment control measures that would be implemented by contractors as part of a SWPPP, Erosion and Sediment Control Plan, and the SPCCP include, but would not be limited to, the following, as described for Alternative 1A:

SWPPP

- Capture sediment via sedimentation and stormwater detention features.
- Implement concrete and truck washout facilities and appropriately sized storage, treatment, and disposal practices.
- Implement appropriate treatment and disposal of construction site dewatering from excavations to prevent discharges to surface waters.
- Prevent transport of sediment at the construction site perimeter, toe of erodible slopes, soil stockpiles, and into storm drains.
- Reduce runoff velocity on exposed slopes.
- Inspection and monitoring. A Qualified SWPPP Developer (QSD) would determine the combined Risk Level (Level 1, 2, or 3) of each construction site, which involves an evaluation of the site's "Sediment Risk" and "Receiving Water Risk." The SWPPP will also include a site and BMP inspection schedule. Performance standards will be met by implementing stormwater pollution

prevention BMPs that are tailored to specific site conditions, including the Risk Level of individual construction sites.

- Common to all Risk Levels:
  - Dischargers will ensure that all inspection, maintenance repair, and sampling activities at the construction site will be performed or supervised by a QSP representing the discharger.
  - Develop and implement a written site-specific Construction Site Monitoring Program (CSMP).
- Inspection, monitoring, and maintenance activities based on the Risk Level of the construction site (as defined in the SWRCB General Permit).
  - Risk Level 1 Sites:
    - Perform weekly inspections of BMPs, and at least once each 24-hour period during extended storm events.
    - At least two business days (48 hours) prior to each qualifying rain event (a rain event producing 0.5 inch or more of precipitation), visually inspect: (a) stormwater drainage areas to identify any spills, leaks, or uncontrolled pollutant sources; (b) all BMPs to identify whether they have been properly implemented in accordance with the SWPPP; and (c) stormwater storage and containment areas to detect leaks and ensure maintenance of adequate freeboard.
    - Visually observe stormwater discharges at all discharge locations within two business days (48 hours) after each qualifying rain event and identify additional BMPs and revise the SWPPP accordingly.
    - Conduct minimum quarterly visual inspections of each drainage area for the presence of (or indications of prior) unauthorized and authorized non-stormwater discharges and their sources.
    - Collect one or more samples during any breach, malfunction, leakage, or spill observed during a visual inspection which could result in the discharge of pollutants to surface waters that will not be visually detectable in stormwater.
  - Risk Level 2 Sites:
    - Risk Level 2 dischargers will perform all of the same visual inspection, monitoring, and maintenance measure specified for Risk Level 1 dischargers.
    - Risk Level 2 dischargers will perform sampling and analysis of stormwater discharges to characterize discharges associated with construction activity from the entire disturbed area at all discharge points where stormwater is discharged off site.
    - At a minimum, Risk Level 2 dischargers will collect and analyze three samples per day for pH and turbidity of a qualifying rain event.
    - Dischargers who deploy an Active Treatment Systems (ATS) on their site, or a portion on their site, will collect ATS effluent samples and measurements from the discharge pipe or another location representative of the nature of the discharge.
  - Risk Level 3 Sites:
    - Risk Level 3 dischargers will perform all of the same visual inspection, monitoring, and maintenance measure specified for Risk Level 1 and Risk Level 2 dischargers.

- In the event that a Risk Level 3 discharger violates a numerical effluent limit (NEL) of the General Permit (i.e., pH and turbidity), and has a direct discharge into receiving waters, the discharger will subsequently sample receiving waters for all parameter(s) monitored in the discharge.
- Risk Level 3 dischargers disturbing 30 acres or more of the landscape and with direct discharges into receiving waters will conduct or participate in a benthic macroinvertebrate bioassessment of receiving waters prior to commencement of construction activity. The SWPPP will also specify the forms and records that must be uploaded to SWRCB online Stormwater Multiple Application and Report Tracking System (SMARTS), such as quarterly non-stormwater inspection and annual compliance reports. If the QSP determines the site is Risk Level 2 or 3, water sampling for pH and turbidity will be required and the SWPPP will specify sampling locations and schedule, sample collection and analysis procedures, and recordkeeping and reporting protocols. In accordance with the CGP numeric action level requirements, the project contractor will modify existing BMPs or implement new BMPs when effluent monitoring indicates that daily average runoff pH is outside the range of 6.5 to 8.5 and that the daily average turbidity is greater than 250 nephelometric turbidity units (NTUs). Additionally, if a given construction component is Risk Level 3, for that component will report to the SWRCB when effluent monitoring indicates that daily average runoff pH is outside the range of 6.0 to 9.0 and that the daily average turbidity is greater than 500 NTUs. In the event that the turbidity NEL is exceeded, it may also be required to sample and report to the SWRCB pH, turbidity, and suspended sediment concentration of receiving waters for the duration of construction.

- The project contractor will also conduct sampling of runoff effluent when a leak, spill, or other discharge of non-visible pollutants is detected.
- The CGP has specific monitoring and action level requirements for the Risk Levels, which are summarized in Table 3B-3 (Appendix 3B, *Environmental Commitments*).
- The QSP will be responsible for day-to-day implementation of the SWPPP, including BMP inspections, maintenance, water quality sampling, and reporting to SWRCB. If the water quality sampling results indicate an exceedance of allowable pH and turbidity levels, the QSD will modify the type and/or location of the BMPs by amending the SWPPP.

Erosion and Sediment Control Plan

- Install physical erosion control stabilization features (e.g., hydroseeding, mulch, silt fencing) to capture sediment and control both wind and water erosion.
- Design grading to be compatible with adjacent areas and result in minimal disturbance of the terrain and natural land features.
- Divert runoff away from steep, denuded slopes, or other critical areas with barriers, berms, ditches, or other facilities.
- Retain trees and natural vegetation to the extent feasible to stabilize hillsides, retain moisture, and reduce erosion.

- Limit construction, clearing of vegetation, and disturbance of soils to areas of proven stability.
- Implement construction management and scheduling measures to avoid exposure to rainfall events, runoff, or flooding at construction sites to the extent feasible.
- Use sediment ponds, silt traps, wattles, straw bale barriers or similar measures to retain sediment transported by runoff water onsite.
- Collect and direct surface runoff at non-erosive velocities to the common drainage courses.

SPCCP

- Absorbent pads, pillows, socks, booms, and other spill containment materials will be maintained at the hazardous materials storage sites for use in the event of spills.
- When transferring oil or other hazardous materials from trucks to storage containers, absorbent pads, pillows, socks, booms or other spill containment material will be placed under the transfer area.
- Absorbent pads and mats will be placed on the ground beneath equipment before refueling and maintenance.
- Equipment used in direct contact with water will be inspected daily to prevent the release of oil.
- Oil-absorbent booms will be used when equipment is used in or immediately adjacent to waters.
- Fuel transfers will take place a minimum distance from exclusion/drainage areas and streams, and absorbent pads will be placed under the fuel transfer operation.
- Equipment will be refueled only in designated areas.
- Staging areas will be designed to contain contaminants such as oil, grease, and fuel products so that they do not drain toward receiving waters or storm drain inlets.

By implementing measures and BMPs as part of these environmental commitments, the project would meet the requirements described in the Central Valley Regional Water Quality Control Board's *Water Quality Control Plan for the Sacramento and San Joaquin River Basins* (Basin Plan) for turbidity generation, which are as follows.

- Where natural turbidity is between 0 and 5 NTUs, increases shall not exceed 1 NTU.
- Where natural turbidity is between 5 and 50 NTUs, increases shall not exceed 20%.
- Where natural turbidity is between 50 and 100 NTUs, increases shall not exceed 10 NTUs.
- Where natural turbidity is greater than 100 NTUs, increases shall not exceed 10%.

Turbidity levels would be monitored throughout construction as part of the SWPPP (see summary above and Appendix 3B, *Environmental Commitments*). In the event that any of these thresholds were exceeded, all turbidity-producing activities would be halted until turbidity levels subsided and/or appropriate corrective measures were taken. Turbidity effects in the Sacramento River and Clifton Court Forebay would be limited to the June 1 through October 31 in-water work period for the intake locations, a period with the least potential for most fish species to be in the vicinity of the in-water construction activities.

HMMP

Contractors working on the construction elements of Alternative 4A will develop and implement an HMMP before beginning construction. A specific protocol for the proper handling and disposal of hazardous materials will be established before construction activities begin and will be enforced by the project proponents. The HMMP will include, but not be limited to, the following measures or practices.

- Storage and transfer of hazardous materials will not be allowed within 100 feet of streams or sites known to contain sensitive biological resources except with the permission of CDFW.
- Soils contaminated by spills or cleaning wastes will be contained and removed to an approved disposal site.
- Storage or use of hazardous materials in or near wet or dry streams will be consistent with the Fish and Game Code and other state laws.

Dispose of Spoils, Reusable Tunnel Material, and Dredged Material

Contractors will properly handle, manage, and dispose of spoils, reusable tunnel material (RTM), and dredged material. Spoils and RTM will be stored in designated spoils and RTM areas, respectively. Discharges from RTM dewatering operations will be done in such a way as to not cause erosion at the discharge point. Spoils materials will not be placed in sensitive habitat areas, such as wetlands, vernal pools, alkali wetlands or grassland, native grasslands, riparian, or in floodplains identified by the Federal Emergency Management Agency (FEMA). Debris, rubbish, and other materials not directed to be salvaged will be removed from the work site as the contractor's property. Removed material will be disposed of in an approved disposal site and the contractor will obtain permits required for such disposal.

Following completion of construction, restoration of the RTM dewatering sites will be designed to prevent surface erosion and subsequent siltation of adjacent water bodies.

Dredged material will be disposed of in upland disposal sites to help ensure that the material will not be in contact with surface water. Handling and management of dredged material will include, but not be limited to, the following measures in addition to complying with applicable local, state and federal regulations.

- Conduct dredging activities in a manner that will not cause turbidity increases in the receiving water, as measured in surface waters 300 feet down-current from the construction site, to exceed the Basin Plan objectives beyond an approved averaging period by the Regional Water Quality Control Board (RWQCB) and CDFW.
- Silt curtains will be utilized to control turbidity if turbid conditions generated during dredging exceed the agreed-upon implementation requirements for compliance with the Basin Plan objectives.
- Design, construct, operate, and maintain the dredge material disposal site to prevent inundation or washout due to floods with a 100-year return frequency.
- Maintain 2 feet of freeboard in all dredge material disposal site settling pond(s) at all times when they may be subject to washout from a flooding event.
- Constructed DMD sites using appropriate BMPs to prevent discharges of contaminated stormwater to surface waters or groundwater.

Under Alternative 4A, five barge landings would be constructed and approximately 2,500 barge trips are projected to carry construction materials to the barge unloading facilities. The barge trips would take place continuously throughout construction, indicating that periodic turbidity pulses from propeller wash and wakes at the barge landings could occur year-round at the tunnel shaft locations. This potential impact would be minimized by implementing measures as part of a Barge Operations Plan (Appendix 3B, *Environmental Commitments*).

Barge Operations Plan

Construction contractors would implement the following avoidance measures to ensure that the goal of avoiding impacts on aquatic resources from tugboat and barge operations will be achieved.

- Training of tugboat operators.
- Prior to bringing equipment into the Delta, inspect and clean all in-water equipment such as barges and small work boats to prevent introduction of invasive aquatic species (plants, fish and animals)
- Dock approach and departure protocol
  - All vessels will approach and depart from the intake and barge landing sites at dead slow in order to reduce vessel wake and propeller wash at the sites frequented by tug and barge traffic.
  - In order to minimize bottom disturbance, anchors and barge spuds will be used to secure vessels only when it is not possible to tie up.
  - Barge anchoring will be pre-planned. Anchors will be lowered into place and not be allowed to drag across the channel bed.
  - Vessel operators will limit vessel speed as necessary to maintain wake of less than 2 feet (66 cm) at shore.
  - Vessel operators will avoid pushing stationary vessels up against the cofferdam, dock or other structures for extended periods since this could result in excessive directed propeller wash impinging on a single location. Barges will be tied up whenever possible to avoid the necessity of maintaining stationary position by tugboat or by the use of barge spuds.
  - Limiting vessel speed to minimize the effects of wake impinging on unarmored or vegetated banks and the potential for vessel wake to strand small fish; limiting the direction and\or velocity of propeller wash to prevent bottom scour and loss of aquatic vegetation; and prevention of spillage of materials and fluids from vessels, among other potential effects.
  - When transporting loose materials (e.g., sand, aggregate), barges will use deck walls or other features to prevent loose materials from blowing or washing off of the deck.

The plan would specify operating criteria during barge landing and departure designed to minimize erosion and turbidity generation associated with vessel wakes and propeller wash.

As noted above and for Alternative 1A, delta smelt evolved in environments with relatively high natural turbidity levels and are well-adapted to turbidity, which is generally higher in the west Delta and Suisun Bay than in the tidal freshwater environment where the proposed north Delta intakes would be constructed, modification of Clifton Court Forebay would occur, and the Head of Old River operable barrier would be constructed.

With environmental commitments, turbidity levels would be expected to be maintained within the natural range of variability likely to occur under baseline conditions. The environmental commitments summarized in this impact and contained in Appendix 3B, *Environmental Commitments* (*Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*) would be expected to effectively limit any increases in turbidity, such that any effects on delta smelt would be minimal, and not adverse.

Accidental Spills

Construction of Alternative 4A could result in accidental spills of contaminants, including cement, oil, fuel, hydraulic fluids, paint, and other construction-related materials, resulting in localized water quality degradation. As noted for Alternative 1A, such effects could in turn result in adverse effects on delta smelt, through direct injury and mortality or delayed effects on growth and survival, depending on nature and extent of the spill and the contaminants involved.

The greatest potential for an adverse water quality impact is associated with an accidental spill from construction activities occurring in or near surface waters. The north Delta intakes, construction and operation of the temporary barge landings at the tunnel shafts, and modification of Clifton Court Forebay all involve extensive in-water work. Other construction elements that occur in upland areas or are isolated from fish-bearing waters, have little potential for accidental spills that could affect fish. Implementation of environmental commitments (*Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material; and Barge Operations Plan*), described in the summary below and specifically the *Spill Prevention, Containment, and Countermeasure Plan* (see of Appendix 3B, *Environmental Commitments*) would be expected to minimize the potential for introduction of contaminants to surface waters and provide for effective containment and cleanup should accidental spills occur. On this basis, the likelihood of adverse effects on delta smelt resulting from accidental spills is considered negligible. Therefore, there would not be an adverse impact to delta smelt from accidental spills.

SPCCP

Contractors involved in construction and maintenance of Alternative 4A will develop and implement SPCCPs. Multiple SPCCPs will be developed to take into account site-specific conditions, and implemented to minimize effects from spills of oil or oil-containing products during Alternative 4A construction and operation. The SPCCPs will include, but not be limited to, the following measures and practices in addition to those listed above under *Temporary Increases in Turbidity*.

- Personnel will be trained in emergency response and spill containment techniques, and will also be made aware of the pollution control laws, rules, and regulations applicable to their work.
- Petroleum products will be stored in non-leaking containers at impervious storage sites from which runoff is not permitted to escape.
- Contaminated absorbent pads, pillows, socks, booms, and other spill containment materials will be placed in non-leaking sealed containers until transport to an appropriate disposal facility.
- All reserve fuel supplies will be stored only within the confines of a designated staging area.

- All stationary equipment will be positioned over drip pans.
- In the event of a spill, personnel will identify and secure the source of the discharge and contain the discharge with sorbents, sandbags, or other material from spill kits and will contact appropriate regulatory authorities (e.g., National Response Center will be contacted if the spill threatens navigable waters of the United States or adjoining shorelines, as well as other response personnel).

Methods of cleanup may include the following.

- Physical—Physical methods for the cleanup of dry chemicals include the use of brooms, shovels, sweepers, or plows.
- Mechanical—Mechanical methods could include the use of vacuum cleaning systems and pumps.
- Chemical—Cleanups of material can be achieved with the use of appropriate chemical agents such as sorbents, gels, and foams.

Disturbance of Contaminated Sediments

The construction footprint for Alternative 4A includes areas with known or potentially contaminated sediments, indicating the potential for release and dispersal of these contaminants if these sediments are disturbed during construction. As noted for Alternative 1A, individual delta smelt could be directly exposed to elevated levels of contaminants if they are in immediate proximity to construction activities that disturb contaminated sediments. Bed disturbance could also result in indirect effects on delta smelt. Toxins in river channel sediments can enter the food chain via benthic organisms. If contaminated sediments are disturbed and become suspended in the water column, they also become available directly to pelagic organisms, including covered fish species and planktonic food sources of covered species. The bioaccumulation of toxins can lead to lethal and sublethal effects.

The potential effects of toxins on fish such as delta smelt would depend on the types and concentrations of the toxins in disturbed sediments, but few chemical data are available related to sediments in the construction areas. Toxins that tend to bind to particulates do not mix homogeneously into the sediment, and concentrations can vary widely over a small area.

The three proposed water intakes would be located in the Sacramento River, downstream of the main urban area of the City of Sacramento, with sediments at these locations being affected by historical and current urban discharges from the city. Metals (lead and copper), hydrocarbons, organochlorine pesticides, and PCBs are common urban contaminants with the greatest affinity for sediments; these contaminants could be present in sediments that would be disturbed during installation of the cofferdams and dredging. In addition, mercury is present in the Sacramento River system and could be sequestered in bottom sediments. The barge landings would be constructed on smaller waterways, which are more likely to contain agricultural-related toxins such as copper and organochlorine pesticides; the same may be true for the modification of Clifton Court Forebay, which receives water conveyed through the smaller waterways surrounding it, as well as for the Head of Old River operable barrier area, which is downstream from major agricultural areas in the San Joaquin valley.

Metals, PCBs, and hydrocarbons (typically oil and grease) are common urban contaminants that are introduced to aquatic systems via nonpoint-source stormwater drainage, industrial discharges, and municipal wastewater discharges. Many of these contaminants readily adhere to sediment particles and tend to settle out of solution relatively close to the primary source of contaminants. PCBs are persistent, adsorb to soil and organics, and bioaccumulate in the food chain. Lead and other metals also will adhere to particulates and organics, and many metals will also bioaccumulate to levels sufficient to cause adverse biological effects. Hydrocarbons biodegrade over time in an aqueous environment and do not tend to bioaccumulate; thus, they are not persistent.

As noted for Alternative 1A, because the toxins are entering the water column attached to sediment, their movement is closely linked to turbidity, which is an indicator of the amount of particulates in the water column. Turbidity, and in turn suspension of sediments, would be minimized by implementation of environmental commitments described in the summary below and in Appendix 3B, *Environmental Commitments* (*Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). In addition, exposure of sensitive fish species such as delta smelt to any disturbed contaminated sediments would be minimized because in-water construction activities would occur between June 1 and October 31 when most covered fish species are least abundant in the in-water construction area (see Section 11.3.1.1, *Potential Impacts Resulting from Construction and Maintenance of Water Conveyance Facilities* in the Draft EIR/EIS).

Prior to the onset of construction activities, field management and construction personnel will be trained on the need to avoid and protect sensitive resources during construction of Alternative 4A. Turbidity and sediment control measures would be implemented by contractors as part of a SWPPP and an Erosion and Sediment Control Plan, as described above under *Temporary Increases in Turbidity*.

To avoid effects from disturbing contaminated sediments, the construction contractors will develop and implement an HMMP before beginning construction. Multiple HMMPs would be developed to take into account specific site conditions. In addition to the measures described under *Temporary Increases in Turbidity*, HMMP measures to address contaminated sediments will include, but not be limited to, the following.

- Soils contaminated by spills or cleaning wastes will be contained and removed to an approved disposal site.
- Storage or use of hazardous materials in or near wet or dry streams will be consistent with the Fish and Game Code and other state laws.
- Hazardous waste generated at work sites, such as contaminated soil, will be segregated from other construction spoils and properly handled, hauled, and disposed of at an approved disposal facility by a licensed hazardous waste hauler in accordance with state and local regulations. The contractor will obtain permits required for such disposal.

Proper handling, storage, and disposal of contaminated sediments would avoid and minimize the entry of contaminants into water bodies. In addition to measures described in *Disposal of Spoils, Reusable Tunnel Material, and Dredged Material* under *Temporary Increases in Turbidity,* above, measures relevant to this impact include the following (see Appendix 3B for the complete plan).

- RTM and RTM decant liquid will undergo chemical characterization by the contractor(s) prior to reuse or discharge, respectively, to meet NPDES and the Central Valley Water Board requirements.

- Should RTM or RTM decant liquid constituents exceed discharge limits, these tunneling byproducts will be treated to comply with NPDES permit requirements. Discharges from RTM dewatering operations will be done in such a way as to not cause erosion at the discharge point.
- If RTM liquid requires chemical treatment, chemical treatment will be nontoxic to aquatic organisms.
- Hazardous materials excavated during construction will be segregated from other construction spoils and properly handled in accordance with applicable state and local regulations. Riverine or in-Delta sediment dredging and dredge material disposal activities involve potential contaminant discharges not addressed through typical NPDES or SWRCB General Permit processes. Construction of Dredge Material Disposal (DMD) sites will likely be subject to the SWRCB General Permit (Order No. 2009-0009-DWQ).
- Contractors undertaking construction of Alternative 4A will implement BMPs such as, but not limited to:
    - Prior to initiating any dredging activity, contractors will prepare and implement a pre-dredge sampling and analysis plan (SAP) (as part of the water plan required per standard DWR contract specifications Section 01570) to evaluate the presence of contaminants that may impact water quality from a variety of discharge routes.
    - The DMD will be designed to contain all of the dredged material to the extent practicable, and all systems and equipment associated with necessary return flows from the DMD site to the receiving water will be operated to maximize treatment of return water and optimize the quality of the discharge.
    - DMD sites will be constructed using appropriate BMPs to prevent discharges of contaminated stormwater to surface waters or groundwater.

To address contamination risk from barge operations, construction contractors will develop, submit, and implement a barge operations plan per standard DWR contract specifications as part of the traffic plans required in Section 01570. This plan is intended to protect aquatic species and habitat in the vicinity of barge operations. If and when avoidance is not possible, the plan will include provisions to minimize, reduce, or mitigate effects on aquatic species.

The barge operations plan will be part of a comprehensive traffic control plan coordinated with the Coast Guard for large channels, which will address traffic routes and machines used to deliver materials to and from the barges. The plan will address contamination risks such as the following:

- Accidental material spillage.
- Sediment and benthic (bottom-dwelling) community disturbance from accidental or intentional barge grounding or deployment of barge spuds (extendable shafts for temporarily maintaining barge position).
    - Hazardous materials spills (e.g., fuel, oil, hydraulic fluids).

The plan will serve as a guide to barge operations and to a Biological Monitor who will evaluate barge operations with respect to stated performance measures. Construction contractors operating barges as part of Alternative 4A facilities construction will be responsible for operating their vessels safely; developing and implementing the barge operations plan; reporting any spills, incidents or deviations from the plan that might pose risks to species or water quality to the Project Biological

Monitor and/or DWR; and following all other relevant plans. Therefore, there would not be an adverse impact to delta smelt from the disturbance of contaminated sediments.

Underwater Noise

The assessment of underwater noise impacts on fish is based on the overlap of construction activities (timing, location, duration) with the spatial and temporal distribution of sensitive species and life stages. An important measure for reducing the potential exposure of the population to pile driving noise is the restriction of in-water pile driving activities to June 1 through October 31, a period when most fish are not present in the construction area. The project proponents intend to construct sheetpile cofferdams at the intakes and at the head of Old River barrier using vibratory pile driving for at least 80–90% of the time, depending on the specific site conditions. In addition, the project proponents propose to install piles using vibratory methods or other non-impact driving methods for the intakes, wherever feasible, to minimize adverse effects on fish and other aquatic organisms (Mitigation Measure AQUA-1a). However, the degree to which vibratory driving can be performed effectively is unknown at this time due to as yet undetermined geologic conditions at the construction sites. The remaining pile driving would be conducted using an impact pile driver. Once constructed, if the foundation design for either the intakes or head of Old River barrier requires piles, pile driving to construct foundations would be conducted from within the cofferdam; it is still undetermined if the foundation will use piles or drill-shaft methods, which does not require pile driving. If piles are included in the design, project proponents will isolate pile driving activities within dewatered cofferdams as a means of minimizing noise levels and potential adverse effects on fish. However, some uncertainty also exists regarding the extent to which the cofferdams can be dewatered and therefore the magnitude at which this measure can minimize underwater noise. If the cofferdams cannot be dewatered, or if pile driving noise exceeds applicable thresholds, project proponents will construct a bubble curtain or other attenuation device to minimize underwater noise (Mitigation Measure AQUA-1b). Project proponents will work with contractors to minimize pile driving, particularly impact pile driving, by using floating docks instead of pile-supported docks, wherever feasible considering the load requirements of the landings and the site conditions. If pile supported docks are required, piles would be designed to safely support the docks and to minimize underwater noise. If dock piles for barge landings cannot be installed using vibratory methods, attenuation devices will be used to reduce the area that would be exposed to underwater sound levels (Mitigation Measure AQUA-1b). Since the specific construction mechanisms are currently under development, to address these uncertainties, this analysis presents worst-case impacts based on the use of an impact driver in open water with no attenuation measures. It should also be recognized that the computed distances over which pile driving sounds are expected to exceed the injury and behavioral thresholds assume an unimpeded open water propagation path. However, site conditions such as major channel bends and other in-water structures can reduce these distances by impeding the propagation of underwater sound waves.

Table 4.3.7-1 presents the computed impact areas and schedule for each facility or structure where pile driving is proposed to occur in open water or on land adjacent to open water (<200 feet). Sound monitoring data from similar pile driving operations (impact driving) indicate that single-strike peak SPLs and SELs exceeding the interim injury thresholds are expected to be limited to areas within 10–14 meters (33–46 feet) of the source piles (Table B.7-79 in Appendix B of this RDEIR/SDEIS), potentially causing direct injury or mortality of fish close to the source piles. This risk may extend up to 3,280 feet away for fish that remain within this distance of the source piles over the course of a full day of pile driving operations. Assuming that impact driving is the principal pile driving method, cumulative exposures of fish to underwater noise levels exceeding the injury thresholds could occur up to 2,814 feet away from the source piles during cofferdam installation, 3,280 feet away from the source piles during foundation pile installation, and 1,522 feet away from the source piles during bridge pile installation. Such exposures could occur over periods of 42 days during cofferdam installation, 8 days during foundation pile installation, and 5 days during bridge pile installation.

Table 4.3.7-1. Estimated Distances and Areas of Waterbodies Subject to Pile Driving Noise Levels Exceeding Interim Injury and Behavioral Thresholds, and Proposed Timing and Duration of Proposed Pile Driving Activities for Facilities or Structures in or Adjacent to Sensitive Rearing and Migration Corridors of the Covered Species (Alternative 4A)

Facility or Structure	Average Width of Water Body (feet)	Distance to Cumulative 187 and 183 dB SEL Injury Threshold[1, 2] (feet)	Potential Impact Area[3] (acres)	Distance to 150 dB RMS Behavioral Threshold[2] (feet)	Year of Construction	Duration of Pile Driving (days)

Foundation		1,774	14	9,607	Year 7	7

[1] Distances to injury thresholds are governed by the distance to "effective quiet" (150 dB SEL).

[2] Distance to injury and behavioral thresholds assume an attenuation rate of 4.5 dB per doubling of distance and an unimpeded propagation path; on-land pile driving, vibratory driving or other non-impact driving methods, dewatering of cofferdams, and the presence of major river bends or other channel features can impede sound propagation and limit the extent of underwater sounds exceeding the injury and behavioral thresholds.

[3] Based on the area of open water subject to underwater sound levels exceeding the cumulative SEL thresholds for fish larger than 2 grams (187 dB) and smaller than 2 grams (183 dB); for open channels, this area is calculated by multiplying the average channel width by twice the distance to the injury thresholds, assuming an unimpeded propagation path upstream and downstream of the source piles.

Table 11-8 presents the life stages of delta smelt and the months of their potential presence in the north, east, and south Delta during the proposed in-water construction window (June 1–October 31). Delta smelt are considered highly vulnerable to pile driving noise because of their small size and inability of eggs and larvae to actively avoid elevated noise levels. Larval and juvenile delta smelt are smaller than 2 grams while adults are close to 2 grams in size (mature male and female delta smelt average 2.1 grams and 2.7 grams with a standard error of 0.3 and 0.6 grams, respectively [Foott and Bigelow 2010]); therefore, the interim threshold of 183 dB SEL is applicable to the majority of the population when evaluating the potential for injury or mortality of delta smelt due to pile driving noise.

Because delta smelt are generally found in the west Delta and Cache Slough/Liberty Island area during the spring and summer, the majority of individuals would not be exposed to construction-related underwater noise. However, delta smelt could be present at low abundance in the north, east, and south Delta during the period when in-water construction activity would occur, indicating some potential for exposure. Adults, which complete their spawning cycle and die by mid- to late June, could be exposed to pile driving noise following the onset of in-water pile driving in June. If a portion of the population spawns upstream of the construction areas, larvae could potentially drift through the areas affected by underwater sound. Thus, the potential exists for small numbers of spawning adults (during June) or larval delta smelt (during June and July) to occur in the vicinity of the intakes and the barge landings during the in-water construction period. With implementation of proposed timing restrictions on in-water pile driving activities (June 1 through October 31) and the use of vibratory pile driving methods whenever feasible (Mitigation Measure AQUA-1a), potential injury or mortality of delta smelt from pile driving noise is expected to be minimal and unlikely to have significant population-level effects.

Other construction activities that can generate underwater noise exceeding background levels (e.g., barge operations) are not expected to result in direct harm to delta smelt or other fish species. These kinds of activities typically produce noise levels below the behavioral effects threshold of 150 dB RMS, which may temporarily alter fish behavior but does not result in permanent harm or injury.

Fish Stranding

As described for Alternative 1A, in-water work activities have the potential to cause take of fish through the process of capturing and rescuing stranded or trapped fish from construction areas. In-water work activities at the north Delta intakes would include installation of sheet pile cofferdams at each intake location to isolate active construction activities from the Sacramento River and minimize the potential for increases in turbidity. In addition, sheet pile cofferdams and dewatering during modification of Clifton Court Forebay could result in stranding of delta smelt and other fish that would require capture and rescue.

Although delta smelt larval and adult life stages are potentially present in the vicinity of the intakes and Clifton Court Forebay from January through July, the timing of cofferdam installation (June through August) would avoid the majority of the spawning and larval recruitment season when delta smelt are most likely to be present (see Table 11-8). Potential effects of fish stranding typically result in direct or indirect injury or mortality from subsequent dewatering of work areas and other construction activities. These effects would be minimized by implementation of environmental commitments described in the summary below and in Appendix 3B, *Environmental Commitments* (*Fish Rescue and Salvage Plan*). Although fish would likely avoid the noise and activity of sheet pile installation, cofferdams have the potential to entrap some fish. While the number of fish affected is unknown, entrapment could include a few hundred fish (total of all species), potentially including a small number of delta smelt.

Fish Rescue and Salvage Plan

As noted for Alternative 1A, DWR will develop the Fish Rescue and Salvage Plan and submit it to the appropriate resource agencies (CDFW, USFWS, and NMFS) for their review and acceptance, and revise it accordingly. The plan will include detailed procedures for fish rescue and salvage to minimize the number of fish stranded during placement and removal of cofferdams at the intake construction sites. The plan will identify the appropriate procedures for removing fish from the construction zone, and preventing fish from re-entering the construction zone during construction, or prior to dewatering. The plan will include detailed fish collection, holding, handling, and release procedures.

Prior to construction site dewatering, fish will be captured and relocated to avoid direct mortality and to minimize take. The appropriate fish collection method will be determined by a qualified fish biologist, in consultation with the designated resource agency biologist, and based on site-specific conditions prior to dewatering the cofferdam. Collection methods may include use of seines (nets) and/or dip nets to collect and remove fish, and electrofishing techniques may also be permitted. Collection methods have varying degrees of effectiveness and may result in some trapped or stranded fish not being rescued. Although the use of these methods can also result in fish injury or mortality, these effects are typically minor, and often avoided by appropriate training. Therefore, there would not be an adverse impact to delta smelt from fish stranding.

The results of the fish rescue and salvage operations (including date, time, location, comments, method of capture, fish species, number of fish, approximate age, condition, release location, and release time) will be reported to the appropriate resource agencies, as specified in the pertinent permits.

In-Water Work Activities

As described for Alternative 1A, in-water work activities under Alternative 4A have the potential to injure or kill fish such as delta smelt through direct physical injury from construction activities. In-water work activities at the north Delta intakes would include installation of sheet pile cofferdams at each intake location, piles at each barge landing, placement of riprap to protect the stream banks adjacent to the intakes from erosion, and dredging. Modification of Clifton Court Forebay and construction of the Head of Old River operable barrier would include major in-water activities such as excavation, fill, and sheet pile cofferdam installation.

Although fish would likely avoid the noise and activity of pile installation and placement of riprap protection, these activities have the potential to result in direct and indirect injury or mortality; trapped or stranded fish would be susceptible to increased sound exposure effects from pile driving, riprap placement can crush or displace fish, and dredging activities can also crush or entrain fish. Delta smelt larval and adult life stages may potentially be present in the vicinity of the intakes, barge landings, and Clifton Court Forebay during January through July; however, the timing of cofferdam and riprap installation (June through October) would avoid most of the spawning season (January through June, with peak numbers in the north Delta during February through May) when delta smelt are most likely to be present (see Table 11-8). In-water work at the Head of Old River operable barrier would occur between August 1 and November 30, therefore minimizing potential for effects on delta smelt. In addition to these timing restrictions, potential in-water activity effects would be minimized by implementation of the environmental commitments described in Appendix 3B, *Environmental Commitments*, including *Erosion and Sediment Control Plan*; *Dispose of Spoils, Reusable Tunnel Material, and Dredged Material*; and *Barge Operations Plan*. Therefore, there would not be an adverse impact to delta smelt from in-work water activities. Pertinent aspects of these plans include, respectively the following.

- Install physical erosion control stabilization features (hydroseeding, mulch, silt fencing, fiber rolls, sand bags, and erosion control blankets) to capture sediment and control both wind and water erosion.
- Divert runoff away from steep, denuded slopes, or other critical areas with barriers, berms, ditches, or other facilities.
- Discharges from RTM dewatering operations will be done in such a way as to not cause erosion at the discharge point. If RTM liquid requires chemical treatment, chemical treatment will be nontoxic to aquatic organisms.
- Following completion of construction, restoration of the RTM dewatering sites will be designed to prevent surface erosion and subsequent siltation of adjacent water bodies.
- Conduct dredging within the allowable seasonal "work windows" established by the regulatory agencies.
- Conduct dredging activities in a manner that will not cause turbidity increases in the receiving water, as measured in surface waters 300 feet down-current from the construction site, to exceed the Basin Plan objectives beyond an approved averaging period by the RWQCB and CDFW.
- The DMD will be designed to contain all of the dredged material to the extent practicable, and all systems and equipment associated with necessary return flows from the DMD site to the receiving water will be operated to maximize treatment of return water and optimize the quality of the discharge.
- The Barge Operations Plan will include training of tugboat operators, limiting vessel speed to minimize the effects of wake impinging on unarmored or vegetated banks and the potential for vessel wake to strand small fish, limiting the direction and\or velocity of propeller wash to prevent bottom scour and loss of aquatic vegetation, and preventing spills of materials and fluids from vessels.
- In order to minimize bottom disturbance, anchors and barge spuds will be used to secure vessels only when it is not possible to tie up.
- Barges will not be anchored where they will ground during low tides.
- When transporting loose materials (e.g., sand, aggregate), barges will use deck walls or other features to prevent loose materials from blowing or washing off of the deck.

Loss of Spawning, Rearing, or Migration Habitat

As noted for Alternative 1A, in-water construction would temporarily or permanently alter habitat conditions in the vicinity of the construction activities, but the use of the affected habitats for delta smelt spawning and rearing is likely limited and therefore would not be expected to affect population productivity. Construction of the three intake structures and associated permanent bankline modifications would result in a permanent modification of 2.6 miles of Sacramento River channel margin within potential delta smelt migration, spawning, and rearing habitat. Cofferdams would isolate the work areas, temporarily reducing the width of riverine habitat available to fish for migration and rearing, but this will have an insignificant effect on upstream and downstream fish passage because the cofferdams would typically occupy only about 10% of the cross section of the river, and cumulatively occupy only a couple of miles of the overall river length. These isolated areas also represent a very small portion of the available migration and rearing habitat in the Delta, and there is no indication that these areas are uniquely important to the overall viability of the delta smelt population. Alternative 4A will result in the permanent loss of low-quality migration, spawning, and rearing habitat where the existing river banks and bed areas would be replaced with permanent in-water structures.

Each of the five proposed barge landings would include in-water and over-water structures, such as piling dolphins, docks, ramps, and possibly conveyors for loading and unloading materials; and vehicles and other machinery. As noted for Alternative 1A, the barge landings would each occupy approximately 15,000 square feet of nearshore habitat within their respective delta channels (see Mapbook M3-4 for locations). In addition to effects of the constructed barge landings on habitat, barge operations have the potential to affect bottom sediments and benthic habitat through propeller wash effects. This is most relevant in the vicinity of the barge landings and in narrow channels where tugboats will be near the channel bottom and could stir up bottom sediments and submerged aquatic vegetation, potentially resulting in temporary disturbance of rearing habitat. As described for Alternative 1A, tugboat and barge speeds in the narrow channels would be low enough that vessel wakes are not expected to affect shoreline habitat.

Potential effects of these in-water structures and activities would be minimized by limiting the size of the in-water structures where practicable, limiting the amount of dredging and other habitat disturbing activities, enhancing channel margin habitat through *Environmental Commitment 6 Channel Margin Enhancement*, adhering to the approved in-water construction window (expected to be June 1 through October 31), and implementing environmental commitments described in Appendix 3B, *Environmental Commitments*, including *Erosion and Sediment Control Plan*; *Dispose of Spoils, Reusable Tunnel Material, and Dredged Material*; and *Barge Operations Plan*. Specific measures of those plans previously described for turbidity, accidental spills, and in-water work activities also would address the loss of habitat. Therefore, there would not be an adverse impact to delta smelt from the loss of spawning, rearing, and migration habitat. Additional potentially relevant elements of the Erosion and Sediment Control Plan include the following.

- Conduct frequent site inspections (before and after significant storm events) to ensure that control measures are working properly and to correct problems as needed.
- Deposit or store excavated materials away from drainage courses.
- Vegetative material from work site clearing will be chipped, stockpiled, and spread over the topsoil after earthwork is completed when practical and appropriate to do so.
- Rocks and other inorganic grubbed materials will be placed in the common backfill whenever possible. Debris, rubbish, and other materials not directed to be salvaged will be removed from the work site.

Predation

As noted for Alternative 1A, in-water pilings and over-water structures, such as those that would be constructed at the barge landings, have the potential to provide habitat for predatory fish that may prey on delta smelt. Pilings and other structures may provide perching habitat for avian predators and cover for introduced predacious fish species. While fish predators could use this cover to ambush prey, and potentially improve their foraging success, avian predators are unlikely to forage directly from the docks or piles. The overwater piers and support structures would represent a very small increase in the overall predator habitat the Delta and so it is unlikely that temporary structures associated with construction would increase habitat availability sufficiently to significantly increase the potential for predation relative to baseline conditions. This is particularly true given that several of the barge unloading sites are either outside the main distribution of delta smelt (i.e., Glannvale Tract on Snodgrass Slough) or are in south Delta channels where survival would be expected to be low in any case, because of entrainment by the south Delta export facilities and related predation (i.e., Old River at Victoria Island and Old River at the northeast corner of Clifton Court Forebay). In addition, all the barge landings would be removed after construction and thus any predation effects would be temporary.

This indicates that increased predation on delta smelt associated with project construction is likely to be low. Although it is plausible that localized increases in predation rates could occur because of in-water and over-water structures providing suitable predator habitat at places where delta smelt could occur, these localized increases are not expected to have wide-spread or population-level effects. Therefore, there would not be an adverse impact to delta smelt from increased predation.

Summary

Construction of Alternative 4A includes several elements with the potential to cause adverse effects on delta smelt through spills of hazardous materials or underwater noise. However, adverse effects will be effectively avoided and minimized by siting construction in areas that are minimally used by this species, and through the use of in-water work windows, activity-specific timing restrictions, and environmental commitments.

Alternative 4A includes several environmental commitments that will avoid and limit spills, potentially leading to adverse water quality effects on delta smelt. These include *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan;* and *Disposal of Spoils, Reusable Tunnel Material, and Dredged Material* (see Appendix 3B, *Environmental Commitments* of the Draft EIR/EIS). These commitments would guide rapid and effective response in the case of inadvertent spills of hazardous materials. In combination with the species' natural tolerance to elevated turbidity levels, and limited occurrence in the construction areas, these environmental commitments would be expected to protect delta smelt from any adverse water quality effect resulting from project construction.

Delta smelt could be adversely affected by elevated underwater noise associated with impact pile driving and direct exposure to construction-related disturbance. The number of individuals affected is expected to be limited, based on the fact that delta smelt are typically present at low densities in the affected habitats during the in-water work window. The in-water work window will minimize, but perhaps not completely avoid, the potential for injury or mortality. Mitigation Measures AQUA-1a and AQUA-1b would further minimize adverse effects from impact pile driving. Implementation of environmental commitments *Fish Rescue and Salvage Plan* and *Barge Operations Plan* (as described in Appendix 3B, *Environmental Commitments*) would also minimize adverse effects from construction-related disturbance. As a result, while these construction activities could adversely affect individual delta smelt, these effects would not result in adverse population-level effects on delta smelt.

Construction would not be expected to measurably increase predation rates relative to baseline conditions because the locally increased predator habitat and predation from temporary construction structures would not have population-level effects.

Construction of Alternative 4A will result in both temporary and permanent alteration of migration, spawning, and rearing habitats used by delta smelt. However, these effects are not expected to be adverse from a population standpoint, because local water quality conditions (very low electrical conductivity and typically low turbidity) in the proposed north Delta intakes reach limits habitat suitability. In addition, changes to Clifton Court Forebay occur in a marginal environment within which delta smelt are trapped once entrained, with little prospect of effective salvage. The principal in-water work activities at the Head of Old River operable barrier will be conducted during August–November, and therefore would have minimal temporal overlap with delta smelt; the location of this site generally would be expected to result in minimal spatial overlap with delta smelt in any case. Moreover, any habitat losses will be offset by restoration of 59 acres of tidal habitat and the beneficial operational effects of Alternative 4A (described below) on the Delta as a whole.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-1, the effect would not be adverse for delta smelt.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-1, the impact of the construction of the water conveyance facilities on delta smelt or critical habitat would not be significant except for construction noise associated with pile driving outside the work window. Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

BDCP proponents will include specification in any construction contracts involving the installation of in-water or nearshore pilings, that piles will be installed using vibratory methods, or other non-impact driving methods, wherever feasible, especially outside of the in-water work window. Such methods have been shown to effectively minimize physical or substantial behavioral effects on fish and other aquatic species. The method selected will be based on geotechnical studies that will be conducted to determine the feasibility of vibratory installation of sheet pile, intake pipe foundation piles, and dock piles for barge landings. Additionally, the vibratory hammer will be started gradually to alert fish in the area that vibration will occur.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

If Mitigation Measure AQUA-1a cannot be implemented during pile driving activities that occur in-water, project proponents will implement Mitigation Measure AQUA-1b, which would include the monitoring of noise and if necessary, the attenuation of noise through either the dewatering of the cofferdam area and/or the installation of a bubble curtain or other attenuation device to minimize underwater noise. This measure would not be applicable to sheet pile installations, where it would not be feasible to surround the entire sheet pile wall, and which are expected to be installed using a vibratory hammer for at least 80–90% of the time. Where impact pile driving is required, DWR will monitor underwater sound levels to determine compliance with the underwater noise effects thresholds at a distance appropriate for protection of the species (183 dB $SEL_{cumulative}$ for fish less than 2 grams; 187 dB $SEL_{cumulative}$ for fish greater than 2 grams). If noise is expected to exceed applicable thresholds, an attenuation device or other mechanism to minimize noise will be implemented.

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

NEPA Effects: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect delta smelt. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on delta smelt from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1.The potential effects of the maintenance of water conveyance facilities under Alternative 4A would be the same as those described for Alternative 4 (see Impact AQUA-2). As concluded in Alternative 4, Impact AQUA-2, the impact would not be adverse for delta smelt or their designated critical habitat.

CEQA Conclusion: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect delta smelt. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on delta smelt from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1. As described in Alternative 4, Impact AQUA-2 for delta smelt, the impact of the maintenance of water conveyance facilities on delta smelt or critical habitat would not be significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Water Exports from SWP/CVP South Delta Facilities

Alternative 4A would result in lower overall entrainment of delta smelt than NAA_ELT. The predicted entrainment of larval/juvenile delta smelt at the south Delta export facilities was generally lowest under Scenario H4_ELT operations, and highest under the NAA_ELT and H3_ELT scenarios (Figure 11-4A-1). Both of the Alternative 4A subscenarios would result in lower entrainment of delta smelt in wet and above-normal water years; however, only H4_ELT provided for lower predicted larval/juvenile entrainment in below-normal and dry water years, and both of the subscenarios had similar entrainment to the NAA_ELT in critical water years.

The predicted entrainment of adult delta smelt was generally lower than NAA_ELT under Alternative 4A operations (Figure 11-4A-2). This pattern was most pronounced and most similar among subscenarios in wet and above-normal water years in which predicted entrainment was lowered by about one-third and one-quarter respectively. The predictions of adult delta smelt entrainment were lower than, but increasingly similar to, the NAA_ELT as modeled hydrology got drier (below-normal, dry, critical). Estimated entrainment under Scenario H3_ELT would be 0.02

less (21% lower in relative terms) than NAA_ELT for adults and similar to NAA_ELT for the larvae/juveniles (Table 11-4A-1). These differences represent 0.02 (2%) of the total population.

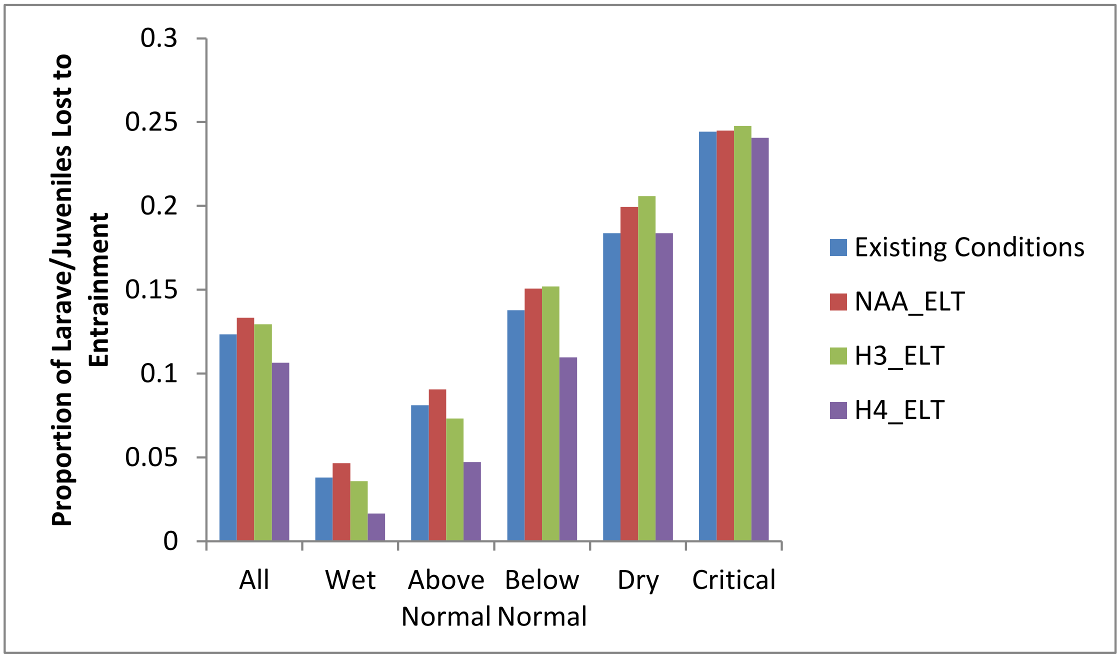

Figure 11-4A-1. Average Annual Estimated Proportion of the Larval/Juvenile Delta Smelt Population Lost to Entrainment at the SWP/CVP South Delta Facilities for Alternative 4A (Scenarios H3_ELT and H4_ELT), Based on the Proportional Entrainment Regression

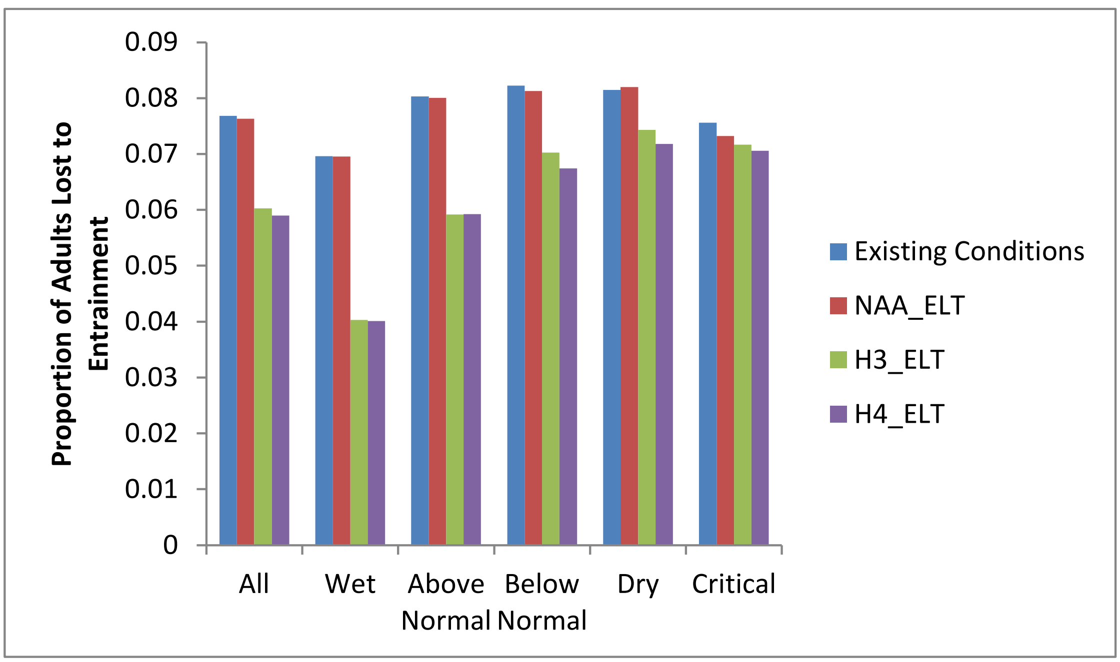

Figure 11-4A-2. Average Annual Estimated Proportion of the Adult Delta Smelt Population Lost to Entrainment at the SWP/CVP South Delta Facilities for Alternative 4A (Scenarios H3_ELT and H4_ELT), Based on the Proportional Entrainment Regression

Table 11-4A-1. Proportional Entrainment Index of Delta Smelt at SWP/CVP South Delta Facilities for Alternative 4A (Scenario H3_ELT)

	Proportional Entrainment[a] Difference in Proportions (Relative Change in Proportions)	
Water Year	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Total Population		
Wet	-0.032 (-29%)	-0.040 (-34%)
Above Normal	-0.029 (-18%)	-0.038 (-22%)
Below Normal	0.002 (1%)	-0.010 (-4%)
Dry	0.015 (6%)[b]	-0.001 (0%)
Critical	0.0 (0%)	0.001 (0%)
All Years	-0.011 (-5%)	-0.020 (-10%)
Juvenile Delta Smelt (March–June)		
Wet	-0.002 (-6%)	-0.011 (-23%)
Above Normal	-0.008 (-10%)	-0.017 (-19%)
Below Normal	0.014 (10%)[b]	0.001 (1%)
Dry	0.022 (12%)[b]	0.006 (3%)
Critical	0.004 (1%)	0.003 (1%)
All Years	0.006 (5%)	-0.004 (-3%)
Adult Delta Smelt[c] (December–March)		
Wet	-0.029 (-42%)	-0.029 (-42%)
Above Normal	-0.021 (-26%)	-0.021 (-26%)
Below Normal	-0.012 (-15%)	-0.011 (-14%)
Dry	-0.007 (-9%)	-0.008 (-9%)
Critical	-0.004 (-5%)	-0.002 (-2%)
All Years	-0.017 (-22%)	-0.016 (-21%)

Shading indicates >5% or more increased entrainment.

Note: Negative values indicate lower entrainment loss under Alternative 4A (Scenario H3_ELT) than under existing biological conditions.

[a] Proportional entrainment index calculated in accordance with USFWS BiOp (U.S. Fish and Wildlife Service 2008a).

[b] Results reflect influence of sea level rise on X2: Existing Conditions does not include sea level rise, whereas Alternative 4A includes 15 cm of sea level rise, which results in greater X2 and therefore greater estimated entrainment per the relationship from the USFWS BiOp (U.S. Fish and Wildlife Service 2008a).

[c] Adult proportional entrainment adjusted according to Kimmerer (2011).

Entrainment losses of delta smelt at the SWP/CVP south Delta facilities are related to OMR flows. Both Alternative 4A subscenarios include the same south Delta operational criteria, but the differences in spring outflow result in minor differences in actual operations, and resultant minor differences in entrainment effects on delta smelt (Figures 11-4A-1 and 11-4A-2). Scenario H4_ELT includes enhanced spring outflow, which is partly achieved by reducing exports, which increases OMR flows. Scenario H3_ELT does not include enhanced spring outflow, although it does include stricter south Delta operational criteria for OMR flows as compared to NAA_ELT. Because delta smelt entrainment occurs primarily in the winter and spring, Scenario H3 represents the greatest potential effects on delta smelt entrainment under Alternative 4A based on methods that correlate spring OMR flows and delta smelt entrainment.

Water Exports from SWP/CVP North Delta Intake Facilities

The impact would be the same as Impact AQUA-3 in Alternative 4 for north Delta intakes. Potential entrainment and impingement risks at the proposed north Delta facilities would be limited because it is outside the main range of delta smelt (see discussion for Alternative 1A). The intakes would be screened and would exclude delta smelt of around 22 mm and larger.

Predation Associated with Entrainment

Under Alternative 4A, pre-screen predation losses at the south Delta facilities would be reduced commensurate with the reductions in entrainment described above. Predation loss at the north Delta intakes may occur but would be limited because few delta smelt are anticipated to occur that far upstream.

NEPA Effects: Delta smelt entrainment under Alternative 4A would not be adverse relative to the NAA_ELT; model predictions indicate that notable reductions in entrainment would occur. Thus, Alternative 4A is likely to benefit delta smelt due to lower average entrainment and associated predation losses at the south Delta export facilities coupled with expectations of minimal entrainment risk at the north Delta facilities.

CEQA Conclusion: As described above (Table 11-4A-1), under Scenario H3_ELT entrainment at the south Delta SWP/CVP water export facilities averaged across all years would be 0.017 less (a 22% relative decrease) for adult delta smelt, and 0.006 more (a 5% relative increase) for larval/juvenile delta smelt compared to Existing Conditions. However, the percentage of the larval/juvenile population affected would be small (<1%). Contrary to the NEPA conclusion set forth above, these results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially increase larval/juvenile proportional entrainment in some water year types.

However, and as noted for Alternative 4, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur in 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. For a thorough discussion of the methodologies used to predict sea level rise and climate change as of 2060, see Chapter 29, *Climate Change*, in the Draft EIR/EIS, and Appendix 5A, *Modeling Methodology*, in the Draft EIR/EIS. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between Alternative 4A (H3_ELT) and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 4A on delta smelt entrainment would be beneficial. Larval-juvenile delta smelt entrainment would be generally similar to conditions without Alternative 4a (entrainment is reduced by 3%). Scenarios H3 and H4 represent the range of conditions expected under Alternative 4A, and therefore entrainment is expected to be reduced under Alternative 4A. Pre-screen delta smelt predation losses at the south Delta facilities would be no greater and may be lower compared to Existing Conditions due to lower overall entrainment. Predation losses at the north Delta intakes would be minimal because delta smelt rarely occur in that vicinity. These results represent the increment of change attributable to the alternative having factored out differences across time periods (e.g., sea level rise giving greater X2), which addresses the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required because Alternative 4A would reduce delta smelt entrainment.

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

NEPA Effects: Although there are operational differences between Alternative 4A and Alternative 4, the main points from the analysis from Alternative 4 also apply to all operational scenarios under Alternative 4A: there is no evidence that the delta smelt population is limited by availability of suitable spawning habitat and spawning is cued by water temperature, which would not be affected by water operations under Alternative 4A. However, as noted in the BDCP public draft Appendix 5.E (section 5.E.4.4.2), hereby incorporated by reference, under Alternative 4 (H3_LLT, i.e., ESO_LLT using the scenario nomenclature from the BDCP) there is the potential for salinity to be greater than is optimal for delta smelt egg/larvae in Suisun Marsh, during February-June in drier years (see Figure 5.E.4-49). This effect arises largely because of tidal restoration increasing the tidal prism in Suisun Marsh and Montezuma Slough Salinity Control Gate operations. Under Alternative 4A, both the amount of restoration and gate operations would be the same as NAA_ELT, therefore it would be expected that salinity would be more similar in Suisun Marsh. Therefore, there will be no adverse effect on delta smelt spawning.

CEQA Conclusion: As described above and for Alternative 4, operations under Alternative 4A would not reduce abiotic spawning habitat availability or change water temperatures for spawning delta smelt under any of the proposed flow scenarios. After accounting for climate change, there would be little difference in salinity during sensitive egg/larval time periods in Suisun Marsh, as discussed above in the NEPA Effects. Consequently, the impact would be less than significant, and no mitigation is required.

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

Issues related to rearing habitat for delta smelt and the methods used to assess potential effects are described for Alternative 4; much of the same discussion applies for Alternative 4A, which includes Fall X2 per the 2008 Delta Smelt BiOp, as does the NAA_ELT scenario; the Existing Conditions scenario does not. To reiterate the issues related to methods presented in Alternative 4, and as described in the Low Salinity Zone discussion within Section 11.1.2.2, there are remaining uncertainties regarding the contribution of the survivorship of delta smelt in the fall period to interannual population variability, concerns regarding the current sampling data, and the need for investigation of the potential application of a habitat index that applies multiple habitat characteristics. The CAMT process is investigating these and other questions to better understand how summer and fall flow conditions influence the abundance of delta smelt. However, these CAMT efforts remain incomplete and while they can and will be applied in the future, this information is currently unavailable. Additionally, consistent with the existing RPA adaptive management the adaptive management and monitoring program described in Section 4.1, Alternative 4A would implement investigations to better understand all factors affecting delta smelt abundance.

However, to inform this current impact assessment, the analysis of rearing habitat effects on delta smelt relies on a technique based on the method of Feyrer and coauthors (2011) which estimates the extent of abiotic habitat for delta smelt in the fall (September–December, the older juvenile rearing and maturation period) as a function of changes in X2 (as detailed in *BDCP Effects Analysis – Appendix 5.C, Flow, Section 5C.5.4.5.1 Delta Smelt Fall Abiotic Habitat Index hereby incorporated by reference*; see also discussion in the Low Salinity Zone discussion within Section 11.1.2.2).

As described for Alternative 4, Feyrer and coauthors (2011) demonstrated that X2 in the fall correlates nonlinearly with an index of delta smelt abiotic habitat in the West Delta, Suisun Bay, and Suisun Marsh subregions, as well as smaller portions of the Cache Slough, South Delta, and North Delta subregions (see Figure 3 of Feyrer et al. 2011). Investigations in recent years have indicated that delta smelt occur year-round in the Cache Slough subregion, including Cache Slough, Liberty Island, and the Sacramento Deep Water Ship Channel (Baxter et al. 2010; Sommer et al. 2011). Whether the same individuals are residing in these areas for their full life cycles or different individuals are moving between upstream and downstream habitats is not known (Sommer et al. 2011). The delta smelt fall abiotic habitat index is the surface area of water in the west Delta, Suisun Bay, and Suisun Marsh (as well as smaller portions of the Cache Slough, South Delta, and North Delta subregions) weighted by the probability of presence of delta smelt based on water clarity (Secchi depth) and salinity (specific conductance) in the water. Feyrer and coauthors' (2011) method found these two variables to be significant predictors of delta smelt presence in the fall. They also concluded that water temperature was not a predictor of delta smelt presence in the fall, although it has been shown to be important during summer months (Nobriga 2008). Manly et al. (2015) commented on the analysis of Feyrer et al. (2011) and found that the amount of variability in delta smelt presence explained by water clarity and salinity decreased when a region factor was included in the analysis, and suggested that inclusion of a region factor and an independent abundance term could improve the original habitat index of Feyrer et al. (2011). Based on the observations of Manly et al. (2015), the analysis of Alternative 4A presented herein based on Feyrer et al. (2011) gives more weight to dynamic habitat effects (e.g., changes in salinity and the location of the low-salinity zone) than static habitat (geographic regions). Feyrer et al. (2015) responded to Manly et al. (2015) and noted that the additional independent abundance term did not add appreciable explanatory power; they also acknowledged that water clarity and salinity (i.e., Secchi depth and conductivity) could not match observed proportions of samples with delta smelt present in some regions, which suggests that factors other than water clarity and salinity affect delta smelt occurrence; however, they also noted that adding a region factor (as was done by Manly et al. 2015) does not provide any insight into what these other factors might be.

As noted for Alternative 4, the degree of individual movement between upstream and downstream habitats has not been confirmed (Sommer et al. 2011), although emerging evidence suggests that a substantial fraction of the fish occurring in the upstream areas are residing there throughout the year (Hobbs 2012.).

Disagreements regarding the relationship between Fall X2 and delta smelt abundance prompted the CAMT process, which is currently investigating these relationships through a multi-agency collaborative process which may yield additional or different insight regarding how fall habitat conditions affect rearing and overall success of delta smelt.

As described in *BDCP Effects Analysis–Appendix 5.C, Flow, Section 5C.4.5.2. Delta Smelt Fall Abiotic Habitat Index hereby incorporated by reference*, the method based on Feyrer et al. (2011) was applied to estimate delta smelt abiotic habitat indices. Adjustments to the Feyrer et al. (2011) method are not available to reflect the ELT timeframe that is pertinent to Alternative 4A, so the following analysis only includes quantitative results reflecting flow-based differences between scenarios; in any case, the extent of restoration proposed under Environmental Commitment 4 is small (59 acres) and would have minimal influence on the results.

The abiotic habitat index under Scenarios H3 and H4 operations, are virtually identical to each other and to NAA_ELT (Table 11-4A-3; Figure 11-4A-3). This reflects the inclusion of Fall X2 in all of these scenarios.

The effects of Alternative 4A in the LLT generally would be similar to effects described for Alternative 4A in the ELT. However, Fall X2 would be slightly further eastward in the years when the USFWS 2008 BiOp Fall X2 action is not implemented, because the lack of substantial restoration under Alternative 2D allows for slightly different operations. As shown in the sensitivity analysis modeling for Alternative 4A, this would result in Alternative 4A having similar fall X2 as NAA_LLT in drier years (see Figure 70 in Appendix B), which would result in a similar abiotic habitat index under Alternative 4A compared to NAA (as opposed to the small increase under A4A_ELT compared to NAA_ELT shown in Table 11-4A-3).

NEPA Effects: Alternative 4A includes Fall X2 per the FWS BiOp and therefore results in a similar (3% across all water year types) extent of abiotic rearing habitat as NAA_ELT, based on the abiotic habitat index method described above (Table 11-4A-3). As such, there would be no effect.

CEQA Conclusion: The average fall abiotic habitat index for Alternative 4A would be greater than Existing Conditions (Scenario H3_ELT: 29% greater; Scenario H4_ELT:30% greater) (Table 11-4A-3). Note that the CEQA analysis predicts a greater increase in the abiotic habitat index relative to baseline than the NEPA analysis. This reflects Existing Conditions not including the Fall X2 requirement. The NEPA analysis isolates the effect of the alternative from the effects of sea level rise, climate change, future water demands, and implementation of required actions such as the Fall X2 requirement.

When compared to NAA_ELT and informed by the NEPA analysis, the average delta smelt abiotic habitat index under Alternative 4A restoration would be similar to NAA_ELT with Fall X2 under Scenarios H3_ELT and H4_ELT. Overall, there would be a beneficial impact on the species compared to existing conditions without Fall X2. Therefore, since Alternative 4A would benefit rearing delta smelt because the abiotic habitat index would be greater than Existing Conditions, the impact is less than significant. No mitigation would be required.

Table 11-4A-3. Differences in Delta Smelt Fall Abiotic Index between Alternative 4A (Scenarios H3_ELT and H4_ELT) and Existing Biological Conditions Scenarios, Averaged by Prior Water Year Type

	EXISTING CONDITIONS vs. Alternative 4A		NAA_ELT vs. Alternative 4A	
Water Years	H3_ELT	H4_ELT	H3_ELT	H4_ELT
All	1,150 (29%)	1,184 (30%)	99 (2%)	132 (3%)
Wet	2,478 (53%)	2,485 (53%)	38 (1%)	46 (1%)
Above Normal	2,013 (53%)	2,032 (53%)	68 (1%)	88 (2%)
Below Normal	271 (7%)	354 (9%)	232 (6%)	316 (8%)
Dry	150 (4%)	212 (6%)	161 (5%)	222 (6%)
Critical	9 (0%)	11 (0%)	9 (0%)	11 (0%)

Note: Negative values indicate lower habitat indices under alternative scenarios. Water year 1922 was omitted because water year classification for prior year was not available.

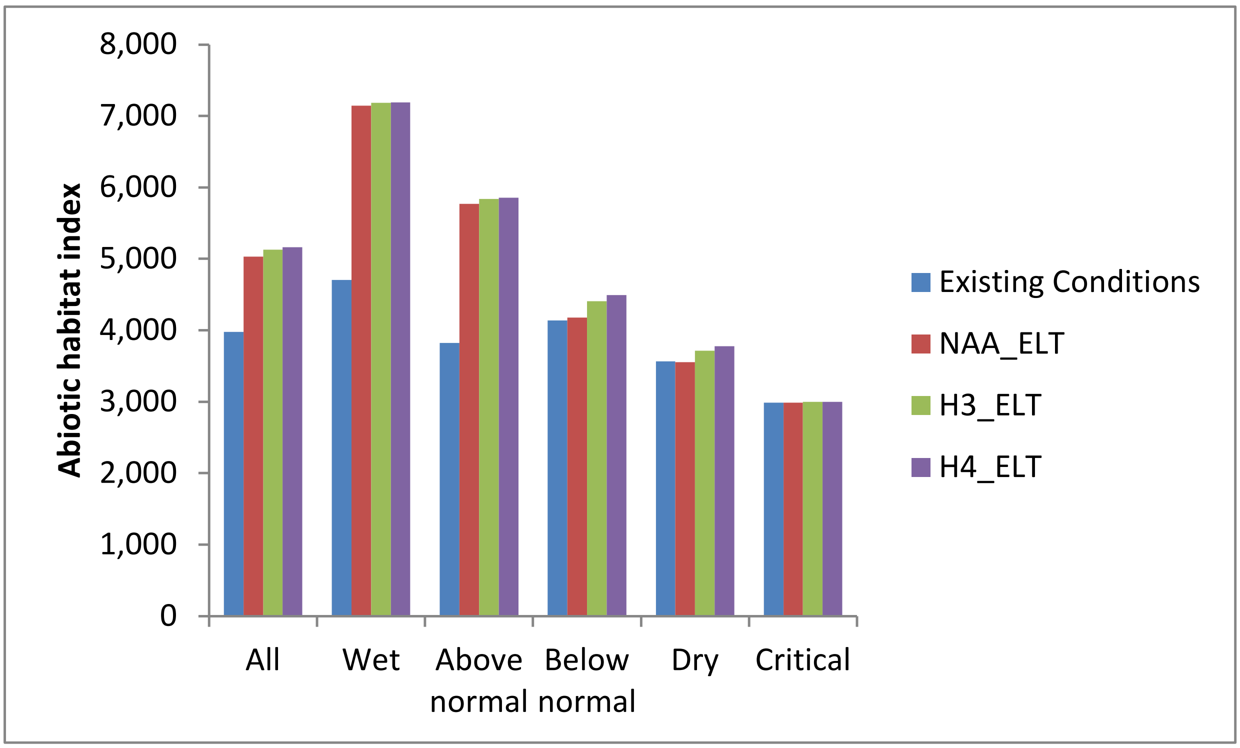

Figure 11-4A-3. Delta Smelt Fall Abiotic Habitat Index, Averaged By Water Year Type, without Restoration under Alternative 4A (Scenarios H3_ELT and H4_ELT).

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

As described for Alternative 4, the initiation of delta smelt upstream migration is associated with pulses of freshwater inflow, which are turbid, cool, and less saline (Grimaldo et al. 2009). Changes in flow under Alternative 4A could change turbidity, but are not expected to result in changes in water temperatures or pulses of local rainwater into the Delta. As described above in Impact AQUA-4 and in the discussion of Alternative 4, in-Delta water temperatures would not change in response to Alternative 4A flows. The modeling results indicate no biologically meaningful changes in water temperature within the Delta under Alternative 4, and this would also be the case for Alternative 4A.

As described in more detail for Alternative 4, turbid water is an important habitat characteristic for delta smelt (Nobriga 2008; Feyrer et al. 2011). Operation of the north Delta intakes (water conveyance facilities) is estimated to result in around 8 to 9% less sediment entering the Plan Area from the Sacramento River, the main source of sediment for the Delta and downstream subregions. In addition, sediment could be accreted (captured) in restored areas (*Environmental Commitment 4 Tidal Natural Communities Restoration*). These actions could limit sediment supply to areas currently important to delta smelt, such as Suisun Bay, which would result in less seasonal deposition of sediment that could be resuspended by wind-wave action to make/keep the overlying water column turbid. Therefore, there is a potential for a slight increase in water clarity, and a corresponding reduction in habitat quality for delta smelt. However, Alternative 4A is not expected to affect suspended sediment concentration during the first flush of precipitation that cues delta smelt migration. As such, turbidity cues associated with adult delta smelt migration should not change. With regard to suspended sediment concentrations at other times of the year, any effect will be minimized through the reintroduction of sediment collected at the north Delta intakes into tidal natural communities restoration projects (Environmental Commitment 4), consistent with the Environmental Commitment addressing Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material.

NEPA Effects: Alternative 4A may decrease sediment supply to the estuary by 8 to 9 percent, with the potential for decreased habitat suitability for delta smelt in some locations, but there would not be an adverse effect during the migration period and water temperature would not be affected by Alternative 4A water operations. These minor potential changes in turbidity are not likely affect migration cues and therefore the impact on migration conditions for delta smelt would not be adverse relative to NAA_ELT.

CEQA Conclusion: As described above, operations for all flow operating scenarios under Alternative 4A would not substantially alter the turbidity cues associated with winter flush events that may initiate migration, nor would there be appreciable changes in water temperatures. Consequently, the impact on adult delta smelt migration conditions would be less than significant, and no mitigation is required.

Restoration Measures (Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A, upon which the discussion of impacts for Alternative 4 is based. In particular, *Environmental Commitment 4 Tidal Natural Communities Restoration* is reduced from 65,000 acres to 59 acres, so that any impacts would be extremely small. The mechanisms of impacts of tidal habitat restoration on delta smelt are anticipated to be similar under Alternative 4A compared to those described in detail for Alternative 1A, although would be considerably reduced in magnitude in proportion to the difference in restoration. The effects of restoration measures described for delta smelt under Alternative 1A (Impacts AQUA-7 through AQUA-9) appropriately disclose the nature of the anticipated effects of habitat restoration in Alternative 4A.

The following impacts are those presented under Alternative 4 and Alternative 1A that are anticipated to be similar in nature for Alternative 4A, but would occur to a lesser extent because of the reduced extent of the restoration measures under Alternative 4A.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

The effects of construction of restoration measures on delta smelt under Alternative 4A are similar in nature to those discussed in more detail under Alternative 1A: temporary increases in turbidity; increased exposure to mercury and methylmercury; accidental spills; disturbance of contaminated sediments; in-water work activities; and predation. In-water and shoreline restoration construction activities may result in short-term effects on delta smelt through direct disturbance, short-term water quality impacts, and increased exposure to contaminants associated with the incidental disturbance of contaminated sediments. Overall and as noted for Alternative 1A, the effect of restoration construction activities on the bioavailability of contaminants is expected to be minimal, as they would likely be localized, sporadic, and of low magnitude. Implementation of the environmental commitments described in Appendix 3B, *Environmental Commitments*, would minimize or eliminate effects on delta smelt. The relevant environmental commitments are: Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; and Disposal of Spoils, Reusable Tunnel Material, and Dredged Material. Pertinent details of these plans are provided under Impact AQUA-1 for Alternative 1A. Given the reduced extent of restoration under Alternative 4A relative to Alternative 1A, the effects of construction of restoration measures on delta smelt would be expected to be less than for Alternative 1A.

NEPA Effects**:** The effects of short-term construction activities would not be adverse to delta smelt because in-water work would occur when they are not present and environmental commitments would limit the potential for construction-related effects.

CEQA Conclusion**:** Habitat restoration activities under Alternative 4A could result in short-term effects on delta smelt but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce delta smelt habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Effects of implementing the habitat restoration measures on delta smelt will depend on the life stage present in the area of elevated toxins and the duration of exposure. Formation and release of toxic constituents from sediments (e.g., in restored areas) is tied to inundation. The highest concentrations will occur during seasonal high water and to a lesser extent for short time periods on a tidal cycle in marshes. A complete analysis can be found in the *BDCP Effects Analysis – Appendix 5D, Contaminants.* Because the extent of tidal habitat restoration is reduced to a relatively small acreage (59 acres) under Alternative 4A compared to Alternative 1A, any effects of contaminants associated with restoration measures on delta smelt would be expected to be orders of magnitude less for Alternative 4A than for Alternative 1A. As discussed for Alternative 1A, potential effects to delta smelt could occur as a result of exposure to mercury; selenium; copper; ammonia; and pyrethroids, organophosphate pesticides, and organochlorine pesticides.

NEPA Effects**:** Overall the effects of contaminants associated with restoration measures under Alternative 4A would not be adverse for delta smelt with respect to selenium, copper, ammonia, pesticides, and methylmercury (with implementation of *Environmental Commitment 12*

Methylmercury Management) because restoration activities would be minimal and delta smelt do not bioaccumulate contaminants.

***CEQA Conclusion*:** As described in more detail for Alternative 1A, methylmercury could be generated by inundation of restoration areas under Alternative 4A. However, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury at restoration areas. Alternative 4A is not expected to substantially increase the potential exposure of fish because elevated bioavailability likely would be localized near restored areas and over a relatively short time period. Because of the relatively small extent of restoration, the potential impact of contaminants is considered less than significant. No mitigation is required.

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

Of the various habitat restoration measures proposed under Alternative 4A, *Environmental Commitment 4 Tidal Natural Communities Restoration*, is most relevant to delta smelt. Tidal habitat restoration under Alternative 4A is intended to offset any loss/modification of suitable habitat for delta smelt (for spawning and rearing) because of construction of the water facilities, in addition to restoring any function such habitat has for prey production and export to open-water areas used more extensively by delta smelt.

NEPA Effects: It is concluded that the effect of restoration activities under Alternative 4A relative to NAA_ELT would not be adverse because restoration is intended to provide habitat benefits to delta smelt.

CEQA Conclusion: The impacts associated with habitat restoration actions are considered less than significant because they are intended to restore suitable habitat and habitat functions lost to construction of water facilities. Consequently, this impact would be less than significant and no additional mitigation is required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

Alternative 4A includes three Environmental Commitments which are reduced in their extent compared to the conservation measures proposed under Alternative 4. While the extent of these environmental commitments for Alternative 4A are less than under Alternative 4 the nature of the mechanisms remains the same. Alternative 4A includes environmental commitments related to methylmercury management, reduction of predatory fish, and the installation of a non-physical barrier. The effects of each are described below.

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (Environmental Commitment 12)

As noted under Impact AQUA-8, Environmental Commitment 12 will, where practicable, attempt to minimize conditions that promote production of methylmercury in restored areas and its subsequent introduction to the foodweb, and to covered species such as delta smelt in particular. As described for Alternative 1A, Environmental Commitment 12 describes pre-design characterization, design elements, and best management practices to attempt to minimize methylation of mercury, and requires monitoring and reporting of observed methylmercury levels.

NEPA Effects: The effects of methylmercury management on delta smelt would not be adverse because it is designed to improve water quality and habitat conditions.

CEQA Conclusion: Effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts would be less than significant. Consequently, no mitigation is required.

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (Environmental Commitment 15)

Environmental Commitment 15 Localized Reduction of Predatory Fish is intended to reduce localized abundance of fish predators of salmonids at the north and south Delta export facilities. Active capture methods could include boat electrofishing, hook-and-line fishing, predator lottery fishing tournaments, and other means of passive and active capture. The methods would be developed to most efficiently target predatory fishes and to minimize the potential for bycatch of delta smelt and any other covered species. In addition, the two locations at which Environmental Commitment 15 would be undertaken are either outside the main range of delta smelt (i.e., the north Delta intakes) or are in a low-survival environment (Clifton Court Forebay and the fish salvage facilities of the south Delta export facilities)

NEPA Effects: There would be no effect on delta smelt from localized reduction of predatory fish because the target species are salmonid predators and, as discussed above, the methods used would aim to avoid bycatch of other species such as delta smelt.

CEQA Conclusion: *Environmental Commitment 15 Localized Reduction of Predatory Fish* is intended to reduce localized abundance of fish predators of salmonids in the Delta, as discussed above. Therefore there would be no impact on delta smelt.

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (Environmental Commitment 16)

As described for Alternative 1A, nonphysical barriers (NPBs) are designed to alter juvenile salmon migration routes using sound, light, and bubbles and are not intended for delta smelt. Alternative 4A proposes only one location for a NPB, at the divergence of Georgiana Slough from the Sacramento River. The in-water structures associated with this barriers may attract fish predators, increasing localized predation risk for delta smelt migrating past the barriers, but the extent of this effect is highly uncertain and, given the geographic location of the barrier, would have low overlap with delta smelt's typical distribution. The 2011 pilot study for an NPB at Georgiana Slough did not find that predation of juvenile salmonids was greater near the barrier than locations further away (California Department of Water Resources 2012).

NEPA Effects: NPBs would not have adverse effects on delta smelt because the barrier would be outside the main range of the species and the potential for predation of delta smelt around the barriers is low.

CEQA Conclusion: As discussed above, there would be no demonstrable effect of this conservation measure on delta smelt. Consequently, this impact is less than significant and no mitigation would be required.

Longfin Smelt

Construction and Maintenance of Water Conveyance Facilities

The discussion of potential effects to delta smelt from construction and maintenance of the water conveyance facilities under Alternative 4A is also relevant to longfin smelt, although the potential for longfin smelt to overlap construction and maintenance periods is even more limited than for delta smelt (Table 11-8).

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

The potential effects of construction of the water conveyance facilities on longfin smelt would be the same as described for Alternative 4 because they include the same construction activities for the water conveyance facilities. This section provides additional detail on underwater noise impacts which are also applicable to Alternative 4.

Table 11-8 presents the life stages of longfin smelt and the months of their potential presence in the north, east, and south Delta during the proposed in-water construction window (June 1–October 31). Construction of the barge landings, CCF cofferdams, CCF siphons, and HOR operable barrier in the south Delta and east Delta would be the primary locations where longfin smelt could be affected by pile driving, as longfin smelt are only expected to occur at the intake construction sites during the early portion of the in-water work window. As discussed for delta smelt, implementation of Mitigation Measures AQUA-1a and AQUa-1b would minimize potential adverse effects associated with pile driving noise outside the work window.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-19, the effect would not be adverse for longfin smelt.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-19, the impact of the construction of water conveyance facilities on longfin smelt would not be significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

NEPA Effects: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect delta smelt. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on delta smelt from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1. The potential effects of water conveyance facilities maintenance under Alternative 4A would be the similar to those described for Alternative 4, Impact AQUA-20. As concluded in Alternative 4, Impact AQUA-20, the impact would not be adverse for longfin smelt.

CEQA Conclusion: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect delta smelt. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on delta smelt from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1. As described in Alternative 4, Impact AQUA-20, the impact of the maintenance of water conveyance facilities on longfin smelt would not be significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Water Exports from SWP/CVP South Delta Facilities

For larval longfin smelt, entrainment risk was simulated using particle tracking modeling for wetter and drier starting distributions. Alternative 4A would result in reduced longfin smelt larvae entrainment compared to the NAA_ELT. Average particle entrainment by the south Delta facilities was 1.4–1.6% under Scenario H3_ELT, which does not include enhanced spring outflow, and was lower than the 1.5–1.9% entrainment under NAA_ELT (Table 11-4A-4). Under Scenario H4_ELT for Alternative 4A, which includes enhanced spring outflow, larval longfin smelt entrainment would be lower than H3_ELT and therefore even less than NAA_ELT, because of the enhanced spring outflow criteria that results in a further reduction in south Delta exports.

Table 11-4A-4. Percentage of Particles (and Difference) Representing Longfin Smelt Larvae Entrained by the South Delta Facilities under Alternative 4A (Scenario H3_ELT) and Baseline Scenarios

	Percent Particles Entrained			Difference (and Relative Difference)	
Starting Distribution	EXISTING CONDITIONS	NAA_ELT	H3_ELT	H3_ELT vs. EXISTING CONDITIONS	H3_ELT vs. NAA_ELT
Wetter	1.7	1.5	1.4	-0.31 (-19%)	-0.16 (-11%)
Drier	2.1	1.9	1.6	-0.53 (-25%)	-0.32 (-17%)

Note: 60-day DSM2-PTM simulation of wetter and drier starting distributions. Negative values indicate lower entrainment under the alternative compared to the baseline scenario.

For juveniles and adults, entrainment at the south Delta facilities (entrainment index based on the salvage-density method[1], averaged across all water year types) under H3_ELT would be 37% lower

[1] Although the salvage-density method gives estimates of entrainment loss or salvage in numbers of fish and there are a number of factors included in the calculations such as multipliers applied for prescreen loss and normalization to population size, it is most appropriate to view the results comparatively, i.e., to compare relative differences between scenarios as opposed to examining the estimates of total number of fish lost to entrainment or salvaged. In essence, the salvage-density method provides an entrainment index that reflects export pumping

for juveniles and 52% lower for adults compared to baseline conditions (Table 11-4A-5). Scenario H4_ELT would result in even greater reductions in entrainment, due to higher spring outflows and the associated reduction in south Delta exports. Under all Alternative 4A scenarios, the predicted average adult and juvenile entrainment would be less in all five water year types.

Table 11-4A-5. Longfin Smelt Entrainment Index at the SWP and CVP Salvage Facilities—Differences (Absolute and Percentage) between Model Scenarios for Alternative 4A (Scenario H3_ELT)

		Absolute Difference (Percent Difference)	
Life Stage	Water Year Types	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Juvenile (March–June)	Wet	-34,106 (-53%)	-37,987 (-56%)
	Above Normal	-785 (-17%)	-1062 (-22%)
	Below Normal	-486 (-16%)	-484 (-16%)
	Dry	8,921 (2%)	-38,267 (-7%)
	Critical	-198,499 (-35%)	-173,992 (-32%)
	All Years	-86,038 (-32%)	-108,770 (-37%)
Adult (December–March)	Wet	-72 (-56%)	-78 (-58%)
	Above Normal	-251 (-39%)	-302 (-43%)
	Below Normal	-815 (-42%)	-907 (-45%)
	Dry	-320 (-27%)	-336 (-28%)
	Critical	-6,112 (-25%)	-3,991 (-18%)
	All Years	-1,854 (-51%)	-1,924 (-52%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Water Exports from SWP/CVP North Delta Intake Facilities

As described under Alternative 1A for Impact AQUA-22, longfin smelt are not known to spawn in the reach of the Sacramento River where the north Delta diversions will be built. Therefore, entrainment of longfin smelt at the proposed north Delta intakes would be extremely low because this species is only expected to occur occasionally in very low numbers this far upstream on the Sacramento River.

Predation Associated with Entrainment

Pre-screen predation losses of longfin smelt at the SWP/CVP south Delta water export facilities are believed to be high and proportional to entrainment. It is assumed that pre-screen predation losses of longfin smelt would be similar to delta smelt based on their similar size, shape, and pelagic nature. Predation losses of both juvenile and adult longfin smelt under Alternative 4A would be no greater than baseline and may be lower, given the much lower entrainment losses at the south Delta facilities (32–37% lower for juveniles and 51–52% lower for adults) compared to NAA (Table 11-4A-5). Predation loss at the proposed north Delta intakes would be unlikely because longfin smelt do not generally occur that far upstream on the Sacramento River. Under the range of flow operating

weighted by each covered species' seasonal pattern of abundance in the Plan Area, as reflected by historical salvage data.

scenarios for Alternative 4A, entrainment-related predation loss would be reduced relative to NAA_ELT, with the greatest decreases in entrainment occurring under Scenario H4_ELT.

NEPA Effects: Entrainment and entrainment-related predation of juvenile and adult longfin smelt would be reduced substantially under Alternative 4A compared to NAA_ELT across all water years (Table 11-4A-5). Entrainment and associated predation loss of longfin smelt at the proposed north Delta intakes would be unlikely since longfin smelt are not expected to occur in that area of the Sacramento River. Alternative 4A would not have an adverse effect on entrainment and entrainment-related predation and would likely provide a benefit to the species because of substantial reductions in juvenile and adult entrainment at the south Delta facilities.

CEQA Conclusion: Entrainment and entrainment-related predation of all life stages of longfin smelt at the south Delta facilities would be reduced under Alternative 4A compared to Existing Conditions. Particle entrainment, representing larval longfin smelt, was lower under Alternative 4A for both drier and wetter starting distributions (refer to *BDCP Appendix 5.B* for further details). Entrainment loss would be substantially lower for both juvenile (32% less) and adult longfin smelt (51% less) (Table 11-4A-5). Entrainment to the north Delta intakes would be unlikely because longfin smelt are not expected to occur in the vicinity of the intakes. Therefore, Alternative 4A would not have a significant impact on entrainment and entrainment-related predation and would likely provide a benefit to the species because of the substantial reductions in south Delta entrainment.

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

Background on the general distribution of longfin smelt and the evidence for relationships between longfin smelt abundance with freshwater outflow is provided in detail in the discussion for Alternative 4. The mechanisms of this correlation are not well understood, and efforts are underway to determine what flow-related factors, if any, have a causal relationship with longfin smelt abundance, and how that relates to the various life stages present in the Delta in the winter and spring months. Additionally, sample biases related to when and where longfin smelt are sampled may influence these correlations, and the regional contribution to the overall longfin smelt population is unknown; this is a large focus of the study plan resulting from the Settlement Agreement between DFW and DWR/State Water Contractors related to longfin smelt. However, at this time, the best available relationship between longfin smelt abundance and changes in water facility operations is based on Kimmerer et al. (2009), the application of which shows that outflow in January through June correlates to longfin smelt abundance. As such, the X2–longfin smelt abundance relationship provided by Kimmerer et al. (2009) was used to evaluate the effects of the alternatives on longfin smelt, following the historical observation that lower X2 (farther downstream) correlates with increased recruitment (represented by abundance indices in trawl surveys), although it is not understood if or how this would affect spawning, egg incubation, and/or rearing longfin smelt. Consistent with the adaptive management and monitoring program described in Section 4.1, Alternative 4A would implement investigations to better understand all factors affecting longfin smelt abundance. However, for purposes of this impact assessment, the relationships between X2 and longfin smelt abundance developed by Kimmerer et al. (2009) were used to determine how the changes in winter-spring X2 position described above might influence longfin smelt abundance the following fall.

Table 11-4A-7. Differences in Mean Monthly Delta Outflow (cfs) between NAA_ELT and Alternative 4A Scenarios H3_ELT and H4_ELT, by Water Year Type, for Winter-Spring (December–June)

Month	Water-Year Type	NAA_ELT vs. H3_ELT	NAA_ELT vs. H4_ELT
January	Wet	-2,114 (-2.3%)	-2,143 (-2.4%)
	Above Normal	-2,256 (-4.6%)	-1,507 (-3.1%)
	Below Normal	112 (0.5%)	98 (0.4%)
	Dry	751 (5.1%)	1,033 (7%)
	Critical	-138 (-1.1%)	-237 (-2%)
	All	-837 (-1.9%)	-691 (-1.5%)
February	Wet	-1,048 (-1%)	-1,595 (-1.5%)
	Above Normal	271 (0.4%)	-1,018 (-1.6%)
	Below Normal	-2,540 (-6.8%)	-1,359 (-3.6%)
	Dry	-1,347 (-6.4%)	-1,397 (-6.7%)
	Critical	30 (0.2%)	107 (0.85%)
	All	-1,018 (-1.8%)	-1,178 (-2.1%)
March	Wet	-1,113 (-1.4%)	1,155 (1.4%)
	Above Normal	-1,144 (-2.1%)	222 (0.4%)
	Below Normal	-1,901 (-8.4%)	1,909 (8.5%)
	Dry	-2,234 (-11.5%)	-623 (-3.2%)
	Critical	-352 (-2.9%)	-167 (-1.4%)
	All	-1,387 (-3.2%)	563 (1.3%)
April	Wet	-5,630 (-10.3%)	-633 (-1.2%)
	Above Normal	-5,805 (-18.6%)	71 (0.2%)
	Below Normal	-2,792 (-13.2%)	4,872 (23%)
	Dry	-1,507 (-11.2%)	-202 (-1.5%)
	Critical	-246 (-2.8%)	-51 (-0.6%)
	All	-3,478 (-11.7%)	590 (2%)
May	Wet	-4,587 (-12%)	206 (0.5%)
	Above Normal	-3,126 (-13.5%)	1,560 (6.7%)
	Below Normal	-1,140 (-7.7%)	1,810 (12.3%)
	Dry	-325 (-3.3%)	352 (3.6%)
	Critical	-254 (-4%)	-182 (-2.9%)
	All	-2,215 (-10.5%)	653 (3.1%)
June	Wet	-311 (-1.7%)	-609 (-3.4%)
	Above Normal	648 (6.4%)	509 (5%)
	Below Normal	757 (9.4%)	269 (3.3%)
	Dry	319 (4.5%)	345 (4.8%)
	Critical	-14 (-0.3%)	-13 (-0.2%)
	All	193 (1.8%)	1 (0%)
December	Wet	-1,728 (-3.5%)	-2,143 (-2.4%)
	Above Normal	-36 (-0.2%)	-1,507 (-3.1%)
	Below Normal	-174 (-1.3%)	98 (0.4%)
	Dry	500 (5.9%)	1,033 (7%)
	Critical	-216 (-3.9%)	-237 (-2%)
	All	-505 (-2.1%)	-691 (-1.5%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Under Scenario H3_ELT, which does not include enhanced spring outflow, modeled average Delta spring outflow is often lower than NAA_ELT. The spring outflow under H4_ELT, which includes enhanced spring outflow, was greater than NAA_ELT in a number of years, as illustrated by differences in water-year-type average Delta outflow (see Table 11-4A-7 above). Based on Kimmerer et al. 2009, the longfin smelt abundance for H3_ELT ranged from a reduction of 19-22% compared to Existing Conditions, to a reduction of 11% to an increase of 7% compared to NAA_ELT (Table 11-4A-8). For H4_ELT, which includes enhanced spring outflow and climate change effects, the predicted longfin smelt abundance ranged from a reduction of 10% to 12% compared to Existing Conditions to an increase of 18% to 22% when compared to NAA_ELT, based on the X2-abundance equations in Kimmerer et al. (2009). In addition, the method does not articulate the potential changes in spawning, egg incubation, or rearing habitat as a result of changes in X2 because no specific correlations between these life stages and X2 has been established. Studies examining the relationship between flow and longfin smelt abundance would be undertaken as part of the Adaptive Management and Monitoring Program in order to address the current uncertainty that exists surrounding the mechanism through which higher Delta outflow improves the production and survival of early life stages of longfin smelt. Results of these investigations will continue to be reviewed and considered in the coming years, in making management decisions regarding outflows necessary for longfin smelt.

NEPA Effects: Under Alternative 4A, water operations would result in a potential decrease in longfin smelt abundance if spring outflows are not at least as high as the NAA_ELT, based on the application of the Kimmerer et al. 2009 flow-abundance regression. As such, Scenario H3_ELT has the potential to be adverse. However, as described above and in Section 4.1, Alternative 4A operations will be subject to adjustment via adaptive management, which is intended to allow for further evaluation of spring outflow, and adjustments necessary to ensure that longfin smelt are not adversely affected by project operations. Scenario H4_ELT generally increases abundance and therefore would not be adverse. Further, Mitigation Measure AQUA-22d would ensure January through June delta outflows do not result in changes in longfin smelt abundance. Therefore, under Alternative 4A, this impact would not be adverse.

Table 11-4A-8. Estimated Differences Between Alternative 4A (Scenarios H3_ELT and H4_ELT) and Baseline for Longfin Smelt Relative Abundance in the Fall Midwater Trawl or Bay Midwater Trawl Based on the X2-Relative Abundance Regression of Kimmerer et al. (2009)

	Fall Midwater Trawl Relative Abundance		Bay Midwater Trawl Relative Abundance	
Water Year Type	EXISTING CONDITIONS vs. Alternative 4A	NAA_ELT vs. Alternative 4A[1]	EXISTING CONDITIONS vs. Alternative 4A	NAA_ELT vs. Alternative 4A[1]
Scenario H3_ELT				
All	-1,502 (-17%)	-475 (-6%)	-4,686 (-19%)	432 (3%)
Wet	-3,195 (-17%)	-909 (-5%)	-10,611 (-19%)	2,268 (7%)
Above Normal	-1,684 (-17%)	-685 (-8%)	-5,014 (-20%)	-700 (-4%)
Below Normal	-855 (-19%)	-331 (-8%)	-2,168 (-22%)	-717 (-11%)
Dry	-396 (-17%)	-134 (-7%)	-904 (-21%)	-235 (-7%)
Critical	-65 (-6%)	-7 (-1%)	-132 (-8%)	-74 (-5%)
Scenario H4_ELT				
All	-622 (-7%)	404 (5%)	-2,120 (-9%)	1,167 (6%)
Wet	-1,882 (-10%)	404 (2%)	-6,625 (-12%)	1,210 (3%)
Above Normal	-50 (0%)	949 (10%)	(0%)	2,960 (13%)
Below Normal	176 (4%)	699 (18%)	510 (5%)	1,812 (22%)
Dry	-187 (-8%)	75 (4%)	-414 (-9%)	180 (5%)
Critical	-52 (-5%)	6 (1%)	-107 (-6%)	10 (1%)

Shading indicates relative abundance decrease of 10% or greater under H3_ELT.

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

[1] Note that longfin smelt abundance has been declining and is expected to continue to decline under the NAA such that increases in longfin smelt abundance shown in the comparison of NAA_ELT vs. Alternative 4A may not reflect absolute increases of longfin smelt abundance."

CEQA Conclusion: Under Alternative 4A scenario H3_ELT, average Delta outflow during winter/spring generally would be similar to Existing Conditions during December-March, with some exceptions by water year type, and lower in April–June (Table 11-4A-9). Under Scenario H4_ELT, average Delta outflows generally would be similar to Existing Conditions, but would be lower in June.

Table 11-4A-9. Differences in Mean Monthly Delta Outflow (cfs) between Existing Conditions and Alternative 4A Scenarios H3_ELT and H4_ELT, by Water Year Type, for Winter-Spring (December–June)

Month	Water-Year Type	EXISTING CONDITIONS vs. H3_ELT	EXISTING CONDITIONS vs. H4_ELT

	Critical	10 (0.2%)	10 (0.2%)
	All	-1,626 (-12.7%)	-1,818 (-14.2%)
December	Wet	-154 (-0.3%)	1,192 (2.5%)
	Above Normal	1,334 (7.4%)	1,433 (8%)
	Below Normal	1,161 (9.7%)	1,314 (11%)
	Dry	82 (0.9%)	35 (0.4%)
	Critical	-241 (-4.4%)	-320 (-5.8%)
	All	327 (1.4%)	773 (3.4%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Average relative abundance of longfin smelt, as estimated by the Kimmerer et al. (2009) method which directly correlates winter-spring Delta outflow to longfin smelt abundance, is up to 19% to 22% lower under Scenario H3_ELT compared to Existing Conditions (17–19% lower across all water year types; Table 11-4A-8). For H4_ELT, which includes enhanced spring outflow, the longfin smelt abundance is up to 10% to 12% lower compared to Existing Conditions (5–7% lower across all water year types), based on Kimmerer et al. (2009).

Contrary to the NEPA conclusion set forth above, these results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce relative abundance based on Kimmerer et al. (2009).

However, and as noted for Alternative 4, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed above and in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the second NOP for the BDPC was prepared (2009). Both the action alternative and the NEPA baseline (NAA) models anticipated future conditions that would occur at 2025, including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the NEPA analysis, which compares results between the alternative and NAA_ELT, is a better approach with respect to these issues because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis, above, the average longfin smelt abundance, based on Kimmerer et al. (2009), was up to 8–11% less under H3_ELT (across all water years: 6% decrease to 3% increase; Table 11-4A-8). Abundance relative to NAA_ELT increased up to 18% to 22% (across all water years: 5–6% increase) for H4_ELT, which includes enhanced spring outflow compared to NAA_ELT (Table 11-4A-7). These results represent the increment of change attributable to the alternative, and addressing the limitations of the comparison based on the CEQA baseline (Existing Conditions). Furthermore, the Adaptive Management and Monitoring Program included in Alternative 4A would allow for an evaluation of the necessary volume and timing of spring outflow. However, based on the Kimmerer et al. regression applied for this analysis, H3 would result in a significant impact on longfin smelt due to a substantial decrease in abundance, while H4 would have a beneficial impact because the abundance would be increased. Because of the potential for this alternative to substantially reduce longfin smelt abundance, this impact is considered significant. Implementing Mitigation Measure AQUA-22d would reduce this impact to a less-than-significant level.

Mitigation Measure AQUA-22d: Ensure January through June Delta Outflows do Not Result in Changes in Longfin Smelt Abundance

Initial operations would set delta outflow such that longfin smelt abundance would not be reduced. This could be accomplished by reducing SWP/CVP exports, transferring water from non-CVP/SWP sources to increase outflow, or using water stored in Oroville. Science developed through the Adaptive Management Program (described in Section 4.1) will be used to make appropriate adjustments to operations, including outflow, to minimize effects on longfin smelt. These operations would be implemented consistent with applicable biological opinions, incidental take statements, and other permits.

Restoration Measures (Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

As described for delta smelt, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A, upon which the discussion of impacts for Alternative 4 is based. In particular, *Environmental Commitment 4 Tidal Natural Communities Restoration* is reduced from 65,000 acres to 59 acres, so that any impacts related restoration construction would be extremely small. The mechanisms for potential effect of habitat restoration on longfin smelt are very similar to those for delta smelt (see Impacts AQUA-7, AQUA-8, and AQUA-9), although longfin smelt would be expected to have less temporal and spatial overlap with restored areas, during and after construction, than delta smelt.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Please refer to discussion of Impact AQUA-7 under Alternative 4A for delta smelt.

***NEPA Effects*: The effects of short-term construction activities would not be adverse to longfin smelt because in-water work would occur when they are not present and environmental commitments would limit the potential for construction-related effects.**

CEQA Conclusion: As discussed for Alternative 1A, habitat restoration activities could result in short-term effects on longfin smelt but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce longfin smelt habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Please refer to discussion of Impact AQUA-8 under Alternative 4A for delta smelt.

NEPA Effects: Overall and consistent with the conclusion for Alternative 1A, the effects of contaminants associated with restoration measures under Alternative 4A would not be adverse for longfin smelt with respect to selenium, copper, ammonia, pesticides, and methylmercury because longfin smelt would have relatively little opportunity to bioaccumulate these contaminants (because of their diet, the duration they spend in the Delta, and their relatively short life spans) and because of implementation of *Environmental Commitment 12 Methylmercury Management*.

CEQA Conclusion: As noted for delta smelt and as described in more detail for Alternative 1A, methylmercury could be generated by inundation of restoration areas under Alternative 4A. However, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury at restoration areas. Alternative 4A is not expected to substantially increase the potential exposure of fish because elevated bioavailability likely would be localized near restored areas and over a relatively short time period. Because of the relatively small extent of restoration, the potential impact of contaminants is considered less than significant. Consequently, no mitigation would be required.

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

The potential effects of restored habitat conditions on longfin smelt would be similar to those discussed for delta smelt (see the discussion under Impact AQUA-9), although longfin smelt occupy such areas for shorter time periods than delta smelt and therefore would not be affected to as great an extent.

NEPA Effects: The effect of restoration activities would not be adverse for longfin smelt because restoration will increase habitat availability.

CEQA Conclusion: The impacts associated with habitat restoration actions are considered less than significant because they are intended to restore suitable habitat and habitat functions lost to construction of water facilities. No additional mitigation is required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

As described for delta smelt, Alternative 4A includes three other Environmental Commitments, which are reduced in their extent relative to the Conservation Measures included in other Alternatives (e.g., Alternative 1A and Alternative 4). While the extent of these measures is reduced compared to these alternatives, the nature of the mechanisms remains the same.

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (Environmental Commitment 12)

As noted for delta smelt under Impact AQUA-10, Environmental Commitment 12 is intended to minimize conditions that promote production of methylmercury in restored areas and its subsequent introduction to the foodweb, and to covered species such as longfin smelt. As described for Alternative 1A, Environmental Commitment 12 describes pre-design characterization, design elements, and best management practices to attempt to minimize methylation of mercury, and requires monitoring and reporting of observed methylmercury levels.

NEPA Effects: The effects of methylmercury management on longfin smelt would not be adverse because it is designed to improve water quality and habitat conditions.

CEQA Conclusion: Effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts would be less than significant to longfin smelt. Consequently, no mitigation is required.

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (Environmental Commitment 15)

Environmental Commitment 15 Localized Reduction of Predatory Fish is intended to reduce localized abundance of fish predators of salmonids in the Delta.

NEPA Effects: There is a potential for incidental benefit to longfin smelt from localized reduction of predatory fish, although the target species are salmonid predators.

CEQA Conclusion: *Environmental Commitment 15 Localized Reduction of Predatory Fish* is intended to reduce localized abundance of fish predators of salmonids in the Delta. Therefore there would be no impact on longfin smelt.

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (Environmental Commitment 16)

Potential impacts on longfin smelt from the installation of an NPB at the divergence of Georgiana Slough from the Sacramento River are expected to be similar to those for delta smelt (see Impact AQUA-14), with even less potential for any effect because of even lower overlap of longfin smelt distribution with the proposed location of the NPB.

NEPA Effects: There would be no demonstrable effect of the NPB on longfin smelt because they are not likely to be in the area of the barrier and the potential for predation of longfin smelt around the barriers is low.

CEQA Conclusion: As discussed above, there would be no demonstrable effect of this conservation measure on longfin smelt. Consequently, the impact is less than significant and no mitigation would be required.

Winter-Run Chinook Salmon

Construction and Maintenance of Water Conveyance Facilities

The discussion of potential effects to delta smelt from construction and maintenance of the water conveyance facilities under Alternative 4A is also relevant to winter-run Chinook salmon because the same types of impact mechanisms would apply. However, adult and juvenile winter-run Chinook salmon would have somewhat greater potential to overlap construction and maintenance than delta smelt (Table 11-8).

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

The potential effects of construction of the water conveyance facilities on winter-run Chinook salmon would be the same as described for Alternative 4 (Impact AQUA-37). This section provides additional detail on underwater noise impacts which are also applicable to Impact AQUA-37 in Alternative 4.

Table 11-8 presents the life stages of the four runs of Chinook salmon and the months of their potential presence in the north, east, and south Delta during the proposed in-water construction period (June 1–October 31). Winter-run, spring-run, fall-run, and late fall–run Chinook salmon eggs and fry would not be exposed to underwater noise from pile driving activities because the proposed construction activities are located in areas that do not provide suitable habitat for these life stages or because these life stages would not be present during the proposed in-water construction period.

Under Alternative 4A, the potential for exposure of adult and juvenile winter-, spring-, and late fall-run Chinook salmon to pile driving noise is highest in the north Delta (Sacramento River in the vicinity of the three proposed intakes) which serves as the primary migration route utilized by adults to access upstream spawning areas, and the primary migration route for juveniles entering the Delta and estuary from upstream spawning and rearing areas. Restricting in-water pile driving to June 1 to October 31 avoids the peak migration periods of winter-, spring-, and late fall-run adults and juveniles. Some overlap with winter-run and spring-run adults may occur at the end of the migration season in June or July, and with late fall-run adults at the beginning of the migration season in October. Adult fall-run Chinook salmon, which migrate through the north, east, and south Delta on their way to upstream spawning areas in the Sacramento, San Joaquin, and east Delta tributaries, may be present in the vicinity of the intake structures and barge unloading facilities during in-water pile driving activities from August through October. Most juvenile Chinook salmon occur in the Delta from late fall through spring (November through May) although some fall- and spring-run smolts may encounter pile driving noise at the end of the outmigration season in June.

To minimize potential adverse effects when adult and juvenile salmon may be present, DWR proposes to use vibratory driving to the extent feasible to minimize both the area and duration of potentially harmful underwater noise levels associated with impact driving in open water. In addition, construction of the intake facilities would be spread out over a period of five years, limiting the number of sites and duration of pile driving encountered by adults and juveniles in any given year (Table 4.3.7-1 under Delta Smelt). Although pile driving activities could occur 42 to 55 days per season at each intake location, in-water pile driving will not be continuous and limited to daylight hours only, resulting in 12-16 hour periods each day for migrating fish to pass the construction sites undisturbed.

It is unlikely that pile driving sounds will cause injury or mortality of adult salmon based on the large size, mobility, and anticipated behavior during their migration through the affected areas. Adult Chinook salmon are large (typically 9–10 kilograms) and presumably much less vulnerable to pile driving noise than smaller fish targeted for protection by the SPL and SEL injury criteria (approximately 2 grams or smaller). In addition, migrating adult salmon are expected to readily avoid or swim away from areas of elevated noise. Similar pile driving operations indicate that single-strike peak SPLs and SELs exceeding the injury criteria would be limited to small areas immediately adjacent to source piles (<33–46 feet) and thus would affect only a small portion of the total channel width available for adults to pass (Table 4.3.7-1 under Delta Smelt). However, the potential for injury still exists because migrating adults would be faced with passing through larger channel reaches (spanning the entire channel width at most locations) subject to noise levels exceeding the cumulative thresholds for >2-gram fish (187 dB SEL). The potential for injury is considered low due to the large size of adults and rapid migration rates to upstream holding and spawning areas. While limited evidence suggests that pile driving operations may disrupt normal migratory behavior in salmonids (Feist et al. 1992), any delays in migration are expected to be minor because of the intermittent nature of pile driving and the daily cessation of pile driving at night.

Juvenile salmon are at higher risk of injury and mortality than adults because of their small size. However, the June 1 through October 31 pile driving period will avoid the primary juvenile outmigration period for all runs of Chinook salmon (November through May), and thus minimize the potential for adverse effects. Most juvenile Chinook salmon migrating through the Delta after June 1 or before October 31 are large, actively migrating smolts (> 2 grams) that are known to move rapidly through the Delta and estuary during their seaward migration (Williams 2006). These larger juveniles may be exposed to noise levels exceeding the injury thresholds for >2-gram fish (187 dB SEL) as they pass through the affected channel reaches. However, exposure is expected to be limited by their rapid migration rate and opportunities to pass the affected reaches at night after daily pile driving operations have ceased. In general, downstream movement of juvenile Chinook salmon occurs mainly at night or during the hours between dusk and dawn, limiting exposure of juveniles to pile driving noise to daylight hours; for example, Chapman et al. (2013) found that late fall-run Chinook salmon migrating through the Delta were ~70% nocturnal. For winter-run Chinook salmon, juveniles migrating in October may be smaller individuals < 60 mm, which would be more susceptible to pile-driving noise, but the proportion of all juveniles occurring in October is very small; the main migration into the Delta typically begins in November or December (del Rosario et al. 2013), outside the pile driving period. As discussed above, limited evidence suggests that pile driving noise may disrupt normal migratory behavior in salmonids. For juveniles, these behavioral effects may include responses that disrupt normal feeding, resting, and sheltering behavior, resulting in potential adverse effects on growth and survival (e.g., increased vulnerability to predation). Thus, pile driving activities could lead to indirect mortality if juveniles are exposed to a range of noise levels that could cause behavioral effects.

Based on the foregoing analysis, the potential exists for some injury and mortality of juvenile Chinook salmon from pile driving noise but only a small proportion of the population is at risk based on the low degree of overlap of pile driving activities with outmigration timing, and the relatively large size and mobility of juveniles that may encounter pile driving noise (migrating smolts). Implementation of Mitigation Measures AQUA-1a and AQUA-1b will further reduce this risk.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-37, the effect would not be adverse for winter-run Chinook salmon. Implementation of the measures described in Appendix 3B, *Environmental Commitments*, such as *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan* would guide rapid and effective response in the case of inadvertent spills of hazardous materials. This species' natural tolerance to turbidity, would likely avoid the risk of any adverse turbidity effects resulting from project construction. Construction would not be expected to increase predation rates relative to baseline conditions. Construction will result in both temporary and permanent alteration of rearing and migratory habitats used by Chinook salmon. However, Alternative 4A includes Environmental Commitment 4 to restore tidal habitat and Environmental Commitment 6 to restore channel margin habitat. The direct effects of underwater construction noise on Chinook salmon that may be present could be adverse if Chinook salmon are exposed. However, implementation of Mitigation Measures AQUA-1a and AQUA-1b, combined with the in-water work window that would minimize exposure, would reduce the potential for effects from underwater noise and this effect would not be adverse.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-37, the impact of the construction of water conveyance facilities on winter-run Chinook salmon would not be significant except for construction noise associated with pile driving. Construction of Alternative 4A involves several elements with the potential to affect winter-run Chinook salmon. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect Chinook salmon. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on Chinook salmon from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1. The potential effects of water conveyance facilities maintenance under Alternative 4A would be similar to those described for Alternative 4, Impact AQUA-38. As concluded in Alternative 4, Impact AQUA-38, the impact would not be adverse for winter-run Chinook salmon.

CEQA Conclusion: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect delta smelt. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on delta smelt from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1. As described in Alternative 4, Impact AQUA-38, the impact of the maintenance of water conveyance facilities on Chinook salmon would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

The proportion of juvenile winter-run Chinook salmon subject to entrainment is low under Existing Conditions and NAA_ELT (annual index of abundance average 1.4%) and Alternative 4A would further reduce entrainment of juvenile winter-run Chinook salmon at the south Delta facilities. For example, Scenario H3_ELT would reduce the proportion of juvenile winter-run Chinook entrained in the south Delta export facilities (average of 0.6%). As such, average entrainment under Scenario H3_ELT would be reduced by 54% (~3,800 fish[2]: Table 11-4A-10) across all water years compared

[2] As noted for longfin smelt, although the salvage-density method gives estimates of entrainment loss or salvage in numbers of fish and there are a number of factors included in the calculations such as multipliers applied for prescreen loss and normalization to population size, it is most appropriate to view the results comparatively, i.e., to compare relative differences between scenarios as opposed to examining the estimates of total number of fish lost

to NAA_ELT. Entrainment would be substantially reduced in wet and above normal water year types (65–72% less than NAA_ELT) and would be moderately reduced in below normal, dry, and critical water year types (14–44% less than NAA_ELT).

Scenario H4_ELT would be expected to have similar or slightly lower entrainment of winter-run Chinook salmon as Scenario H3_ELT because south Delta exports during the spring (March–May) under H4_ELT would be less compared to H3_ELT.

Table 11-4A-10. Juvenile Winter-Run Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 4A (Scenario H3_ELT)

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-7,947 (-70%)	-8,670 (-72%)
Above Normal	-4,246 (-64%)	-4,396 (-65%)
Below Normal	-3,044 (-42%)	-3,230 (-44%)
Dry	-928 (-24%)	-793 (-22%)
Critical	-260 (-21%)	-170 (-14%)
All Years	-3,625 (-53%)	-3,773 (-54%)

Note:
Estimated annual number of fish lost, based on normalized data.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Water Exports from SWP/CVP North Delta Intake Facilities

As noted for Alternative 4, the effect of Alternative 4A on entrainment and impingement at the north Delta intakes would be the same as described for Alternative 1A (Impact AQUA-39), but the degree would be less because Alternative 4A would have fewer intakes. State-of-the-art[3] fish screens operated with an adaptive management plan would be expected to eliminate entrainment and impingement risk for juvenile winter-run Chinook salmon. Biologically-based triggers to minimize effects on salmonids and sturgeon during their migration past the intakes are being developed through the ESA consultation process.

Predation Associated with Entrainment

Entrainment-related predation loss of winter-run Chinook salmon at the south Delta facilities under this alternative would be no greater than loss under NAA_ELT and may be lower than loss under NAA_ELT due to a decrease in entrainment loss. Entrainment-related predation losses at the south

to entrainment or salvaged. In essence, the salvage-density method provides an entrainment index that reflects export pumping weighted by each covered species' seasonal pattern of abundance in the Plan Area, as reflected by historical salvage data. This same caveat applies to the other salmonids, the sturgeons, and the lampreys, which all use the salvage-density method.

[3] The fish screens would be state of the art by incorporating the best available technology and operating to fishery agency standards of protection for fishes. The features of the fish screens are described in more detail in Section 3.6.1.1 of Chapter 3, Description of Alternatives.

Delta under Scenario H4_ELT may be similar or slightly lower than under Scenario H3_ELT as spring outflow is increased and south Delta exports are decreased under Scenario H4_ELT.

Predation at the north Delta would be increased due to the installation of the proposed SWP/CVP North Delta intake facilities on the Sacramento River. Bioenergetics modeling with a median predator density predicts increased predation loss of about 4,200 juveniles, or 0.16% of the winter-run Chinook salmon juvenile index of abundance under Alternative 4A (Table 11-4A-11). Note that this estimate does not provide context to the level of predation in this reach that would occur without implementation of Alternative 4A. See additional discussion under Impact AQUA-42.

Table 11-4A-11. Winter-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion (NDD) Intakes (Three Intakes for Alternative 4A)

Striped Bass at NDD (Three Intakes)			Winter-Run Chinook Consumed	
Density Assumption	Bass per 1,000 Feet of Intake	Total Number of Bass	Number	Percentage of Annual Juvenile Production Entering the Delta[1]
Low	18	86	633	0.02%
Median	119	571	4,182	0.16%
High	219	1,051	7,696	0.30%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (*BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference).

[1] Estimated as 2.6 million juveniles. See Section 5.F.3.2.1 in *BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference.

NEPA Effects: In conclusion, Alternative 4A would reduce overall entrainment and associated predation losses of juvenile winter-run Chinook salmon relative to NAA_ELT. This effect would not be adverse and would provide a benefit to the species because of the reductions in entrainment loss and mortality.

CEQA Conclusion: As described above, entrainment and associated predation losses of juvenile winter-run Chinook salmon at the south Delta facilities would decrease under Alternative 4A compared to Existing Conditions (Table 11-4A-10). Overall, impacts of water operations on entrainment of juvenile Chinook salmon (winter-run ESU) would be less than significant and may be beneficial. No mitigation would be required.

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

In general, the effects of Alternative 4A on spawning and egg incubation habitat for winter-run Chinook salmon relative to the NAA are not adverse.

H3_ELT/ESO_ELT[4]

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam were examined during the May through September winter-run spawning and incubation period

[4] H3_ELT/ESO_ELT is the acronym used for Alternative 4A, Scenario H3 in the early long-term implementation period.

(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation. Mean flows under H3_ELT at Keswick would generally be similar to flows under NAA_ELT, with flows under H3_ELT up to 12% higher than under NAA_ELT during May through July and up to 15% lower during August and September. Mean flows upstream of Red Bluff would generally be more similar between H3_ELT and NAA_ELT than those at Keswick. Based on these flow results, it is expected that H3_ELT would have little effect on flow-related winter-run Chinook salmon spawning and egg incubation habitat due to their low magnitude and frequency.

Shasta Reservoir storage volume at the end of May influences flow rates below the dam during the May through September winter-run spawning and egg incubation period. Mean Shasta May storage under H3_ELT would be similar (<5% difference) to storage under NAA_ELT for all water year types (Table 11-4A-12).

Table 11-4A-12. Difference and Percent Difference in Mean May Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Alternative 4A (Scenario H3_ELT)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-13 (-0.3%)	0 (0%)
Above Normal	-73 (-2%)	-46 (-1%)
Below Normal	-83 (-2%)	13 (0.3%)
Dry	-223 (-6%)	-19 (-1%)
Critical	-205 (-8%)	92 (4%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Mean water temperatures for each water year type in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be negligible differences (<5%) in mean water temperature between H3_ELT and NAA_ELT for all months and water year types throughout the period at both locations, except for August of critical years at Keswick, which would be 7% warmer under H3_ELT. If extreme drought conditions occur again in the future, DWR and Reclamation would work in close coordination with regulatory agencies to manage reservoir operations to avoid negative impacts to fish, as is currently being done.

The number of days when temperatures exceeded the analysis criterion (i.e., 56°F identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period. The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between H3_ELT and baselines in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-15. There would be 4 (5%) more years with a "red" level of concern under H3_ELT. These differences would not be biologically meaningful to winter-run Chinook salmon spawners and eggs, as the 4 years constitute a small proportion of the 82 year period used for this analysis, as long as the years were not consecutive, which they were not in this case. If multiple years of drought occurs in the future, DWR and Reclamation would work in close coordination with regulatory agencies to manage reservoir operations to avoid negative impacts to fish, as is currently being done.

Table 11-4A-13. Maximum Water Temperature Thresholds for Covered Salmonids and Sturgeon Provided by NMFS and Used in the BDCP Effects Analysis

Location	Period	Maximum Water Temperature (°F)	Purpose
Upper Sacramento River			
Bend Bridge	May–Sep	56	Winter- and spring-run spawning and egg incubation
		63	Green sturgeon spawning and egg incubation
Red Bluff	Oct–Apr	56	Spring-, fall-, and late fall–run spawning and egg incubation
Hamilton City	Mar–Jun	61 (optimal), 68 (lethal)	White sturgeon spawning and egg incubation
Feather River			
Robinson Riffle (RM 61.6)	Sep–Apr	56	Spring-run (Sep-Jan) and steelhead (Jan-Apr) spawning and incubation
	May–Aug	63	Spring-run and steelhead rearing
Gridley Bridge	Oct–Apr	56	Fall- and late fall–run spawning and steelhead rearing
	May–Sep	64	Green sturgeon spawning, incubation, and rearing
American River			
Watt Avenue Bridge	May–Oct	65	Juvenile steelhead rearing

Table 11-4A-14. Number of Days per Month Required to Trigger Each Level of Concern for Water Temperature Exceedances in the Sacramento River for Covered Salmonids and Sturgeon Provided by NMFS and Used in the BDCP Effects Analysis

Exceedance above Water Temperature Threshold (°F)	Level of Concern			
	None	Yellow	Orange	Red
1	0–9 days	10–14 days	15–19 days	≥20 days
2	0–4 days	5–9 days	10–14 days	≥15 days
3	0 days	1–4 days	5–9 days	≥10 days

Table 11-4A-15. Differences between H3_ELT and NAA_ELT in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Red	28 (55%)	4 (5%)
Orange	-14 (-82%)	-3 (-50%)
Yellow	-11 (-100%)	-1 (-100%)
None	-3 (-100%)	0 (NA)

Note: For definitions of levels of concern, see Table 11-4A-14.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 56°F at Bend Bridge were summed for all years by month and water year type during May through September (Table 11-4A-16). The monthly total degree-days under H3_ELT would be up to 8% lower than under NAA_ELT during May and June, up to 9% higher during August and September, and similar for July. However, the CALSIM modeling used for this analysis assumed a change in release patterns between May and September compared to NAA_ELT that is driving this increase in temperatures later in the summer. In reality, Shasta reservoir would not be operated differently from NAA_ELT, using real time operations and adaptive management, and temperatures are expected to be similar to those under NAA_ELT.

Table 11-4A-16. Differences between H3_ELT and NAA_ELT in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
May	Wet	502 (133%)	3 (0.3%)
	Above Normal	130 (61%)	-105 (-23%)
	Below Normal	270 (123%)	-18 (-4%)
	Dry	186 (100%)	-99 (-21%)
	Critical	212 (96%)	-6 (-1%)
	All	1,300 (107%)	-225 (-8%)
June	Wet	336 (88%)	-29 (-4%)
	Above Normal	94 (64%)	-20 (-8%)
	Below Normal	121 (87%)	-19 (-7%)
	Dry	147 (78%)	-62 (-16%)
	Critical	185 (46%)	-59 (-9%)
	All	883 (70%)	-189 (-8%)
July	Wet	166 (32%)	-56 (-8%)
	Above Normal	105 (130%)	29 (18%)
	Below Normal	156 (106%)	-28 (-8%)
	Dry	340 (121%)	83 (15%)
	Critical	735 (89%)	-49 (-3%)
	All	1,502 (81%)	-21 (-1%)
August	Wet	952 (137%)	16 (1%)
	Above Normal	279 (68%)	-7 (-1%)
	Below Normal	465 (175%)	-27 (-4%)
	Dry	1,119 (167%)	311 (21%)
	Critical	1,209 (81%)	-67 (-2%)
	All	4,024 (114%)	226 (3%)
September	Wet	92 (12%)	83 (11%)
	Above Normal	146 (20%)	266 (45%)
	Below Normal	742 (99%)	289 (24%)
	Dry	1,368 (107%)	119 (5%)
	Critical	981 (47%)	-49 (-2%)
	All	3,329 (60%)	708 (9%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under H3_ELT would be lower or similar to mortality under NAA_ELT except in below normal water years (23% greater), although the absolute increase in mortality for this water year type would be less than 1% (Table 11-4A-17). Therefore, the increase in mortality from NAA_ELT to H3_ELT, although large on a relative scale, would be negligible at an absolute scale to the winter-run population. If multiple years of drought occurs in the future, DWR and Reclamation would work in close coordination with regulatory agencies to manage reservoir operations to avoid negative impacts to fish, as is currently being done.

Table 11-4A-17. Difference and Percent Difference in Percent Mortality of Winter-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0.4 (100%)	0 (0%)
Above Normal	0.4 (80%)	0 (0%)
Below Normal	0.6 (60%)	0.3 (23%)
Dry	2 (107%)	0 (0%)
Critical	18 (68%)	-4 (-9%)
All	3 (72%)	-1 (-7%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

SacEFT predicts that there would be a 20% relative decrease in the percentage of years with good spawning availability, measured as weighted usable area, under H3_ELT compared to NAA_ELT (Table 11-4A-18). On an absolute scale, this reduction would be small (i.e., 9% lower). SacEFT predicts that the percentage of years with good (lower) redd scour risk would be similar to the percentage of years under NAA_ELT. SacEFT predicts that the percentage of years with good egg incubation conditions under H3_ELT would be 9% lower than under NAA_ELT. SacEFT predicts that the percentage of years with good (lower) redd dewatering risk under H3_ELT would be 7% lower than the percentage of years under NAA_ELT. These results indicate that Alternative 4A would cause a modest reduction in spawning WUA, egg incubation conditions, and red dewatering risk.

The biological significance of a 9% reduction in available suitable spawning habitat varies at the population level in response to a number of factors, including adult escapement. For those years when adult escapement is less than the carrying capacity of the spawning habitat, a reduction in area would have little or no population level effect. In years when escapement exceeds carrying capacity of the reduced habitat, competition among spawners for space (e.g., increased redd superimposition) would increase, resulting in reduced reproductive success. The reduction in the frequency of years in which spawning habitat availability is considered to be good by SacEFT could result in reduced reproductive success and abundance of winter-run Chinook salmon if the number of spawners is limited by spawning habitat quantity. However, it is unlikely that spawning habitat is limiting to winter-run Chinook salmon due to their small spawning adult population sizes in recent years relative to historical numbers.

Table 11-4A-18. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Winter-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Spawning WUA	-21 (-36%)	-9 (-20%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-9 (-9%)	-9 (-9%)
Redd Dewatering Risk	2 (8%)	-2 (-7%)
Juvenile Rearing WUA	-5 (-10%)	8 (22%)
Juvenile Stranding Risk	-8 (-40%)	-20 (-63%)

WUA = Weighted Usable Area.

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

H4_ELT/HOS_ELT

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H4_ELT between May and September would generally be similar to flows under NAA_ELT (Appendix B, Section B.7). May storage in Shasta Reservoir under H4_ELT would be similar to storage under NAA_ELT, except in critical water years in which storage would be 11% greater under H4_ELT (Table 11-4A-19).

Table 11-4A-19. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Shasta Reservoir for H4_ELT Scenario

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	-10 (-0.2%)	2 (-0%)
Above Normal	-53 (-1.2%)	-26 (-0.6%)
Below Normal	-67 (-1.6%)	29 (0.7%)
Dry	-141 (-3.7%)	62 (1.7%)
Critical	-53 (-2.2%)	244 (11.4%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Mean water temperatures for each water year type in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between H4_ELT and NAA_ELT in any month or water year type throughout the period at either location.

The number of days when temperatures exceeded the analysis criterion (i.e., 56°F identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period. The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between H4_ELT and NAA_ELT in the levels of concern across all months and all 82 modeled years are presented in Table 11-4A-20. There would be little difference in the highest level of concern between H4_ELT and NAA_ELT. There would be 1 (17%) more year with an "orange" level of concern and 1 more year with a "yellow" level of concern under H4_ELT, which would not be biologically meaningful to winter-run Chinook salmon spawners and eggs.

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4A-21). The monthly total degree-days under H4_ELT would be lower than under NAA_ELT for all 5 months, with up to 13% lower total degree-days (August). Total degree-days under H4_ELT would be most similar to that under NAA_ELT for the months of June and September.

Table 11-4A-20. Differences between H4_ELT and NAA_ELT in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Red	21 (41%)	-3 (-4%)
Orange	-10 (-59%)	1 (17%)
Yellow	-9 (-82%)	1 (100%)
None	-2 (-67%)	1 (NA)

Note: For definitions of levels of concern, see Table 11-4A-14.

Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Table 11-4A-21. Differences between H4_ELT and NAA_ELT in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
May	Wet	502 (133%)	3 (0%)
	Above Normal	149 (70%)	-86 (-19%)
	Below Normal	291 (133%)	3 (1%)
	Dry	244 (131%)	-41 (-9%)
	Critical	188 (85%)	-30 (-7%)
	All	1,374 (113%)	-151 (-6%)
June	Wet	362 (94%)	-3 (0%)
	Above Normal	150 (101%)	36 (14%)
	Below Normal	144 (104%)	4 (1%)
	Dry	202 (107%)	-7 (-2%)
	Critical	141 (35%)	-103 (-16%)
	All	999 (79%)	-73 (-3%)
July	Wet	175 (34%)	-47 (-6%)
	Above Normal	63 (78%)	-13 (-8%)
	Below Normal	158 (107%)	-26 (-8%)
	Dry	345 (122%)	88 (16%)
	Critical	569 (69.1%)	-215 (-13%)
	All	1,310 (71%)	-213 (-6%)
August	Wet	853 (122%)	-83 (-5%)
	Above Normal	199 (49%)	-87 (-13%)
	Below Normal	406 (153%)	-86 (-11%)
	Dry	673 (100%)	-135 (-9%)
	Critical	709 (48%)	-567 (-21%)
	All	2,840 (81%)	-958 (-13%)
September	Wet	47 (6%)	38 (5%)
	Above Normal	9 (1%)	129 (22%)
	Below Normal	737 (99%)	284 (24%)
	Dry	1,138 (89%)	-111 (-4%)
	Critical	514 (25%)	-516 (-17%)
	All	2,445 (44%)	-176 (-2%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NEPA Effects: Alternative 4A does not propose any changes in Shasta Reservoir operating criteria, and CALSIM results show that Reclamation could operate Shasta in such a manner that it does not affect upstream storage or flows substantially as compared to the NAA_ELT. However, the CALSIM modeling used for this analysis assumed a change in release patterns between May and September, compared to NAA. This resulted in the available analytical tools showing conflicting results regarding the temperature effects of relatively small changes in predicted summer and fall flows.

Several models (CALSIM, SRWQM, and Reclamation Egg Mortality Model) generally show no change in upstream conditions as a result of Alternative 4A. However, one model, SacEFT, shows adverse effects under some conditions, primarily in the later summer. After extensive investigation of these modeling results, they appear to be a function of high model sensitivity to relatively small changes in estimated upstream conditions combined with the assumed CALSIM release patterns, which may or may not accurately predict adverse effects. Temperature and end of September storage criteria from the NMFS (2009a) BiOp for Shasta reservoir are maintained, in order to minimize adverse effects to spawning and incubating salmonids including winter-run Chinook salmon. Review of modeling results by FWS and NMFS has confirmed that no additional upstream criteria are necessary to meet the NMFS BiOp criteria under Alternative 4A and, because operations of Alternative 4A will require continued compliance with the NMFS BiOp for Shasta operations, regardless of Delta operations, this effect would not be adverse.

CEQA Conclusion: Collectively, the results of the Impact AQUA-40 CEQA analysis show that the difference between the CEQA baseline and Alternative 4A could be significant because, when compared to the CEQA baseline, the alternative, including climate change, would substantially reduce the quantity and quality of spawning and egg incubation habitat for winter-run Chinook salmon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, the comparison to the NAA_ELT is a better approach because it isolates the effects of the alternative from those of sea level rise, climate change, and future water demand. Based on this identification of the actual increment of change attributable to the alternative, Alternative 4A would not affect the quantity and quality of spawning and egg incubation habitat for winter-run Chinook salmon relative to the Existing Conditions.

H3_ELT/ESO_ELT

CALSIM flows in the Sacramento River between Keswick and Red Bluff Diversion Dam were examined during the May through September winter-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* Mean flows between Keswick and Red Bluff Diversion Dam under H3_ELT would be similar to or up to 15% lower than flows under Existing Conditions during May through August. Mean flows during September would be up to 24% lower (dry years) and 34% higher (above normal years) than flows under Existing Conditions.

Shasta Reservoir mean storage volume at the end of May under H3_ELT would be similar to storage under Existing Conditions in wet, above normal, and below normal water years and 6% and 8% lower than storage under Existing Conditions in dry and critical water years, respectively (Table 11-4A-12). This indicates that there would be a small effect of H3_ELT on flows during the spawning and egg incubation period in drier water years.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between H3_ELT and Existing Conditions during May and June. Mean water temperature at Keswick would be up to 14% higher under H3_ELT in July through September. Higher temperatures are persistent throughout the two months of August and September at Keswick, which would cause a negative effect on winter-run Chinook salmons spawning and egg incubation. Mean temperature at Bend Bridge would be 5% higher under H3_ELT than under Existing Conditions in August of critical year types. There would be no other differences (<5%) at Bend Bridge.

The number of days when temperatures exceeded the analysis criterion (i.e., 56°F identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period. The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. The number of years classified as "red" would increase by 55% (28 years) under H3_ELT relative to Existing Conditions (Table 11-4A-15). This would cause a negative effect to winter-run Chinook salmon spawning and egg incubation.

Total degree-days exceeding 56°F at Bend Bridge were summed for all years by month and water year type during May through September (Table 11-4A-16). The monthly total degree-days would be 60% to 107% higher under H3_ELT than under Existing Conditions depending on month. This would cause a negative effect to winter-run Chinook salmons spawning and egg incubation.

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under H3_ELT would be 60% to 107% greater (relative scale) than mortality under Existing Conditions depending on water year type (Table 11-4A-17). However, the increase would be more than 5% of the winter-run population on an absolute scale, and therefore be biologically meaningful, only in critical years (18% higher). Overall, these results indicate that H3_ELT, in combination with climate change effects, would cause increased winter-run Chinook salmon mortality in the Sacramento River in critical years.

SacEFT predicts that there would be a 36% relative decrease in the percentage of years with good spawning availability, measured as weighted usable area, under H3_ELT compared to Existing Conditions (Table 11-4A-18) as a result of the combined effects of climate change and Alternative 4A. SacEFT predicts that the percentage of years with good (lower) redd scour risk under H3_ELT and climate change would be similar to the percentage of years under Existing Conditions. SacEFT predicts that the percentage of years with good egg incubation conditions under H3_ELT and climate change would be 9% lower than under Existing Conditions. SacEFT predicts that the percentage of years with good (lower) redd dewatering risk under H3_ELT and climate change would be 8% greater than the percentage of years under Existing Conditions. These results indicate that Alternative 4A, in combination with climate change effects, which are the primary driver for these changes, would cause large reductions in spawning WUA. However, due to the highly suppressed population size of winter-run Chinook salmon relative to historical population sizes, it is unlikely that spawning habitat is currently limiting.

H4_ELT/HOS_ELT

Mean flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H4_ELT between May and August would generally be similar to or up to 14% lower than flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows during September would be up to 20% lower (dry years) and 53% higher (above normal years) than flows under Existing Conditions. Mean May storage in Shasta Reservoir under H4_ELT would be similar to storage under Existing Conditions in all water year types (Table 11-4A-19). Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H3_ELT and Existing Conditions at either location.

The number of days when temperatures exceeded the analysis criterion (i.e., 56°F identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period. The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H4_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-20. There would be a 41% increase in the number of years with a red level of concern under H4_ELT relative to Existing Conditions.

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4A-21). The monthly total degree-days under H4_ELT would range from 44% to 113% higher than under Existing Conditions depending on month.

Summary of CEQA Conclusion

Under Alternative 4A, egg mortality (according to the Reclamation egg mortality model) in drier water years, during which winter-run Chinook salmon would already be stressed due to reduced flows and increased temperatures, would be up to 18% greater (absolute difference) than egg mortality under the CEQA baseline. The extent of spawning habitat and egg incubation conditions according to the SacEFT model are predicted to be 21% and 9% lower, respectively, on an absolute scale. Years with water temperatures at the red level of concern and exceedances above NMFS temperature thresholds would be substantially greater under Alternative 4A relative to the CEQA baseline. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of winter-run as a result of egg mortality, although, due to the highly suppressed population size of winter-run Chinook salmon relative to historical population sizes, it is unlikely that spawning habitat is currently limiting.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows, reservoir storage, and water temperatures in the Sacramento River would generally be similar between NAA_ELT and Alternative 4A. SacEFT predicts that the extent of spawning habitat and egg incubation conditions in the Sacramento River would result in adverse effects under some conditions. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows, reservoir storage, and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

In general, Alternative 4A would not adversely affect rearing habitat for fry and juvenile winter-run Chinook salmon relative to the NAA_ELT.

H3_ELT/ESO_ELT

Sacramento River flows between Keswick and upstream of Red Bluff Diversion Dam were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can lead to reduced extent and quality of fry and juvenile rearing habitat. Mean flows under H3_ELT during August through October and December would generally be similar to flows under NAA_ELT, with minor exceptions. Flows during November under H3_ELT would be up to 23% lower than flows under NAA_ELT. The biological implications of this reduction during November is analyzed below in the SALMOD and SacEFT analyses, which analyze the effects of flow changes on weighted usable rearing area for winter-run Chinook salmon in the Sacramento River.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be negligible differences (<5%) in mean water temperature between H3_ELT and NAA_ELT in any month or water year type throughout the period at either location, except a 7% increase for August of critical years.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under H3_ELT would be 22% greater on a relative scale (8% on an absolute scale) than the percentage of years under NAA_ELT (Table 11-4A-18). However, the percentage of years with good (low) juvenile stranding risk under H3_ELT is predicted to be 63% lower on a relative scale (20% on an absolute scale) than under NAA_ELT. These results indicate that while the quantity of juvenile rearing habitat in the Sacramento River would slightly increase under H3_ELT, its quality, with respect to stranding risk, would be reduced. However, although there would be an improvement in rearing weighted usable area, it would not likely result in a benefit to the population due to the highly suppressed population sizes in recent years.

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under H3_ELT would be 7% lower than under NAA_ELT. These results are inconsistent with SacEFT results, which indicate that juvenile stranding risk would increase under H3_ELT (Table 11-4A-18).

Both SacEFT and SALMOD are considered to be reliable models for winter-run Chinook salmon in the Sacramento River. SALMOD has been used for decades for assessing changes in flows associated with SWP and CVP and SacEFT has been peer-reviewed. Therefore, results of both models were used to draw conclusions about winter-run Chinook salmon rearing conditions. Although SALMOD does not parse out stranding effects specifically, the model incorporates effects to all early life stages, including eggs, fry, and juveniles. Therefore, although SacEFT predicts that juvenile stranding risk may increase under H3_ELT, when combined with all early life stage effects in SALMOD, the effects of H3_ELT would be marginally beneficial to winter-run Chinook salmon survival. Further, these results indicate that the November flow reductions in the Sacramento River identified above would not have a biological effect on winter-run Chinook salmon rearing.

H4_ELT/HOS_ELT

Mean flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H4_ELT during August through October and December would be similar to flows under NAA_ELT, with minor exceptions, but flows in November would be lower for all water year types (11% to 20% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in this reach of the Sacramento River under H4_ELT during November are very similar to those under H3_ELT. As described above, under H3_ELT, further biological modeling indicated that these November flow reductions would not cause a biologically meaningful effect on winter-run Chinook salmon. Although no further biological modeling was conducted for H4_ELT, it can be concluded, based on the similar nature of these results, that these reductions under H4_ELT would also not cause a biologically meaningful effect on winter-run Chinook salmon rearing.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between H4_ELT and NAA_ELT in any month or water year type throughout the period at either location.

NEPA Effects: Collectively, these modeling results indicate that the effect of Alternative 4A is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat or substantially interfere with winter-run Chinook salmon rearing. Differences in flows and temperatures are generally small and inconsistent among months and water year types. SALMOD and SacEFT predicted contradicting results regarding habitat-related mortality. SacEFT found that juvenile stranding risk is expected to increase. However, SALMOD results include the effects to all early life stages combined and, therefore, are more representative of the overall effects to winter-run Chinook salmon in the upper Sacramento River. The SALMOD model found that Alternative 4A would provide a minor beneficial effect (7% reduction in habitat-related mortality) to early life stages of winter-run Chinook salmon. Flow and temperature results are predominantly similar between H3 and H4.

CEQA Conclusion: In general, Alternative 4A would not reduce the quantity and quality of fry and juvenile rearing habitat for winter-run Chinook salmon relative to Existing Conditions.

H3_ELT/ESO_ELT

Sacramento River flows between Keswick and Red Bluff Diversion Dam were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can lead to reduced extent and quality of fry and juvenile rearing habitat. Mean flows under H3_ELT during August and October through December would generally be similar to or up to 20% lower than flows under Existing Conditions. Flows under H3_ELT during September would be up to 24% lower (dry years) and 34% higher (above normal years) than flows under Existing Conditions.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperature at Keswick would be higher (by up to 14%, but generally less than 8%) under H3_ELT than under Existing Conditions in August through October, depending on month and water year type. There would be an increase of 6% in mean water temperature at Bend Bridge for August of critical years, but no other differences in water temperature at this location, and no differences (<5%) between Existing Conditions and H3_ELT in mean water temperature during November and December for any of the water year type at either location.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under H3_ELT, combined with climate change, would be 10% lower on a relative scale (5% on an absolute scale) than under Existing Conditions (Table 11-4A-18). The percentage of years with good (low) juvenile stranding risk under H3_ELT is predicted to be 40% lower on a relative scale (8% on an absolute scale) than the percentage under Existing Conditions. These results indicate that the quantity and quality, with respect to stranding risk, of juvenile rearing habitat in the Sacramento River would be marginally lower under H3_ELT relative to Existing Conditions.

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under H3_ELT would be 28% lower than under Existing Conditions. These results are somewhat inconsistent with SacEFT results, which indicate that the number of years with good juvenile rearing WUA and with good (low) stranding risk would both marginally increase under H3_ELT (Table 11-4A-18). Both SacEFT and SALMOD are considered to be reliable models for winter-run Chinook salmon in the Sacramento River. SALMOD has been used for decades for assessing changes in flows associated with SWP and CVP. Therefore, results of both models were used to draw conclusions about winter-run Chinook salmon rearing conditions. The SALMOD model incorporates effects to all early life stages, including eggs, fry, and juveniles. Therefore, although SacEFT predicts that juvenile stranding risk may increase under H3_ELT, when combined with all early life stage effects in SALMOD, the effects of H3_ELT would be marginally beneficial to winter-run Chinook salmon.

H4_ELT/HOS_ELT

Mean flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H4_ELT in August and October through December would generally be similar to or up to 19% lower than flows under Existing Conditions. Flows under H4_ELT during September would be up to 53% higher (above normal years) and up to 20% lower (dry years) than flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*) There would be no differences (<5%) in mean monthly water temperature between H4_ELT and Existing Conditions in any month or water year type throughout the period at either location.

Summary of CEQA Conclusion

These modeling results indicate that the impact would be less than significant because it does not have the potential to substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish, and no mitigation is necessary. Flows under Alternative 4A would be highly variable relative to Existing Conditions and there would be small increases under the alternative in water temperatures during some of the period of presence. SALMOD and SacEFT predicted contradicting results regarding habitat-related mortality, although because SALMOD incorporates more of the life cycle of winter-run Chinook salmon, its results are more representative of overall effects to winter-run Chinook salmon in the upper Sacramento River. Overall, the impact would be less than significant and no mitigation is required. Flow and temperature results are predominantly similar between H3 and H4.

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

In general, the effects of Alternative 4A on winter-run Chinook salmon migration conditions relative to the NAA are not adverse because the primary impact mechanism is the change in flow past the proposed NDD, and as described in Chapter 3, the operations of the NDD would take into account triggers developed by DFW and NMFS that would allow for adjustments in NDD operations to minimize and avoid effects on Chinook salmon and steelhead.

Upstream of the Delta

H3_ELT/ESO_ELT

Flows in the Sacramento River upstream of Red Bluff were examined for the July through November juvenile emigration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). A substantial reduction in flow may reduce the ability of juvenile winter-run to migrate effectively through the Sacramento River due to a reduction in olfactory cues, although there is little empirical evidence supporting this. Mean flows under H3_ELT would be up to 18% lower than under NAA_ELT during November and generally similar to NAA_ELT during the rest of the juvenile winter-run Chinook salmon migration period (July through October), with minor exceptions.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperature would be 7% higher under H3_ELT than under NAA_ELT for August of critical years. There would be no other differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location.

Flows in the Sacramento River upstream of Red Bluff during the adult winter-run Chinook salmon upstream migration period (December through August) under H3_ELT would generally be similar to those under NAA_ELT.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location, except a 7% increase in water temperature under H3_ELT at Bend Bridge for August of critical years.

H4_ELT/HOS_ELT

Flows in the Sacramento River upstream of Red Bluff during the July through November juvenile emigration period under H4_ELT would generally be similar to flows under NAA_ELT, except in November, in which flows would be lower for all water year types (up to 15% lower for below normal years) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These flow reductions would not be of sufficient frequency or magnitude to cause biologically meaningful effects on migrating juveniles.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period at either location.

Mean flows in the Sacramento River upstream of Red Bluff during the adult winter-run Chinook salmon upstream migration period (December through August) under H4_ELT would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period at either location.

Through-Delta

H3_ELT/ESO_ELT

Juveniles

Plan Area flows have considerable importance for downstream migrating juvenile salmonids (primarily for those remaining in the Sacramento River as opposed to entering the Yolo Bypass at Fremont Weir) and would be affected by the north Delta diversions, as discussed above for winter-run Chinook (Impact AQUA-42 for Alternative 1A). Average monthly Sacramento River flows below the NDD under H3_ELT for juvenile winter-run migrants (November through May) would be reduced 4% to 30% compared to NAA_ELT, depending on water year type (Appendix B, *Supplemental Modeling for Alternative 4A,* Section B.7), assuming that NDD operations are based solely on operations described in Table 3-16 in Chapter 3 of Appendix A of this RDEIR/SDEIS. Note that the modeling of NAA_ELT does not account for any flow entering the Yolo Bypass because of Fremont Weir modifications that would occur separately from Alternative 4A (but which are included in the modeling of H3_ELT and H4_ELT; see also Section 4.1.2.2 of Section 4); this would slightly decrease the amount of water in the Sacramento River under NAA_ELT, so the above comparison of H3_ELT vs. NAA_ELT is conservative. As noted for Alternative 4 and described in more detail for Alternative 1A, *CM1 Water Facilities and Operation* includes bypass flow criteria that will be managed in real time, based on triggers developed by DFW and NMFS, to minimize adverse effects of diversions at the north Delta intakes on downstream-migrating salmonids. Additional detail is provided in Chapter 3, Section 3.6.4.2.

Potential predation effects at the north Delta intakes for juvenile salmonids remaining in the Sacramento River (as opposed to entering the Yolo Bypass) could occur if predatory fish aggregated along the screens as has been observed at other long screens in the Central Valley (Vogel 2008). Baseline levels of predation are uncertain, however. Analysis by a bioenergetics model (Appendix 5.F, *Biological Stressors on Covered Fish,* Section 5.F.3.2.1) suggests that considerably less than 0.3% of winter-run juveniles could be preyed upon (Table 11-4A-11). Using another scenario of predation that assumes a 5% loss per intake (based on GCID losses, Vogel 2008) would yield a cumulative loss of about 12% of the annual production that reaches the north Delta. The three intake structures and associated permanent bankline modifications would result in a permanent loss of up to 13.7 acres aquatic habitat and the permanent modification of 2.6 miles of shoreline along the migration route. There are appreciable uncertainties in the analysis of predation loss, including unknown baseline levels of predation[5], uncertainty in the bioenergetics model parameters, and the comparability of the GCID intakes for estimating loss rates. As discussed for Alternative 1A, the GCID screen and the proposed north Delta diversion intake screens are substantially different. The GCID is located along a relatively narrow oxbow channel (about 10 to 50 meters wide) while the north Delta intakes would be located on the much wider channel of the mainstem lower Sacramento River (about 150 to 180 meters wide). In addition, the fish tested at GCID were relatively small (average length generally less than 70 mm; Vogel 2008) in comparison to the size of winter-run Chinook salmon that would generally occur near the north Delta intakes (average length generally greater than 70 mm; del Rosario et al. 2013), which could have resulted in different susceptibility to predation. For the purposes of the analysis of Alternative 4A, it is assumed that all juvenile salmon migrating down the mainstem Sacramento River would come in close proximity to the intakes, although there is high uncertainty with this assumption. However, the estimates of predation loss at GCID are for a single large diversion intake, while Alternative 4A would have three north Delta intakes. Thus, while factors unique to the GCID screen may increase predation loss estimates relative to the north Delta, the cumulative amount of intake structure proposed under the Plan would be much larger than the GCID screen, increasing exposure of juvenile salmon to screen-related impacts. Overall, a fixed 5% loss per intake represents a conservative upper bound on predation loss.

Through-Delta survival by juvenile winter-run Chinook salmon, as estimated by the Delta Passage Model under Scenario H3_ELT, averaged 32.8% across all years, 25.5% in drier years, and 45.0% in wetter years (for further details, refer to *BDCP Appendix 5.C, Section 5C.5.3.1.3.1 herby incorporated by reference*). Average juvenile through-Delta survival under H3_ELT was similar or slightly lower than NAA_ELT (1.6% less, a 4.7% relative decrease), based on operations assuming no adjustments made in real-time in response to actual presence of fish (Table 11-4A-23). However, as noted previously in the introduction to the impact assessment for Alternative 4A and above, the modeling of NAA_ELT does not account for actions that would be pursued as part of other projects and programs, notably Yolo Bypass improvements and tidal habitat restoration under the NMFS and USFWS BiOps. To provide perspective on the potential for such changes to influence the results of the DPM, a modification to the NAA_ELT results (termed NAA_ELT (mod.) in Table 11-4A-23) was created by post-processing the outputs of the NAA_ELT scenario. The post-processing consisted of substituting year-specific Yolo Bypass entry percentages and Yolo Bypass survival from the H3_ELT scenario into the results from the NAA_ELT scenario; this was done to represent the Fremont Weir

[5] Data from the GCID study by Vogel (2008) for releases made in 2007—this being the only year of the study in which flow-control blocks at the weir at the downstream end of the fish screen were removed, to reduce predatory fish concentration—indicate that the proportion of tagged juvenile Chinook salmon released at the upstream end of the fish screen that were recaptured at a downstream location was similar or slightly greater than for fish released at the downstream end of the fish screen, when standardized for the distance that these fish had to travel to the release point. These data suggest that survival along the screen was at least similar to survival in the portion of the channel without the screen (i.e., screen survival was similar to baseline survival, if the latter is assumed to be represented by the channel downstream of the screen). However, test fish were released at the downstream end of the screen (below the flow-control weir) prior to the fish that were at the upstream end of the fish screen, which could have confounded comparisons of relative survival between these groups if predatory fishes became partly satiated prior to the arrival of the fish released at the upstream end of the screen (thus making their survival relatively higher).

modifications that would occur under NAA_ELT through a separate Yolo Bypass improvements program that is assumed to occur irrespective of Alternative 4A. These results illustrated that there would be a slightly larger incremental difference in survival under H3_ELT when considering incorporating Yolo Bypass improvements as part of NAA_ELT: across all years, the mean through-Delta survival under H3_ELT was 1.6% less (a 4.7% relative decrease) than NAA_ELT compared to 2.0% less (a 5.8% relative decrease) compared to NAA_ELT (mod.). The overall difference was driven mostly by the relatively larger difference in drier years, for which the mean through-Delta survival under H3_ELT was 1.7% less (a 6.3% relative decrease) than NAA_ELT, compared to 2.5% less (an 8.9% relative decrease) than NAA_ELT (mod.). The post-processing of the NAA_ELT outputs to give the NAA_ELT (mod.) results does not account for the resulting slightly lower flow in the Sacramento River (which would slightly reduce through-Delta survival outputs from the DPM because of the flow-survival relationships included in the model) because of increased flow entering the Yolo Bypass. The post-processing of the NAA_ELT outputs to give the NAA_ELT (mod.) results also does not account for changes in hydraulics at important channel divergences, particularly between the Sacramento River and Georgiana Slough, that would occur with the 8,000 acres of tidal habitat restoration under the NAA_ELT; as illustrated in the Draft BDCP (See *BDCP Appendix 5.C, Sections 5C.4.3.2.6 and 5C.5.3.8 incorporated by reference*), habitat restoration in the north Delta and the resulting dampening of tidal influence in the Sacramento River would tend to result in less fish entering the low-survival interior Delta, slightly increasing survival. It is assumed in this analysis that these opposing factors balance each other out, so that for the purposes of this analysis, the difference between H4_ELT and NAA_ELT (mod.) provides a reasonable indication of the difference in through-Delta survival between NAA_ELT and Alternative 4A (Scenario H4_ELT, in this case).

Table 11-4A-23. Through-Delta Survival (%) of Emigrating Juvenile Winter-Run Chinook Salmon under Alternative 4A (Scenarios H3_ELT and H4_ELT)

	Average Percentage Survival					Difference in Percentage Survival (Relative Difference)					
	SCENARIO					EXISTING CONDITIONS vs. Alt 4A Scenario		NAA_ELT vs. Alt 4A Scenario			
Water Year Type	EXISTING CONDITIONS	NAA_ ELT	NAA_ ELT (mod.)	H3_ ELT	H4_ ELT	H3_ELT	H4_ELT	H3_ELT	H4_ELT	H3_ELT (vs. NAA_ELT mod.)	H4_ELT (vs. NAA_ELT mod.)
Wetter Years	46.3	46.3	46.3	45.0	46.0	-1.3 (-2.8%)	-0.4 (-0.8%)	-1.2 (-2.7%)	-0.3 (-0.7%)	-1.2 (-2.7%)	-0.4 (-0.9%)
Drier Years	28.0	27.3	28.0	25.5	25.6	-2.4 (-8.7%)	-2.4 (-8.6%)	-1.7 (-6.3%)	-1.7 (-6.2%)	-2.5 (-8.9%)	-2.5 (-8.9%)
All Years	34.9	34.4	34.9	32.8	33.2	-2.1 (-6.0%)	-1.7 (-4.9%)	-1.6 (-4.7%)	-1.2 (-3.5%)	-2.0 (-5.8%)	-1.7 (-4.9%)

Note: Average Delta Passage Model results for survival to Chipps Island.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
Wetter = Wet and Above Normal Water Years (6 years).
Drier = Below Normal, Dry and Critical Water Years (10 years).
H3_ELT = ESO_ELT operations, H4_ELT = High Outflow.
NAA_ELT (mod.) = NAA_ELT with Yolo Bypass entry % and Yolo Bypass survival of H3_ELT

Adults

As noted for Alternative 4, adult salmonids migrating through the delta use flow and olfactory cues for navigation to their natal streams (Marston et al. 2012), as discussed for winter-run Chinook under Impact AQUA-42 for Alternative 1A. Attraction flows and olfactory cues in the west Delta would be altered because of shifts in exports from the south Delta to the north Delta. Flows in the Sacramento River downstream of the north Delta intake diversions would be reduced, with concomitant proportional increases in San Joaquin River flow, with differences between water-year types because of differences in the relative proportion of water being exported from the north Delta and south Delta facilities (Appendix B, *Supplemental Modeling for Alternative* 4A, Section B.7).

As described for Alternative 4, these changes may slightly decrease the Sacramento River olfactory cues used by migrating adults, although the changes are within the dilution factor and the behavioral response is uncertain. Fingerprint analyses determined that attraction flow, as estimated by the percentage of Sacramento River water at Collinsville, declined from NAA_ELT to Scenario H3_ELT operations by up to 6% during the peak migration period for winter-run adults (December through February) and by 10–12% in March–April (Table 11-4A-24). As noted for Alternative 4, the Sacramento River would still represent a substantial proportion of Delta outflows. Under Scenario H4_ELT, the difference would be less due to increased spring outflows in March, April, and May. Overall, the reductions in olfactory cues resulting from all scenarios would be less than the magnitude of change in dilution (20% or more) reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect adult Chinook salmon migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 for Alternative 1A.

Table 11-4A-24. Percentage (%) of Water at Collinsville that Originated in the Sacramento River during the Adult Winter-Run Chinook Salmon Migration Period for Alternative 4A (Scenario H3_ELT)

Month	EXISTING CONDITIONS	NAA_ELT	H3_ELT	EXISTING CONDITIONS vs. H3_ELT	NAA vs. H3_ELT
December	67	67	65	-1	-1
January	76	75	73	-2	-2
February	75	74	69	-6	-4
March	78	77	69	-9	-8
April	77	76	67	-10	-9
May	69	67	61	-8	-7
June	64	61	57	-7	-5
July	64	65	58	-6	-6
	Shading indicates 10% or greater absolute difference.				

H4_ELT/HOS_ELT

Juveniles

Plan Area flows have considerable importance for downstream migrating juvenile salmonids and would be affected by the north Delta diversions, as discussed for winter-run Chinook above (Impact AQUA-42 for Alternative 1A). Under H4_ELT, average Sacramento River flows below the NDD during the juvenile winter-run migration period (November–May) would range from being reduced by 32% to being increased by 15%, depending on water year type, compared to NAA_ELT (Appendix B, *Supplemental Modeling for Alternative 4A,* Section B.7). As described for the analysis of H3_ELT, the water conveyance facilities include bypass flow criteria that will be managed in real time to minimize adverse effects of diversions at the north Delta intakes on downstream-migrating salmonids, including the use of biological and hydrological triggers developed by NMFS and DFW to adjust NDD operations to protect migrating salmonids. Note also that, as described in the DPM analysis of H3_ELT above, CALSIM modeling of NAA_ELT does not include the slightly reduced Sacramento River flow that would occur because of Yolo Bypass improvements (more flow entering the Bypass through a modified Fremont Weir).

Through-Delta survival of juvenile winter-run Chinook salmon estimated by DPM under Scenario H4_ELT averaged 33.2% across all years, 25.6% in drier years, and 46.0% in wetter years (Table 11-4A-23; for further details, refer to *BDCP Appendix 5.C, Section 5C.5.3.1.3.1 incorporated by reference*). Average through-Delta juvenile survival under Scenario H4_ELT was generally similar to (in wetter years) or slightly lower than (in drier years) NAA_ELT based on operations assuming no adjustments made in real-time in response to actual presence of fish (Table 11-4A-23). However, as noted for the discussion of the H3_ELT scenario above, the DPM modeling results do not account for the inclusion of Yolo Bypass improvements in NAA_ELT. As done for the H3_ELT scenarios analysis, by assuming the same Yolo Bypass survival and entry as H3_ELT for NAA_ELT (mod.), there were slightly greater differences between H4_ELT and NAA_ELT (mod.) than between H4_ELT and NAA_ELT (Table 11-4A-23).

Overall, the relatively small difference in through-Delta survival between H3_ELT and H4_ELT is explained by the relatively low overlap of the winter-run Delta entry distribution with the spring period that has differing outflows for H3_ELT and H4_ELT. In addition, the DPM has less representation of intermediate-outflow years where the differences among the Alternative 4A operations (i.e., H3_ELT vs. H4_ELT) are more pronounced than wetter or drier years.

Adults

Results for H4_ELT regarding attraction flows and olfactory cues are presented as part of the corresponding discussion under H3_ELT (above).

NEPA Effects: Modeling analyses indicate that upstream migratory conditions would generally not change under Alternative 4A. Within the Delta, adult attraction flows under Alternative 4A would not be substantially different from those under NAA_ELT and the identified differences are not expected to result in behavioral changes in upstream migration.

Near-field effects of Alternative 4A on winter-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating winter-run Chinook salmon, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus, as described for Alternative 4, the level of impacts associated with 3 new intakes would be considerably lower than those expected from having 5 new intakes in the river (as examined for Alternative 1A, for example). Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 12% mortality above current baseline levels). As noted for Alternative 4, Environmental Commitment 15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, as described in the adaptive management and monitoring program in Section 4.1, several pre-construction studies to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Similarly, Alternative 4A also includes investigations to better understand factors affecting juvenile through-Delta migration (as described in the adaptive management and monitoring program in Section 4.1) and includes biologically-based triggers to inform real-time operations of the NDD, intended to provide adequate migration conditions for winter-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

As noted for Alternative 4, two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 4A related to reduced interior Delta entry (Environmental Commitment 16) and reduced south Delta entrainment suggest that these could offset the far-field effects of reduced flow (see, for example, Table 5.C.5.3-36 in the *BDCP Effects Analysis Appendix 5.C hereby incorporated by reference*). The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and will be investigated as part of the adaptive management and monitoring program described in Section 4.1.

As described for Alternative 4, the DPM is a flow-based model incorporating flow-survival and junction routing relationships with flow modeling of water operations to estimate relative differences between scenarios in smolt migration survival throughout the entire Delta. The DPM predicted that smolt migration survival under Alternative 4A would be similar or slightly lower than survival estimated for NAA_ELT, based on operations assuming no adjustments made in real-time in response to actual presence of fish. Although refinements to the DPM are likely to occur based on new data available from future studies and the current analysis has some uncertainty, the DPM analysis of Alternative 4A on juvenile winter-run Chinook salmon migration suggests a potential adverse effect of small magnitude. Note that the DPM focuses on smolt-sized individuals (70 mm or more) and is not based on survival data for fry-sized individuals, which also may be migrating and could be affected by Alternative 4A operations. There are no fry through-Delta survival data to inform the effects to these individuals in relation to operations and it is uncertain whether the relative difference between scenarios estimated from the DPM for smolt-sized fish would be representative of relative differences for fry. The potential adverse effect to all sizes of juvenile winter-run Chinook salmon would be minimized through the bypass flow criteria and real-time operations outlined above, as well as inclusion within Alternative 4A of specific important environmental commitments. These include *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of winter-run Chinook salmon juveniles into the low-survival interior Delta.

CEQA Conclusion: In general, Alternative 4A would not reduce migration conditions for winter-run Chinook salmon relative to Existing Conditions.

Upstream of the Delta

H3_ELT /ESO_ELT

Flows in the Sacramento River upstream of Red Bluff were examined during the July through November juvenile emigration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). A reduction in flow may reduce the ability of juvenile winter-run to migrate effectively through the Sacramento River. Mean flows for juvenile migrants under H3_ELT, combined with climate change, would be similar to or up to 16% lower than flows under Existing Conditions during July, August, October, and November, and would be up to 22% lower (dry years) and 32% higher (above normal years) during September.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperature at Keswick would be higher (by up to 14%, but generally less than 8%) under H3_ELT than under Existing Conditions in July through October, depending on month and water year type. There would be an increase of 6% in mean water temperature at Bend Bridge for August of critical years, but no other differences in water temperature at this location, and no differences (<5%) between Existing Conditions and H3_ELT in mean water temperature during November for any of the water year type at either location.

Flows in the Sacramento H3_ELT River upstream of Red Bluff were examined during the adult winter-run Chinook salmon upstream migration period (December through August). Flows under H3_ELT would generally be similar to flows under Existing Conditions throughout the adult migration period, except during August, in which flows would be up to 13% lower (critical years) under H3_ELT. These flow reductions would not be frequent or large enough to cause a biologically meaningful effect on adult migrants.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperature at Keswick would be higher (by up to 14%, but generally less than 8%) under H3_ELT than under Existing Conditions in July and August, depending on month and water year type. There would be an increase of 6% in mean water temperature at Bend Bridge for August of critical years, but no other differences in water temperature at this location, and no differences (<5%) between Existing Conditions and H3_ELT in mean water temperature during December through June for any of the water year type at either location. These small increases are not expected to cause a biologically meaningful effect to adult migrants, which are less sensitive to temperatures than eggs and fry.

H4_ELT/HOS_ELT

Mean flows in the Sacramento River upstream of Red Bluff during the July through November juvenile emigration period under H4_ELT would generally be similar to or greater than flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) except during September (up to 18% lower for dry years and 49% higher for above normal years).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT for all months, water year types, and locations.

Mean flows in the Sacramento River upstream of Red Bluff during the adult winter-run Chinook salmon upstream migration period (December through August) under H4_ELT would generally be similar to flows under Existing Conditions, with minor exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT for all months, water year types, and locations.

Through-Delta

Juveniles

During the juvenile winter-run Chinook salmon emigration period (November through May), mean monthly flows in the Sacramento River below the NDD under H3_ELT averaged across years would be lower (13% to 23% lower monthly mean) compared to Existing Conditions. As described above in the discussion of NEPA Effects, potential predation losses at the three north Delta intakes would range from considerably less than 1% (bioenergetics modeling; Table 11-4A-11) to about 12% (conservative upper bound based on 5% loss per intake) of the annual production that reaches the north Delta. In addition, the three intake structures would permanently displace approximately 13.7 acres of in-water habitat.

Through-Delta survival by juvenile winter-run Chinook salmon, as estimated by the Delta Passage Model under Scenario H3_ELT, would be slightly lower than Existing Conditions for H3_ELT (2.1% less, a 6% relative decrease), with the greatest reduction in drier years (2.4% lower, a 8.7% relative decrease) (Table 11-4A-23), although this estimate does not account for the adjustments that can be made during real-time operations to further protect migrating fish as necessary.

Under Scenario H4_ELT, average survival was 1.7% less (a 4.9% relative decrease) than Existing Conditions, with a 2.4% reduction under H4_ELT in drier years (an 8.6% relative decrease).

Adults

Flows in the Sacramento River downstream of the north Delta intake diversions would be reduced, slightly reducing the olfactory cues for migrating adult salmon. Under Scenario H3_ELT, the proportion of Sacramento River water was reduced no more than 8% during peak migration (December through February) and reduced by 12–13% in March-May compared to Existing Conditions (Table 11-4A-24). As described in the NEPA Effects, the reductions in percentage are small in comparison with the magnitude of change in dilution (20% or more) reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect adult Chinook salmon migration. The Sacramento River would still represent a substantial proportion of Delta outflows. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 for Alternative 1A.

Summary of CEQA Conclusion

Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce juvenile migration conditions for winter-run Chinook salmon upstream of the Delta. Under Alternative 4A, there would be reductions in flow and increased temperatures in the

Sacramento River that could lead to biologically meaningful reductions in juvenile migration conditions, thereby reducing survival relative to Existing Conditions. Reduced migration conditions would delay or eliminate successful migration necessary to complete the winter-run Chinook salmon life cycle. Winter-run Chinook salmon juvenile survival through the Delta for Alternative 4A would be similar or slightly lower than for Existing Conditions. However, as described in the adaptive management and monitoring program in Section 4.1, several pre-construction studies to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Similarly, Alternative 4A also includes investigations to better understand factors affecting juvenile through-Delta migration (as described in the adaptive management and monitoring program in Section 4.1) and includes biologically-based triggers to implement real time operations. As noted in the NEPA Effects discussion, due to the inclusion of bypass flow criteria, real-time operational adjustments, *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 15 Localized Reduction of Predatory Fishes*, and *Environmental Commitment 16 Nonphysical Barriers*, the impacts would be minimized in the Delta.

This interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA and informed by the NEPA analysis above, there would be negligible effects on mean monthly flow and water temperatures for the juvenile and adult migration periods. Therefore, it is concluded that this impact is less than significant and no mitigation is required.

Environmental Commitments 4, 6, 7, and 10

As described for delta smelt and longfin smelt, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A, upon which the discussion of impacts for Alternative 4 is based. *Environmental Commitment 4 Tidal Natural Communities Restoration* is reduced from 65,000 acres to 59 acres, so that any impacts would be extremely small; *Environmental Commitment 6 Channel Margin Enhancement* is reduced from 20 miles to 4.6 miles and *Environmental Commitment 7 Riparian Natural Community Restoration* is reduced from 5,000 acres to 205 acres. The mechanisms of impacts of habitat restoration on winter-run Chinook salmon are anticipated to be similar under Alternative 4A to those described in detail for Alternative 1A, although the magnitude would be considerably reduced in proportion to the difference in restoration area. The effects of restoration measures described for delta smelt under Alternative 1A

(Impacts AQUA-43 through AQUA-45) appropriately disclose the nature of the anticipated effects of habitat restoration Environmental Commitments in Alternative 4A on Chinook salmon.

The following impacts are those presented under Alternative 4 and Alternative 1A that are anticipated to be similar in nature for Alternative 4A, but would occur to a lesser extent because of the reduced extent of the restoration measures as Environmental Commitments under Alternative 4A.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

The effects of construction of restoration measures on winter-run Chinook salmon under Alternative 4A are similar in nature to those discussed in more detail under Alternative 1A: temporary increases in turbidity; increased exposure to mercury and methylmercury; accidental spills; disturbance of contaminated sediments; in-water work activities; and predation. In-water and shoreline restoration construction activities may result in short-term effects on winter-run Chinook salmon through direct disturbance, short-term water quality impacts, and increased exposure to contaminants associated with the incidental disturbance of contaminated sediments. Overall and as noted for Alternative 1A, the effect of restoration construction activities on the bioavailability of contaminants is expected to be minimal, as they would likely be localized, sporadic, and of low magnitude. Implementation of the environmental commitments described in Appendix 3B, *Environmental Commitments*, would minimize or eliminate effects on winter-run Chinook salmon. The relevant environmental commitments are: *Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; and Disposal of Spoils, Reusable Tunnel Material, and Dredged Material.* Pertinent details of these plans are provided under Impact AQUA-1 for delta smelt under Alternative 1A. Given the greatly reduced extent of restoration under Alternative 4A relative to Alternative 1A, the effects of construction of restoration measures on winter-run Chinook salmon would be expected to be less than for Alternative 1A.

NEPA Effects**:** The effects of short-term construction activities would not be adverse to winter-run Chinook salmon due the environmental commitments described above as well as the limited extent of restoration that would occur.

CEQA Conclusion**:** As discussed for Alternative 1A, habitat restoration activities could result in short-term effects on winter-run Chinook salmon but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce winter-run Chinook salmon habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Alternative 4A habitat restoration actions could result in the disturbance or mobilization of upland and aquatic contaminants that could affect winter-run Chinook salmon (e.g., by causing bioaccumulation). A detailed analysis of the potential effects based on the larger extent of tidal habitat restoration proposed under Alternative 4 can be found in the *BDCP Effects Analysis – Appendix 5D*, *Contaminants (hereby incorporated by reference)*. Potential impacts on winter-run

Chinook salmon from effects of methylmercury, selenium, copper, ammonia, and pesticides associated with habitat restoration activities would be similar to those discussed for delta smelt (see Impact AQUA-8). The Yolo Bypass, a notable rearing area for juvenile Chinook salmon, is an area expected to be among the highest for potential methylmercury production and would be inundated more under improvements that would be implemented as part of the NAA_ELT (see discussion in section 4.2.7 of Section 4) and that would also exist under Alternative 4A. While juvenile Chinook salmon show high spatial variability in the bioaccumulation of methylmercury (Henery et al. 2010), it has not been demonstrated that these accumulations impair small fishes. Future exposure levels in restored habitats that are similar to current levels may not affect the species' viability, though they may be of concern for passing mercury up the food web to birds and humans. As described in *BDCP Effects Analysis – Appendix D*, *Contaminants, Section 5D.4.1 Mercury (hereby incorporated by reference)*, the amounts of methylmercury mobilized and resultant effects on covered fish species are not currently quantifiable.

Within the relatively small extent of habitat restored under *Environmental Commitment 4 Tidal Natural Communities Restoration*, it is anticipated that any potential effects of methylmercury on winter-run Chinook salmon will be addressed through implementation of Environmental Commitment 12. Environmental Commitment 12 is intended to minimize methylmercury exposure associated with restoration measures for juvenile Chinook salmon. Additional analysis and tools may be developed to further reduce methylmercury exposure as the habitat restoration actions are refined and analyzed in site-specific documents. The site-specific analysis is the appropriate place to assess the potential for risk of methylmercury exposure for Chinook salmon once site-specific sampling and other information can be developed.

NEPA Effects: The effect contaminants related to restoration is not adverse to winter-run Chinook salmon with respect to selenium, copper, ammonia, pesticides, and methylmercury (with implementation of Environmental Commitment 12).

CEQA Conclusion: Alternative 4A restoration actions are likely to result in slightly increased production, mobilization, and bioavailability of methylmercury. However, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury from restoration areas. Therefore, the impact of contaminants is considered less than significant because it would not substantially affect winter-run Chinook salmon either directly or through habitat modifications. Consequently, no mitigation would be required.

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

Restored habitat under *Environmental Commitment 4 Tidal Natural Communities Restoration* and *Environmental Commitment 6 Channel Margin Enhancement* is intended to offset habitat loss/modification caused by construction and operation of the water facilities proposed under Alternative 4A.

NEPA Effects: The effects of restored habitat conditions on winter-run Chinook salmon would not be adverse because restoration is intended to provide habitat benefits to Chinook salmon.

CEQA Conclusion: As described above, habitat restoration would be undertaken to offset loss/modification of habitat from water facility construction and operation. The effects of restored habitat conditions on winter-run Chinook salmon would be less than significant. Consequently, no mitigation would be required.

Environmental Commitments 12, 15, and 16

As noted for delta smelt and longfin smelt, Alternative 4A includes three other Environmental Commitments environmental commitments, which are reduced in their extent relative to the Conservation Measures included in other alternatives in the Draft EIR/EIS (e.g., Alternative 1A and Alternative 4). While the extent of these commitments is reduced compared to these alternatives, the nature of the mechanisms remains the same.

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (Environmental Commitment 12)

As noted under Impact AQUA-10 for delta smelt under Alternative 4A, Environmental Commitment 12 will attempt to minimize conditions that promote production of methylmercury in restored areas and its subsequent introduction to the foodweb, and to covered species such as winter-run Chinook salmon. As described for Alternative 1A, Environmental Commitment 12 describes pre-design characterization, design elements, and best management practices to attempt to minimize methylation of mercury, and requires monitoring and reporting of observed methylmercury levels.

NEPA Effects: The effects of methylmercury management on winter-run Chinook salmon would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: Effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts would be less than significant. Consequently, no mitigation is required.

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (Environmental Commitment 15)

Environmental Commitment 15 Localized Reduction of Predatory Fish would involve efforts to reduce predation by predatory fish at the proposed north Delta intakes and at the south Delta export facilities, including Clifton Court Forebay.

NEPA Effects: To the extent that localized predator control efforts of *Environmental Commitment 15 Localized Reduction of Predatory Fish* reduce the local abundance of fish predators at the north Delta diversions and near the south Delta export facilities (e.g., in Clifton Court Forebay), it is possible, but not assured, that there would be some reduction in losses to predation of juvenile winter-run Chinook salmon (predation of adults is not a concern). This is of relevance given the potential effects on winter-run Chinook salmon juveniles because of operations of the NDD (see Impact AQUA-42). Environmental Commitment 15 would not have an adverse effect on Chinook salmon and could potentially benefit the species. Due to the uncertainty in the effectiveness of Environmental Commitment 15, however, it is concluded that there would be no demonstrable effect of this commitment on Chinook salmon.

CEQA Conclusion: Environmental Commitment 15 would not have a significant impact on Chinook salmon and could potentially benefit the species. Due to the uncertainties associated with this Environmental Commitment, however, it is concluded that there would be no demonstrable effect on winter-run Chinook salmon. Consequently, no mitigation would be required.

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (Environmental Commitment 16)

Under Alternative 4A, an NPB at the divergence of Georgiana Slough from the Sacramento River would be intended to guide juvenile salmonid fish such as winter-run Chinook salmon away from Georgiana Slough and the interior Delta, wherein survival is relatively low compared to the Sacramento River (Perry et al. 2010). Exploration with the DPM of the potential effects of an NPB at this location suggests that with effectiveness similar to that observed during a pilot study in 2011 (Perry et al. 2012), through-Delta survival of winter-run Chinook salmon juveniles would not differ greatly between Alternative 4A and Existing Conditions or NAA_ELT (see Table 5.C.5.3-36 in the *BDCP Effects Analysis Appendix 5.C hereby incorporated by reference*). As discussed for Alternative 1A, the physical structure of an NPB may provide habitat for piscivorous fish in the area and increase localized predation risk, but the NPB is intended to improve migratory conditions for juvenile Sacramento River salmon, limiting their overall susceptibility to predation in the Delta.

NEPA Effects: The effects of NPBs would not be adverse because it would improve migration conditions for Chinook salmon.

CEQA Conclusion: As discussed above, the NPB at the divergence of Georgiana Slough from the Sacramento River has the potential to reduce the proportion of winter-run Chinook salmon entering the low-survival interior Delta. The impacts of *Environmental Commitment 16 Nonphysical Fish Barriers* are expected to be less than significant. Consequently, no mitigation would be required.

Spring-Run Chinook Salmon

Construction and Maintenance of Water Conveyance Facilities

The discussion of potential effects to delta smelt from construction and maintenance of the water conveyance facilities under Alternative 4A is also relevant to spring-run Chinook salmon. Adult and juvenile spring-run Chinook salmon would have the potential to overlap construction and maintenance to a minor degree (Table 11-8).

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

The potential effects of construction of the water conveyance facilities on spring-run Chinook salmon would be the same as described for Alternative 4 (Impact AQUA-55). The potential effects of underwater noise as a result of construction of the water conveyance facilities on spring-run Chinook salmon would be the same as described above for winter-run Chinook (Impact AQUA-37), which provides additional detail on underwater noise impacts which are also applicable to Impact AQUA-55 in Alternative 4.

NEPA Effects: Potential effects of construction of the water conveyance facilities on spring-run Chinook salmon would be similar to those discussed for winter-run Chinook salmon (see Impact AQUA-37 for winter run Chinook salmon). Construction of Alternative 4A involves several elements with the potential to cause adverse effects on spring-run Chinook salmon. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment,* *and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*); environmental commitments; and through implementation of the avoidance and minimization measures included in Mitigation Measures AQUA-1a and AQUA-1b. The effects would not be adverse for spring-run Chinook salmon.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-55, the impact of the construction of water conveyance facilities on spring-run Chinook salmon would not be significant except for construction noise associated with pile driving. Potential effects of construction of the water conveyance facilities on spring-run Chinook salmon would be similar to those discussed for winter-run Chinook salmon (see Impact AQUA-37 for winter run Chinook salmon). Construction of Alternative 4A involves several elements with the potential to affect spring-run Chinook salmon. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

NEPA Effects: The potential effects of water conveyance facilities maintenance under Alternative 4A would be the similar to those described for Alternative 4, Impact AQUA-56. As concluded in Alternative 4, Impact AQUA-38, the impact would not be adverse for spring-run Chinook salmon.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-56, the impact of the maintenance of water conveyance facilities on spring-run Chinook salmon would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Average entrainment of juvenile spring-run Chinook salmon at the south Delta export facilities would be reduced nearly 40% under the Scenario H3_ELT compared to NAA_ELT (Table 11-4A-25). The greatest reduction would be in wet years, when entrainment would be reduced 63% (~58,000 fish) compared to NAA_ELT. Entrainment loss under Scenario H4_ELT would further reduce south Delta entrainment relative to the Scenario H3_ELT as spring exports would be lower under H4_ELT compared to H3_ELT.

Table 11-4A-25. Juvenile Spring-Run Chinook Salmon Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 4A (Scenario H3_ELT)

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-53,805 (-61%)	-57,967 (-63%)
Above Normal	-7,403 (-28%)	-8,520 (-31%)
Below Normal	-1,357 (-21%)	-1,669 (-25%)
Dry	1,698 (10%)	74 (0%)
Critical	-2,622 (-22%)	-1,916 (-17%)
All Years	-13,318 (-35%)	-14,788 (-38%)

Note: Estimated annual number of fish lost, based on normalized data.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

The proportion of the annual spring-run Chinook salmon index of abundance (assumed to be 750,000 juveniles approaching the Delta) lost at the south Delta facilities averaged 5.2% across all years under the NAA_ELT, and decreased to 3.3% under Alternative 4A Scenario H3_ELT. The greatest improvement was in wet years, when the proportion lost decreased by 7.7% under Alternative 4A Scenario H3_ELT (4.6%) compared to NAA_ELT (12.4%). As noted above, entrainment under Scenario H4_ELT is expected to further reduce entrainment losses relative to NAA_ELT.

Water Exports from SWP/CVP North Delta Intake Facilities

As noted for Alternative 4, the effect of Alternative 4A on entrainment and impingement at the north Delta intakes would be the same as described for Alternative 1A (Impact AQUA-57), but the degree would be less because Alternative 4A would have fewer intakes. State-of-the-art fish screens operated with an adaptive management plan would be expected to eliminate entrainment risk for juvenile spring-run Chinook salmon.

Predation Associated with Entrainment

Entrainment-related predation loss of spring-run Chinook salmon at the south Delta facilities would be no greater and may be lower than baseline due to a reduction in entrainment loss. Entrainment-related predation losses are expected to decrease under Scenario H4_ELT compared to Scenario H3_ELT.

Predation at the north Delta would be increased at the proposed North Delta intake facilities on the Sacramento River. As noted for Alternative 4, bioenergetics modeling with a median predator density predicts a predation loss of about 8,000 juveniles, or 0.2% of the spring-run juvenile population under Alternative 4A (Table 11-4A-26). This minimal predation loss would not be adverse. Note that this estimate does not provide context to the level of predation in this reach that would occur without implementation of Alternative 4A. See additional discussion under Impact AQUA-42 for winter-run Chinook salmon.

Table 11-4A-26. Juvenile Spring-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion (NDD) Intakes for Alternative 4A (Three Intakes)

Striped Bass at NDD (Three Intakes)			Spring-Run Chinook Consumed	
Density Assumption	Bass per 1,000 feet of Intake	Total Number of Bass	Number	Percentage of Annual Production Entering the Delta[1]
Low	18	86	1,204	0.03%
Median	119	571	7,961	0.19%
High	219	1,051	14,650	0.35%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (*BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference).
[1] Estimated as 4.2 million juveniles. See Section 5.F.3.2.1 in *BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference.

NEPA Effects: In conclusion, Alternative 4A would reduce overall entrainment and associated predation losses of juvenile spring-run Chinook salmon relative to NAA _ELT. Conditions under Scenario H4_ELT would further reduce entrainment losses compared to Scenario H3_ELT. The effect of Alternative 4A would not be adverse and may provide some benefit.

CEQA Conclusion: Entrainment losses of juvenile spring-run Chinook salmon at the south Delta facilities will be substantially reduced under the Scenario H3 operations for Alternative 4A for all water year types (35% average reduction in entrainment index) compared to Existing Conditions (Table 11-4A-25). The proportion of the annual spring-run Chinook index of abundance entrained at the south Delta facilities averaged 5.0% across all years under Existing Conditions, and would decrease to 3.3% under Alternative 4A. The greatest improvement would be in wet years, when the proportion lost would decrease by just over 7% under Scenario H3_ELT (4.6%) compared to Existing Conditions (11.8%). Under Scenario H4_ELT, entrainment losses are expected to further decrease relative to Existing Conditions. Predation loss at the north Delta intakes would have minor population level effects on spring-run Chinook salmon (<0.4% of the annual index of abundance). Overall, impacts to spring-run Chinook salmon under Alternative 4A would not be significant and would in fact be beneficial because of the reductions in entrainment losses at the south Delta facilities across all water-years compared to existing biological conditions. No mitigation would be required.

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

In general, the effects of Alternative 4A on spawning and egg incubation habitat for spring-run Chinook salmon relative to the NAA are not adverse.

H3_ELT/ESO_ELT

Sacramento River

There has been a small, inconsistent spawning population (<400 individuals) in the mainstem Sacramento River primarily upstream of Red Bluff Diversion Dam over the past decade (Azat 2012).

Flows in the Sacramento River between Keswick and upstream of Red Bluff were examined during the spring-run Chinook salmon spawning and incubation period (September through January)

(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT during all months except November would generally be similar to those under NAA_ELT, with minor exceptions. Flows under H3_ELT during November would be up to 23% lower than flows during NAA_ELT, depending on water year type and location.

Shasta Reservoir storage volume at the end of September influences flows downstream of the dam during the spring-run spawning and egg incubation period (September through January). Mean storage under H3_ELT would generally be similar to storage under NAA_ELT in all water year types (Table 11-4A-27), so there would be no biologically meaningful effects.

Table 11-4A-27. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Scenario H3_ELT and Two Baseline Scenarios.

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-308 (-9%)	-11 (-0.4%)
Above Normal	-363 (-11%)	0 (0%)
Below Normal	-230 (-8%)	-63 (-2%)
Dry	-171 (-7%)	31 (1%)
Critical	-134 (-11%)	-65 (7%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between H3_ELT and NAA_ELT in any month or water year type throughout the period at either location.

The number of days when temperatures exceeded the analysis criterion (i.e., 56°F identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September At Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period. The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H3_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-15 for Bend Bridge and in Table 11-4A-28 for Red Bluff. At Bend Bridge, there would be 4 (5%) more years with a "red" level of concern under H3_ELT, which would not be biologically meaningful to spring-run Chinook salmon spawners and eggs, as 4 years constitutes a small proportion of the 82 year period examined. At Red Bluff, there would be 1 (5%) more year with a "red" level of concern under H3_ELT, which would not be biologically meaningful to spring-run Chinook salmon spawners and eggs, as 1 year is such a small proportion of the 82 year period.

Table 11-4A-28. Differences between Baseline and H3_ELT Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F are within Each Level of Concern, Sacramento River at Red Bluff, October through April

Level of Concern[a]	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Red	10 (83%)	1 (5%)
Orange	5 (83%)	-2 (-15%)
Yellow	14 (108%)	1 (4%)
None	-29 (-57%)	0 (0%)

[a] For definitions of levels of concern, see Table 11-4A-14.

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, the monthly total degree-days under H3_ELT would be 8% lower than under NAA_ELT for May and June, 9% higher for September, and would be similar for July and August (Table 11-4A-16). At Red Bluff, total degree-days under H3_ELT would be 19% higher than those under NAA_ELT for March and would be similar for the remaining months of the period (Table 11-4A-29).

Table 11-4A-29. Differences between Baseline and H3_ELT Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Red Bluff, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
October	Wet	442 (172%)	20 (3%)
	Above Normal	209 (80%)	12 (3%)
	Below Normal	246 (118%)	-12 (-3%)
	Dry	403 (82%)	29 (3%)
	Critical	357 (60%)	-58 (-6%)
	All	1,657 (91%)	-9 (0%)
November	Wet	9 (900%)	1 (11%)
	Above Normal	4 (NA)	1 (33%)
	Below Normal	2 (NA)	0 (0%)
	Dry	37 (463%)	-5 (-10%)
	Critical	20 (500%)	2 (9%)
	All	72 (554%)	-1 (-1%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	1 (NA)	0 (0%)
	Above Normal	1 (NA)	1 (NA)
	Below Normal	10 (111%)	9 (90%)
	Dry	21 (150%)	1 (3%)
	Critical	11 (1100%)	0 (0%)
	All	44 (183%)	11 (19%)
April	Wet	101 (88%)	4 (2%)
	Above Normal	77 (55%)	5 (2%)
	Below Normal	87 (110%)	-7 (-4%)
	Dry	109 (59%)	2 (1%)
	Critical	40 (333%)	-2 (-4%)
	All	414 (78%)	2 (0%)

NA = could not be calculated because the denominator was 0.
Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under H3_ELT would be similar to mortality under NAA_ELT in wet, dry, and critical years, but greater in above normal and below normal water years (26% to 32% greater, respectively) (Table 11-4A-30). Relative increases of 26% and 32% mortality of the spring-run population in above and below normal water years represent 4% and 7% increases, respectively, on an absolute scale and, therefore, would not cause a biologically meaningful effect to spring-run Chinook salmon due to this small magnitude. Combining all water years, there would also be no effect of H3_ELT on egg mortality (2% absolute increase; 7% relative increase).

Table 11-4A-30. Difference and Percent Difference in Percent Mortality of Spring-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	4 (41%)	0.2 (1%)
Above Normal	7 (52%)	4 (26%)
Below Normal	16 (134%)	7 (32%)
Dry	22 (114%)	1 (3%)
Critical	19 (25%)	1 (1%)
All	13 (57%)	2 (7%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

SacEFT predicts that there would be a 4% relative decrease (2% on an absolute scale) in the percentage of years with good spawning availability, measured as weighted usable area, under H3_ELT relative to NAA_ELT (Table 11-4A-31). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under H3_ELT relative to NAA_ELT. SacEFT predicts that there would be an 11% decrease on a relative scale (7% on absolute scale) in the percentage of years with good (lower) egg incubation conditions under H3_ELT relative to NAA_ELT. SacEFT predicts that there would be a 5% relative decrease (2% on an absolute scale) in the percentage of years with good (lower) redd dewatering risk under H3_ELT relative to NAA_ELT. It is unlikely that spawning habitat availability is currently limiting to spring-run Chinook salmon due to deeply suppressed escapement values over the past decade. Given this, these values may be less important to spring-run Chinook salmon spawning.

Table 11-4A-31. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Spring-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Spawning WUA	-15 (-21%)	-2 (-4%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-28 (-33%)	-7 (-11%)
Redd Dewatering Risk	-10 (-20%)	-2 (-5%)
Juvenile Rearing WUA	6 (27%)	3 (12%)
Juvenile Stranding Risk	1 (5%)	0 (0%)

WUA = Weighted Usable Area.
Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

The results of the SacEFT model and Reclamation egg mortality model are consistent with regard to predicted conditions for spring-run salmon eggs. SacEFT predicts that egg incubation habitat would decrease (7% absolute scale decrease) and the Reclamation egg mortality model predicts that overall egg mortality would increase 7% under the H3_ELT. This level of agreement in the results of the two models is likely somewhat coincidental because the models employ different sets of data. The SacEFT uses mid-August through early March as the egg incubation period, based on Vogel and Marine (1991), and the reach between ACID Dam and Battle Creek for redd locations. The Reclamation egg mortality model uses the number of days after Julian week 33 (mid-August) that it takes to accumulate 750 temperature units to hatching and another 750 temperature units to emergence. Temperatures units are calculated by subtracting 32°F from daily river temperature and are computed on a daily basis. As a result, egg incubation duration is generally mid-August through January, but is dependent on river temperature. The Reclamation model uses the reach between ACID Dam and Jelly's Ferry (approximately 5 river miles downstream of Battle Creek), which includes 95% of Sacramento River spawning locations based on 2001–2004 redd survey data (Reclamation 2008). The SacEFT model has been peer-reviewed, and the Reclamation egg mortality model has been extensively reviewed and used in prior biological assessments and BiOps. Therefore, both results are considered valid and were considered in drawing conclusions about spring-run egg mortality in the Sacramento River.

Clear Creek

Mean flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under H3_ELT would generally be similar to flows under NAA_ELT throughout the spring-run spawning and egg incubation period for all water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning is assumed to occur. The greatest reduction in flows under H3_ELT would be the same as that under NAA_ELT in all water year types (Table 11-4A-32).

Water temperatures were not modeled in Clear Creek.

Table 11-4A-32. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0 (NA)	0 (NA)
Above Normal	-41 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-67 (NA)	0 (0%)
Critical	-33 (-50%)	0 (0%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) where spring-run Chinook salmon primarily spawn during September through January. Flows under H3_ELT would not differ from NAA_ELT because minimum Feather River flows are included in the FERC settlement agreement (California Department of Water Resources 2006) and would be met for all model scenarios (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Oroville Reservoir storage volume at the end of September influences flows downstream of the dam during the spring-run spawning and egg incubation period. Mean storage volume at the end of September under H3_ELT would be similar to storage under NAA_ELT in wet, above normal, and below normal water years and 15% and 12% greater in dry and critical water years (Table 11-4A-33).

Table 11-4A-33. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Alternative 4 (Scenario H3)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-676 (-23%)	46 (2%)
Above Normal	-681 (-29%)	-125 (-7%)
Below Normal	-392 (-19%)	-67 (-4%)
Dry	-65 (-5%)	173 (15%)
Critical	26 (3%)	108 (12%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month during the egg incubation period to the flow in September when spawning is assumed to occur. Minimum flows in the low-flow channel during October through January were identical between H3_ELT and NAA_ELT (Appendix 11C, *CALSIM II*

Model Results utilized in the Fish Analysis). Therefore, there would be no effect of H3_ELT on redd dewatering in the Feather River low-flow channel.

Mean water temperatures in the low-flow channel would not differ between NAA_ELT and H3_ELT (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Effects of H3_ELT on water temperature-related spawning and egg incubation conditions for spring-run Chinook salmon in the Feather River were analyzed by comparing the percent of months between September through January over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4A-34). There would be no differences between NAA_ELT and H3_ELT in the percent of months exceeding the threshold in December and January, and negligible differences (<5% on an absolute scale) in November. However, for September there would be an 11% increase (absolute difference) in the percent of months exceeding the threshold by >5°F and a 6% increase in percent of months exceeding the threshold by >4°F.

Table 11-4A-34. Differences between Baseline and H3_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, September through January

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3_ELT					
September	0 (0%)	0 (0%)	6 (7%)	11 (15%)	16 (39%)
October	22 (100%)	16 (217%)	7 (120%)	6 (250%)	4 (150%)
November	9 (350%)	7 (600%)	2 (200%)	2 (NA)	0 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
NAA_ELT vs. H3_ELT					
September	0 (0%)	0 (0%)	0 (0%)	6 (8%)	11 (24%)
October	-5 (-10%)	0 (0%)	-4 (-21%)	-2 (-22%)	-2 (-29%)
November	1 (13%)	0 (0%)	-1 (-25%)	0 (0%)	-1 (-100%)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

The effects of H3_ELT on water temperature-related spawning and egg incubation conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the September through January spring-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-4A-35). Combining all water year types, there would be a reduction of 17 degree-months in the number of degree-months exceeding the NMFS threshold under H3_ELT relative to NAA_ELT for October, an increase of 17 degree-months for September. There would be negligible differences in degree months between NAA_ELT and H3_ELT in the other months. Results are highly variable when separating out by water year type, ranging from 9% more degree-months (absolute difference) under H3_ELT in below normal water years during September to 9% fewer degree-months under H3_ELT in dry water years during October. The absolute scale is used to compare results for these analyses because the large relative differences (percent differences) between NAA_ELT and H3_ELT in most cases are mathematical artifacts due to the small values of degree-months for NAA_ELT (i.e., dividing by a small number amplifies the relative difference), which would not translate into biologically meaningful effects on spring-run Chinook salmon.

Table 11-4A-35. Differences between Baseline and H3_ELT Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, September through January

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
September	Wet	-5 (-5%)	4 (4%)
	Above Normal	0 (0%)	3 (8%)
	Below Normal	14 (23%)	9 (14%)
	Dry	31 (45%)	2 (2%)
	Critical	10 (15%)	-1 (-1%)
	All	50 (14%)	17 (4%)
October	Wet	10 (200%)	0 (0%)
	Above Normal	8 (80%)	0 (0%)
	Below Normal	11 (157%)	-3 (-14%)
	Dry	12 (171%)	-9 (-32%)
	Critical	8 (100%)	-5 (-24%)
	All	49 (132%)	-17 (-17%)
November	Wet	0 (NA)	-1 (-100%)
	Above Normal	3 (100%)	0 (0%)
	Below Normal	2 (200%)	-2 (-40%)
	Dry	10 (NA)	3 (43%)
	Critical	2 (NA)	-1 (-33%)
	All	17 (425%)	-1 (-5%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

H4_ELT /HOS_ELT

Sacramento River

Mean flows in the Sacramento River between Keswick and upstream of RBDD under H4_ELT during the September through January spring-run Chinook salmon spawning and egg incubation period would generally be similar to flows under NAA_ELT, except during November (up to 20% lower, depending on water year type and location).

Shasta Reservoir storage at the end of September under H4_ELT would be similar to storage under NAA_ELT, except in critical water years (24% higher) (Table 11-4A-36).

Table 11-4A-36. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Baseline and H4_ELT Scenarios

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	-302 (-9.1%)	-5 (-0.2%)
Above Normal	-371 (-11.6%)	-7 (-0.3%)
Below Normal	-143 (-5%)	24 (0.9%)
Dry	-144 (-5.8%)	58 (2.6%)
Critical	36 (3%)	235 (23.7%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

The number of days when temperatures exceeded the analysis criterion (i.e., 56°F identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September at Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period. The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H4_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-20 for Bend Bridge and in Table 11-4A-37 for Red Bluff. At Bend Bridge, there would be 1 (17%) more years with an "orange" level of concern under H4_ELT. This difference would not be biologically meaningful to spring-run Chinook salmon spawners and eggs. At Red Bluff, there would be 6 (27%) fewer years with any of the three "levels of concern", indicating that water temperatures would be within an acceptable range more often under H4_ELT than under NAA_ELT.

Table 11-4A-37. Differences between Baseline and H3_ELT Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Red Bluff, October through April

Level of Concern[a]	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Red	9 (75%)	0 (0%)
Orange	2 (33%)	-5 (-38%)
Yellow	12 (92%)	-1 (-4%)
None	-23 (-45%)	6 (27%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

[a] For definitions of levels of concern, see Table 11-4A-14.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, there would be reductions under H4_ELT relative to NAA_ELT in the monthly total degree-days exceeding the 56°F threshold for all of the months (Table 11-4A-21). At Red Bluff, exceedances above the threshold under H4_ELT would be 9 degree-days (16%) higher than those under NAA_ELT for March, and lower or similar for the remaining months (Table 11-4A-38). On an absolute scale, the 9 degree-day increase during March, because it is the sum of differences in degree-days for March summed over the 82-year period, would not translate into a biologically meaningful effect on spring-run Chinook salmon.

Table 11-4A-38. Differences between Baseline and H3 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Red Bluff, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
October	Wet	406 (158%)	-16 (-2%)
	Above Normal	191 (73%)	-6 (-1%)
	Below Normal	229 (110%)	-29 (-6%)
	Dry	286 (58%)	-88 (-10%)
	Critical	201 (34%)	-214 (-21%)
	All	1,313 (72%)	-353 (-10%)
November	Wet	7 (700%)	-1 (-11%)
	Above Normal	4 (NA)	1 (33%)
	Below Normal	1 (NA)	-1 (-50%)
	Dry	31 (388%)	-11 (-22%)
	Critical	13 (325%)	-5 (-23%)
	All	56 (431%)	-17 (-20%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	1 (NA)	0 (0%)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	10 (111%)	9 (90%)
	Dry	20 (143%)	0 (0%)
	Critical	11 (1,100%)	0 (0%)
	All	42 (175%)	9 (16%)
April	Wet	97 (84%)	0 (0%)
	Above Normal	68 (49%)	-4 (-2%)
	Below Normal	99 (125%)	5 (3%)
	Dry	118 (63%)	11 (4%)
	Critical	49 (408%)	7 (13%)
	All	431 (81%)	19 (2%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Clear Creek

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under H4_ELT would generally be similar to those under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Also, flows would generally be similar between H4_ELT and H3_ELT such that results of the redd dewatering analysis would be similar between H4_ELT and H3_ELT. Therefore, no analysis of redd dewatering risk was conducted for H4_ELT in Clear Creek. Due to similar flows between H4_ELT and H3_ELT, effects of H4_ELT on spring-run Chinook salmon spawning and egg incubation habitat in Clear Creek would not be different from effects of H3_ELT. Therefore, there would be no effects of H4_ELT on spring-run Chinook salmon spawning and egg incubation in Clear Creek relative to the NAA_ELT.

Feather River

Flows in the Feather River low-flow channel during the spring-run Chinook salmon spawning and egg incubation period (September through January) would be the same between NAA_ELT and H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Oroville Reservoir storage volume at the end of September under H4_ELT would generally be similar to storage under NAA_ELT in wet and above normal water years, slightly (9%) lower in below normal water years, and moderately to substantially higher in dry and critical years (28% to 44% higher), respectively) (Table 11-4A-39). Higher storage in drier water year types would generally benefit spring-run Chinook salmon spawning and egg incubation habitat.

Table 11-4A-39. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Oroville Reservoir for H4 Scenarios

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA vs. H4_ELT
Wet	-664 (-22.9%)	58 (2.6%)
Above Normal	-576 (-24.3%)	-20 (-1.1%)
Below Normal	-481 (-23.8%)	-156 (-9.2%)
Dry	74 (5.4%)	311 (27.7%)
Critical	310 (31.5%)	393 (43.5%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Mean water temperatures in the low-flow channel would not differ between NAA_ELT and H4_ELT (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Increases in the percent of months exceeding the 56°F threshold between NAA_ELT and H4_ELT would occur during October and November, with up to 10% (absolute difference) more months exceeding the threshold under H4_ELT (Table 11-4A-40).

Table 11-4A-40. Differences between Baselines and H4_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, September through January

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H4_ELT					
September	0 (0%)	-1 (-1%)	4 (4%)	5 (7%)	-1 (-3%)
October	19 (83%)	20 (267%)	16 (260%)	15 (600%)	14 (550%)
November	17 (700%)	15 (1200%)	7 (600%)	4 (NA)	1 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
NAA_ELT vs. H4_ELT					
September	0 (0%)	-1 (-1%)	-2 (-3%)	0 (0%)	-6 (-14%)
October	-9 (-18%)	4 (16%)	5 (29%)	6 (56%)	7 (86%)
November	10 (100%)	7 (86%)	4 (75%)	1 (50%)	0 (0%)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Total degree-months of exceedance above the 56°F threshold under H4_ELT would be up to 48 degree-months greater than those under NAA_ELT for September through November (all water years combined) (Table 11-4A-41). An increase of 48 degree-months would not be biologically meaningful, given the 82-year period of analysis. The total degree-months of exceedance for the other months of the period would be similar between H4_ELT and NAA_ELT. Overall, effects of H4_ELT on spring-run Chinook salmon spawning and egg incubation habitat in the Feather River would generally be negligible or beneficial compared to the NAA_ELT.

Table 11-4A-41. Differences between Baseline Scenarios and H4_ELT Scenario in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, September through April

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
September	Wet	7 (6%)	16 (16%)
	Above Normal	10 (23%)	13 (33%)
	Below Normal	36 (60%)	31 (48%)
	Dry	27 (39%)	-2 (-2%)
	Critical	-6 (-9%)	-17 (-22%)
	All	74 (21%)	41 (11%)
October	Wet	35 (700%)	25 (167%)
	Above Normal	14 (140%)	6 (33%)
	Below Normal	24 (343%)	10 (48%)
	Dry	38 (543%)	17 (61%)
	Critical	3 (38%)	-10 (-48%)
	All	114 (308%)	48 (47%)
November	Wet	12 (NA)	11 (1,100%)
	Above Normal	6 (200%)	3 (50%)
	Below Normal	12 (1,200%)	8 (160%)
	Dry	15 (NA)	8 (114%)
	Critical	0 (NA)	-3 (-100%)
	All	45 (1,125%)	27 (123%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

NEPA Effects: Collectively, these modeling results indicate that the effect of Alternative 4A on spring-run Chinook salmon spawning and egg incubation conditions would not be adverse because the alternative does not substantially reduce the amount of suitable spawning and egg incubation habitat or substantially interfere with winter-run Chinook salmon spawning and egg incubation. There are no substantial changes to flows, cold water pool storage, or water temperatures that would cause a biologically meaningful negative effect to spring-run Chinook salmon spawners or eggs. Biological models including the Reclamation Egg Mortality Model and SacEFT also indicate that there would be no biologically meaningful effects.

CEQA Conclusion: Collectively, the results of the Impact AQUA-58 CEQA analysis show that the difference between the CEQA baseline and Alternative 4A could be significant because, when compared to the CEQA baseline, the alternative, including climate change, would substantially reduce the quantity and quality of spawning and egg incubation habitat for spring-run Chinook salmon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, the comparison to the NAA_ELT is a better approach because it isolates the effects of the alternative from those of sea level rise, climate change, and future water demand. Based on this identification of the actual increment of change attributable to the alternative, Alternative 4A would not affect the quantity and quality of spawning and egg incubation habitat for spring-run Chinook salmon relative to the CEQA conclusion.

H3_ELT /ESO_ELT

Sacramento River

Flows in the Sacramento River between Keswick and upstream of Red Bluff were examined during the spring-run Chinook salmon spawning and incubation period (September through January). Mean flows under H3_ELT during October and November would be similar to or up to 20% lower than flows under Existing Conditions, depending on water year type and location. Mean flows under H3_ELT during September would be up to 24% lower and up to 34% higher than flows under Existing Conditions depending on water year type and location. And mean flows under H3_ELT during January and December would generally be similar to flows under Existing Conditions.

Shasta Reservoir mean storage volume at the end of September would be 7% to 11% lower under H3_ELT relative to Existing Conditions depending on water year type (Table 11-4A-27).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At Keswick, the mean monthly (all water years combined) temperatures under H3_ELT would be 6% greater for both September and October than those under Existing Conditions, but they would not be different for other months during the period. Differences by water year type were <10% except for September of critical water years (10.3% higher). At Bend Bridge, there would be no differences (<5%) in water temperatures between H3_ELT and Existing Conditions for all months and water year types during the period.

The number of days when temperatures exceeded the analysis criterion (i.e., 56°F identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September at Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period. The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern," as defined in Table 11-4A-14. Differences between baselines and H3_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-15 for Bend Bridge and in Table 11-4A-28 for Red Bluff. At Bend Bridge, there would be a 55% increase in the number of years with a "red" level of concern under H3_ELT relative to Existing Conditions. At Red Bluff, there would be 83%, increases in the number of years for both "red" and "orange" levels of concern under H3_ELT relative to Existing Conditions, and a 108% increase for the "yellow" level of concern.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days (all water years combined) under H3_ELT would be 60% to 114% higher than that under Existing Conditions depending on month throughout the period (Table 11-4A-16). At Red Bluff, total degree-days under H3_ELT would be 78% to 554% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4A-29).

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under H3_ELT would be 25% to 134% greater than mortality under Existing Conditions depending on water year type (Table 11-4A-30).

SacEFT predicts that there would be a 21% relative decrease in the percentage of years with good spawning availability, measured as weighted usable area, under H3_ELT compared to Existing Conditions (Table 11-4A-31). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under H3_ELT relative to Existing Conditions. SacEFT predicts that there would be a 33% relative decrease in the percentage of years with good (lower) egg incubation conditions under H3_ELT compared to Existing Conditions. SacEFT predicts that there would be a 20% relative decrease in the percentage of years with good (lower) redd dewatering risk under H3_ELT compared to Existing Conditions. These results indicate that spawning and egg incubation conditions for spring-run Chinook salmon under H3_ELT would be substantially lower relative to Existing Conditions. Spawning habitat consists of the appropriate depth, substrate, and water temperatures, among other variables. SacEFT indicates that depth, as a result of flow, and temperature conditions would be degraded under H3_ELT relative to Existing Conditions. However, it is not known whether spawning habitat is limiting to the spring-run Chinook salmon population in the Sacramento River, especially given the recent sharp decline in annual escapement estimates.

Clear Creek

Flows in Clear Creek were examined during the spring-run Chinook salmon spawning and egg incubation period (September through January). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions, except for a 40% increase for January of wet years, a 19% decrease for September of critical years, and 10% increases for January and December of critical years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning is assumed to occur. The greatest reduction in flows under H3_ELT would be 41 cfs, 67 cfs, and 33 cfs lower (worse) than under Existing Conditions in above normal, dry, and critical years, respectively, and would be 53 cfs higher (better) than under Existing Conditions in below normal years (Table 11-4A-32).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River low-flow channel under H3_ELT are not different from Existing Conditions during the September through January spring-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in October through

January (800 cfs) would be equal to or greater than the spawning flows in September (773 cfs) for all model scenarios.

Oroville Reservoir mean storage volume at the end of September would be similar or up to 29% lower under H3_ELT relative to Existing Conditions, depending on water year type (Table 11-4A-33).

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning is assumed to occur. Minimum flows in the low-flow channel during October through January were identical between H3_ELT and Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of H3_ELT on redd dewatering in the Feather River low-flow channel.

Mean monthly water temperatures in the low-flow channel under H3_ELT would be no different (<5%) under H3_ELT relative to Existing Conditions during the September through January spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Effects of H3_ELT on water temperature in the Feather River were analyzed by determining the percent of months between September and January over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4A-34). In general, the percent of months exceeding the threshold under H3_ELT would be similar to or greater by up to 22% (absolute difference) than the percent under Existing Conditions. This comparison includes the effects of climate change.

The effects of H3_ELT on water temperature in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the September through January spring-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-4A-35). Total degree-months (all water years combined) would be 14% to 425% higher under H3_ELT relative to Existing Conditions for September through November and would be the identical for December and January. These comparisons include the effects of climate change.

H4_ELT /HOS_ELT

Sacramento River

Mean flows in the Sacramento River between Keswick and upstream of RBDD under H4_ELT during the September through January spring-run Chinook salmon spawning and egg incubation period would be up to 20% lower and 53% higher than flows under Existing conditions during September and would be generally similar or up to 19% lower than flows under Existing conditions during October through January.

Shasta Reservoir mean storage at the end of September under H4_ELT would be similar to or up to 12% lower than storage under Existing Conditions, depending on water year type (Table 11-4A-36).

Mean water temperatures in the Sacramento River under H4_ELT would not differ (<5%) from those under Existing Conditions for any month or water year type at both Keswick and Bend Bridge (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Clear Creek

Mean flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under H4_ELT would generally be similar to those under Existing Conditions, except for a 40% increase for January of wet years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effects of H4_ELT on spring-run Chinook salmon spawning and egg incubation in Clear Creek relative to Existing Conditions.

Feather River

Flows in the Feather River low-flow channel during the spring-run Chinook salmon spawning and egg incubation period (September through October) would be similar between Existing Conditions and H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Oroville Reservoir mean storage volume at the end of September under H4_ELT would be similar to or greater than storage under Existing Conditions in dry and critical water years (32% higher for critical year types) and about 24% lower in below normal, above normal and wet water years (Table 11-4A-39). Higher storage in drier water year types would generally benefit spring-run Chinook salmon spawning and rearing habitat.

Mean water temperatures in the low-flow channel would be up to no different (<5%) under H4_ELT relative to Existing Conditions during the September through January spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

There would be an increased percent of months (up to 20% on an absolute scale) above the 56°F threshold under H4_ELT compared to Existing Conditions during September through November and no change in December and January (Table 11-4A-40).

The total number of degree-months (all water year types combined) exceeding the threshold under H4_ELT would be up to 1,125% higher than the number under Existing Conditions during September through November, but no there would be no differences during December and January (Table 11-4A-41).

Summary of CEQA Conclusion

Under Alternative 4A (including climate change effects), there are flow and storage reductions, as well as temperature increases in the Sacramento River that would lead to biologically meaningful increases in egg mortality and overall reduced habitat conditions for spawning spring-run and egg incubation, as compared to Existing Conditions. Flows in the Feather River low-flow channel do not differ between Alternative 4A and Existing Conditions. However, water temperature analyses in the Feather River low-flow channel using thresholds developed in coordination with NMFS indicate that there would be moderate to large negative effects on temperature conditions during spring-run Chinook salmon spawning and egg incubation.

Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of spring-run as a result of egg mortality.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows, reservoir storage, and water temperatures in the Sacramento River would be similar between NAA_ELT and Alternative 4A. There would be no effects of Alternative 4A on spawning and egg incubation conditions in Clear Creek, and small beneficial or no effects on flows, reservoir storage, and water temperatures in the Feather River. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

In general, Alternative 4A would not affect the quantity and quality of rearing habitat for fry and juvenile spring-run Chinook salmon relative to the NAA_ELT.

H3_ELT /ESO_ELT

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). At Keswick, mean flows under H3_ELT would be up to 23% lower during November than under NAA_ELT and would generally be similar in the remaining months. Upstream of Red Bluff, mean flows under H3_ELT would be up to 18% lower during November than under NAA_ELT and similar in the remaining months. These results indicate that there would be very few reductions in flows due to H3_ELT in the Sacramento River.

As reported in Impact AQUA-40, May Shasta mean storage volume under H3_ELT would be similar to storage under NAA_ELT for all water year types (Table 11-4A-12), so there would be no biologically meaningful effects on downstream flows.

As reported in Impact AQUA-58, September Shasta mean storage volume under H3_ELT would generally be similar to storage under NAA_ELT in all water year types (Table 11-4A-27).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the November through March spring-run Chinook salmon juvenile rearing period (Appendix

11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location except for a 7% increase for August in critical years at Keswick.

SacEFT predicts that the percentage of years with good juvenile rearing WUA conditions under H3_ELT would be 12% greater than that under NAA_ELT (Table 11-4A-31) and predicts no difference in the percentage of years with good (lower) juvenile stranding risk conditions under H3_ELT. On an absolute scale, juvenile rearing WUA increase in only 3% of years, which would not have a biologically meaningful effect on spring-run Chinook salmon.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality would be similar to (<5% different from) NAA_ELT.

Clear Creek

Mean flows in Clear Creek during the November through March rearing period under H3_ELT would be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during November through June were reviewed to determine flow-related effects on larval and juvenile spring-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low-flow channel throughout this period under H3_ELT would not differ from those under NAA_ELT. In the high-flow channel, mean flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT for February through June (by up to 106% greater for June, above normal years). For November through January, flows would generally be similar to those under NAA_ELT, with minor exceptions.

May Oroville mean storage volume under H3_ELT would be similar to storage under NAA_ELT for all water year types (Table 11-4A-42).

As reported in Impact AQUA-58, September Oroville mean storage volume under H3_ELT would be similar to volume under NAA_ELT in wet, above normal, and below normal water years and 12% to 15% greater than volume under NAA_ELT during dry and critical water years (Table 11-4A-33). Consequently, there would be minimal effects on downstream flows.

Table 11-4A-42. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Alternative 4A (Model Scenario H3_ELT)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-21 (-1%)	-2 (-0.05%)
Above Normal	-111 (-3%)	-52 (-2%)
Below Normal	-162 (-5%)	3 (0.1%)
Dry	-332 (-12%)	18 (1%)
Critical	-157 (-9%)	-17 (-1%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Mean water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location.

The percent of months exceeding the 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during May and June (Table 11-4A-43). Although spring-run typically rear in the Feather River from November through June, NMFS requested that these months be evaluated to be consistent with water temperature targets set during the Oroville Dam FERC relicensing process, and evaluated in the NMFS (2009) Draft BiOp on the Oroville Dam project. As indicated in Table 11-4A-13, this criterion applies to both spring-run Chinook salmon and steelhead rearing. Therefore, the months of interest to spring-run Chinook salmon here are May and June only. The steelhead analysis below includes the remaining months. In general, differences in the percent of months exceeding the threshold between NAA_ELT and H3_ELT would be negligible (<5% on an absolute scale), although there are some small (up to 9% on an absolute scale) decreases in percent of months exceeding the threshold during June and August, depending on the degrees above the threshold.

Table 11-4A-43. Differences between Baseline and H3_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 63°F Threshold, May through August

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3_ELT					
May	4 (NA)	2 (NA)	0 (NA)	0 (NA)	0 (NA)
June	20 (36%)	20 (73%)	15 (300%)	4 (NA)	0 (NA)
July	0 (0%)	0 (0%)	1 (1%)	26 (36%)	36 (91%)
August	0 (0%)	11 (13%)	27 (47%)	26 (91%)	26 (263%)
NAA_ELT vs. H3_ELT					
May	0 (0%)	1 (100%)	0 (NA)	0 (NA)	0 (NA)
June	-4 (-5%)	-7 (-14%)	-9 (-30%)	0 (0%)	0 (NA)
July	0 (0%)	0 (0%)	0 (0%)	0 (0%)	1 (2%)
August	0 (0%)	0 (0%)	5 (6%)	0 (0%)	6 (21%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

The effects of H3_ELT on water temperature-related juvenile rearing conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 63°F NMFS threshold during May and June for all 82 years (Table 11-4A-44). As discussed above, although this table includes results through August, only May and June results apply to spring-run Chinook salmon. The steelhead analysis below includes the remaining months. Combining all water year types, there would be little difference in total degree-months (<5 degree-months) exceeded between NAA_ELT and H3_ELT during May and a (16 degree-month reduction (12% lower) during June). There would be small decreases (up to 6 degree-months) for the different water year types in June.

Table 11-4A-44. Differences between Baseline and H3_ELT Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Feather River above Thermalito Afterbay, May through August

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
May	Wet	0 (NA)	0 (NA)
	Above Normal	1 (NA)	0 (0%)
	Below Normal	0 (NA)	0 (NA)
	Dry	2 (NA)	1 (100%)
	Critical	2 (NA)	0 (0%)
	All	5 (NA)	1 (25%)
June	Wet	11 (73%)	-6 (-19%)
	Above Normal	6 (43%)	-2 (-9%)
	Below Normal	7 (54%)	-6 (-23%)
	Dry	13 (57%)	-2 (-5%)
	Critical	10 (167%)	0 (0%)
	All	47 (66%)	-16 (-12%)
July	Wet	24 (20%)	1 (1%)
	Above Normal	9 (20%)	-1 (-2%)
	Below Normal	15 (25%)	0 (0%)
	Dry	19 (27%)	0 (0%)
	Critical	22 (42%)	4 (6%)
	All	89 (26%)	4 (1%)
August	Wet	17 (19%)	7 (7%)
	Above Normal	9 (36%)	2 (6%)
	Below Normal	15 (39%)	1 (2%)
	Dry	28 (70%)	4 (6%)
	Critical	14 (33%)	-6 (-10%)
	All	83 (35%)	8 (3%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

H4_ELT/HOS_ELT

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be up to 20% lower than flows under NAA_ELT during November and would generally be similar to flows under NAA_ELT in remaining months and water year types of the period.

September Shasta mean storage volume under H4_ELT would be similar to September storage volume under NAA_ELT in all years except critical, in which storage would be 24% greater under H4_ELT (Table 11-4A-36).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period at either location.

Clear Creek

Mean flows in Clear Creek during the November through March rearing period under H4_ELT would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, effects of H4_ELT regarding larval and juvenile spring-run Chinook salmon rearing habitat in Clear Creek would be similar to those under NAA_ELT.

Feather River

Flows in the Feather River low-flow channel during November through June would not differ between NAA_ELT and H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the high-flow channel during the November through June juvenile rearing period under H4_ELT would generally be similar to or greater than flows under NAA_ELT for February through June (by up to 548% greater for April, below normal years). For November through January, flows would generally be similar to those under NAA_ELT, with a few exceptions.

May Oroville mean storage under H4_ELT would be 11% to 16% lower than storage under NAA_ELT in wet, above normal, and below normal water years, similar in dry water years, and 24% greater in critical water years (Table 11-4A-45). September Oroville storage under H4_ELT would be similar to storage under NAA_ELT in wet, above normal, and below normal years, but 28% and 44% higher in dry and critical years, respectively (Table 11-4A-39).

Table 11-4A-45. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Baseline and H4_ELT Scenarios

Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Wet	-399 (-11%)	379 (-11%)
Above Normal	-613 (-18%)	-553 (-16%)
Below Normal	-613 (-19%)	-448 (-15%)
Dry	-331 (-12%)	19 (1%)
Critical	267 (15%)	407 (24%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period at either location.

Differences in the percent of months exceeding the 63°F threshold between NAA_ELT and H4_ELT would be negligible (<5% on an absolute scale) for May and 1% to 14% lower (absolute difference) for June (Table 11-4A-46). This represents a small benefit of H4_ELT on spring-run spawning habitat conditions in the Feather River.

Table 11-4A-46. Differences between Baseline and H4 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 63°F Threshold, May through August

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H4_ELT					
May	2 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
June	10 (18%)	17 (64%)	11 (225%)	2 (NA)	0 (NA)
July	0 (0%)	0 (0%)	0 (0%)	21 (29%)	28 (72%)
August	0 (0%)	11 (13%)	22 (38%)	22 (78%)	12 (125%)
NAA_ELT vs. H4_ELT					
May	-1 (-33%)	-1 (-100%)	0 (NA)	0 (NA)	0 (NA)
June	-14 (-17%)	-10 (-18%)	-12 (-43%)	-1 (-33%)	0 (NA)
July	0 (0%)	0 (0%)	-1 (-1%)	-5 (-5%)	-6 (-8%)
August	0 (0%)	0 (0%)	0 (0%)	-4 (-7%)	-7 (-25%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Combining all water year types, total degree-months above the 63°F threshold under H4_ELT would be similar (<5 degree-months difference) to those under NAA_ELT for May, but 131 degree-months lower for June, (Table 11-4A-47). This represents a small benefit of H4_ELT on spring-run spawning habitat conditions in the Feather River.

Table 11-4A-Table 11-4A-47. Differences between Baseline and H4 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Feather River above Thermalito Afterbay, May through August

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
May	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	-1 (-100%)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	-1 (-100%)
	Critical	0 (NA)	-2 (-100%)
	All	0 (NA)	-4 (-100%)
June	Wet	-15 (-100%)	-32 (-100%)
	Above Normal	-14 (-100%)	-22 (-100%)
	Below Normal	-13 (-100%)	-26 (-100%)
	Dry	-22 (-96%)	-37 (-97%)
	Critical	-4 (-67%)	-14 (-88%)
	All	-68 (-96%)	-131 (-98%)
July	Wet	-85 (-71%)	-108 (-76%)
	Above Normal	-22 (-50%)	-32 (-59%)
	Below Normal	-35 (-59%)	-50 (-68%)
	Dry	-34 (-48%)	-53 (-59%)
	Critical	-36 (-69%)	-54 (-77%)
	All	-213 (-62%)	-298 (-69%)
August	Wet	56 (63%)	46 (46%)
	Above Normal	32 (128%)	25 (78%)
	Below Normal	38 (100%)	24 (46%)
	Dry	54 (135%)	30 (47%)
	Critical	31 (74%)	11 (18%)
	All	210 (90%)	135 (44%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because rearing habitat conditions would not be substantially reduced. Both SacEFT and SALMOD predicts no substantial effects on spring-run rearing habitat in the Sacramento River. In the Feather River, habitat conditions would improve under Alternative 4A relative to the NAA_ELT, particularly in the H4 scenario. There would be no effects on spring-run Chinook salmon rearing in Clear Creek.

CEQA Conclusion: In general, Alternative 4A could reduce the quantity and quality of rearing habitat for spring-run Chinook salmon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of rearing habitat for spring-run Chinook salmon relative to the CEQA baseline.

H3_ELT /ESO_ELT

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). At Keswick, mean flows under H3_ELT would be up to 14% greater during February, up to 18% lower during November, and similar in the remaining three months. Upstream of Red Bluff, mean flows under H3_ELT would generally be similar to those under Existing Conditions throughout the period. These results indicate that there would be very little reduction in flows due to H3_ELT in the Sacramento River.

As reported in Impact AQUA-40, Shasta Reservoir mean storage volume at the end of May under H3_ELT would be similar to volume under Existing Conditions for all water years types (Table 11-4A-19). As reported in AQUA-58, Shasta Reservoir storage volume at the end of September under H3_ELT would be up to 11% lower relative to Existing Conditions (Table 11-4A-27).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both sites, mean water temperature under H3_ELT would be similar to (<5%) those under Existing Conditions in all months except for July through October at Keswick, in which temperatures in critical years would be 14% higher for August, 10% higher for September, and 9% higher for July under H3_ELT. Temperatures in the other year types in July through October would be up to 8% higher under H3_ELT.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under H3_ELT would be 27% higher than under Existing Conditions (Table 11-4A-31). In addition, the percentage of years with good (low) juvenile stranding risk under H3_ELT is predicted to be 5% higher than under Existing Conditions. This indicates that the quantity and quality of juvenile rearing habitat in the Sacramento River would be higher under H3_ELT relative to Existing Conditions.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality under H3_ELT would be 9% lower than under Existing Conditions.

Clear Creek

Flows in Clear Creek during the November through March rearing period under H3_ELT would generally be similar to flows under Existing Conditions, except during January and February of wet year types, in which flows would be 40% and 13% greater, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Relatively constant flows in the low-flow channel throughout the November through June rearing period under H3_ELT would not differ from those under Existing Conditions. In the high-flow channel, flows under H3_ELT during January through March, November, and December would be up to 48% lower than flows under Existing Conditions, and during April through June would be up to 140% greater than flows under Existing Conditions.

May Oroville mean storage volume under H3_ELT would be 12% lower than volume under Existing Conditions in dry year types and generally similar to volume under Existing Conditions in other water year types (Table 11-4A-42).

As reported in Impact AQUA-58, September Oroville mean storage volume under H3_ELT would be similar to or up to 29% lower than storage volume under Existing Conditions depending on water year type (Table 11-4A-33).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean water temperatures under H3_ELT would be similar (<5%) for all months and water year types. In the high-flow channel, mean water temperatures under H3_ELT would be similar for all months and water years types except July of critical years (6.5% higher) and August of dry years (5.3% higher).

Effects of H3_ELT on water temperature-related effects on spring-run Chinook salmon juvenile rearing conditions in the Feather River were analyzed by comparing the percent of months during May and June over the 82-year CALSIM modeling period that exceed a 63°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4A-43). Although spring-run typically rear in the Feather River from November through June, NMFS requested that these months be evaluated to be consistent with water temperature targets set during the Oroville Dam FERC relicensing process, and evaluated in the NMFS (2009) Draft BiOp on the Oroville Dam project. As indicated in Table 11-4A-13, this criterion applies to both spring-run Chinook salmon and steelhead rearing. Therefore, the months of interest to spring-run Chinook salmon here are May and June only. The steelhead analysis below includes the remaining months. In general, the percent of months exceeding the threshold under H3_ELT would be similar or up to 20% greater (absolute difference) than those under Existing Conditions. This comparison includes the effects of climate change.

The effects of H3_ELT on water temperature-related juvenile rearing conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 63°F NMFS threshold during May through August for all 82 years (Table 11-4A-44). As discussed above, although this table includes results through August, only May and June results apply to spring-run Chinook salmon. The steelhead analysis below includes the remaining months. Combining all water year types, there would be a very small difference (5 degree-months) between Existing Conditions and H3_ELT during May, but 47 degree-month increases for June. These comparisons include the effects of climate change.

H4_ELT/HOS_ELT

Sacramento River

Mean flows in the Sacramento River between Keswick and upstream of RBDD under H4_ELT during the September through January spring-run Chinook salmon spawning and egg incubation period would generally be similar to or slightly lower than flows under Existing Conditions during January and October through December, and would be up to 20% lower and 53% higher in September. September mean Shasta storage volume under H4_ELT would be similar to or up to 12% lower than storage volume under Existing Conditions (Table 11-4A-36).

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, there would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month or water year type.

Clear Creek

Flows in Clear Creek during the November through March rearing period under H4_ELT would generally be similar to or up to 40% higher than flows under Existing Conditions. Therefore, effect of H4_ELT regarding larval and juvenile spring-run Chinook salmon rearing habitat in Clear Creek would be similar to or beneficial relative to Existing Conditions.

Feather River

Flows in the Feather River low-flow channel during November through June would not differ between Existing Conditions and H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). In the high-flow channel, mean flows under H4_ELT would be up to 36% lower than flows under Existing Conditions during November through March and up to 509% greater than flows under Existing Conditions during April through June.

May Oroville mean storage volume under H4_ELT would be 11% to 19% lower relative to Existing Conditions except in critical water years, in which storage would be 15% greater (Table 11-4A-45). September Oroville mean storage under H4_ELT would be similar to storage under Existing Conditions in dry water years, 32% greater in critical water years, and about 24% lower in wet, above normal, and below normal water years (Table 11-4A-39).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, mean water temperatures under H4_ELT would be no different (<5%) as temperatures under Existing Conditions for all months and water year types.

Differences in the percent of months exceeding the 63°F threshold between Existing Conditions and H4_ELT would be negligible (<5% on an absolute scale) during May and between 0% and 17% (absolute difference) higher under H4_ELT during June (Table 11-4A-46). These comparisons include the effects of climate change.

Combining all water year types, total degree-months above the 63°F threshold under H4_ELT would be the same as those under Existing Conditions during May, but 68 and 213 degree-months lower than those under Existing Conditions for June and July, and 210 degree-months higher for August (Table 11-4A-47). Changes by water year type are the same direction (positive or negative) as the differences of the months that combined the water year types. These comparisons include the effects of climate change.

Summary of CEQA Conclusion

Under Alternative 4A, there would be small to moderate flow reductions and temperature increases in the Feather River. SacEFT predicts improvements to spawning habitat availability for spring-run Chinook salmon in the Sacramento River under Alternative 4A and SALMOD predict slightly reduced habitat conditions. Exceedances above NMFS temperature thresholds would be higher under

Alternative 4A relative to Existing Conditions. Results would be similar among model scenarios. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce rearing habitat and substantially reduce the number of spring-run Chinook salmon as a result of fry and juvenile mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 4A on flows, reservoir storage, and water temperatures during the months and locations analyzed would be minimal. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact would be less than significant and no mitigation is required.

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

In general, the effects of Alternative 4A on spring-run Chinook salmon migration conditions relative to the NAA_ELT are not adverse.

Upstream of the Delta

H3_ELT/ESO_ELT

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were evaluated during the December through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under NAA_ELT during this period.

Mean water temperatures in the Sacramento River at Red Bluff were examined during the December through May juvenile Chinook salmon spring-run emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type.

Flows in the Sacramento River upstream of Red Bluff were evaluated during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under NAA_ELT during this Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Mean Shasta Reservoir storage at the end of September under H3_ELT would be similar to storage under NAA_ELT (Table 11-4A-36).

Clear Creek

Mean flows in Clear Creek during the November through May juvenile Chinook salmon spring-run migration period under H3_ELT would be similar to flows under NAA_ELT throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean flows in Clear Creek during the April through August adult spring-run Chinook salmon upstream migration period under H3_ELT would generally be similar to flows under NAA_ELT, with minor exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under NAA_ELT in all months and water year types of the period, with minor exceptions.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be up to 50% lower than flows under NAA_ELT during July and August, up to 77% greater than flows under NAA_ELT during June, and generally similar to flows under NAA_ELT during April and May. Although these flow reductions would be of moderate to large magnitude, flows under H3_ELT during these months would generally exceed flows suggested by NMFS during the Alternative 4a planning process at similar or greater frequencies as those under NAA_ELT (Table 11-4A-48).

Therefore, these reduced flows would not affect spring-run Chinook salmon in a biologically meaningful way.

Table 11-4A-48. Differences (Percentage Differences) in the Percentage of Years Exceeding NMFS Suggested Minimum Flows in the Feather River High-Flow Channel (at Thermalito)

	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Above Normal Water Year Type		
October	0 (0%)	0 (0%)
November	0 (0%)	0 (0%)
December	9 (50%)	-9 (-25%)
January	-18 (-40%)	9 (50%)
February	9 (14%)	9 (14%)
March	9 (25%)	0 (0%)
April	0 (NA)	0 (NA)
May	9 (100%)	9 (100%)
June	9 (13%)	0 (0%)
July	0 (0%)	0 (0%)
August	9 (10%)	0 (0%)
September	36 (57%)	0 (0%)
Below Normal Water Year Type		
October	-15 (-18%)	0 (0%)
November	-8 (-10%)	0 (0%)
December	-7 (-25%)	0 (0%)
January	-36 (-83%)	0 (0%)
February	-14 (-33%)	7 (34%)
March	-14 (-67%)	0 (0%)
April	0 (NA)	0 (NA)
May	0 (NA)	0 (NA)
June	21 (33%)	14 (20%)
July	0 (0%)	0 (0%)
August	0 (0%)	0 (0%)
September	-29 (-36%)	-50 (-50%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

H4_ELT /HOS_ELT

Sacramento River

Mean flows under H4_ELT in the Sacramento River upstream of Red Bluff during the December through May juvenile spring-run Chinook salmon migration period would be similar to flows under NAA_ELT for all months and water year types of the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT during the April through August adult upstream migration period would also be similar to flows under NAA_ELT.

September Shasta storage volume under H4_ELT would be similar to storage volume under NAA_ELT except in critical water years, in which it would be 24% greater under H4_ELT (Table 11-4A-36).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Clear Creek

Mean flows under H4_ELT in Clear Creek during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effects of H4_ELT on juvenile or adult spring-run Chinook salmon migration in Clear Creek relative to NAA_ELT.

Feather River

Flows under H4_ELT were evaluated in the Feather River at the confluence with the Sacramento River during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT during November through March would generally be similar to flows under NAA_ELT, but would be up to 119% greater during April and May. Flows during July and August would be consistently lower than flows under NAA_ELT (up to 42% lower in August of wet years), although 42% greater in critical years during August. Flows during April through June would be similar to or up to 119% greater than flows under NAA_ELT. Flows under H4_ELT during these months would generally exceed flows suggested by NMFS during the Alternative 4a planning process at similar frequencies as those under NAA_ELT (Table 11-4A-49). Therefore, these reduced flows would not affect spring-run Chinook salmon in a biologically meaningful way.

Table 11-4A-49. Differences (Percentage Differences) in the Percentage of Years Exceeding NMFS Suggested Minimum Flows in the Feather River High-Flow Channel (at Thermalito) between Baseline and H4 Model Scenarios

	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Above Normal Water Year Type		
October	9.1 (12.5%)	9.1 (12.5%)
November	0 (0%)	0 (0%)
December	9.1 (50%)	-9.1 (-25%)
January	-18.2 (-40%)	9.1 (50%)
February	0 (0%)	0 (0%)
March	0 (0%)	-9.1 (-20%)
April	27.3 (NA)	27.3 (NA)
May	36.4 (400%)	36.4 (400%)
June	0 (0%)	-9.1 (-11.1%)
July	-9.1 (-9.1%)	-9.1 (-9.1%)
August	-18.2 (-20%)	-27.3 (-27.3%)
September	18.2 (28.6%)	-18.2 (-18.2%)
Below Normal Water Year Type		
October	-7.7 (-9.1%)	7.7 (11.1%)
November	0 (0%)	7.7 (11.1%)

March	0 (0%)	14.3 (201.4%)
April	42.9 (NA)	42.9 (NA)
May	35.7 (NA)	35.7 (NA)
June	14.3 (22.2%)	7.2 (10.1%)
July	-7.1 (-7.1%)	-7.1 (-7.1%)
August	-21.4 (-21.4%)	-21.4 (-21.4%)
September	-50 (-63.6%)	-71.4 (-71.4%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Through-Delta

Juveniles

Scenario H3_ELT operations would reduce OMR reverse flows (Appendix B, *Supplemental Modeling for Alternative 4A,* Section B.7), with a corresponding increase in net positive downstream flows, during the outmigration period of spring-run Chinook salmon through the interior Delta channels. Conditions under Scenario H3_ELT would result in slightly decreased overall average OMR flows in April and May relative to NAA_ELT, however overall average flows during these months would still be net positive (flowing towards the sea) because of relatively high average positive flows in wet water years, with negative mean negative flows in drier years of no less than around -1,500 cfs. OMR flows under Scenario H4_ELT would generally be improved compared to NAA_ELT conditions during all water year types throughout the migration period, or similar in April and May. These improved net positive downstream flows would be substantial benefits of the proposed operations.

Flows downstream of the north Delta intakes would be reduced, which may increase predation potential. During the juvenile spring-run Chinook salmon emigration period (December through May), mean monthly flows under Scenario H3_ELT in the Sacramento River below the NDD would be lower (13% to 22% reduced in monthly mean across years) compared to NAA_ELT. Mean flows by water-year type range from 2% lower in December of critical years up to 30% lower in April of above normal years. Under the high spring outflow Scenario, H4_ELT, mean flows during April and May would not decrease as much compared to NAA_ELT (4% to 9% lower under H4_ELT, compared to 18-22% lower under H3_ELT). As noted for winter-run Chinook salmon under the discussion of Impact AQUA-42, the modeling of NAA_ELT does not account for any flow entering the Yolo Bypass because of Fremont Weir modifications that would occur separately from Alternative 4A (but which are included in the modeling of H3_ELT and H4_ELT; see also section 4.1.1.3 of Section 4); this would slightly decrease the amount of water in the Sacramento River under NAA_ELT, so the above comparison of H3_ELT vs. NAA_ELT is conservative. Alternative 4A includes real-time biological and hydrological triggers developed by NMFS and DFW to adjust NDD operations to protect migrating salmonids above and beyond the operational criteria for NDD. Additional detail is provided in Chapter 3 Section 3.6.4.2.

As described above under *Predation Associated with Entrainment*, the three North Delta intake facilities proposed on the Sacramento River under Alternative 4A would attract predatory fish to the structure. Potential predation at the three North Delta intakes was estimated in two ways. As noted in Alternative 4, bioenergetics modeling with a median predator density predicts a predation loss of about 8,000 juveniles, or 0.2% of the spring-run juvenile population under Alternative 4A (Table 11-4A-26). In addition, the three intake structures and associated permanent bankline modifications would result in a permanent loss of up to 13.7 acres of aquatic habitat and the permanent modification of 2.6 miles of shoreline. A conservative assumption of 5% loss per intake would yield a cumulative loss of about 12% of juvenile spring-run Chinook salmon that reach the north Delta. This assumption is uncertain and represents an upper bound estimate. For a discussion of this topic see Impact AQUA-42 for Alternative 1A and additional discussion under Impact AQUA-42 of Alternative 4A for winter-run Chinook salmon.

As estimated by the Delta Passage Model, through-Delta survival under Scenario H3_ELT by juvenile spring-run Chinook salmon averaged 29% across all years, ranging from about 23% in drier years to 38% in wetter years (Table 11-4A-51). Scenario H3_ELT survival was slightly lower than NAA_ELT in both drier years (1.1% less survival, or 4.5% less in relative difference) and wetter years (3.1%

reduced survival, or 7.4% less in relative difference) (Table 11-4A-51). These results are based on operations that do not assume any adjustments made in real time to response to actual presence of fish.

Average survival under Scenario H4_ELT (high outflow) was 30.6%, compared to 30.7% for NAA_ELT. In wetter years, Scenario H4 had 1.7% greater survival, a 4% relative difference compared to NAA_ELT. This difference was driven by appreciably higher survival in wetter years (the above-normal year of 1980 and the wet year of 1984) as a result of greater outflow under Scenario H4_ELT. However, as noted for winter-run Chinook salmon in the discussion of Impact AQUA-42, the DPM modeling results do not account for the inclusion of Yolo Bypass improvements in NAA_ELT. Applying the same modification to NAA_ELT outputs as described in the discussion of Impact AQUA-42 resulted in the relative difference between NAA_ELT and H3_ELT/H4_ELT increasing: for H3_ELT, the relative difference across all years increased from 6% less compared to NAA_ELT to nearly 8% less compared to NAA_ELT (mod.); whereas for H4_ELT, the relative difference across all years increased from 0.3% less compared to NAA_ELT to 2.4% less compared to NAA_ELT (mod.) (Table 11-4A-51).

Table 11-4A-51. Through-Delta Survival (%) of Emigrating Juvenile Spring-Run Chinook Salmon under Alternative 4A (Scenarios H3_ELT and H4_ELT)

	Average Percentage Survival					Difference in Percentage Survival (Relative Difference)					
	Scenario					EXISTING CONDITIONS vs. Alt 4A Scenario		NAA_ELT vs. Alt 4A Scenario			
Water Year Type	EXISTING CONDITIONS	NAA_ ELT	NAA_ ELT (mod.)	H3_ ELT	H4_ ELT	H3_ELT	H4_ELT	H3_ELT	H4_ELT	H3_ELT (vs. NAA_ELT mod.)	H4_ELT (vs. NAA_EL T mod.)
Wetter Years	42.1	41.4	41.6	38.3	43.1	-3.8 (-9.1%)	0.9 (2.2%)	-3.1 (-7.4%)	1.7 (4.1%)	-3.3 (-7.9%)	1.4 (3.5%)
Drier Years	24.8	24.3	25.2	23.2	23.1	-1.6 (-6.4%)	-1.7 (-6.7%)	-1.1 (-4.5%)	-1.2 (-4.9%)	-2.0 (-7.9%)	-2.1 (-8.2%)
All Years	31.3	30.7	31.3	28.8	30.6	-2.5 (-8.0%)	-0.7 (-2.2%)	-1.8 (-6.0%)	-0.1 (-0.3%)	-2.5 (-7.9%)	-0.7 (-2.4%)

Note: Average Delta Passage Model results for survival to Chipps Island.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
Wetter = Wet and Above Normal Water Years (6 years).
Drier = Below Normal, Dry and Critical Water Years (10 years).
H3_ELT = ESO_ELT operations, H4_ELT = High Outflow.
NAA_ELT (mod.) = NAA_ELT with Yolo Bypass entry % and Yolo Bypass survival of H3_ELT.

Adults

As described for winter-run Chinook, attraction flows and olfactory cues in the west Delta would be altered because of shifts in exports from the south Delta to the north Delta. Flows in the Sacramento River downstream of the north Delta intake diversions would be reduced, with concomitant proportional increases in San Joaquin River flows. The flow changes under Scenario H3_ELT would slightly decrease the olfactory cues for migrating adult salmon in the Sacramento River (by 9% or less compared to NAA_ELT) and slightly increase the olfactory cues for the San Joaquin River (Table

11-4A-52). As noted for Alternative 4, the Sacramento River would still represent a substantial proportion of Delta outflows; the changes are within the typical range and behavioral response is uncertain. Conditions under Scenario H4_ELT are expected to reduce the magnitude of this effect because it would involve fewer exports from the north Delta compared to Scenario H3_ELT.

Table 11-4A-52. Percentage (%) of Water at Collinsville that Originated in the Sacramento during the Adult Spring-Run Chinook Salmon Migration Period for Alternative 4A (Scenario H3_ELT)

Month	EXISTING CONDITIONS	NAA_ELT	H3_ELT	EXISTING CONDITIONS vs. H3_ELT	NAA vs. H3_ELT
March	78	77	69	-9	-8
April	77	76	67	-10	-9
May	69	67	61	-8	-7
June	64	61	57	-7	-5
	Shading indicates 10% or greater absolute difference.				
Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).					

NEPA Effects: Upstream of the Delta, these modeling results indicate that the effect would not be adverse because it does not have the potential to substantially interfere with the movement of fish. Flows in the Sacramento River and Clear Creek, and water temperatures in the Sacramento and Feather Rivers would generally not be affected by Alternative 4A. Flows in the Feather River under Alternative 4A scenarios would be lower during summer months, although flows would otherwise be similar to or greater than the NEPA baseline and would generally exceed NMFS thresholds at similar or greater frequencies than those under the baseline.

Near-field effects of Alternative 4A NDD on spring-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating spring-run Chinook salmon, although there is high uncertainty regarding the overall effects. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 12% mortality above current baseline levels). As noted for Alternative 4, Environmental Commitment 15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, as described in the adaptive management and monitoring program in Section 4.1, several pre-construction studies to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Similarly, Alternative 4A also includes investigations to better understand factors affecting juvenile through-Delta migration (as described in the adaptive management and monitoring program in Section 4.1) and includes biologically-based triggers to inform real-time operations of the NDD, intended to provide adequate migration conditions for spring-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of predation-related mortality expected from near-field effects at the NDD remains highly uncertain.

As noted for Alternative 4 and as discussed for winter-run Chinook salmon above, two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 4A related to reduced interior Delta entry (Environmental Commitment 16) and reduced south Delta entrainment suggest that these could offset the far-field effects of reduced flow (see, for example, Table 5.C.5.3-36 in the *BDCP Effects Analysis Appendix 5.C hereby incorporated by reference*). As noted for winter-run Chinook salmon, the overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and will be investigated as part of the adaptive management and monitoring program described in Section 4.1.

As described for Alternative 4 and as discussed for winter-run Chinook salmon above, the DPM is a flow-based model incorporating flow-survival and junction routing relationships with flow modeling of Alternative 4a operations to estimate relative differences between scenarios in smolt migration survival throughout the entire Delta. The DPM predicted that smolt migration survival under Alternative 4A would be somewhat lower than survival estimated for NAA_ELT, based on operations assuming no adjustments made in real-time in response to actual presence of fish. Although refinements to the DPM are likely to occur based on new data available from future studies and the current analysis has some uncertainty, the DPM analysis of Alternative 4A on juvenile spring-run Chinook salmon migration suggests a potential adverse effect of small magnitude. As noted for winter-run Chinook salmon, the DPM focuses on smolt-sized individuals (70 mm or more) and is not based on survival data for fry-sized individuals, which also may be migrating and could be affected by Alternative 4A operations. There are no fry through-Delta survival data to inform the effects to these individuals in relation to operations and it is uncertain whether the relative difference between scenarios estimated from the DPM for smolt-sized fish would be representative of relative differences for fry. The potential adverse effect of Alternative 4A would be minimized through the bypass flow criteria and real-time operations outlined above, as well as inclusion within Alternative 4A of specific important Environmental Commitments. These include *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of spring-run Chinook salmon juveniles into the low-survival interior Delta.

CEQA Conclusion: In general, Alternative 4A would not substantially affect migration conditions for spring-run Chinook salmon relative to the CEQA baseline.

Upstream of the Delta

H3_ELT /ESO_ELT

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were examined during December through May juvenile spring-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions during all months and water year types of the period.

Mean water temperatures in the Sacramento River at Red Bluff were examined during the December through May juvenile Chinook salmon spring-run emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type.

Flows in the Sacramento River upstream of Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions, with minor exceptions.

Mean water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type.

Mean September Shasta Reservoir storage volumes under H3_ELT would be up to 11% lower than those under Existing Conditions (Table 11-4A-27).

Clear Creek

Flows in Clear Creek were examined during the November through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to or up to 40% greater than flows under Existing Conditions, depending on water year type.

Flows in Clear Creek were examined during the April through August adult spring-run Chinook salmon upstream migration period. Mean flows under H3_ELT would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to or up to 17% lower than flows under Existing Conditions during January through March, would be 19% lower in critical years and 18% higher in above normal years in December, and would be similar during November, April and May.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type.

Flows were examined for the Feather River at the confluence with the Sacramento River during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be up to 55% lower than flows under Existing Conditions during July and August, would be up to 71% greater in June, and similar during April and May. However, the frequencies of exceedance above flow thresholds suggested by NMFS during the Alternative 4a planning process under H3_ELT would be similar to those under Existing Conditions during the two periods in above normal water years (Table 11-4A-48). The frequencies of exceedance during the two periods in below normal water years would be lower during January through March.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month and water year type except July of critical years, in which temperatures under H3_ELT would be 6% greater.

H4_ELT/HOS_ELT

Sacramento River

Mean flows under H4_ELT in the Sacramento River upstream of Red Bluff during the December through May juvenile spring-run Chinook salmon migration period would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT during the April through August adult upstream migration period would generally be similar to flows under Existing Conditions.

Mean Shasta Reservoir storage at the end of September under H4_ELT would be similar to or up to 12% lower than storage under Existing Conditions (Table 11-4A-36).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT.

Clear Creek

Flows under H4_ELT in Clear Creek during the November through May juvenile spring-run Chinook salmon migration period would generally be similar to or up to 40% greater than flows under Existing Conditions, and flows during the April through August adult upstream migration period would generally be similar (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be occasional beneficial effects of H4_ELT on spring-run Chinook salmon migration conditions in Clear Creek relative to Existing Conditions.

Feather River

Flows under H4_ELT were evaluated in the Feather River at the confluence with the Sacramento River during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT during November through March would generally be similar to flows under Existing Conditions. Flows during April and May would be similar to or up to 112% greater than flows under Existing Conditions. Flows under H4_ELT during April through August would, as described above, be up to 112% greater in April and May than flows under Existing Conditions, but flows would be up to 51% lower in June through August

The exceedance of monthly minimum flows in the Feather River suggested by NMFS during the Alternative 4a planning process was evaluated for H4_ELT relative to Existing Conditions (Table 11-4A-49). The percent of years exceeding minimum flows would be lower under H4_ELT relative to Existing Conditions during January, July and August of both above normal and below normal water years.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT except in July and of critical years, for which temperatures under H4_ELT would be 5% higher.

Through-Delta

Juveniles

Scenario H3_ELT has lower through-Delta survival averaged across all years compared to Existing Conditions (2.5% reduced survival, or 8% less in relative difference) (Table 11-4A-51). Survival under the high outflow Scenario H4_ELT would be similar to Existing Conditions (0.7% less averaged for all years, a 2.2% relative difference), particularly in wetter years; this estimate does not account for the adjustments that can be made during real-time operations to further protect migrating spring-run Chinook. Overall reductions in OMR reverse flows under all flow scenarios for Alternative 4A would be beneficial (Appendix B, *Supplemental Modeling for Alternative 4A*, Section B.7). Conditions under Scenario H4_ELT would further improve OMR flow conditions (i.e., less reverse) relative to Scenario H3_ELT. Flows below the north Delta intakes would be reduced, which may increase predation potential. The impact is considered less than significant due to somewhat lower survival under Alternative 4A relative to Existing Conditions being minimized by bypass flow criteria, real-time operational adjustments based on biological and hydrological triggers developed by NMFS and DFW to adjust NDD operations to protect migrating salmonids, and the inclusion in Alternative 4A of Environmental Commitment 6, Environmental Commitment 15, and Environmental Commitment 16 (see additional discussion below).

Adults

As described above, attraction flows will be altered because of shifts in exports from the south Delta to the north Delta These changes would slightly decrease the olfactory cues for migrating adult salmon in the Sacramento River (reduced by 8–10% in March–May under the Scenario H3_ELT compared to Existing Conditions) and slightly increase olfactory cues for the San Joaquin River (Table 11-4A-52). Conditions between all flow scenarios under Alternative 4A would be similar; there would only be small changes in olfactory cues for migrating adult spring-run Chinook salmon. Overall, impacts related to migration conditions for spring-run Chinook salmon are considered less than significant.

Summary of CEQA Conclusion

Collectively, the results indicate that the effects would be less than significant because it would not substantially reduce the suitability of migration habitat or interfere with the movement of fish. Flows in the Sacramento River and Clear Creek and water temperatures in the Sacramento and Feather Rivers would generally not be affected by Alternative 4A. Flows would be lower in 2 months of the 5-month adult migration period in the Feather River, although flows generally exceed NMFS thresholds as often as flows under the CEQA baseline throughout the period. Reductions in spring-run Chinook salmon juvenile survival under Alternative 4A relative to Existing Conditions suggested by the DPM would be limited during all water year types by bypass flow criteria, real-time operational adjustments, and the inclusion in Alternative 4A of Environmental Commitment 6, Environmental Commitment 15, and Environmental Commitment 16 (see additional discussion below). Additionally, as described in the adaptive management and monitoring program in Section 4.1, several pre-construction studies to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Similarly, Alternative 4A also includes investigations to better understand factors affecting juvenile through-Delta migration (as described in the adaptive management and monitoring program in Section 4.1) and includes biologically based triggers for real time operations. With incorporation of these measures and the lack of difference in adult migration cues between Alternative 4A scenarios and Existing Conditions, the impact would be less than significant. No mitigation is necessary.

Restoration Measures (Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

As described for winter-run Chinook salmon, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A, upon which the discussion of impacts for Alternative 4 is based. The general discussion of impacts to winter-run Chinook salmon (Impacts AQUA-43, AQUA-44, and AQUA-45) also applies to spring-run Chinook salmon.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-43) is also applicable to spring-run Chinook salmon.

NEPA Effects: For the same reasons described under Impact AQUA-43, the effects of short-term construction activities would not be adverse to spring-run Chinook salmon because effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and implementing the commitments described in detail under Impact AQUA-1 and in Appendix 3B, *Environmental Commitments*.

CEQA Conclusion: As discussed for winter-run Chinook salmon, habitat restoration activities could result in short-term effects on spring-run Chinook salmon, primarily as a result of increased potential for contaminated sediments to enter the water column. However, these effects are likely to be localized, sporadic, and of low magnitude. Adverse effects during restoration would be avoided by limiting the frequency, duration, and spatial extent of in-water work and implementing the commitments described in detail under Impact AQUA-1 and in Appendix 3B, *Environmental Commitments*. The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce spring-run Chinook salmon habitat, restrict its range or interfere with its movement. Additionally, there would be substantial long-term net benefits of habitat restoration. Consequently, no additional mitigation would be required.

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-44) is also applicable to spring-run Chinook salmon.

NEPA Effects: As noted for winter-run Chinook salmon, the effect of restoration measures on chemical contaminants is not adverse to spring-run Chinook salmon with respect to selenium, copper, ammonia, pesticides, and methylmercury (with implementation of Environmental Commitment 12).

CEQA Conclusion: As noted for winter-run Chinook salmon, the impact of contaminants is considered less than significant. Alternative 4A restoration actions are likely to result in slightly increased production, mobilization, and bioavailability of methylmercury. However, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury from restoration areas and it would not substantially affect spring-run Chinook salmon either directly or through habitat modifications. Consequently, no mitigation would be required.

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-45) is also applicable to spring-run Chinook salmon.

NEPA Effects: The effects of restored habitat conditions on spring-run Chinook salmon would not be adverse because restoration is intended to provide habitat benefits to Chinook salmon.

CEQA Conclusion: As described for winter-run Chinook salmon, habitat restoration would be undertaken to offset loss/modification of habitat from water facility construction and operation. The effects of restored habitat conditions on spring-run Chinook salmon would be less than significant. Consequently, no mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

As noted for winter-run Chinook salmon, Alternative 4A includes three other Environmental Commitments, which are reduced in their extent relative to the Conservation Measures included in other Alternatives (e.g., Alternative 1A and Alternative 4). While the extent of these measures is reduced compared to these alternatives, the nature of the mechanisms remains the same. The general discussion of impacts to winter-run Chinook salmon (Impacts AQUA-46, AQUA-49, and AQUA-50) also applies to spring-run Chinook salmon.

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (Environmental Commitment 12)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-46) is also applicable to spring-run Chinook salmon.

NEPA Effects: The effects of methylmercury management on spring-run Chinook salmon would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As noted for winter-run Chinook salmon, effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts would be less than significant. Consequently, no mitigation is required.

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (Environmental Commitment 15)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-49) is also applicable to spring-run Chinook salmon.

NEPA Effects: As noted for winter-run Chinook salmon, Environmental Commitment 15 would not have adverse impacts and could benefit spring-run Chinook salmon. Due to the uncertainty in the effectiveness of Environmental Commitment 15, however, it is concluded that there would be no demonstrable effect of this conservation measure on spring-run Chinook salmon.

CEQA Conclusion: As noted for winter-run Chinook salmon, Environmental Commitment 15 would not have a significant impact and could benefit spring-run Chinook salmon. Due to the uncertainties associated with this Environmental Commitment, however, it is concluded that there would be no demonstrable effect on spring-run Chinook salmon. Consequently, no mitigation would be required.

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (Environmental Commitment 16)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-50) is also applicable to spring-run Chinook salmon.

NEPA Effects: The effects of the NPB would not be adverse because it is intended to improve migratory conditions for juvenile Sacramento River salmon.

CEQA Conclusion: As concluded for winter-run Chinook salmon, the impacts of *Environmental Commitment 16 Nonphysical Fish Barriers* are expected to be less than significant because it is intended to improve migratory conditions for juvenile Sacramento River salmon. Consequently, no mitigation would be required.

Fall-/Late Fall–Run Chinook Salmon

Construction and Maintenance of Water Conveyance Facilities

The discussion of potential effects to delta smelt from construction and maintenance of Water Conveyance Facilities under Alternative 4A is also relevant to fall-run/late fall-run Chinook salmon. Adult and juvenile fall-run/late fall-run Chinook salmon would have the potential to overlap construction and maintenance to a minor degree (Table 11-8).

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

The potential effects of construction of the water conveyance facilities on fall-run/late fall-run Chinook salmon would be the same as those described for Alternative 4, Impact AQUA-73.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-73, the effect would not be adverse for fall-run/late fall-run Chinook salmon.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-73, the impact of construction of the water conveyance facilities on fall-run/late fall-run Chinook salmon would not be significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect Chinook salmon. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on Chinook salmon from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1.The potential effects of the maintenance of the water conveyance facilities under Alternative 4A would be the same as those described for Alternative 4, Impact AQUA-74. The impact would not be adverse for fall-run/late fall-run Chinook salmon.

CEQA Conclusion: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect Chinook salmon. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on Chinook salmon from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1.As described in Alternative 4, Impact AQUA-74, the impact of maintenance of the water conveyance facilities on fall-run/late fall-run Chinook salmon would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Overall entrainment under Alternative 4A at the south Delta export facilities would be reduced for all water year types (Table 11-4A-53). Under Scenario H3_ELT, average entrainment across all years would be reduced 42% (~24,000 fish) for fall-run Chinook salmon and reduced 33% (643 fish) for late fall-run Chinook salmon compared to NAA_ELT.

Table 11-4A-53. Juvenile Fall-Run and Late Fall-Run Chinook Salmon Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 4A (Scenario H3_ELT)

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Fall-run Chinook Salmon		
Wet	-79,680 (-62%)	-85,155 (-64%)
Above Normal	-13,483 (-41%)	-14,279 (-42%)
Below Normal	-4,120 (-30%)	-3,951 (-29%)
Dry	933 (5%)	-760 (-4%)
Critical	-13,262 (-32%)	-11,208 (-29%)
All Years	-22,380 (-41%)	-23,707 (-42%)
Late fall-run Chinook Salmon		
Wet	-2,724 (-46%)	-2,895 (-47%)
Above Normal	-225 (-39%)	-223 (-39%)
Below Normal	-24 (-43%)	-26 (-45%)
Dry	-39 (-28%)	-30 (-23%)
Critical	-35 (-22%)	-25 (-16%)
All Years	-622 (-32%)	-643 (-33%)
	Shading indicates10% or greater increased entrainment.	

Note: Estimated annual number of fish lost, based on normalized data.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

The annual juvenile population that approaches the Delta is assumed to be 23 million fall-run Chinook salmon and 1 million late fall-run Chinook salmon (juvenile index of abundance). The proportion of juvenile index of abundance lost at the south Delta facilities is very low for both runs under NAA_ELT (fall-run 0.24%, late fall-run 0.20% averaged for all years), and under Scenario H3_ELT decreases to negligible levels (fall-run 0.14%; late fall-run 0.13%).

Lower south Delta export pumping during the spring under Scenario H4_ELT would result in lower entrainment during this period than under Scenario H3_ELT.

Water Exports from SWP/CVP North Delta Intake Facilities

The impact would be similar in type to Alternative 1A, but the degree would be less because Alternative 4A would have fewer intakes. Thus under Alternative 4A there would be about a 40% reduction in impingement and predation risk relative to Alternative 1A (Impact AQUA-75).

Predation Associated with Entrainment

Entrainment-related predation loss at the south Delta facilities would be no greater and may be lower than NAA_ELT, due to a reduction in entrainment loss. Scenario H3_ELT entrainment-related predation losses are expected to decrease under Scenario H4_ELT.

Predation at the north Delta would be increased due to the installation of the proposed SWP/CVP North Delta intake facilities on the Sacramento River, although the magnitude of this increase is uncertain. Bioenergetics modeling with a median predator density predicts a predation loss under Alternative 4A of less than 0.6% of the annual juvenile production (155,000 fall-run juveniles, 0.24% annual production; 25,000 late fall-run juveniles, 0.57% annual production) (Table 11-4A-54). Note that this estimate does not provide context to the level of predation in this reach that would occur without implementation of Alternative 4A. See additional discussion under Impact AQUA-78.

Table 11-4A-54. Fall-Run and Late Fall-Run Chinook Salmon Juvenile Predation Loss at the Proposed North Delta Diversion (NDD) Intakes for Alternative 4A (Three Intakes)

Striped Bass at NDD (Three Intakes)			Fall-Run Chinook		Late Fall-Run Chinook	
Density	Bass per 1,000 Feet of Intake	Total Number of Bass	Number Consumed	Percentage of Annual Production Entering the Delta[1]	Number Consumed	Percentage of Annual Production Entering the Delta[1]
Low	18	86	22,025	0.04%	3,703	0.09%
Median	119	571	145,610	0.24%	24,483	0.57%
High	219	1,051	267,971	0.44%	45,056	1.05%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (Appendix 5F Biological Stressors).

[1] Estimated as 61.6 million for fall-run and 4.3 million for late fall-run. See Section 5.F.3.2.1 in *BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference.

NEPA Effects: In conclusion, Alternative 4A would reduce overall entrainment and associated predation losses of juvenile fall-run Chinook salmon and late fall-run Chinook salmon relative to NAA_ELT. The population benefit would be minor because entrainment losses affect a small proportion of the total juvenile population. Conditions under Scenario H4_ELT would further reduce entrainment losses compared to Scenario H3_ELT. The effect of Alternative 4A would not be adverse.

CEQA Conclusion: Scenario H3_ELT would substantially reduce entrainment at the south Delta facilities for fall-run (41% less) and late fall-run Chinook salmon (32% less) compared to Existing Conditions. Proportional losses of the juvenile population (juvenile index of abundance) would be slightly reduced from already-low levels (less than 0.25% on average). Under Scenario H4_ELT, entrainment losses are expected to further decrease relative to Existing Conditions. Overall, impacts to fall-run and late fall-run Chinook salmon under Alternative 4A would be less than significant. No mitigation would be required.

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 4A would not affect the quantity and quality of spawning and egg incubation habitat for fall-/late fall-run Chinook salmon relative to the NAA_ELT.

H3_ELT/ESO_ELT

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to NAA_ELT during October through January, except for November, in which flow would be up to 18% lower.

Shasta Reservoir storage at the end of September would affect flows during the fall-run spawning and egg incubation period. As reported in Impact AQUA-58, mean end of September Shasta Reservoir storage under H3_ELT would be similar to storage under NAA_ELT in all water year types (Table 11-4A-27).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month, during October through April, and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H3_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-28. There would be 1 (5%) more years with a "red" level of concern under H3_ELT relative to NAA_ELT. This difference would not be biologically meaningful to fall-run Chinook salmon spawners and eggs.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H3_ELT would be 11 degree-days (19% higher) than those under NAA_ELT during March, but were similar during the remaining months (Table 11-4A-29). This total degree-day difference during March across 82 years would correspond to a negligible difference per day. Therefore, this would not result in a negative effect on fall-run Chinook salmon spawning and egg incubation.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under H3_ELT would be similar to mortality under NAA_ELT in all water year types except below normal years, for which mortality under H3_ELT would be 11% higher (Table 11-4A-55). However, the corresponding absolute increase would be 2% of the fall-run population, which is not substantial. (Therefore, these results indicate that H3_ELT would have negligible effects on fall-run Chinook salmon egg mortality.

Table 11-4A-55. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	4 (40%)	0.2 (1%)
Above Normal	5 (46%)	1 (7%)
Below Normal	7 (62%)	2 (11%)
Dry	7 (47%)	-0.4 (-2%)
Critical	5 (18%)	-0.3 (-1%)
All	5 (39%)	0.4 (2%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

SacEFT predicts that there would be a 33% increase in the percentage of years with good spawning habitat availability for fall-run Chinook salmon, measured as weighted usable area, under H3_ELT relative to NAA_ELT (Table 11-4A-56). SacEFT predicts that there would be a 12% reduction in the percentage of years with good (lower) redd scour risk under H3_ELT relative to NAA_ELT. SacEFT predicts that there would be no difference in the number of years with good egg incubation conditions between H3_ELT and NAA_ELT. SacEFT predicts that there would be a 7% decrease in the number of years with good redd dewatering risk conditions under H3_ELT relative to NAA_ELT.

Table 11-4A-56. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Fall-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3_ELT	NAA vs. H3_ELT
Spawning WUA	9 (19%)	14 (33%)
Redd Scour Risk	-3 (-5%)	-8 (-12%)
Egg Incubation	-5 (-5%)	0 (0%)
Redd Dewatering Risk	0 (0%)	-2 (-7%)
Juvenile Rearing WUA	1 (3%)	-4 (-11%)
Juvenile Stranding Risk	-8 (-26%)	0 (0%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
WUA = Weighted Usable Area.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to flows under NAA_ELT during February through May.

Shasta Reservoir storage at the end of September would affect flows during the fall-run spawning and egg incubation period. As reported in Impact AQUA-58, end of September Shasta Reservoir storage under H3_ELT would be similar to storage under NAA_ELT in all water year types (Table 11-4A-27).

The Reclamation egg mortality model predicts that late fall-run Chinook salmon egg mortality in the Sacramento River under H3_ELT would be similar to or lower than mortality under NAA_ELT in all water years (Table 11-4A-57).

Table 11-4A-57. Difference and Percent Difference in Percent Mortality of Late Fall-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA vs. H3_ELT
Wet	2 (80%)	-0.1 (-3%)
Above Normal	1 (48%)	-1 (-14%)
Below Normal	2 (120%)	0.1 (3%)
Dry	2 (69%)	-0.1 (-2%)
Critical	1 (60%)	0 (0%)
All	2 (76%)	-0.1 (-3%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month, during October through April, and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H3_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-28. There would be 1 (5%) more year with a "red" level of concern under H3_ELT. This difference would not be biologically meaningful to late fall-run Chinook salmon spawners and eggs.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H3_ELT would be 19% higher than those under NAA _ELT during March and similar during the remaining months (Table 11-4A-29).

SacEFT predicts that there would be difference 6% reduction in in the percentage of years with good spawning availability for late fall-run Chinook salmon, measured as weighted usable area, between NAA_ELT and H3_ELT (Table 11-4A-58). SacEFT predicts that there would be a 1% reduction in redd scour risk between NAA_ELT and H3_ELT. SacEFT predicts that there would be no difference in the percentage of years with good (lower) egg incubation conditions and redd dewatering risk between H3_ELT and NAA_ELT.

Table 11-4A-58. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Late Fall-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Spawning WUA	-7 (-13%)	-3 (-6%)
Redd Scour Risk	-3 (-4%)	-1 (-1%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	-6 (-10%)	0 (0%)
Juvenile Rearing WUA	-2 (-4%)	-14 (-25%)
Juvenile Stranding Risk	-21 (-29%)	-9 (-15%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
WUA = Weighted Usable Area.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Clear Creek flows below Whiskeytown Reservoir were examined for the September through February fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under NAA_ELT.

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning is assumed to occur. The greatest monthly reduction in Clear Creek flows during September through February under H3_ELT would be the same as those under NAA_ELT for all water year types (Table 11-4A-59).

Table 11-4A-59. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through February Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0 (NA)	0 (NA)
Above Normal	-41 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-67 (NA)	0 (0%)
Critical	-33 (-50%)	0 (0%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.
[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Fall-Run

Flows in the Feather River in the low-flow and high-flow channels were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the low-flow channel under H3_ELT would be identical to those under NAA_ELT. Flows in the high-flow channel under H3_ELT would generally be similar to than those under NAA_ELT, with a few exceptions.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel during November through January were identical between H3_ELT and NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of H3_ELT on redd dewatering in the Feather River low-flow channel.

Mean monthly water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location.

Effects of H3_ELT on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were analyzed by comparing the percent of months between October through April over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold at Gridley (Table 11-4A-60). In general, differences in the percent of months exceeding the threshold between NAA_ELT and H3_ELT would be negligible (<5% on an absolute scale), although there would be a 5% reduction (absolute difference) in months exceeding the threshold by >5°F during October.

Table 11-4A-60. Differences between Baseline and H3_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 56°F Threshold, October through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3_ELT					
October	0 (0%)	7 (9%)	11 (15%)	25 (61%)	26 (140%)
November	14 (367%)	5 (400%)	2 (NA)	0 (NA)	0 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	15 (200%)	5 (133%)	4 (300%)	1 (NA)	1 (NA)
April	9 (12%)	12 (22%)	20 (64%)	12 (71%)	7 (67%)
NAA_ELT vs. H3_ELT					
October	-1 (-1%)	-1 (-1%)	0 (0%)	-1 (-2%)	-5 (-10%)
November	1 (8%)	0 (0%)	0 (0%)	-1 (-100%)	0 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	4 (20%)	0 (0%)	0 (0%)	-1 (-50%)	0 (0%)
April	0 (0%)	1 (2%)	0 (0%)	0 (0%)	2 (15%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

The effects of H3_ELT on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months in the Feather River at Gridley for months that exceed the 56°F NMFS threshold during the October through April fall-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-4A-61). Combining all water year types, there would be little difference in total degree-months exceeded between NAA_ELT and H3_ELT. Overall, these methods, combined with other temperature analyses, indicate that there would be no effect of H3_ELT on temperature-related fall-run Chinook salmon spawning and egg incubation conditions in the Feather River.

Table 11-4A-61. Differences between Baseline and H3_ELT Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River at Gridley, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
October	Wet	32 (44%)	-2 (-2%)
	Above Normal	12 (27%)	-2 (-3%)
	Below Normal	13 (24%)	-4 (-6%)
	Dry	21 (40%)	-1 (-1%)
	Critical	18 (44%)	0 (0%)
	All	96 (36%)	-9 (-2%)
November	Wet	1 (NA)	0 (0%)
	Above Normal	3 (150%)	0 (0%)
	Below Normal	3 (300%)	0 (0%)
	Dry	6 (NA)	0 (0%)
	Critical	4 (400%)	0 (0%)
	All	17 (425%)	0 (0%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	1 (NA)	0 (0%)
	Above Normal	0 (0%)	1 (NA)
	Below Normal	7 (700%)	1 (14%)
	Dry	7 (175%)	0 (0%)
	Critical	6 (150%)	0 (0%)
	All	21 (210%)	2 (7%)
April	Wet	16 (114%)	1 (3%)
	Above Normal	9 (39%)	1 (3%)
	Below Normal	6 (15%)	0 (0%)
	Dry	18 (37%)	2 (3%)
	Critical	14 (48%)	3 (8%)
	All	63 (41%)	7 (3%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under H3_ELT would be similar to or lower than mortality under NAA_ELT in all water years, including above normal and below water years, in which, although there would be a 17% and 19% relative increase, the absolute increase would be 0.4% and 0.6% of the fall-run population, respectively (Table 11-4A-62). Therefore, this increase would not cause an overall effect to fall-run Chinook salmon.

Table 11-4A-62. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Feather River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	2 (107%)	0.2 (7%)
Above Normal	2 (145%)	0.4 (17%)
Below Normal	2 (106%)	0.6 (19%)
Dry	3 (127%)	-1 (-22%)
Critical	5 (110%)	-1 (-5%)
All	3 (119%)	-0.1 (-2%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would be similar to or up to 25% greater than flows under NAA_ELT during October, similar to or up to 15% lower than flows under NAA_ELT during November, and generally similar in December and January.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in October, when spawning is assumed to occur. The greatest reductions in American River flows during November through January under H3_ELT would range from 30% to 52% (absolute difference) greater in magnitude than under NAA_ELT in wet, below normal, and critical water years and 9% to 13% lower in magnitude than NAA_ELT in above normal and dry water years (Table 11-4A-63).

Table 11-4A-63. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in the American River at Nimbus Dam during the October through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA vs. H3_ELT
Wet	-18 (-83%)	-39 (NA)
Above Normal	15 (50%)	9 (37%)
Below Normal	-25 (-131%)	-30 (-197%)
Dry	32 (68%)	13 (45%)
Critical	-16 (-30%)	-52 (-329%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in October, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Mean water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4A-64). The percent of months exceeding the threshold under H3_ELT would generally be similar to the percent under NAA_ELT, except for the >5.0°F exceedance category during November, which would be 4% lower (absolute difference) under H3_ELT.

Table 11-4A-64. Differences between Baseline and H3_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 56°F Threshold, November through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3_ELT					
November	32 (70%)	35 (127%)	28 (209%)	26 (1050%)	14 (1100%)
December	1 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	6 (50%)	5 (67%)	5 (200%)	1 (100%)	2 (NA)
April	17 (25%)	12 (20%)	17 (38%)	17 (54%)	5 (18%)
NAA_ELT vs. H3_ELT					
November	-5 (-6%)	1 (2%)	-1 (-3%)	-2 (-8%)	-4 (-20%)
December	0 (0%)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	0 (0%)	-1 (-9%)	-2 (-25%)	0 (0%)	0 (0%)
April	0 (0%)	0 (0%)	-1 (-2%)	0 (0%)	0 (0%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4A-65). Total degree-months would be similar between NAA_ELT and H3_ELT for all months.

Table 11-4A-65. Differences between Baseline and H3 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the American River at the Watt Avenue Bridge, November through April

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
November	Wet	34 (136%)	-5 (-8%)
	Above Normal	16 (145%)	-1 (-4%)
	Below Normal	22 (275%)	-4 (-12%)
	Dry	25 (192%)	-1 (-3%)
	Critical	19 (119%)	1 (3%)
	All	116 (159%)	-10 (-5%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	1 (NA)	0 (0%)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	1 (NA)	0 (0%)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	2 (100%)	0 (0%)
	Above Normal	3 (NA)	0 (0%)
	Below Normal	2 (67%)	0 (0%)
	Dry	3 (75%)	-2 (-22%)
	Critical	6 (60%)	-1 (-6%)
	All	16 (84%)	-3 (-8%)
April	Wet	22 (79%)	0 (0%)
	Above Normal	14 (64%)	0 (0%)
	Below Normal	15 (42%)	-1 (-2%)
	Dry	15 (20%)	0 (0%)
	Critical	14 (24%)	-2 (-3%)
	All	80 (36%)	-3 (-1%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under H3_ELT would be similar to mortality under NAA_ELT (Table 11-4A-66).

Table 11-4A-66. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the American River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	15 (99%)	-0.2 (-1%)
Above Normal	14 (130%)	-1 (-3%)
Below Normal	13 (105%)	0.3 (1%)
Dry	10 (59%)	0 (0%)
Critical	4 (19%)	0 (0%)
All	12 (77%)	0 (0%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to flows under NAA_ELT throughout the period.

Water temperatures throughout the Stanislaus River would be similar under NAA_ELT and H3_ELT throughout the October through January period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to flows under NAA_ELT throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences in mean flows between H3_ELT and NAA_ELT throughout the period for all water year types

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT /HOS_ELT

Sacramento River

Fall-Run

Mean flows in the Sacramento River upstream of Red Bluff during October through January under H4_ELT would be similar to flows under NAA_ELT, except during November in which flows would be up to 15% lower, depending on water year type) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

September Shasta mean storage volume under H4_ELT would be similar to storage volume under NAA_ELT, except in critical water years, in which storage volume would be 24% greater under H4_ELT (Table 11-4A-36).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H4_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-67. There would be 6 (27%) more years without any of the three levels of concern, under H4_ELT relative to NAA_ELT. These results suggest that water temperatures would improve for fall-run Chinook salmon spawning and egg incubation in the Sacramento River under H4_ELT.

Table 11-4A-67. Differences between Baseline Scenarios and H4_ELT Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Red Bluff, October through April

Level of Concern[a]	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Red	9 (75%)	0 (0%)
Orange	2 (33%)	-5 (-38%)
Yellow	12 (92%)	-1 (-4%)
None	-23 (-45%)	6 (27%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
[a] For definitions of levels of concern, see Table 11-4A-14.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H4_ELT would be 10% lower than those under NAA_ELT for October, 20% lower for November, 16% higher for March, and would be similar for the remaining four months (Table 11-4A-68). The largest difference in degree-days would be the 353 degree-day reduction for October.

Table 11-4A-68. Differences between Baseline and H4_ELT Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Red Bluff, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA vs. H4_ELT
October	Wet	406 (158%)	-16 (-2%)
	Above Normal	191 (73%)	-6 (-1%)
	Below Normal	229 (110%)	-29 (-6%)
	Dry	286 (58%)	-88 (-10%)
	Critical	201 (34%)	-214 (-21%)
	All	1,313 (72%)	-353 (-10%)
November	Wet	7 (700%)	-1 (-11%)
	Above Normal	4 (NA)	1 (33%)
	Below Normal	1 (NA)	-1 (-50%)
	Dry	31 (388%)	-11 (-22%)
	Critical	13 (325%)	-5 (-23%)
	All	56 (431%)	-17 (-20%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	1 (NA)	0 (0%)

	Below Normal	99 (125%)	5 (3%)
	Dry	118 (63%)	11 (4%)
	Critical	49 (408%)	7 (13%)
	All	431 (81%)	19 (2%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Due to similar Sacramento River flows, reservoir storage, and water temperatures between H4_ELT and H3_ELT, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H4_ELT would be similar to results for analyses under H3_ELT. As a result, these additional analyses were not conducted for H4_ELT. Overall, results for H4_ELT would be similar to those for H3_ELT.

Late Fall-Run

There would be no difference (<5%) in mean flows in the Sacramento River upstream of Red Bluff during February through May between NAA_ELT and H4_ELT in any month or water year type throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

September Shasta mean storage volume under H4_ELT would be similar to storage volume under NAA_ELT except in critical water years, in which storage volume would be 24% greater under H4_ELT (Table 11-4A-36).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H4_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-67. There would be 6 (27%) more years without any of the three levels of concern, under H4_ELT relative to NAA_ELT. These results indicate that water temperature conditions would improve for late fall-run Chinook salmon spawning and egg incubation in the Sacramento River under H4_ELT.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H4_ELT would be 10% lower than those under NAA_ELT for October, 20% lower for November, 16% higher for March, and would be similar for the remaining four months (Table 11-4A-68). The largest difference in degree-days would be the 353 degree-day reduction for October, which would correspond to a <0.2°F change per day, which is not expected to affect spawning and egg incubation.

Due to similar Sacramento River flows, reservoir storage, and water temperatures between H4_ELT and H3_ELT, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H4_ELT would be similar to results for analyses under H3_ELT. As a result, these additional analyses were not conducted for H4_ELT. Overall, results for H4_ELT would be similar to those for H3_ELT.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

There would be no differences (<5%) between H4_ELT and NAA_ELT in mean flows in Clear Creek below Whiskeytown Reservoir during October through January for any month or water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Fall-Run

Mean flows in the Feather River low-flow channel during October through January would be the same (<5%) between H4_ELT and NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT in the high-flow channel would generally be similar to those under NAA_ELT, with minor exceptions.

Differences in the percent of months exceeding the 56°F NMFS threshold between NAA_ELT and H4_ELT would be negligible (<5% on an absolute scale) during all months except October, March, and April, in which the percent of months under H4_ELT would be similar to or up to 20% lower than (absolute difference) those under NAA_ELT (Table 11-4A-69). This method indicates that there would be benefits of H4_ELT on temperature-related fall-run Chinook salmon spawning and egg incubation conditions in the Feather River.

Table 11-4A-69. Differences between Baselines and H4_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 56°F Threshold, October through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H4_ELT					
October	1 (1%)	7 (9%)	5 (7%)	22 (55%)	26 (140%)
November	12 (333%)	9 (700%)	4 (NA)	0 (NA)	0 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	2 (33%)	2 (67%)	2 (200%)	1 (NA)	0 (NA)
April	-11 (-16%)	-6 (-11%)	2 (8%)	2 (14%)	-1 (-11%)
NAA_ELT vs. H4_ELT					
October	0 (0%)	-1 (-1%)	-6 (-7%)	-4 (-6%)	-5 (-10%)
November	0 (0%)	4 (60%)	1 (50%)	-1 (-100%)	0 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-9 (-47%)	-2 (-29%)	-1 (-25%)	-1 (-50%)	-1 (-100%)
April	-20 (-25%)	-17 (-25%)	-17 (-34%)	-10 (-33%)	-6 (-38%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Combining all water year types, there would be no difference between NAA_ELT and H4_ELT in total degree-months exceeded in all months except October, November, March, and April. For October and November, degree-months would be higher by 8% and 62%, respectively, while for March and April they would be lower by 14% and 19%, respectively (Table 11-4A-70). Splitting monthly results into water year types yields highly variable outcomes. There would be small increases and decreases in degree-months under H4_ELT relative to NAA_ELT depending on month and water year type. Large relative differences between NAA _ELT and H4_ELT during some months and water year types are mathematical artifacts due to small values of degree-months for NAA_ELT and would not translate into biologically meaningful effects on fall-run Chinook salmon. Overall, this method indicates that there would be no effects of H4_ELT on temperature-related fall-run Chinook salmon spawning and egg incubation conditions in the Feather River.

Table 11-4A-70. Differences between Baselines and H4_ELT Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River at Gridley, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
October	Wet	47 (64%)	13 (12%)
	Above Normal	15 (34%)	1 (2%)
	Below Normal	24 (44%)	7 (10%)
	Dry	31 (58%)	9 (12%)
	Critical	18 (44%)	0 (0%)
	All	135 (51%)	30 (8%)
November	Wet	8 (NA)	7 (700%)
	Above Normal	3 (150%)	0 (0%)
	Below Normal	7 (700%)	4 (100%)
	Dry	10 (NA)	4 (67%)
	Critical	2 (200%)	-2 (-40%)
	All	30 (750%)	13 (62%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)

	Critical	6 (150%)	0 (0%)
	All	15 (150%)	-4 (-14%)
April	Wet	5 (36%)	-10 (-34%)
	Above Normal	-4 (-17%)	-12 (-39%)
	Below Normal	-16 (-40%)	-22 (-48%)
	Dry	16 (33%)	0 (0%)
	Critical	14 (48%)	3 (8%)
	All	15 (10%)	-41 (-19%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during October through January would generally be similar between H4_ELT and NAA_ELT, except during October, in which flows would be up to 24% higher under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4A-71). The percent of months exceeding the threshold under H4_ELT would be similar to or up to 11% lower (absolute difference) than the percent under NAA_ELT.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4A-72). Total degree-months would generally be similar between NAA_ELT and H4_ELT for all months.

Table 11-4A-71. Differences between Baseline and H4_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 56°F Threshold, November through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H4_ELT					
November	27 (59%)	26 (95%)	23 (173%)	17 (700%)	10 (800%)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	2 (20%)	5 (67%)	4 (150%)	1 (100%)	1 (NA)
April	11 (16%)	6 (10%)	10 (22%)	10 (31%)	4 (14%)
NAA_ELT vs. H4_ELT					
November	-10 (-12%)	-7 (-12%)	-6 (-14%)	-11 (-36%)	-7 (-40%)
December	-1 (-100%)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)

	Critical	7 (70%)	0 (0%)
	All	19 (100%)	0 (0%)
April	Wet	19 (68%)	-3 (-6%)
	Above Normal	14 (64%)	0 (0%)
	Below Normal	16 (44%)	0 (0%)
	Dry	14 (18%)	-1 (-1%)
	Critical	17 (29%)	1 (1%)
	All	80 (36%)	-3 (-1%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be similar to flows under NAA_ELT throughout the period.

Water temperatures throughout the Stanislaus River would be similar under NAA_ELT and H4_ELT throughout the October through January period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be similar to flows under NAA_ELT throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences in mean flows between H4_ELT and NAA throughout the period for all water year types.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, it is concluded that the effect is not adverse because spawning and egg incubation habitat conditions are not substantially reduced. There are no reductions in flows under Alternative 4A or increases in temperatures that would translate into biologically meaningful effects on fall-/late fall-run Chinook salmon. In all rivers, there are no large or consistent differences relative to NAA_ELT. Biological modeling results also indicate that Alternative 4A would not substantially affect fall-/late fall–run Chinook salmon spawning and egg incubation habitat relative to the NAA_ELT. There would generally be no differences among scenarios.

CEQA Conclusion: In general, Alternative 4A would degrade the quantity and quality of spawning and egg incubation habitat for fall-/late fall-run Chinook salmon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of spawning and egg incubation habitat for fall-/late fall-run Chinook salmon relative to the CEQA baseline.

H3_ELT /ESO_ELT

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would be up to 16% lower than flows under Existing Conditions during October and November, and similar during December and January.

Shasta storage volume at the end of September would be 7% to 11% lower under H3_ELT relative to Existing Conditions depending on water year type (Table 11-4A-27).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT during the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between H3_ELT and baselines in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-28. There would be 10 (83%) and 5 (83%) more years with "red" and "orange" levels of concern under H3_ELT than under Existing Conditions. Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H3_ELT would be 78% to 554% higher than those under Existing Conditions during October, November, March, and April, and there were no differences during December through February (Table 11-4A-29).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under H3_ELT would be 18% to 62% greater than mortality under Existing Conditions, depending on water year type (Table 11-4A-55).

SacEFT predicts that there would be a 19% increase in the percentage of years with good spawning availability, measured as weighted usable area, under H3_ELT relative to Existing Conditions (Table 11-4A-56). SacEFT predicts that there would be a 5% reduction in the percentage of years with good (lower) redd scour risk under H3_ELT relative to Existing Conditions. SacEFT predicts that there would be a 5% relative decrease in the percentage of years with good (lower) egg incubation conditions under H3_ELT compared to Existing Conditions. SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd dewatering risk between H3_ELT and Existing Conditions.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II*

Model Results utilized in the Fish Analysis). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions for all months and water year types during the period.

Shasta storage volume at the end of September would be 7% to 11% lower under H3_ELT relative to Existing Conditions, depending on water year type (Table 11-4A-27).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between H3_ELT and baselines in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-28. There would be 10 (83%) and 5 (83%) more years with "red" and "orange" levels of concern under H3_ELT than under Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H3_ELT would be 78% to 554% higher than those under Existing Conditions during October, November, March, and April, and there would be no differences during December through February (Table 11-4A-29).

The Reclamation egg mortality model predicts that late fall-run Chinook salmon egg mortality in the Sacramento River under H3_ELT would be 60% to 120% greater than mortality under Existing Conditions (Table 11-4A-57). However, absolute differences in the percent of the late-fall population subject to mortality would be minimal in all water years.

SacEFT predicts that there would be a 13% relative decrease in the percentage of years with good spawning availability, measured as weighted usable area, under H3_ELT compared to Existing Conditions (Table 11-4A-58). SacEFT predicts that there would be a 4% relative decrease in the percentage of years with good (lower) redd scour risk under H3_ELT compared to Existing Conditions. SacEFT predicts that there would be no difference in the percentage of years with good (lower) egg incubation conditions under H3_ELT relative to Existing Conditions. SacEFT predicts that there would be a 10% relative decrease in the percentage of years with good (lower) redd dewatering risk under H3 compared to Existing Conditions.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined during the September through February fall-run spawning and egg incubation period. Flows under H3_ELT would be up to 40% greater during January and February, and generally similar during September through December to flows under Existing Conditions, with minor exceptions.

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning occurred. Clear Creek flows would be reduced during October through February under H3_ELT up to 67% (absolute difference) in above normal, dry, and critical water years and increased in below normal water years (Table 11-4A-59).

Feather River

Fall-Run

Flows in the Feather River low-flow channel during October through January under H3_ELT would be identical to those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the high-flow channel under H3_ELT would be up to 47% lower than flows under Existing Conditions during January, up to 24% greater during October, 18% higher and up to 26% lower in December, and generally similar during November.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel were identical between H3_ELT and Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of Alternative 4 on redd dewatering in the Feather River low-flow channel.

Mean water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT and Existing Conditions would be no different (<5%) at either location.

Effects of H3_ELT on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were analyzed by comparing the percent of months between October through April over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold at Gridley (Table 11-4A-60). In general, the percent of months exceeding the threshold under H3_ELT would be up to 25% greater than the percent under Existing Conditions in all months except December, January, and February, during which the percent would not differ from Existing Conditions. This comparison includes the effects of climate change.

The effects of H3_ELT on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the October through April fall-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-4A-61). In general, total degree-months under H3_ELT would be up to 96 degree-months (36%) greater than under Existing Conditions in all months except December, January, and February, during which degree-months would not differ from Existing Conditions. This comparison includes the effects of climate change.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under H3_ELT would be 106% to 145% greater than mortality under Existing Conditions (Table 11-4A-62).

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River under H3_ELT would generally be up to 24% lower than flows under Existing Conditions during November and January, but generally similar to flows under Existing Conditions during October and December, with some exceptions.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in October when spawning is assumed to occur. The greatest monthly reduction in American River flows during November through January under H3_ELT would be 30% to 131% greater magnitude than those under Existing Conditions for all year types except above normal (50% lower magnitude)(Table 11-4A-63).

Mean water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean temperatures under H3_ELT would be 6% to 7% higher than those under Existing Conditions during October of all water year types except critical (5% higher).

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4A-64). The percent of months exceeding the threshold under H3_ELT would be up to 35% greater (absolute difference) than the percent under Existing Conditions during November, March, and April and similar to the percent under Existing Conditions during December through February.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4A-65). Total degree-months under H3_ELT would be 36% to 159% greater than total degree-months under Existing Conditions during November, March and April and similar to total degree months under Existing Conditions during December through February.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under H3_ELT would be 19% to 130% greater than mortality under Existing Conditions (Table 11-4A-66).

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under Existing Conditions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT would not be different (<5%) from those under Existing Conditions for all months and water year types of the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar in all months of the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would be up to 28% greater than flows under Existing Conditions during December, and would generally be similar to flows under Existing Conditions during the other three months of the period.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT /HOS_ELT

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT 4 would generally be similar to flows under Existing Conditions. September Shasta storage volume under H4_ELT would be similar to or up to 12% lower than to storage volume under Existing Conditions, depending on water year type (Table 11-4A-36).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4_ELT during the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H4_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-67. There would be 75% and 33% increases in the number of years with "red" and "orange" levels of concern, respectively, under H4_ELT relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H4_ELT would be 72% to 431% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4A-68).

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff were evaluated during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions. End of September Shasta storage volume under H4_ELT would be up to 12% lower than storage volume under Existing Conditions (Table 11-4A-36).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4_ELT during the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H1in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-67. There would be 75% and 33% increases in the number of years with "red" and "orange" levels of concern, respectively, under H4_ELT relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H4_ELT would be 72% to 431% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4A-68).

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek flows below Whiskeytown Reservoir were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be up to 40% greater during January and February, and generally similar during September through December, than flows under Existing Conditions.

Feather River

Fall-Run

Flows in the Feather River were evaluated in the low- and high-flow channels during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the low-flow channel would be identical between Existing Conditions and H4_ELT. Mean flows in the high-flow channel under

H4_ELT would be up to 36% lower than those under Existing Conditions throughout the period, with a few exceptions.

Mean water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be no different (<5%) under H4_ELT relative to Existing Conditions at either location.

Differences in the percent of months exceeding the 56°F NMFS threshold between Existing Conditions and H4_ELT would be negligible (<5% on an absolute scale) during all months except October, November, March, and April, in which the percent of months under H4_ELT would be similar to or up to 26% higher (absolute difference) than those under Existing Conditions.

Combining all water year types, there would be no difference between Existing Conditions and H4_ELT in total degree-months exceeded in all months except October, November, March, and April, during which degree-months under H4_ELT would be greater by up to 135 degree-months (51% higher).

American River

Fall-Run

Flows were evaluated in the American River at the confluence with the Sacramento River during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT would be up to 25% lower than those under Existing Conditions during November and would generally be similar between Existing Conditions and H4_ELT during the other three months of the period, with a few exceptions.

Mean water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean temperatures under H4 ELT would be 6% to 7% greater than those under Existing Conditions during October of all water year types except critical (5% greater) and would be no different (<5%) for all other months and water year types of the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4A-71). The percent of months exceeding the threshold under H4 ELT would be up to 27% greater (absolute difference) than the percent under Existing Conditions during November, March, and April and similar to the percent under Existing Conditions during December through February.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4A-72). Total degree-months under H4 ELT would be 36% to 159% greater than total degree-months under Existing Conditions during November, March and April and similar to total degree months under Existing Conditions during December through February.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar between Existing Conditions and H4_ELT.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H4_ELT would be no different (<5%) than Existing Conditions throughout the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be generally similar to those under Existing Conditions throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT would generally be similar to flows under Existing Conditions during October, November, and January, and up to 28% greater than flows under Existing Conditions during December.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Under Alternative 4A, there would be moderate to substantial flow reductions and substantial increases in temperatures and temperature exceedances above thresholds in the Sacramento, Feather, and American Rivers, which would interfere with fall-/late fall--run Chinook salmon spawning and egg incubation. Biological models, including the Reclamation egg mortality model and SacEFT, predict substantially degraded spawning and egg incubation habitat conditions in the Sacramento, Feather, and American Rivers. These modeling results are generally consistent for H3_ELT and H4_ELT. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fall-/late fall-run Chinook salmon as a result of egg mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be no effect of Alternative 4A on flows, reservoir storage, and water temperatures that would cause a substantial reduction in fall-/late fall-run Chinook salmon. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 4A would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall-run Chinook salmon relative to the NAA_ELT.

H3_ELT /ESO_ELT

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the Sacramento River upstream of Red Bluff under H3_ELT would generally be similar to flows under NAA_ELT.

Shasta Reservoir storage at the end of September would affect flows during the fall-run larval and juvenile rearing period. As reported in AQUA-58, mean end of September Shasta Reservoir storage under H3_ELT would be similar to storage under NAA_ELT in all water year types (Table 11-4A-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

SacEFT predicts that there would be an 11% decrease (4% on an absolute scale) in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under H3_ELT relative to NAA_ELT (Table 11-4A-56). SacEFT predicts that there would be no difference in the percentage of years with “good” (lower) juvenile stranding risk between H3_ELT and NAA_ELT.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under H3_ELT would be similar to mortality under NAA_ELT.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the March through July late fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).Upstream of Red Bluff, mean flows under H3_ELT would generally be similar to those under NAA throughout the period.

Shasta Reservoir storage at the end of September and May would affect flows during the late fall-run larval and juvenile rearing period. As reported in AQUA-156, end of September Shasta Reservoir storage under H3_ELT would be similar to storage under NAA_ELT in all water year types (Table 11-4A-27).

As reported in AQUA-40, May Shasta storage volume under H3_ELT would be similar to storage under NAA_ELT for all water year types (Table 11-4A-19).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

SacEFT predicts that there would be a 25% relative decrease in the percentage of years with good juvenile rearing habitat availability for late fall-run Chinook salmon, measured as weighted usable area, under H3_ELT compared to NAA_ELT (Table 11-4A-58). SacEFT predicts that there would be a 15% reduction in the percentage of years with “good” (lower) juvenile stranding risk under H3_ELT relative to NAA_ELT, which would be negligible on an absolute scale (4% difference).

SALMOD predicts that late fall-run smolt equivalent habitat-related mortality under H3_ELT would be similar (<5% difference) to mortality under NAA_ELT. These results are inconsistent with SacEFT results, which indicate that juvenile rearing habitat availability would decline under H3_ELT (Table 11-4A-58).

Both SacEFT and SALMOD are considered to be reliable models for late fall-run Chinook salmon in the Sacramento River. SALMOD has been used for decades for assessing changes in flows associated with SWP and CVP and SacEFT has been peer-reviewed. Therefore, results of both models were used to draw conclusions about late fall-run Chinook salmon rearing conditions. The SALMOD model incorporates effects to all early life stages, including eggs, fry, and juveniles. Therefore, although SacEFT predicts that juvenile rearing habitat availability may be reduced under H3_ELT, when combined with all early life stage effects in SALMOD, there would be no effect of H3_ELT on late-fall-run Chinook salmon habitat-related survival of all early life stages, including juveniles. Further, results from SALMOD are consistent with results described above that indicate that there would be no differences in instream flows or reservoir storage between NAA_ELT and H3_ELT.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined for the January through May fall-run Chinook salmon rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to those under NAA_ELT throughout the period.

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low-flow channel throughout this period under H3_ELT would not differ from those under NAA_ELT. In the high-flow channel, mean flows under H3_ELT would generally be similar to those under NAA_ELT during December through April and up to 106% greater during May and June.

As reported in AQUA-59, May Oroville mean storage volume under H3_ELT would be similar to storage under NAA_ELT for all water year types (Table 11-4A-42).

As reported in AQUA-58, September Oroville mean storage volume under H3_ELT would be similar to volume in wet, above normal, and below normal water years and 12% to 15% greater than volume under NAA_ELT during dry and critical water years (Table 11-4A-39).

Mean water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under NAA_ELT throughout the period.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for H3_ELT are not different from those under NAA_ELT, for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures throughout the Stanislaus River would be similar between NAA_ELT and H3_ELT throughout the January through May fall-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis for H3_ELT are not different from those under NAA_ELT, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta for H3_ELT are not different from those under NAA_ELT, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT/HOS_ELT

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were evaluated during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The mean flows under H4_ELT during this period would generally be similar to those under NAA_ELT.

September Shasta mean storage volume under H4_ELT would generally be similar to September storage volume under NAA_ELT, except in critical years (24% higher under H4_ELT) (Table 11-4A-36).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA and H4 in any month or water year type throughout the period.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were evaluated during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT during this period would be similar to those under NAA_ELT for all year types throughout the period.

September Shasta mean storage volume under H4_ELT would be similar to September storage volume under NAA_ELT except in critical years (24% higher under H4) (Table 11-4A-36). May Shasta storage volume under H4_ELT would be similar to May storage volume under NAA_ELT except in critical years (11% higher under H4_ELT) (Table 11-4A-19).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Mean flows in Clear Creek below Whiskeytown Reservoir during January through May under H4_ELT would generally be similar to those under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Fall-Run

Flows in the Feather River were evaluated at both above (low-flow channel) and at (high-flow channel) Thermalito Afterbay during the December through June fall-run juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the low-flow channel would be identical between NAA_ELT and H4_ELT. Mean flows in the high-flow channel would generally be similar to or greater than those under NAA_ELT (up to 548% greater for below normal year types in April) than flows under NAA_ELT.

September Oroville mean storage under H4_ELT would generally be similar to mean storage volume under NAA_ELT in wet, above normal, and below normal water year types and 28% to 44% greater in dry and critical water year types (Table 11-4A-39). May Oroville storage under H4_ELT would be 11% to 16% lower than storage under NAA_ELT in wet, above normal, and below normal water years, similar in dry water years, and 24% greater in critical water years (Table 11-4A-45).

Mean water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period at either location.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were evaluated during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under NAA_ELT throughout the period.

Mean water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Stanislaus River

Fall-Run

Mean flows in the Stanislaus River at the confluence with the San Joaquin River for H4_ELT are not different (<5%) from those under NAA_ELT for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures throughout the Stanislaus River would be similar between NAA_ELT and H4_ELT throughout the January through May fall-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Mean flows in the San Joaquin River at Vernalis for H4_ELT are not different (<5%) from those under NAA_ELT for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Mean flows in the Mokelumne River at the Delta for H4_ELT are not different (<5%) from those under NAA_ELT for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: All changes in flow rates and water temperatures are generally small and infrequent under Alternative 4A relative to the NAA_ELT. Therefore, there would be no biologically meaningful effects to fall- or late fall-run Chinook salmon. Biological modeling generally supports this conclusion, except for a reduction in late fall-run Chinook salmon juvenile rearing habitat conditions predicted by SacEFT. However, review of this result in combination with SALMOD results, which evaluates habitat-related survival of all early life stages and found no effect of Alternative 4A, it is concluded that the effect to juvenile habitat conditions predicted by SacEFT would not have a substantial effect on all early life stages combined, including juveniles, as predicted by SALMOD As such, the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat of fish.

CEQA Conclusion: In general, Alternative 4A would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall-run Chinook salmon relative to Existing Conditions.

H3_ELT /ESO_ELT

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under Existing Conditions throughout the period.

As reported in AQUA-58, end of September Shasta Reservoir mean storage would be 7% to 11% lower under H3_ELT relative to Existing Conditions, depending on water year type (Table 11-4A-27).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period.

SacEFT predicts that there would be a 3% increase in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under H3_ELT relative to Existing Conditions (Table 11-4A-56). SacEFT predicts that there would be a 26% reduction in the percentage of years with "good" (lower) juvenile stranding risk under H3_ELT relative to Existing Conditions.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under H3_ELT would be similar to mortality under Existing Conditions.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the March through July late fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 20% greater during May and June, and similar in the remaining months.

As reported in AQUA-58, mean storage volume at the end of September under H3_ELT would be 7% to 11% lower relative to Existing Conditions, depending on water year type (Table 11-4A-27).

As reported in AQUA-40, Shasta Reservoir mean storage volume at the end of May under H3_ELT would be similar to volume under Existing Conditions for all water year types (Table 11-4A-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento*

River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period.

SacEFT predicts that there would be a 4% reduction in the percentage of years with good juvenile rearing availability for late fall-run Chinook salmon, measured as weighted usable area, under H3_ELT relative to Existing Conditions (Table 11-4A-58). SacEFT predicts that there would be a 29% reduction in the percentage of years with "good" (lower) juvenile stranding risk under H3_ELT relative to Existing Conditions.

SALMOD predicts that late fall-run smolt equivalent habitat-related mortality under H3_ELT would be 4% higher than mortality under Existing Conditions.

Clear Creek

No temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined from January through May fall-run Chinook salmon rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under Existing Conditions, except for critical year types during January through April (10% greater under H3_ELT in all four months) and wet year types in January and February (up to 40% greater under H3_ELT) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low-flow channel throughout the period under H3_ELT would not differ from those under Existing Conditions. In the high-flow channel, relative to Existing Conditions, mean flows under H3_ELT would generally be similar during December, March, and April, lower during January and February (by up to 48%), and higher during May and June (up to 140%).

As reported under AQUA-59, May Oroville mean storage volume under H3_ELT would be up to 12% lower (dry year types) than Existing Conditions (Table 11-4A-42).

As reported in AQUA-58, September Oroville mean storage volume would be 5% to 29% lower under H3_ELT relative to Existing Conditions depending on water year type, except for critical years (Table 11-4A-33).

Mean water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (5%) in mean water temperature between H3_ELT and Existing Conditions in any month or water year type throughout the period at either location.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT during the period would be up to 18% lower and up to 15% higher than flows under Existing Conditions, depending on the month and water year type.

Mean water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT would be no different than (<5%) those under Existing Conditions during the period.

Stanislaus River

Fall-Run

Mean flows in the Stanislaus River at the confluence with the San Joaquin River for H3_ELT would generally be lower than those under Existing Conditions during the January through May fall-run larval and juvenile rearing period for most water year types (up to 29% lower for critical year types in February) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT would be no different than (<5%) those under Existing Conditions throughout the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to or moderately lower than flows under Existing Conditions throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be generally similar to or moderately greater than those under Existing Conditions during January through March and similar to or slightly lower than flows under Existing Conditions during April and May.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT/HOS_ELT

Sacramento River

Fall-Run

Sacramento River mean flows upstream of Red Bluff during January through May under H4_ELT would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta mean storage volume under H4_ELT would generally be similar to or slightly lower than September mean storage volume under Existing Conditions (Table 11-4A-27).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the January through March fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period.

Late Fall-Run

Sacramento River mean flows upstream of Red Bluff during March through July under H4_ELT would generally be similar to flows under Existing Conditions throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

September Shasta mean storage volume under H4_ELT would generally similar to or slightly lower than September mean storage volume under Existing Conditions (Table 11-4A-36). May Shasta mean storage volume under H4_ELT would be similar to mean storage volume under Existing Conditions for all water year types (Table 11-4A-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Mean flows in Clear Creek below Whiskeytown Reservoir during January through May under H4_ELT would be similar to or greater than those under Existing Conditions (up to 40% greater for wet years in January) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Fall-Run

Flows were evaluated in the Feather River both above (low-flow channel) and at (high-flow channel) Thermalito Afterbay during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the low-flow channel would be identical between Existing Conditions and H4_ELT. Mean flows in the high-flow channel under H4_ELT would generally be lower than flows under Existing Conditions during December through February (up to 36% lower for below normal year types in January), similar during March, and greater than flows under Existing Conditions during April through June (up to 509% greater for below normal year types in April).

September Oroville mean storage under H4_ELT would be 23% to 24% lower than flows under Existing Conditions in wet, above normal, and below normal water years, and 5% to 32% higher in dry and critical water years (Table 11-4A-39). May Oroville mean storage would be 11% to 19% lower under H4_ELT than under Existing Conditions in all water year types except critical, in which storage would be 15% higher (Table 11-4A-45).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (5%) in mean water temperature between H4_ELT and Existing Conditions in any month or water year type throughout the period at either location.

American River

Fall-Run

Flows were evaluated in the American River at the confluence with the Sacramento River during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be up to 20% lower than flows under Existing Conditions during May, up to 14% higher during February, and similar, with minor exceptions, in the remaining months of the rearing period.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (5%) in mean water temperature between H4_ELT and Existing Conditions in any month or water year type throughout the period.

Stanislaus River

Fall-Run

Mean flows in the Stanislaus River at the confluence with the San Joaquin River for H4_ELT would be lower for most water year types than those under Existing Conditions in the January through May fall-run larval and juvenile rearing period (up to 29% lower for critical years during February) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between H4_ELT and Existing Conditions in any month or water year type throughout the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be similar to or moderately lower than those under Existing Conditions for most water year types in the January through May fall-run larval and juvenile rearing period. Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4_ELT would be similar to those under Existing Conditions for most water year types than in the January through May fall-run larval and juvenile rearing period.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Under Alternative 4A, including climate change effects, there would be persistent moderate flow reductions in the Feather, American, Stanislaus, Mokelumne, and San Joaquin Rivers, which would interfere with fall-/late fall--run Chinook salmon juvenile rearing habitat conditions. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable rearing habitat and substantially reduce the number of fall-/late fall-run Chinook salmon as a result of degraded juvenile rearing conditions.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands. When compared to NAA_ELT and informed by the NEPA analysis above, flows, reservoir storage, and water temperatures in the Sacramento River would generally be similar between NAA_ELT and Alternative 4A. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under

Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

With implementation of Mitigation Measure AQUA-78d, the effect of Alternative 4A on migration conditions for fall-/late fall–run Chinook salmon relative to the No Action Alternative would not be adverse.

Upstream of the Delta

H3_ELT /ESO_ELT

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for juvenile fall-run migrants during February through May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under NAA_ELT throughout the juvenile migration period.

Mean water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA _ELT and H3_ELT in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined for the adult fall-run Chinook salmon upstream migration period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under NAA_ELT during August, October and December, and would be up to 18% lower during September and November (mean reduction combining all water year types of 6% and 12%, respectively). These reductions would not be of sufficient magnitude or frequency to cause a biologically meaningful effect to fall-run Chinook salmon migration.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Late Fall-Run

Mean flows in the Sacramento River upstream of Red Bluff for juvenile late fall-run migrants (January through March) under H3_ELT would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Mean flows in the Sacramento River upstream of Red Bluff during the adult late fall-run Chinook salmon upstream migration period (December through February) under H3_ELT would be generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA and H3 in any month or water year type throughout the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined for juvenile fall-run migrants during February through May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to those under NAA_ELT.

Flows in Clear Creek below Whiskeytown Reservoir were examined during the adult fall-run Chinook salmon upstream migration period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be similar to flows under NAA_ELT with few exceptions.

Feather River

Fall-Run

Flows in the Feather River at the confluence with the Sacramento River were reviewed for the fall-run juvenile migration period (February through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to or greater than flows under NAA_ELT throughout the period (up to 12% greater for above normal year types in February).

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River were reviewed for the August through December fall-run Chinook salmon adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar or up to 17% greater than those under NAA_ELT during October through December. During August and September, flows would be up to 28% lower than flows under NAA_ELT except in critical water years in which the flows would be up to 21% greater. Mean flow reductions across all water year types for August and September would be 11% and 15%, respectively. These reductions would not be of sufficient magnitude or frequency to cause a biologically meaningful effect to fall-run Chinook salmon migration. Flows would be similar between NAA_ELT and H3_ELT during November.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the August through December fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under NAA_ELT throughout the migration period, except during April of critical years (17% greater mean flow under H3_ELT).

Mean water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Flows in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be up to 25% lower than flows under NAA_ELT during August, September and November, and similar or up to 25% higher during October and December. Mean flow reductions across all water year types during August, September and November would be 11%, 16%, and 10%, respectively. Because these reductions occur in the majority of migration months, this is considered an adverse effects to fall-run Chinook salmon migration conditions.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be no different than (<5%) those under NAA_ELT in all months and water year types throughout the period.

Mean water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be no different than (<5%) those under NAA_ELT in both months and water year types of the period.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in either month or any water year type of the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be no different than (<5%) those under NAA_ELT in all months and water year types throughout the period.

Flows in the San Joaquin River at Vernalis were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean flow between NAA_ELT and H3_ELT in either month or any water year type of the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean flow between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Flows in the Mokelumne River at the Delta were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean flow between NAA_ELT and H3_ELT in either month or any water year type of the period.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT /HOS_ELT

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for the juvenile fall-run Chinook salmon downstream migration period (February through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be similar to flows under NAA_ELT throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined for the adult fall-run Chinook salmon upstream migration period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to those under NAA_ELT except during November, when flows would be up to 15% lower under H4_ELT.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in either month or any water year type of the period.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for the juvenile fall-run Chinook salmon downstream migration period (January through March) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be similar to flows under NAA_ELT throughout the period for all water year types.

Mean water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined for the adult fall-run Chinook salmon upstream migration period (December through February) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under NAA_ELT throughout the period.

Mean water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in either month or any water year type of the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in the Clear Creek below Whiskeytown Reservoir during the February through May fall-run Chinook salmon juvenile migration period under H4_ELT would generally be similar to flows under NAA_ELT, (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Clear Creek below Whiskeytown Reservoir during the August through December fall-run Chinook salmon adult migration period under H4_ELT would generally be no different than (<5%) those under NAA_ELT.

Feather River

Fall-Run

Flows were evaluated in the Feather River at the confluence with the Sacramento River during the February through May juvenile late fall-run Chinook salmon emigration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to or greater than flows under NAA_ELT throughout the period (up to 119% greater for April of below normal year types).

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Flows were evaluated in the Feather River at the confluence with the Sacramento River during the August through December fall-run Chinook salmon adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be lower during August and September than those under NAA_ELT for all water year types except critical year types (up to 42% lower in August of wet years and up to 42% higher in August of critical years). Mean reductions for all water year types combined during August and September would be 32% and 22%, respectively. These reductions are substantial and, therefore, would cause an adverse effect to fall-run Chinook salmon. Mean flows during October through December would generally be similar to flows under NAA_ELT.

American River

Fall-Run

Flows were evaluated in the American River at the confluence with the Sacramento River during the February through May fall-run Chinook salmon juvenile migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be similar to flows under NAA_ELT throughout the period, except for critical years types in April (12% higher under H4_ELT) and May (17% lower under H4_ELT).

Mean water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results* *utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Flows were evaluated in the American River at the confluence with the Sacramento River during the August through December fall-run Chinook salmon adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4 ELT would generally be lower than those under NAA_ELT during September and November (up to 22% lower), but would generally be similar or higher during August, October and December (up to 24% higher). However, flow during August of critical water years would be 33% lower under H4_ELT. These flow reductions would not be frequent or of high enough magnitude to be considered adverse.

Mean water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in either month or any water year type of the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be no different than (<5%) those under NAA_ELT in all months and water year types of the period.

Mean water temperatures in the Stanislaus River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean flows between NAA_ELT and H4_ELT in either month or any water year type of the period.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in either month or any water year type of the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be no different than (<5%) those under NAA_ELT for all months or water year types of the period.

Flows in the San Joaquin River at Vernalis were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean flow between NAA_ELT and H4_ELT in either month or any water year type of the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean flow between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Flows in the Mokelumne River at the Delta were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean flow between NAA_ELT and H4_ELT in either month or any water year type of the period.

Water temperature modeling was not conducted in the Mokelumne River.

Fall-Run

Juveniles

Alternative 4A operations would generally reduce OMR reverse flows under Scenario H3_ELT (Appendix B, Supplemental Modeling for Alternative 4A), with a corresponding increase in net positive downstream flows, during the migration period of Chinook salmon through the interior Delta channels. Conditions under Scenario H4_ELT would further improve overall average OMR flows compared to NAA_ELT. These improved net positive downstream flows would be benefits of the proposed operations.

Predation risk at the north Delta would be increased due to the installation of the proposed SWP/CVP North Delta intake facilities on the Sacramento River. Bioenergetics modeling with a median predator density predicts a predation loss under Alternative 4 of less than 0.6% of the annual juvenile production (0.24% fall run; 0.57% late fall-run) (Table 11-4A-54). A conservative assumption of 5% loss per intake would yield a cumulative loss of about 13% of juvenile fall-run and late fall-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate. For a discussion of this topic see Impact AQUA-42 for Alternative 1A and additional discussion under Impact AQUA-42 of Alternative 4A for winter-run Chinook salmon.

H3_ELT

Flows below the north Delta intakes would be reduced during the juvenile emigration period for fall-run Chinook (February through May) and late fall-run Chinook salmon (January through March), which may increase predation potential. Mean monthly flows averaged across all water years would decrease about 17% to 22% under H3_ELT compared to NAA_ELT. As noted for winter-run and spring-run Chinook salmon, the modeling of NAA_ELT does not account for any flow entering the Yolo Bypass because of Fremont Weir modifications that would occur separately from Alternative 4A (but which are included in the modeling of H3_ELT and H4_ELT; see also section 4.1.1.3 of Section 4); this would slightly decrease the amount of water in the Sacramento River under NAA_ELT, so the above comparison of H3_ELT vs. NAA_ELT is conservative.

Under Scenario H3_ELT, through-Delta survival of Sacramento River fall-run Chinook salmon, as estimated by the Delta Passage Model, averaged 24.3% across all years, 20.6% in drier years and 30.5% in wetter years (Table 11-4A-74). Compared to NAA_ELT, average survival under Scenario H3 would be similar (<4% lower) across all years, although this estimate does not account for the adjustments that can be made during real-time operations to further protect migrating fish. These real-time operational adjustments would be based on biological and hydrological triggers developed by NMFS and DFW to protect migrating salmonids. However, as noted for winter-run Chinook salmon in the discussion of Impact AQUA-42, the DPM modeling results do not account for the inclusion of Yolo Bypass improvements in NAA_ELT. Applying the same modification to NAA_ELT outputs as described in the discussion of Impact AQUA-42 resulted in the relative difference between NAA_ELT and H3_ELT increasing: the relative difference across all years increased from 4% less compared to NAA_ELT to nearly 6% less compared to NAA_ELT (mod.)(Table 11-4A-74).

H4_ELT

Under the high outflow scenario H4_ELT, mean monthly flows below the NDD would decrease by about 4% to 18% during the emigration period, with the greatest relative reduction of 18% in February of below normal years. Under H4_ELT, flow decreases in April and May would be less than 10% compared to NAA_ELT, with small increases in mean monthly flow in some water year types (e.g., 7–15% greater than NAA_ELT in below normal years). Survival based on the DPM under Scenario H4 would be similar to NAA_ELT (<2% relative difference; Table 11-4A-74) based on operations assuming no adjustments made in real-time in response to actual presence of fish; as described above, real-time operational adjustments would be made, based on biological and hydrological triggers developed by NMFS and DFW to protect migrating salmonids. As noted in the discussion for H3_ELT, the DPM modeling results do not account for the inclusion of Yolo Bypass improvements in NAA_ELT. Applying the same modification to NAA_ELT outputs as described in the discussion of Impact AQUA-42 for winter-run Chinook salmon resulted in the relative difference between NAA_ELT and H4_ELT changing slightly: the relative difference across all years changed from 1.6% more compared to NAA_ELT to nearly 0.4% less compared to NAA_ELT (mod.)(Table 11-4A-74).

Overall, Alternative 4A would not have an adverse effect on Sacramento River fall-run Chinook salmon juvenile survival due to relatively low differences in survival for most operations, as well as the inclusion in Alternative 4A of bypass flow criteria, real-time management, and several conservation measures (Environmental Commitment 6, Environmental Commitment 15, Environmental Commitment 16) to offset any adverse effects, as discussed for winter-run Chinook salmon under Impact AQUA-42.

Table 11-4A-74. Through-Delta Survival (%) of Emigrating Juvenile Fall-Run Chinook Salmon under Alternative 4A (Scenarios H3_ELT and H4_ELT)

Note: Average Delta Passage Model results for survival to Chipps Island.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
Wetter = Wet and Above Normal Water Years (6 years).
Drier = Below Normal, Dry and Critical Water Years (10 years).
H3_ELT = ESO_ELT operations, H4_ELT = High Outflow.
NAA_ELT (mod.) = NAA_ELT with Yolo Bypass entry % and Yolo Bypass survival of H3_ELT.
N/A = not applicable because the Mokelumne and San Joaquin populations do not encounter the upstream end of the Yolo Bypass.

Adults

Attraction flows and olfactory cues in the west Delta for migrating adults would be altered because of shifts in exports from the south Delta to the North Delta under Alternative 4A. Sacramento River flows downstream of the north Delta diversion would be reduced, with concomitant increase in San Joaquin River flow contribution.

Results of fingerprint simulation modeling (DSM2 modeling of percentage of water at Collinsville that originated in the Sacramento River water) for Scenario H3_ELT predicted a minimal reduction in Sacramento River source water September–November (1–4% less) compared with NAA (Table 11-4A-75). Studies indicate that a 20% or less reduction in source flows that provides olfactory cues would not adversely affect adult attraction (Fretwell 1989). The reduction in olfactory cues under Scenario H3_ELT is small and is expected to be within the broad range of olfactory cues and migration conditions that currently occur within the lower reach of the Sacramento River.

Table 11-4A-75. Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Adult Fall-Run and Late Fall-Run Chinook Salmon Migration Period for Alternative 4A (Scenario H3_ELT)

	Scenario			Percentage Difference	
Month	EXISTING CONDITIONS	NAA_ ELT	H3_ELT	EXISTING CONDITIONS vs. H3_ELT	NAA vs. H3_ELT
Fall-Run—Sacramento River

March	78	77	69	-9	-8
	Shading indicates 10% or greater absolute difference.				
Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).					

Late Fall-Run

Juveniles

Alternative 4A operations would generally reduce OMR reverse flows under all flow scenarios (Appendix B, Supplemental Modeling for Alternative 4A), with a corresponding increase in net positive downstream flows that would benefit juveniles migrating through the Delta. Reduced flows below the north Delta intakes may increase predation potential. Through-Delta survival by emigrating juvenile late fall-run Chinook salmon under Scenario H3_ELT as estimated with the DPM averaged 22% across all years, 19.4% in drier years, and 26.4% in wetter years (Table 11-4A-76). Juvenile survival under the Scenario H3_ELT was similar or slightly lower than under NAA_ELT for drier, wetter and all years averaged (around 3-4% less in relative difference) based on operations assuming no adjustments made in real-time in response to actual presence of fish (Table 11-4A-76).

The results were similar for H4_ELT, in keeping with the timing of late fall-run emigration through the Delta mostly lying outside the spring period in which H3_ELT operations would differ from H4_ELT operations. However, as noted for winter-run Chinook salmon in the discussion of Impact AQUA-42, the DPM modeling results do not account for the inclusion of Yolo Bypass improvements in NAA_ELT. Applying the same modification to NAA_ELT outputs as described in the discussion of Impact AQUA-42 resulted in the relative difference between NAA_ELT and H3_ELT/H4_ELT increasing: for H3_ELT, the relative difference across all years increased from 3.4% less compared to NAA_ELT to just over 5.8% less compared to NAA_ELT (mod.); whereas for H4_ELT, the relative difference across all years increased from 3.5% less compared to NAA_ELT to 6.1% less compared to NAA_ELT (mod.) (Table 11-4A-51). Overall, Alternative 4A would not have an adverse effect on late fall-run Chinook salmon juvenile survival due to similar survival between Alternative 4A and NAA_ELT during all water year types.

Table 11-4A-76. Through-Delta Survival (%) of Emigrating Juvenile Late Fall-Run Chinook Salmon under Alternative 4A (Scenarios H3_ELT and H4_ELT)

	Average Percentage Survival					Difference in Percentage Survival (Relative Difference)					
	Scenario					EXISTING CONDITIONS vs. Alt 4A Scenario		NAA_ELT vs. Alt 4A Scenario			
Water Year Type	EXISTING CONDITIONS	NAA_ ELT	NAA_ ELT (mod.)	H3_ ELT	H4_ ELT	H3_ELT	H4_ELT	H3_ELT	H4_ELT	H3_ELT (vs. NAA_ELT mod.)	H4_ELT (vs. NAA_ELT mod.)
Wetter	28.8	27.5	28.1	26.4	26.5	-2.4 (-8.2%)	-2.3 (-7.9%)	-1.1 (-4.0%)	-1.0 (-3.7%)	-1.7 (-6.1%)	-1.6 (-5.9%)
Drier	18.8	20.0	20.5	19.4	19.3	0.7 (3.5%)	0.5 (2.7%)	-0.6 (-3.0%)	-0.8 (-3.7%)	-1.1 (-5.5%)	-1.3 (-6.3%)
All Years	22.5	22.8	23.4	22.0	22.0	-0.5 (-2.2%)	-0.5 (-2.2%)	-0.8 (-3.4%)	-0.8 (-3.5%)	-1.4 (-5.8%)	-1.4 (-6.1%)

Note: Delta Passage Model results for survival to Chipps Island.

Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Wetter = Wet and Above Normal Water Years (6 years).

Drier = Below Normal, Dry and Critical Water Years (10 years).

H3_ELT = ESO_ELT operations, H4_ELT = High Outflow.

NAA_ELT (mod.) = NAA_ELT with Yolo Bypass entry % and Yolo Bypass survival of H3_ELT.

Adults

Flows in the Sacramento River downstream of the north Delta intake diversions would be reduced under Alternative 4A, with concomitant proportional increases in San Joaquin River flows. Under Scenario H3_ELT, the percentage of Sacramento River water at Collinsville would be similar in December, and slightly reduced (2% to 8%) in January through March compared to NAA (Table 11-4A-75). The effect on olfactory cues for migrating adults late fall-run Chinook salmon would be negligible because the change in flow proportions is less than 10% in absolute terms.

Mokelumne River

Fall-Run

Juveniles

Through-Delta survival of Mokelumne River fall-run Chinook salmon under Scenario H3_ELT averaged 16.5% across all years (Table 11-4A-74). Survival under Scenario H3_ELT was similar to NAA_ELT averaged across all years (0.6% greater, or 4% more in relative difference) and in drier years (a 1% relative difference), and there was a 2% increase in survival (nearly a 12% relative difference) in wetter years. Juvenile survival under H4_ELT (high outflow) was similar to Scenarios H3_ELT and NAA_ELT in drier years, and slightly increased (by 7.5% relative difference) when averaged across all years. In wetter years, survival increased 3% under Scenario H4_ELT (an 18% relative difference). Overall, Alternative 4A would not have an adverse effect on Mokelumne River fall-run Chinook salmon juvenile survival due to minor differences in survival for most operations, and a moderate increase in survival for the high outflow years, particularly under operations Scenario H4_ELT. Note that this analysis is conservative because increased flow into the Yolo Bypass with Fremont Weir modifications under NAA_ELT would result in less flow remaining in the Sacramento River; these Fremont Weir modifications were not accounted for in the modeling of NAA_ELT. As described in *BDCP Appendix 5.C, Section 5C.4.3.2.2 hereby incorporated by reference*, the export-dependent survival function for juvenile Chinook salmon in the interior Delta (including Mokelumne River fall-run) is a ratio of survival in the mainstem Sacramento River below Georgiana Slough, which has a positive relationship with Sacramento River flow. Thus, the estimates of through-Delta survival under NAA_ELT for Mokelumne River fall-run Chinook salmon that do not account for flow entering the Yolo Bypass because of Fremont Weir modifications would tend to slightly overestimate survival for NAA_ELT; therefore, the differences between NAA_ELT and H3_ELT/H4_ELT discussed above would be somewhat greater if the flow entering Yolo Bypass under NAA_ELT was accounted for.

San Joaquin River

Fall-Run

Juveniles

Under Alternative 4A Scenario H3_ELT operations, through-Delta survival by juvenile fall-run Chinook salmon emigrating from the San Joaquin River averaged 13% across all years, 11% in drier years, and 17% in wetter years (Table 11-4A-74). Compared to NAA_ELT, average survival across all years was lower for both operations scenarios (H3_ELT and H4_ELT). Survival is slightly increased in drier years (1% greater, a 9–11% relative difference). Survival is greatest in wetter years, but is moderately reduced relative to NAA_ELT by about 4% (19-20% relative difference for Scenarios H3_ELT and H4_ELT). As described in *BDCP Appendix 5.C, Section 5C.5.3.4.5 hereby incorporated by reference*, these results are driven by appreciably lower through-Delta survival of San Joaquin River fall-run Chinook salmon under Alternative 4A scenarios relative to NAA_ELT in very wet years (1982/1983). During these types of years, the Head of Old River operable gate would not be closed because of exceedance of the 10,000-cfs Vernalis flow criterion permitting its closure, so less fish would use the main stem San Joaquin River pathway. In addition, south Delta exports would be very low (averaging 40-50 cfs for H3_ELT in 1983, for example) because of operation of the north Delta intakes, which would result in estimated survival that is relatively low because of the DPM's positive relationship between survival and exports, based on current relationships. There is considerable uncertainty in effects on San Joaquin River Chinook salmon survival at such low levels of exports because the studies upon which the DPM flow- and export-survival relationships are based did not include these low levels of exports. SalSim, a recently completed San Joaquin River watershed Chinook salmon analysis tool that includes juvenile survival through the Delta derived in a different manner than DPM, includes a positive relationship between probability of juvenile survival and flow in the mainstem San Joaquin River at Stockton Deepwater Ship Channel; this flow term is positively related to flow at Vernalis, inversely related to south Delta exports, and positively related to Head of Old River barrier operation; the results of SalSim modeling therefore would be expected to illustrate a benefit of Alternative 4A across any modeled year, which is more in keeping with the anticipated effect of the alternative. Overall and in light of these uncertainties, Alternative 4A would not have an adverse effect on through-Delta migration because the reduction in south Delta exports generally would be expected to benefit through-Delta survival.

Adults

The percentage of water at Collinsville that originated from the San Joaquin River is very small (no more than 1% under NAA_ELT) during the fall-run migration period (September to December). The fingerprinting analysis showed a small increase in olfactory cues from the San Joaquin River passing downstream through the Delta under Scenario H3_ELT (Table 11-4A-75). Although the relative change is substantial (i.e., a severalfold increase in the percentage of flow from the San Joaquin River under Scenario H3_ELT compared to NAA_ELT), the percentage of flow attributable to San Joaquin River water under all scenarios is quite low (no more than around 5%). Scenario H4_ELT would not have as great a relative change because exports at the north Delta diversion would be lower than under Scenario H3_ELT. Overall, Alternative 4A operations conditions would incrementally increase olfactory cues associated with attraction flows in the lower San Joaquin River, but the increase would be small. However, even this seemingly small increase could provide moderate benefits: as illustrated in *BDCP Appendix 5.C, Section 5C.5.3.13.1.5 hereby incorporated by reference,* based on the study of Marston et al. (2012), greater olfactory cues under Alternative 4A could decrease severalfold the straying rate of adult San Joaquin River Chinook salmon to the Sacramento River. This would not be an adverse effect on adult fall-run Chinook salmon migrating to the San Joaquin River.

NEPA Effects: Upstream of the Delta, these modeling results indicate that the effect of Alternative 4A could be adverse because flows in the Feather and American Rivers (depending on scenario – H3_ELT or H4_ELT) would be reduced substantially and persistently and could cause biologically meaningful effects to fall-run Chinook salmon adult migration. There are no substantial upstream flow changes in other rivers evaluated and no water temperature-related effects in any river for which temperature modeling is available. However, with implementation of Mitigation Measure AQUA-78d, this impact would not be adverse.

As described for winter-run and spring-run Chinook salmon, near-field effects of Alternative 4A NDD on fall- and late fall-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating fall- and late fall-run Chinook salmon, although there is high uncertainty regarding the overall effects. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 13% mortality above current baseline levels). Environmental Commitment 15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Similarly, Alternative 4A also includes investigations to better understand factors affecting juvenile through-Delta migration (as described in the adaptive management and monitoring program in Section 4.1) and includes biologically based triggers for real time operations. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of predation-related mortality expected from near-field effects at the NDD remains highly uncertain.

As noted for Alternative 4, two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 4A related to reduced interior Delta entry (Environmental Commitment 16) and reduced south Delta entrainment suggest that these could counter the far-field effects of reduced flow (see, for example, Table 5.C.5.3-46 in the *BDCP Effects Analysis Appendix 5.C hereby incorporated by reference*). The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and the adaptive management and monitoring program will investigate these outcomes.

As described for Alternative 4 and as discussed for winter-run and spring-run Chinook salmon above, the DPM is a flow-based model incorporating flow-survival and junction routing relationships with flow modeling of Alternative 4a operations to estimate relative differences between scenarios in smolt migration survival throughout the entire Delta. The DPM predicted that smolt migration survival under Alternative 4A would be similar or slightly lower than survival estimated for NAA_ELT, based on operations assuming no adjustments made in real-time in response to actual presence of fish. Although refinements to the DPM are likely to occur based on new data available from future studies and the current analysis has some uncertainty, the DPM analysis of Alternative 4A on juvenile fall-/late fall-run Chinook salmon migration suggests a potential adverse effect of small magnitude. As noted for winter-run Chinook salmon, the DPM focuses on smolt-sized individuals (70 mm or more) and is not based on survival data for fry-sized individuals, which also may be migrating and could be affected by Alternative 4A operations. There are no fry through-Delta survival data to inform the effects to these individuals in relation to operations and it is uncertain whether the relative difference between scenarios estimated from the DPM for smolt-sized fish would be representative of relative differences for fry. The potential adverse effect on fall-run and late-fall run Chinook salmon would be minimized through the inclusion within Alternative 4A of specific important Environmental Commitments. These include *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects; *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD; and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of Chinook salmon juveniles into the low-survival interior Delta.

Overall, with implementation of Mitigation Measure AQUA-78d to address upstream flow reductions, the effects on fall-/late-fall run Chinook migration are not adverse in the ELT.

The effect of Alternative 4A in the LLT on fall-/late-fall run Chinook upstream migration conditions would be not adverse. Instream flows in the Sacramento, Feather, and American Rivers during late summer and fall months would decline from ELT to LLT such that flows would be substantially reduced under Alternative 4A relative to the NEPA baseline in the LLT, compared to the ELT comparison. Similar to ELT, implementation of Mitigation Measure AQUA-78d will reduce the magnitude of this effect.

CEQA Conclusion: With implementation of Mitigation Measure AQUA-78d, the impact of Alternative 4A on migration conditions for fall-/late fall–run Chinook salmon relative to Existing Conditions would be less than significant.

Upstream of the Delta

H3_ELT /ESO_ELT

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for juvenile fall-run migrants during February through May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under Existing Conditions.

Mean water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined during the adult fall-run Chinook salmon upstream migration period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT during August and September would be up to 22% lower (September of dry years) and up to 32% higher (September of above normal years) than those under Existing Conditions. Mean flows would be up to 17% lower under H3_ELT during October and November, would be similar during December. The flow reductions in three of five migration months would constitute a substantial impact to fall-run Chinook salmon migration conditions.

Mean water temperatures in the Sacramento River at Red Bluff were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month throughout the period.

Late Fall-Run

Mean flows in the Sacramento River upstream of Red Bluff for juvenile late fall-run migrants (January through March) under H3_ELT would be similar to flows under Existing Conditions, with minor exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month throughout the period. Mean flows in the Sacramento River upstream of Red Bluff during the adult late fall-run Chinook salmon upstream migration period (December through February) under H3_ELT would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month throughout the period.

Clear Creek

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined during the juvenile fall-run Chinook salmon upstream migration period (February through May). Mean flows under H3_ELT would generally be similar to or slightly greater than those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean flows in Clear Creek below Whiskeytown Reservoir during the adult fall-run Chinook salmon upstream migration period (August through December) under H3_ELT would generally be similar to those under Existing Conditions, except for September of critical years (19% lower under H3_ELT) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted in Clear Creek

Feather River

Fall-Run

Mean flows in the Feather River at the confluence with the Sacramento River during the fall-run juvenile migration period (February through May) under H3_ELT would generally be similar to or lower than flows under Existing Conditions (up to 15% lower for March of below normal years) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month throughout the period.

Flows in the Feather River at the confluence with the Sacramento River were examined during the August through December fall-run Chinook salmon adult migration period. Mean flows under H3_ELT during August and September would be up to 100% greater (September of wet years) and up to 43% lower (August of dry years) than flows under Existing Conditions. Mean flows under H3_ELT during October through December would be similar to or up to 21% greater (dry years) than those under Existing Conditions, except for 19% lower flow in December of critical years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Feather River at the confluence with the Sacramento River were examined during the August through December fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month throughout the period.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be up to 15% greater than flows under Existing Conditions during February and March, and similar during April, and up to 18% lower than flows under Existing Conditions during January and May, depending on water year type.

Mean water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month throughout the period.

Flows in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT during August, September, and November would be consistently lower than flows under Existing Conditions, ranging from 10% lower to 52% lower. Mean flows under H3_ELT during October and December would be up to 11% lower and up to 15% higher than flows under Existing Conditions, depending on water year type, but mean reductions across water year types would be small (-2% and 4%, respectively).

Mean water temperatures in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT would be 5% higher than those under Existing Conditions during August of dry years and 5% to 6% higher during October, except in critical water years. There would there would be no differences (<5%) during the other three months of the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT throughout this period would generally be lower than Existing Conditions for all water year types (up to 29% lower for February of critical years), except for wet water years, in which flows would be similar or up to 17% greater (February) than flows under Existing Conditions.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month throughout the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions for all months and water year types of the period.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in either month or any water year type of the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions with few exceptions (up to 12% lower).

Flows in the San Joaquin River at Vernalis were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be lower than those under Existing Conditions during August and September (up to 14%), but similar to flows under Existing Conditions during the remaining three months.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under Existing Conditions during March through May, and would be up to 15% higher than flows under Existing Conditions during February.

Flows in the Mokelumne River at the Delta were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be up to 32% lower than flows under Existing Conditions during August and September, and up to 28% greater than flows under Existing Conditions during December. Flows during October and November would be largely similar between H3_ELT and Existing Conditions.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT /HOS_ELT

Sacramento River

Fall-Run

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period. Mean flows under H4_ELT would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4_ELT in any month throughout the period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Flows and water temperatures in the Sacramento River at Red Bluff were examined during the August through December adult fall-run Chinook salmon upstream migration period. Mean flows during September under H4_ELT would be up to 49% greater (above normal years) and up to 18% lower (dry years) than flows under Existing Conditions, but flows during the other four months of the period would generally be similar (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean water temperatures under H4_ELT would not be different (<5%) from those under Existing Conditions(Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Late Fall-Run

Mean flows and water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period. Mean flows under H4_ELT would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in water temperature between Existing Conditions and H4_ELT in any month or water year type. (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean flows and water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period. Mean flows under H4_ELT would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in either month of the period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Clear Creek

Fall-Run

Mean flows in the Clear Creek below Whiskeytown Reservoir during February through May under H4_ELT would generally be similar to or up to 13% greater than flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the Clear Creek below Whiskeytown Reservoir during August through December under H4_ELT would generally be similar to flows under Existing Conditions.

Water temperature modeling was not conducted in Clear Creek.

Feather River

Fall-Run

Flows and water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period. Mean flows under H4_ELT would generally be similar to flows under Existing Conditions during February and March, but would be up to 112% greater during April and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month throughout the period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Flows and water temperatures in the Feather River at the confluence with the Sacramento River were examined during the August through December fall-run Chinook salmon adult upstream migration period. Mean flows under H4_ELT during August and September would be from 51% lower (August of dry years) to 87% higher (September of wet years) than flows under Existing Conditions, and from 26% lower to 19% higher than flows under Existing Conditions during October through December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The prevalence of reduced flows across months and water year types suggests that this would be an adverse effect to fall-run Chinook salmon migration conditions.

Mean water temperatures under H4_ELT would be no different from (<5%) those under Existing Conditions during both months and all water year types (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

American River

Fall-Run

Flows and water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period. Mean flows under H4_ELT would generally be similar to or higher than flows under Existing Conditions during February (up to 14% higher for above normal years), and similar to or lower than flows under Existing Conditions during March through May (up to 20% lower for May of above normal years) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month throughout the period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Flows and water temperatures in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period. Mean flows under H4_ELT during August, September, and November would be lower than those under Existing Conditions for almost all water year types, ranging from 7% lower in November of above normal years to 47% lower in September of critical years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during October and December would generally be similar to or greater than those under Existing Conditions. Mean water temperatures under H4_ELT would be 5% to 6% higher during October than those under Existing Conditions and would be similar during the remainder of the migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT throughout this period would generally be lower than Existing Conditions (up to 29% lower for February of critical years), except in wet years, in which flows would be similar or up to 17% greater (February) than flows under Existing Conditions.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month throughout the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions throughout the migration period.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in either month of the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions for all months with some exceptions (up to 12% lower).

Flows in the San Joaquin River at Vernalis were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT would be over than those under Existing Conditions during August and September (up to 14%), but similar to flows under Existing Conditions during the remaining three months. Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be similar to or up to 15% higher than those under Existing Conditions during February, generally similar during March and April, and up to 11% lower than flows under Existing Conditions during May.

Flows in the Mokelumne River at the Delta were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be up to 32% lower than flows under Existing Conditions during August and September, and up to 28% greater than flows under Existing Conditions during December. Flows during October and November would be largely similar between H4_ELT and Existing Conditions.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Sacramento River

Fall-Run

Juveniles

As described above, Scenario H3_ELT operations would reduce overall OMR reverse flows and reduce Sacramento River flows below the north Delta diversions (Appendix B, Supplemental Modeling for Alternative 4A). Based on the DPM, survival of Sacramento River fall-run Chinook salmon juveniles under Scenario H3_ELT averaged for all years was less than Existing Conditions, was similar in drier years, and was moderately reduced by about 4% (a 12% relative difference) in wetter years (Table 11-4A-74). Under Scenario H4_ELT average survival was similar (~1% or less relative decrease) to Existing Conditions for all years, drier years, and wetter years. These results do not account for adjustments that would be made during real-time operations to further protect migrating fish, based on biological and hydrological triggers developed by NMFS and DFW.

Adults

The percentage of Sacramento River origin flow at Collinsville, would be slightly increased (5% or less in September to December) under Scenario H3_ELT compared to Existing Conditions (Table 11-4A-75). This would not significantly affect olfactory cues for adults migrating to the Sacramento River because the change is less than 10%.

Late Fall-Run

Juveniles

As described above, Alternative 4A operations would reduce OMR reverse flows and reduce Sacramento River flows below the north Delta diversions (Appendix B, Supplemental Modeling for Alternative 4A). Conditions under Scenario H4_ELT would further improve OMR flow conditions relative to the Scenario H3_ELT. As estimated by DPM, through-Delta survival by emigrating juvenile late fall-run Chinook salmon under Scenario H3_ELT averaged across all years was similar (around 2% relative difference) to Existing Conditions (Table 11-4A-76). Survival was marginally greater in drier years (0.7% increase, a 3.5% relative difference) but reduced in wetter years (2.4%, an 8% relative difference). The results for H4_ELT were very similar to those for H3_ELT because the late fall-run migration period lies outside the spring period when H4_ELT and H3_ELT operations differ (higher outflow under H4_ELT). As noted for fall-run Chinook salmon from the Sacramento River (described above), the DPM results do not account for adjustments that would be made during real-time operations to further protect migrating fish, based on biological and hydrological triggers developed by NMFS and DFW.

Adults

As described above, the percentage of Sacramento River water would be slightly reduced in December and March (1% to 9% less) compared to NAA_ELT (Table 11-4A-75). This effect would be less in March under Scenario H4_ELT compared to Scenario H3_ELT due to reduced north Delta exports. Olfactory cues would be slightly decreased, but the impact would be minor because flow changes are than 10% for the bulk of the late fall-run migration.

Mokelumne River

Fall-Run

Average through-Delta survival of emigrating juveniles estimated by DPM under Scenario H3_ELT was similar to Existing Conditions for all years and drier years (less than 2% relative difference), whereas average survival in wetter years was slightly greater than Existing Conditions (1% absolute difference in survival, 5.6% relative difference) (Table 11-4A-74). Average through-Delta survival under Scenario H4_ELT was similar to Existing Conditions in drier years, but was slightly greater than Existing Conditions when averaged over all years (5.6% relative difference) and was moderately greater than Existing Conditions in wetter years (nearly 12% relative difference). This reflected the inclusion of higher outflow in wetter years under H4_ELT compared to H3_ELT.

San Joaquin River

Fall-Run

Juveniles

Under Alternative 4A (operation Scenarios H3_ELT and H4_ELT), mean survival of juveniles migrating from the San Joaquin River averaged around 13% (Table 11-4A-74). Alternative 4A survival under both was similar (less than 5% relative difference) to Existing Conditions when averaged over all years. Survival was slightly greater than Existing Conditions in drier years (0.8–1% greater survival, or 7.5–10% more in relative difference) and moderately reduced in wetter years (2.5–2.7% decrease, or 13-14% less in relative difference). As described for the NEPA analysis above and described further in *BDCP Appendix 5.C, Section 5C.5.3.4.5 hereby incorporated by reference*, these results are driven by appreciably lower through-Delta survival of San Joaquin River fall-run Chinook salmon under Alternative 4A scenarios relative to Existing Conditions in very wet years (1982/1983) during which the Head of Old River operable gate would not be closed and south Delta exports would be very low, resulting in estimated survival that is relatively low because of the DPM's positive relationship between survival and exports. There is considerable uncertainty in effects on San Joaquin River Chinook salmon survival at such low levels of exports because the studies upon which the DPM flow- and export-survival relationships are based did not include these low levels of exports. As noted in the NEPA analysis above, SalSim, a recently completed San Joaquin River watershed Chinook salmon analysis tool that includes juvenile survival through the Delta derived in a different manner than DPM, includes a positive relationship between probability of juvenile survival and flow in the mainstem San Joaquin River at Stockton Deepwater Ship Channel; this flow term is positively related to flow at Vernalis, inversely related to south Delta exports, and positively related to Head of Old River barrier operation; the results of SalSim modeling therefore would be expected to illustrate a benefit of Alternative 4A across any modeled year, which is more in keeping with the anticipated effect of the alternative.

Adults

As described above, the percentage of San Joaquin River water at Collinsville is very small (less than 1% under Existing Conditions) during the fall-run migration period (September to December). Under Scenario H3_ELT operations, this would increase by 1.4–4.8% in September-December (Table 11-4A-75). Olfactory cues for adults migrating to the San Joaquin River would be slightly increased under all flow scenarios for Alternative 4A.

Summary of CEQA Conclusion

These modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce migration conditions for fall-/late fall-run Chinook salmon upstream of the Delta. Under Alternative 4A, instream flows would be lower in multiple upstream rivers during the fall-run Chinook salmon migration period relative to Existing Conditions, depending on scenario (H3_ELT or H4_ELT). Degraded migration habitat conditions would delay or eliminate successful migration necessary to complete the fall-run Chinook salmon life cycle. However, the impact of Alternative 4A across the operational range (Scenarios H3_ELT and H4_ELT) on through-Delta migration conditions would be small due to generally similar juvenile survival and a minor effect on olfactory cues for adults.

This interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

This impact would still be considered significant in the ELT due to changes in upstream flows. However, when informed by the NEPA analysis above, and with the implementation of Mitigation Measure AQUA-78d, this impact would be less than significant to fall-/late fall-run Chinook salmon.

As noted for winter-run and spring-run Chinook salmon and described in the adaptive management and monitoring program in Section 4.1, several pre-construction studies to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Similarly, Alternative 4A also includes investigations to better understand factors affecting juvenile through-Delta migration (as described in the adaptive management and monitoring program in Section 4.1) and includes biologically based triggers for real time operations. Also, with the inclusion of *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 15 Localized Reduction of Predatory Fishes*, and *Environmental Commitment 16 Nonphysical Barriers*, the impacts would be minimized.

Given that Mitigation Measure AQUA-78d reduces this impact to less than significant for fall-run Chinook, the impact on the fall-run Chinook salmon commercial fishery also would be less than significant in the ELT.

Mitigation Measure AQUA-78d: Slightly adjust the timing and magnitude of Shasta, Folsom, and/or Oroville Reservoir releases, within all existing regulations and requirements, to ameliorate changes in instream flows that would cause an adverse effect to fall-run Chinook salmon.

Whenever possible during real-time operations, project proponents will slightly adjust Shasta, Folsom and/or Oroville Reservoir operations to ensure that instream flows are sufficient to minimize or avoid migration-related effects to fall-run Chinook salmon. Based on the timing of the modeled flow fluctuations, it is expected that adjustments to minimize drastic changes in releases during operations among various months in which there are increases and decreases in flow, will minimize or avoid substantial reductions in flow without effects on existing applicable regulations or operations.

Fall-/late fall-run Chinook salmon migration conditions in the Sacramento, Feather, and American rivers, would substantially decline from ELT to LLT. However, when informed by the NEPA analysis above, implementation of Mitigation Measure AQUA-78d will reduce the magnitude of this effect to less than adverse. The commercial fishery effect of Alternative 4 in the LLT would be less than significant in the LLT.

Restoration Measures (Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

As described for winter-run Chinook salmon, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A, upon which the discussion of impacts for Alternative 4 is based. The general discussion of impacts to winter-run Chinook salmon (Impacts AQUA-43, AQUA-44, and AQUA-45) also applies to fall-/late fall-run Chinook salmon, which would have the potential to overlap the effects of restoration measures both temporally and spatially.

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-43) is also applicable to fall-run/late fall-run Chinook salmon.

NEPA Effects: For the reasons described under Impact AQUA-43, the effects of short-term construction activities would not be adverse to fall-run/late fall-run Chinook salmon.

CEQA Conclusion: As discussed for winter-run Chinook salmon, the potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce fall-run/late fall-run Chinook salmon habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-44) is also applicable to fall-run/late fall-run Chinook salmon.

NEPA Effects: As noted for winter-run Chinook salmon, the effect of restoration measures on chemical contaminants is not adverse to fall-run/late fall-run with respect to selenium, copper, ammonia, pesticides, and methylmercury (with implementation of Environmental Commitment 12).

CEQA Conclusion: As noted for winter-run Chinook salmon, the impact of contaminants is considered less than significant because it would not substantially affect fall-run/late fall-run Chinook salmon either directly or through habitat modifications. Consequently, no mitigation would be required.

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-45) is also applicable to fall-run/late fall-run Chinook salmon.

NEPA Effects: The effects of restored habitat conditions on fall-run/late fall-run Chinook salmon would not be adverse because effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and implementing the commitments described in detail under Impact AQUA-1 and in Appendix 3B, *Environmental Commitments*.

CEQA Conclusion: As described for winter-run Chinook salmon, habitat restoration activities could result in short-term effects on fall-run/late fall-run Chinook salmon, primarily as a result of increased potential for contaminated sediments to enter the water column. However, these effects are likely to be localized, sporadic, and of low magnitude. Adverse effects during restoration would be avoided by limiting the frequency, duration, and spatial extent of in-water work and implementing the commitments described in detail under Impact AQUA-1 and in Appendix 3B, *Environmental Commitments*. The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce fall-run/late fall-run Chinook salmon habitat, restrict its range or interfere with its movement. Additionally, there would be substantial long-term net benefits of habitat restoration. Consequently, no additional mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

As noted for winter-run Chinook salmon, Alternative 4A includes three other Environmental Commitments, which are reduced in their extent relative to the Conservation Measures included in other Alternatives (e.g., Alternative 1A and Alternative 4). While the extent of these measures is reduced compared to these alternatives, the nature of the mechanisms remains the same. The general discussion of impacts to winter-run Chinook salmon (Impacts AQUA-46, AQUA-49, and AQUA-50) also applies to fall-run/late fall-run Chinook salmon.

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (Environmental Commitment 12)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-46) is also applicable to fall-run/late fall-run Chinook salmon.

NEPA Effects: The effects of methylmercury management on fall-run/late fall-run Chinook salmon would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As noted for winter-run Chinook salmon, effects of Environmental Commitment 12 Methylmercury Management within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts would be less than significant. Consequently, no mitigation is required.

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (Environmental Commitment 15)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-49) is also applicable to fall-run/late fall-run Chinook salmon.

NEPA Effects: Environmental Commitment 15 would not have an adverse effect on Chinook salmon and could potentially benefit the species. As noted for winter-run Chinook salmon, due to the uncertainty in the effectiveness of Environmental Commitment 15, there would be no demonstrable effect of this conservation measure on fall-run/late fall-run Chinook salmon.

CEQA Conclusion: Due to the uncertainties associated with this Environmental Commitment, there would be no demonstrable effect on fall-run/late fall-run Chinook salmon. Thus, the impact would be less than significant. Consequently, no mitigation would be required.

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (Environmental Commitment 16)

As noted above, the impact discussion for winter-run Chinook salmon (Impact AQUA-50) is also applicable to fall-/late fall–run Chinook salmon. In addition, fall-run Chinook salmon from the San Joaquin River watershed would be unlikely to encounter the nonphysical barrier at the divergence of Georgiana Slough from the Sacramento River.

NEPA Effects: The effects of NPBs would not be adverse, because it is expected to improve Chinook salmon migration conditions.

CEQA Conclusion: As concluded for winter-run Chinook salmon, the impacts of *Environmental Commitment 16 Nonphysical Fish Barriers* are expected to be less than significant because it is expected to improve Chinook salmon migration conditions. Consequently, no mitigation would be required.

Steelhead

Construction and Maintenance of Water Conveyance Facilities

The discussion of potential effects to delta smelt from construction and maintenance of the water conveyance facilities under Alternative 4A is also relevant to steelhead. Adult and juvenile steelhead would have the potential to overlap construction and maintenance to a minor degree (Table 11-8).

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

The potential effects of construction of the water conveyance facilities on steelhead would be the same as described for Alternative 4 (Impact AQUA-91). This section provides additional detail on underwater noise impacts which are also applicable to Impact AQUA-91 in Alternative 4.

Table 11-8 presents the life stages of CCV steelhead and the months of their potential presence in the north, east, and south Delta during the proposed in-water construction period (June 1–October 31). Steelhead eggs and fry would not be exposed to underwater noise from pile driving activities because the proposed construction activities are located in areas that are downstream from the principal spawning and early rearing areas.

Under Alternative 4A, adult steelhead could be exposed to pile driving sound during their migrations past the construction sites of the proposed intakes, barge unloading facilities, and Head of Old River. Based on historical migration timing, migrating adults may be present in the Delta and lower Sacramento and San Joaquin Rivers during their upstream migration from August through November and during their downstream migration as kelts (post-spawn adults) from February through May (Hallock 1961, Busby et al. 1996). Juvenile steelhead emigrate episodically from natal streams during fall, winter, and spring high flows, with peaks in abundance in the spring (March through June) and fall (October through November) (McEwan 2001, Nobriga and Cadrett 2001).

Similar to Chinook salmon, the risk of injury or mortality of adult steelhead from pile driving noise is low because of their large size, high mobility, and rapid migration rates through the Delta and lower rivers. The risk of exposure to harmful levels of underwater noise and/or delays in migration is further reduced by the intermittent nature of pile driving activities, the daily cessation of pile driving at night, and the implementation of vibratory driving or other no-impact pile driving methods whenever feasible. Based on the general timing of steelhead outmigration through the Delta, exposure of juvenile steelhead to pile driving noise will be substantially minimized by the restriction of in-water pile driving period to June 1 through October 31. Most steelhead potentially encountering pile driving noise are large, yearling and older smolts (> 10 grams) that are expected to migrate rapidly through the Delta based on recent telemetry studies using tagged hatchery juveniles (DeLaney et al. 2014). As discussed for Chinook salmon, the restriction of pile driving to daylight hours would also reduce the exposure of juvenile steelhead to pile driving noise because of the general tendency for salmonids to migrate at night. However, pile driving noise could have indirect effects on survival by disrupting feeding, resting, and sheltering behavior of individuals that are within the range of noise levels associated with behavioral effects.

Based on the foregoing analysis, the potential exists for some injury and mortality of juvenile steelhead from pile driving noise but only a small proportion of the population is at risk based on the low degree of overlap of pile driving activities with outmigration timing, and the relatively large size and mobility of juveniles that may encounter pile driving noise (migrating smolts). Implementation of Mitigation Measures AQUA-1a and AQUA-1b will further reduce this risk.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-91, the effect would not be adverse for steelhead. Implementation of the measures described in Appendix 3B, *Environmental Commitments*, such as *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan* would guide rapid and effective response in the case of inadvertent spills of hazardous materials. This species' natural tolerance to turbidity, would likely avoid the risk of any adverse turbidity effects resulting from project construction. Construction would not be expected to increase predation rates relative to baseline conditions. Construction will result in both temporary and permanent alteration of rearing and migratory habitats used by steelhead. However, Alternative 4A includes Environmental Commitment 4 to restore tidal habitat and Environmental Commitment 6 to restore channel margin habitat. The direct effects of underwater construction noise on steelhead that may be present could be adverse if steelhead are exposed. However, implementation of Mitigation Measures AQUA-1a and AQUA-1b, combined with the in-water work window that would minimize exposure, would reduce the potential for effects from underwater noise and this effect would not be adverse.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-91, the impact of the construction of water conveyance facilities on steelhead would not be significant except for construction noise associated with pile driving. Construction of Alternative 4A involves several elements with the potential to affect steelhead. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect steelhead. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on steelhead from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1.The potential effects of the maintenance of water conveyance facilities under Alternative 4A would be the same as those described for Alternative 4, Impact AQUA-92. As concluded in Impact AQUA-92, the impact would not be adverse for steelhead.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-92, the impact of the maintenance of water conveyance facilities on steelhead would be less than significant and no mitigation is required. Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect steelhead. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on steelhead from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1.

Operations of Water Conveyance Facilities

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Water Exports from SWP/CVP South Delta Facilities

Under Alternative 4A, entrainment loss at the south Delta export facilities, as estimated by the salvage density method, would be reduced by about 52% (~4,800 fish; Table 11-4A-77) across all years compared to NAA_ELT. Losses under Scenario H3_ELT would be greatest in below normal (~7,300 fish) and lowest in wet water years (~2,100 fish). Conditions under Scenario H4_ELT would further reduce entrainment loss at the south Delta facilities due to decreased exports.

Table 11-4A-77. Juvenile Steelhead Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 4A (Scenario H3_ELT)

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-4,143 (-66%)	-4,443 (-68%)
Above Normal	-7,358 (-57%)	-7,752 (-58%)
Below Normal	-4,529 (-38%)	-4,674 (-39%)
Dry	-1,750 (-23%)	-1,517 (-21%)
Critical	-1,007 (-17%)	-917 (-16%)
All Years	-4,620 (-51%)	-4,810 (-52%)
	Shading indicates 10% or greater increased entrainment.	

Note: Estimated annual number of fish lost, based on non-normalized data.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Water Exports from SWP/CVP North Delta Intake Facilities

The impact would be similar in type to Alternative 1A, Impact AQUA-93, but the degree would be less because Alternative 4A would have fewer intakes, therefore, under Alternative 4A there would be about a 40% reduction in impingement and predation risk relative to Alternative 1A.

Predation Associated with Entrainment

Entrainment-related predation loss at the south Delta facilities would be no greater and may be lower than baseline (NAA_ELT), due to a reduction in entrainment. Conditions under Scenario H4_ELT would further reduce entrainment-related predation loss compared to Scenario H3_ELT.

Predation at the north Delta would be increased due to the construction of the proposed SWP/CVP water export facilities on the Sacramento River. It is assumed that per capita steelhead predation losses would be similar to those predicted for spring-run Chinook salmon, although slightly reduced because of the larger size of steelhead outmigrants. Bioenergetics modeling with a median predator density of 0.12 predators per foot (0.39 predators per meter) of intake predicts a predation loss of about 0.2% of the juvenile spring-run juvenile population (Table 11-4A-30).

NEPA Effects: In conclusion, operations under Alternative 4A under both flow scenarios (H3_ELT and H4_ELT) would reduce entrainment at the south Delta facilities and minimize or avoid entrainment with screens at the north Delta intakes. Predation loss at the south Delta would be reduced and predation at the north Delta intakes would likely have a very minor impact on the overall steelhead population. The overall effect under Alternative 4A would not be adverse.

CEQA Conclusion: As described above, entrainment losses of juvenile steelhead would decrease under Alternative 4A (H3_ELT) compared to Existing Conditions at the south Delta export facilities (Table 11-4A-77). The screened intakes of the north Delta diversion, as designed, would exclude juvenile salmonids. The impact of predation associated with entrainment would be the same as described above as predation loss at the south Delta (no greater and possibly lower compared with Existing Conditions), but increased slightly at the north Delta intakes. There may be a minor increase in predation loss under Alternative 4A associated with the north Delta intakes, but this is uncertain and the population-level effect would likely be small. Entrainment loss under Scenario H4_ELT is expected to be less compared to Scenario H3_ELT. Overall, the impact would be less than significant and no mitigation is required.

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

In general, Alternative 4A would have negligible effects on spawning and egg incubation habitat for steelhead relative to the NAA_ELT.

H3_ELT/ESO_ELT

Sacramento River

The primary steelhead spawning and egg incubation period extends from January through April. Results of the CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (Keswick Dam to upstream of RBDD) were summarized by month and water-year type based on estimated flows at Keswick and upstream of RBDD (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality. Mean flows under H3_ELT would generally be similar to those under NAA_ELT,. Overall results indicate negligible project-related effects on flow.

SacEFT predicts that there would be no effects between NAA_ELT and H3_ELT in spawning metrics including percentage of years with good spawning availability, measured as weighted usable area, redd scour risk, percentage of years with good (lower) egg incubation conditions, and redd dewatering risk (Table 11-4A-78). Results indicate negligible project-related effects on steelhead habitat metrics related to spawning and egg incubation in the Sacramento River.

Mean water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location. Based on negligible effects on mean flow, SacEFT metrics related to spawning and egg incubation, and water temperature conditions compared to NAA_ELT, project-related effects of H3_ELT on flow would not affect steelhead spawning conditions in the Sacramento River.

Table 11-4A-78. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Steelhead Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Spawning WUA	0 (0%)	0 (0%)
Redd Scour Risk	-3 (-4%)	0 (0%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	-1 (-2%)	0 (0%)
Juvenile Rearing WUA	1 (2%)	-3 (-7%)
Juvenile Stranding Risk	-9 (-26%)	-4 (-14%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
WUA = Weighted Usable Area.

Clear Creek

The primary spawning and egg incubation period for Clear Creek is January through April. Results of the CALSIM analyses of instream flows for the Clear Creek were summarized by month and water-year type for January through April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality.

Mean flows in Clear Creek during January through April under H3_ELT would be similar to those under NAA_ELT. Therefore, H3_ELT would have negligible effects on mean flows in Clear Creek for the primary steelhead spawning and egg incubation period of January to April.

Redd dewatering risk was evaluated for Clear Creek based on flow reductions for each month during the incubation period (January through April); results are summarized in Table 11-4A-79. The greatest monthly reduction in flows under H3_ELT would be no different than that under NAA_ELT.

No water temperature modeling was conducted in Clear Creek.

Based on mean monthly flows and flow reductions, there would be no effects of H3_ELT on steelhead spawning and egg incubation habitat conditions.

Table 11-4A-79. Comparisons of Greatest Monthly Reduction (Percent Change) in Instream Flow under Model Scenarios in Clear Creek during the January–April Steelhead Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-25 (-38%)	0 (0%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in the month when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Steelhead spawning and egg incubation on the Feather River occurs primarily in Hatchery Ditch and the low-flow channel in the general vicinity of the Feather River Hatchery. Effects of H3_ELT on flow during the spawning and egg incubation period (January through April) in the Feather River were evaluated using the results of CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (low-flow channel) based on estimated flows above Thermalito Afterbay (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Although recent surveys have found that very few steelhead (0 to 28%) spawn in the high-flow channel, (J. Kindopp pers. comm.), flows were also evaluated in the high-flow channel based on information in the Feather River at Thermalito Afterbay (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality.

Mean flows in the Feather River high-flow channel during January through April under H3_ELT would generally be similar to flows under NAA_ELT, except for occasional increases (up to 30% higher) and decreases (up to 17% lower) that, due to their low magnitude and frequency, would not amount to a biologically meaningful effect to steelhead.

Instream flows affect physical habitat quality and availability through changes in wetted channel width, water depth, and water velocities. Results of IFIM studies (WUA versus flow relationships) provide information on the spawning habitat conditions in the low-flow channel. Results of CALSIM modeling show that instream flows in the Feather River low-flow channel were the same for NAA_ELT and H3_ELT regardless of month and water year type and range from 700 to 800 cfs under all conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, H3_ELT is not expected to affect physical habitat conditions for steelhead spawning and egg incubation within the Feather River low-flow channel.

Water temperatures in the low-flow channel of the Feather River are determined largely by cold water pool storage in Oroville Reservoir and instream flow releases. Because instream flows in the low-flow channel would be the same under H3_ELT and NAA_ELT, any simulated changes in water temperatures under H3_ELT would be attributed to changes in reservoir storage. Reservoir storage in May and September provides an indicator of cold water pool availability. Mean May Oroville storage volume under H3_ELT would be similar to storage under NAA_ELT in all water year types (Table 11-4A-45). September Oroville storage volume under H3_ELT would be similar to volume in wet, above normal, and below normal water years and 12% to 15% greater than volume under NAA_ELT during dry and critical water years (Table 11-4A-39).

Effects of H3_ELT on water temperature-related spawning and egg incubation conditions for steelhead in the Feather River were analyzed by comparing the percent of months between January through April over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4A-80). Differences in the percent of months exceeding the threshold between NAA_ELT and H3_ELT would be negligible (<5% on an absolute scale).

Table 11-4A-80. Differences between Baseline and H3_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, January through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3_ELT					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	0 (0%)	1 (NA)	1 (NA)	1 (NA)	0 (NA)
April	12 (143%)	5 (100%)	4 (NA)	1 (NA)	0 (NA)
NAA_ELT vs. H3_ELT					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-1 (-50%)	1 (NA)	1 (NA)	1 (NA)	0 (NA)
April	1 (6%)	-1 (-11%)	0 (0%)	0 (0%)	0 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

The effects of H3_ELT on water temperature-related spawning and egg incubation conditions for steelhead in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the January through April steelhead spawning period for all 82 years (Table 11-4A-81). There would be no difference (<5% on an absolute scale) in total degree-months exceeded between NAA_ELT and H3_ELT for any month or water year type.

Table 11-4A-81. Differences between Baseline and H3_ELT Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, January through April

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	3 (300%)	2 (100%)
	All	3 (300%)	2 (100%)
April	Wet	0 (NA)	0 (NA)
	Above Normal	2 (100%)	1 (33%)
	Below Normal	3 (75%)	0 (0%)
	Dry	6 (120%)	-1 (-8%)
	Critical	7 (NA)	0 (0%)
	All	18 (164%)	0 (0%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

Overall for the Feather River, these similarity of flows and water temperature results indicate that H3_ELT would not affect flow and water temperatures conditions for steelhead spawning in the Feather River.

American River

The primary steelhead spawning and egg incubation period for the American River extends from January through April. Results of the CALSIM analyses of instream flows within the lower American River at the confluence with the Sacramento River were summarized by month and water-year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation and rapid reductions in flow can dewater redds leading to mortality. Mean flows under H3_ELT would be similar to flows under NAA_ELT during all months and water year types, with few exceptions.

Mean water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4A-64). Steelhead spawn and eggs incubate in the American River between January and April. During this period, the percent of months exceeding the threshold under H3_ELT would similar to (absolute difference) the percent under NAA_ELT.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4A-65). During the January through April steelhead spawning and egg incubation period, total degree-months would be similar between NAA_ELT and H3_ELT.

Based on mean monthly flows and water temperature effects, effects under H3_ELT in the American River would consist primarily of negligible effects (<5%) on mean monthly flows and water temperatures and would not have biologically meaningful effects on steelhead spawning and egg incubation conditions in the American River.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT throughout this period would be nearly identical to flows under NAA_ELT.

Water temperatures throughout the Stanislaus River would be the same under NAA_ELT and H3_ELT throughout the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT throughout this period would be the same as flows under NAA_ELT.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT/HOS_ELT

Sacramento River

Flows in the Sacramento River at Keswick and upstream of Red Bluff during January through April under H4_ELT would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period at either location. Based on negligible effects on mean flow and water temperature conditions compared to NAA_ELT, project-related effects of H4_ELT on flow would not affect steelhead spawning conditions in the Sacramento River.

Clear Creek

Mean flows in the Clear Creek during January through April under H4_ELT would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek.

Feather River

Flows in the Feather River above Thermalito Afterbay (low-flow channel) during January through April under H4_ELT would be the same as flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the Feather River below Thermalito Afterbay (high-flow channel) during January through April under H4_ELT would generally be similar to or up to 548% greater than flows under NAA_ELT, with mean flow in April for all water year types combined 87% greater under H4_ELT.

Mean September Oroville storage under H4_ELT would be similar to storage under NAA_ELT in wet, above normal, and below normal water years, and would be 28% and 44% greater for dry and critical years, respectively (Table 11-4A-39). May Oroville storage would be 11% to 16 lower under H4_ELT than under NAA_ELT in wet, above normal, and below normal water years, would be 24% greater in critical years, and would be similar in dry years (Table 11-4A-45).

Differences in the percent of months exceeding the 56°F threshold in the Feather River at Gridley between NAA_ELT and H4_ELT would generally be negligible (<5% on an absolute scale) during January through March (Table 11-4A-69). The percent of months exceeding the threshold under H4_ELT during April would be up to 20% lower (absolute difference) than the percent under NAA_ELT. This represents a small benefit of H4_ELT to steelhead spawning habitat conditions in the Feather River.

Differences in the percent of months exceeding the 56°F threshold in the Feather River above Thermalito Afterbay between NAA_ELT and H4_ELT would be negligible during January through March (Table 11-4A-82). During April, the percent of months exceeding the threshold under H4_ELT would be similar to or up to 6% lower (absolute difference) than the percent under NAA_ELT. This represents a small benefit of H4_ELT to steelhead spawning habitat conditions in the Feather River.

Table 11-4A-82. Differences between Baselines and H4_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, January through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H4_ELT					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	0 (0%)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
April	7 (86%)	0 (0%)	1 (NA)	1 (NA)	0 (NA)
NAA_ELT vs. H4_ELT					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-1 (-50%)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
April	-4 (-19%)	-6 (-56%)	-2 (-67%)	0 (0%)	0 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Total degree-months (all water year types combined) above the 56°F threshold in the Feather River at Gridley under H4_ELT would be the same as those under NAA_ELT during January and February (Table 11-4A-70). During March and April, degree-months under H4_ELT would be 4% and 41% lower, respectively. The reductions in degree-months during March under H4_ELT would be too small and infrequent to have a biologically meaningful effect on steelhead spawning habitat conditions in the Feather River, although the reductions during April would represent a moderate benefit to steelhead. Total degree-months above the 56°F threshold in the Feather River above Thermalito Afterbay under H4_ELT would be similar to those under NAA_ELT during January through April (Table 11-4A-83).

Table 11-4A-83. Differences between Baselines and H4_ELT Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River at above Thermalito Afterbay, January through April

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	2 (200%)	1 (50%)
	All	2 (200%)	1 (50%)
April	Wet	0 (NA)	0 (NA)
	Above Normal	1 (50%)	0 (0%)
	Below Normal	0 (0%)	-3 (-43%)
	Dry	7 (140%)	0 (0%)
	Critical	8 (NA)	1 (14%)
	All	15 (136%)	-3 (-10%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

American River

Mean flows in the American River at the confluence with the Sacramento River during January through April under H4_ELT would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period. The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4A-71). Steelhead spawn and eggs incubate in the American River between January and April. During January through April period, the percent of months exceeding the threshold under H4_ELT would be similar to or up to 9% lower (absolute difference) than the percent under NAA_ELT.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4A-72). During the January through April steelhead spawning and egg incubation period, total degree-months would be similar between NAA_ELT and H4_ELT.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT throughout this period would be about the same as those under NAA_ELT.

Water temperatures throughout the Stanislaus River would be similar under NAA_ELT and H4_ELT throughout the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT throughout this period would be identical to flows under NAA_ELT.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, these modeling results indicate that the effects of Alternative 4A on flow would not be adverse because they would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg development. There would be negligible effects on Alternative 4A on mean monthly flows, water temperatures, and reservoir storage in all rivers analyzed. Further, the SacEFT model predicts that there would be no effects to spawning and egg incubation habitat in the Sacramento River.

CEQA Conclusion: In general, Alternative 4A would degrade the quantity and quality of spawning and egg incubation habitat for steelhead relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of spawning and egg incubation habitat for steelhead relative to the CEQA conclusion.

H3_ELT /ESO_ELT

Sacramento River

The primary steelhead spawning and egg incubation period extends from January through April. Results of the CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (Keswick Dam to upstream of RBDD) were summarized by month and water-year type based on estimated flows at RBDD (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality. Mean flows under H3_ELT would generally be similar to those under Existing Conditions, except for February, in which flows would be up to 14% higher, depending on the water year type.

SacEFT predicts little or no change in spawning habitat, egg incubation, redd dewatering risk, and redd scour risk for H3_ELT compared to Existing Conditions (Table 11-4A-78).

Mean water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period at either location. Based on negligible effects on mean flow, SacEFT metrics related to spawning and egg incubation, and water temperature conditions compared to Existing Conditions, project-related effects of H3_ELT on flow would not affect steelhead spawning conditions in the Sacramento River.

Clear Creek

The primary spawning and egg incubation period for Clear Creek is January through April. Results of the CALSIM analyses of instream flows for the Clear Creek were summarized by month and water-year type for January through April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality.

Mean flows under H3_ELT would be similar to or greater than flows under Existing Conditions for all months, including 40% greater flow for January of wet years and 10% greater flow for all four months in critical water years. Increases in flow would have a beneficial effect on spawning conditions.

Redd dewatering risk was evaluated for Clear Creek based on flow reductions for each month during the incubation period (January through April); results are summarized in Table 11-4A-79. The greatest monthly reduction in flows under H3_ELT would be similar to that under Existing Conditions, except for a 25% increase (absolute difference) in the greatest monthly flow reduction in wet years under H3_ELT.

No water temperature modeling was conducted in Clear Creek.

Based on mean flows and increased maximum flow reductions only in wet years, there would be no effects of H3_ELT on steelhead spawning and egg incubation habitat conditions.

Feather River

Effects of H3_ELT on flow during the spawning and egg incubation period (January through April) in the Feather River were evaluated using the results of CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (low-flow channel) based on estimated flows above Thermalito Afterbay (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the high-flow channel were characterized based on information in the Feather River at Thermalito Afterbay (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality.

Results of CALSIM modeling show that instream flows in the Feather River low-flow channel were the same for Existing Conditions and H3_ELT regardless of month and water year type and range from 700 to 800 cfs under all conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, H3_ELT is not expected to affect physical habitat conditions for steelhead spawning and egg incubation within the Feather River low-flow channel.

Mean flows in the Feather River high-flow channel during under H3_ELT would generally be similar to or up to 48% lower than flows under Existing Conditions in January through March, with minor exceptions, and would be similar to or up to 29% greater in April. The reductions in flow would adversely affect spawning and egg incubation habitat.

Mean May Oroville storage volume under H3_ELT would generally be similar to storage under Existing Conditions in wet and above normal water year types and 5% to 12% lower in below normal, dry, and critical water year types (Table 11-4A-42). Mean September Oroville storage volume under H3_ELT would be 5% to 29% lower than volume under Existing Conditions in wet, above normal, below normal, and dry water years and would be similar in critical water years (Table 11-4A-33).

Mean water temperatures in the Feather River low-flow channel (above Thermalito Afterbay) and high-flow channel (below Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, there would be no differences (<5%) in mean water temperatures between H3_ELT and Existing Conditions for all months and water year types throughout the period.

Effects of H3_ELT on water temperature-related spawning and egg incubation conditions for steelhead in the Feather River were analyzed by comparing the percent of months between January through April over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4A-80). Differences in the percent of months exceeding the threshold between Existing Conditions and H3_ELT would be negligible (<5% on an absolute scale), except for a 12% increase (absolute difference) for the >1.0°F above the threshold in April.

The effects of H3_ELT on water temperature-related spawning and egg incubation conditions for steelhead in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold in the low-flow channel (above Thermalito Afterbay) during the January through April steelhead spawning period for all 82 years (Table 11-4A-81). There would be no difference (<5% on an absolute scale) for January through March in total degree-months exceeded between Existing Conditions and H3_ELT for any water year type, and an 18 degree-month increase (164% higher on a relative scale) in April for all water year types combined.

Overall, the effects of H3_ELT on flows in the Feather River below Thermalito Afterbay would include substantial decreases in mean flow during some months and water year types. There would be minor increases in the exceedance of water temperature thresholds in the low-flow channel during April, coupled with reductions in coldwater pool availability in the Oroville Reservoir, especially in September.

American River

The primary steelhead spawning and egg incubation period for the American River extends from January through April. Results of the CALSIM analyses of instream flows within the lower American River at the confluence with the Sacramento River were summarized by month and water-year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation and rapid reductions in flow can dewater redds leading to mortality. Combining water year types, mean flows under H3_ELT would be higher than those under Existing Conditions during January and February and would be similar during March and April.

Mean water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4A-64). Steelhead spawn and eggs incubate in the American River between January and April. During January and February, the percent of month exceeding the threshold under Existing Conditions and H3 would be similar. During March and April, the percent of months exceeding the threshold under H3 would be up to 17% greater (absolute difference) than the percent under Existing Conditions.

Total degree-months (all water year types combined) exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4A-65). During January and February, there would be no difference in total degree-months above the threshold between Existing Conditions and H3_ELT. During March and April, total degree-months under H3_ELT would be 16 and 80 degree-months greater, respectively, than under Existing Conditions.

The effect of H3_ELT on mean flow and water temperature in the American River would be negligible although increased exceedances of the 56°F temperature threshold indicate a negative effect to steelhead spawning and egg incubation conditions.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT throughout this period would generally be similar to or up to 29% lower than flows under Existing Conditions.

Water temperatures throughout the Stanislaus River would be the same under Existing Conditions and H3_ELT throughout the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT throughout this period would be similar to flows under Existing Conditions, with minor exceptions.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT/HOS_ELT

Sacramento River

Mean flows in the Sacramento River at Keswick and upstream of Red Bluff during January through April under H4_ELT would generally be similar to flows under Existing Conditions, with minor exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period at either location.

Clear Creek

Mean flows in the Clear Creek during January through April under H4_ELT would generally be similar to or up to 40% greater than flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek.

Feather River

Flows in the Feather River above Thermalito Afterbay (low-flow channel) during January through April under H4_ELT would be identical to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the Feather River below Thermalito Afterbay (high-flow channel) under H4_ELT would be up to 36% lower than flows under Existing Conditions during January and February, similar during March, and up to 509% greater during April.

May Oroville storage under H4_ELT would be up to 19% lower than storage under Existing Conditions in all water year types except critical water years, in which storage would be 15% greater under H4_ELT (Table 11-4A-45). September Oroville storage under H4_ELT would be about 24% lower than storage under Existing Conditions in wet, above normal, and below normal water years, similar in dry years, and 32% higher in critical years (Table 11-4A-39).

Mean water temperatures in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H4_ELT and Existing Conditions for all months and water year types at either location throughout the period.

Differences in the percent of months exceeding the 56°F threshold between Existing Conditions and H4_ELT would generally be negligible (<5% on an absolute scale) during January through April, except for the >1.0 degree category for April, in which the percent of months exceeding the threshold would be 7% higher (absolute difference) (Table 11-4A-82).

Total degree-months (all water years combined) above the 56°F threshold under H4_ELT would be similar to those under Existing Conditions during January and February, and would be 19 and 80 degree-days higher for March and April, respectively(Table 11-4A-83). These increases, although large when expressed as percentages, constitute a small proportion with respect to the 82-year period of analysis.

American River

Mean flows in the American River at the confluence with the Sacramento River during January through April under H4_ELT would generally be similar to flows under Existing Conditions, with a number of minor exceptions especially in February (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H4_ELT and Existing Conditions for all months and water year types throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4A-71). Steelhead spawn and eggs incubate in the American River between January and April. During January and February, there would be no differences in the percent of month exceeding the threshold between Existing Conditions and H4_ELT. During March and April, the percent of months exceeding the threshold under H4_ELT would be up to 11% greater (absolute difference) than the percent under Existing Conditions.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4A-72). During the January and February, there would be no difference in total degree-months above the threshold between Existing Conditions and H4_ELT. During March and April, total degree-months for all water year types combined under H4_ELT would be 19 and 80 degree-months, respectively, greater than under Existing Conditions.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean Flows under H4_ELT would be lower than those under Existing Conditions for about half of the water year means within the four month period, with up to 29% lower flows under in February of critical water years.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River was evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H4_ELT and Existing Conditions for all months and water year types throughout the period.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions, with minor exceptions.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Under Alternative 4A, there are flow and cold water pool availability reductions in the Feather, American, and Stanislaus Rivers, as well as temperature increases in the Feather and American rivers that would lead to biologically meaningful increases in egg mortality and overall reduced habitat conditions for spawning steelhead and egg incubation, as compared to Existing Conditions. Alternative 4A would not have significant effects on steelhead spawning conditions in the Sacramento River, Clear Creek, San Joaquin River, or the Mokelumne River. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of steelhead as a result of egg mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be negligible effects on mean monthly flows, water temperatures, and reservoir storage. Further, the SacEFT model predicts that there would be no effects to spawning and egg incubation habitat in the Sacramento River. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

In general, the effects of Alternative 4A on steelhead rearing conditions would be negligible relative to the NAA_ELT.

H3_ELT/ESO_ELT

Sacramento River

Juvenile steelhead rear within the Sacramento River and its tributaries throughout the year because juveniles inhabit upstream areas for a period of 1 to 2 years before migrating downstream to the ocean. Results of the CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (Keswick Dam to upstream of Red Bluff) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for effects of H3_ELT. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles, leading to mortality.

In general, mean flows under H3_ELT would be similar to flows under NAA_ELT throughout the year, except during November when the mean flows under H3_ELT would be up to 23% lower at Keswick and up to 18% lower at Red Bluff. These small and isolated reductions would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location.

SacEFT predicts that there would be a 7% reduction in years classified as good juvenile rearing habitat conditions under H3_ELT compared to NAA_ELT, and a 14% reduction in the percentage of years classified "good" with respect to juvenile stranding risk (Table 11-4A-78). On an absolute scale, these changes to rearing WUA and stranding risk would be 3% and 4%, respectively, which would be negligible to juvenile steelhead.

Based on mean monthly flows, SacEFT rearing metrics, and water temperature effects, project-related effects under Alternative 4A in the Sacramento River would not have biologically meaningful negative effects on steelhead rearing conditions. Effects of H3_ELT consist primarily of negligible effects that would not have biologically meaningful effects on rearing success.

Clear Creek

Steelhead rear in Clear Creek throughout the year. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality.

Instream flows estimated from the modeling each month and water-year type were used to compare among model scenarios (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). In general, flows under H3_ELT would be similar to those under NAA_ELT, with minor exceptions.

Evaluation of the minimum instream flows in Clear Creek indicates that H3_ELT would have no effect (0%) on minimum instream flows in any water year type, except for a decrease (-50 cfs or -100%) for dry water years (Table 11-4A-84).

Table 11-4A-84. Minimum Monthly Instream Flow (cfs) for Model Scenarios in Clear Creek during the Year-Round Juvenile Steelhead Rearing Period

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	0 (0%)	0 (0%)
Above Normal	0 (0%)	0 (0%)
Below Normal	-70 (-100%)	0 (NA)
Dry	-50 (-100%)	-50 (-100%)
Critical	-50 (-100%)	0 (NA)

Note: Minimum flows occurred between October and March.
Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

Denton (1986) developed flow recommendations for steelhead in Clear Creek using IFIM (Figure 11-1A-4). The current Clear Creek management regime uses flows slightly lower than those recommended by Denton. Results from a new IFIM study on Clear Creek are currently being analyzed. Depending on results of this study the flow regime could be adjusted in the future. It is expected that the modeled flows will be suitable for the existing steelhead populations in Clear Creek. No change in effect on steelhead in Clear Creek is anticipated.

No water temperature modeling was conducted in Clear Creek.

These results indicate that effects of H3_ELT on flows would not affect juvenile steelhead rearing habitats in Clear Creek.

Feather River

The low-flow channel is the primary reach of the Feather River utilized by steelhead for spawning and rearing. Although there is relatively little natural steelhead production in the river, most steelhead spawning and rearing appears to occur in the low-flow channel in habitats associated with well-vegetated side channels (Cavallo et al. 2003; California Department of Water Resources unpublished data). Because these habitats are relatively uncommon they could limit natural steelhead production. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality.

There would be no change in flows for H3_ELT relative to NAA_ELT in the low-flow channel. Flow in the low-flow channel is projected to remain between 700 and 800 cfs except during occasional flood control releases. This flow is less than pre-dam levels during all months of the year as a result of water diversions through the Thermalito Afterbay. The significance of these flow conditions for steelhead spawning and rearing is uncertain. Feather River screw trap data indicate that Chinook salmon initiate emigration regardless of flow regime (i.e., they do not wait for a high-flow pulse). This is likely true for steelhead as well.

Mean May storage at Oroville under H3_ELT would be similar to that under NAA_ELT for all water year types (Table 11-4A-45). September Oroville storage under H3_ELT would be similar to or up to 15% greater than storage under NAA_ELT (Table 11-4A-39).

The river channel downstream of Thermalito (high-flow channel) offers few of the habitat types upon which steelhead appear to rely in the low-flow channel. Experiments and fish observations also indicate that predation risk for juvenile steelhead is higher downstream of the Thermalito outlet (California Department of Water Resources 2004). Increased predation risk is likely a function of water temperature, where warm water nonnative species such as striped bass, largemouth bass, and smallmouth bass are more prevalent, and in general, predators have greater metabolic requirements. Thus, summer temperatures that exceed 65°F and the absence of preferred steelhead habitat currently appear to limit steelhead rearing in the river downstream of the Thermalito outlet. Comparisons of CALSIM data by month and water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate that mean flows under H3_ELT would generally be similar to or greater than (up to 106% greater for June of below normal water years) those under NAA_ELT in the high-flow channel in all months except July through September. During July through September, flows under H3_ELT would be up to 48% lower than those under NAA_ELT depending on month and water-year type.

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period at either location.

Effects of H3_ELT on water temperature-related juvenile rearing conditions for steelhead in the Feather River were analyzed by comparing the percent of months between May through August over the 82-year CALSIM modeling period that exceed a 63°F temperature threshold in the low-flow channel (above Thermalito Afterbay) and by comparing the percent of months between October and April that exceed a 56°F threshold at Gridley. Results for the low-flow channel (above Thermalito Afterbay) and Gridley are presented for spring-run rearing and fall-run spawning and egg incubation in Impacts AQUA-59 and AQUA-76, respectively. In the low-flow channel and at Gridley, there would generally be only minor differences between NAA_ELT and H3_ELT in the percent of months exceeding the threshold, except in the low-flow channel in June, for which there would be up to a 9% reduction (absolute difference) in the percent of months under H3_ELT.

The effects of H3_ELT on water temperature-related juvenile rearing conditions for steelhead in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 63°F NMFS threshold during May through August in the low-flow channel and the 56°F threshold during October through April at Gridley. Results for the low-flow channel (above Thermalito Afterbay) and Gridley are presented for spring-run rearing and fall-run spawning and egg incubation in Impacts AQUA-59 and AQUA-76, respectively. In the low flow channel and at Gridley, there would be small increases and decreases in exceedances above the thresholds, but overall no biologically meaningful effects.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to or up to 25% greater than flows under NAA_ELT in all months except August, September, and November. Flows during these months would be up to 25% lower under H3_ELT than under NAA_ELT. Because these reductions would occur only during these months and would be generally low to moderate, they are not expected to cause biologically meaningful effects on steelhead juvenile rearing habitat.

Mean water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4A-85). During May through July, and October, the percent of months exceeding the threshold under H3_ELT would be similar to or up to 9% lower (absolute difference) than the percent under NAA_ELT. During August and September, the percent of months exceeding the threshold would increase up to 11% (absolute difference) under H3_ELT.

Table 11-4A-85. Differences between Baseline and H3_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 65°F Threshold, May through October

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3_ELT					
May	26 (131%)	20 (133%)	11 (100%)	6 (100%)	4 (75%)
June	27 (42%)	22 (42%)	17 (42%)	15 (48%)	14 (65%)
July	0 (0%)	1 (1%)	30 (47%)	21 (59%)	25 (143%)
August	0 (0%)	2 (3%)	17 (21%)	49 (103%)	57 (184%)
September	11 (13%)	37 (70%)	32 (100%)	30 (185%)	22 (300%)
October	17 (350%)	10 (400%)	9 (NA)	2 (NA)	1 (NA)
NAA_ELT vs. H3_ELT					
May	-1 (-3%)	-2 (-7%)	-1 (-5%)	0 (0%)	0 (0%)
June	0 (0%)	-2 (-3%)	-5 (-8%)	-7 (-14%)	-9 (-20%)
July	0 (0%)	0 (0%)	-2 (-3%)	-9 (-13%)	-5 (-11%)
August	0 (0%)	0 (0%)	0 (0%)	5 (5%)	11 (15%)
September	2 (3%)	9 (11%)	6 (11%)	7 (19%)	4 (14%)
October	-1 (-5%)	-1 (-9%)	2 (40%)	1 (100%)	1 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4A-86). Total degree-months (all water year types combined) exceeding the threshold would be similar between NAA_ELT and H3_ELT or up to 38 degree-months lower under H3_ELT in all months except August and September, in which degree-months would be 28 degree-months higher under H3_ELT.

Table 11-4A-86. Differences between Baseline and H3_ELT Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 65°F in the American River at the Watt Avenue Bridge, May through October

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
May	Wet	9 (150%)	0 (0%)
	Above Normal	7 (NA)	-2 (-22%)
	Below Normal	7 (233%)	-2 (-17%)
	Dry	22 (100%)	1 (2%)
	Critical	13 (68%)	-1 (-3%)
	All	58 (116%)	-4 (-4%)
June	Wet	31 (182%)	-7 (-13%)
	Above Normal	12 (50%)	-8 (-18%)
	Below Normal	21 (72%)	-7 (-12%)
	Dry	10 (15%)	-17 (-18%)
	Critical	33 (66%)	1 (1%)
	All	107 (57%)	-38 (-13%)
July	Wet	32 (41%)	-16 (-13%)
	Above Normal	9 (33%)	1 (3%)
	Below Normal	12 (35%)	-4 (-8%)
	Dry	35 (56%)	7 (8%)
	Critical	30 (37%)	4 (4%)
	All	118 (42%)	-8 (-2%)
August	Wet	69 (87%)	7 (5%)
	Above Normal	19 (46%)	2 (3%)
	Below Normal	29 (52%)	2 (2%)
	Dry	63 (93%)	15 (13%)
	Critical	40 (51%)	2 (2%)
	All	220 (68%)	28 (5%)
September	Wet	35 (146%)	12 (26%)
	Above Normal	14 (88%)	4 (15%)
	Below Normal	26 (93%)	7 (15%)
	Dry	35 (83%)	5 (7%)
	Critical	25 (51%)	0 (0%)
	All	135 (85%)	28 (11%)
October	Wet	6 (600%)	1 (17%)
	Above Normal	5 (NA)	0 (0%)
	Below Normal	3 (NA)	1 (50%)
	Dry	9 (NA)	0 (0%)
	Critical	9 (180%)	0 (0%)
	All	32 (533%)	2 (6%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

These results indicate that effects of H3_ELT on flow and water temperatures would not reduce juvenile rearing conditions in the American River.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to flows under NAA_ELT throughout the period.

Mean water temperatures throughout the Stanislaus River would be similar under NAA_ELT and H3_ELT throughout the year-round period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to flows under NAA_ELT throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be the same as flows under NAA_ELT throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT /HOS_ELT

Sacramento River

Mean flows in the Sacramento River at Keswick and upstream of Red Bluff under H4_ELT would generally be similar to flows under NAA_ELT year-round, except during November (11% to 20% lower) at Keswick (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These small and isolated reductions would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period at either location.

Clear Creek

Year-round flows in the Clear Creek under H4_ELT would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek.

Feather River

Year-round flows in the Feather River above Thermalito Afterbay (low-flow channel) under H4_ELT would be the same as flows under H3_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the Feather River below Thermalito Afterbay (high-flow channel) under H4_ELT would be similar to or up to 548% higher than (April of below normal water years) flows under NAA_ELT during October through June. During July through September, mean flows would be lower for every water year type (up to 60% lower for September of below normal years), except for critical years during August and September, in which flows under H4_ELT would be 48% and 52% higher.

Mean water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period at either location.

The analysis evaluating the percent of months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be small to moderate benefits (i.e., reduced percent of months exceeding the threshold) of H4_ELT relative to NAA_ELT in the low-flow channel and at Gridley.

The analysis evaluating the total degree-months exceeding water temperature thresholds from NMFS (63°F for the low flow channel and 56°F at Gridley) presented in Impacts AQUA-59 and AQUA-76 indicates that exceedances under H4_ELT would generally be similar to or lower than those under NAA_ELT in the low flow channel and at Gridley during spring and early summer months, but higher during fall months.

Mean May storage would be 11% to 16% lower under H4_ELT relative to NAA_ELT in wet, above normal, and below normal water years, similar in dry years, and 24% higher in critical years (Table 11-4A-45). September Oroville storage under H4_ELT would be similar to or up to 44% greater than storage under NAA_ELT (Table 11-4A-39).

American River

Year-round flows in the American River at the confluence with the Sacramento River under H4_ELT would generally be similar to flows under NAA_ELT, except during August and September, for which mean flows would be up to 33% lower under H4_ELT depending on water year type, and October, for which flows would be up to 24% higher (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4A-87). The percent of months exceeding the threshold under H4_ELT would be similar to or up to 20% lower (absolute difference) than the percent under NAA_ELT for all months.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4A-88). Total degree-months exceeding the threshold would be similar between NAA_ELT and H4_ELT throughout the period, except during July and August, in which total degree-months under H4_ELT would be 11% and 24% lower, and during September, in which total degree-months under H4_ELT would be 11% higher.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT would be similar to flows under NAA_ELT throughout the period.

Mean monthly water temperatures throughout the Stanislaus River would be similar under NAA_ELT and H4_ELT throughout the year-round period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT would be similar to flows under NAA_ELT throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be the same as flows under NAA_ELT throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, these modeling results indicate that the effect of Alternative 4A is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of fry and juvenile mortality. Effects of Alternative 4A on flows and water temperatures would be small and infrequent in the Sacramento River and Clear Creek, and effects in the Feather River and the American River would be more variable, but in general, the overall effects are expected to be slightly beneficial, despite the increased flow variations. Water temperatures in the Sacramento, Feather, American and Stanislaus Rivers would not be affected by Alternative 4A. Overall, Alternative 4A is not expected to have biologically meaningful negative effects on steelhead rearing conditions.

CEQA Conclusion: In general, Alternative 4A would degrade the quantity and quality of rearing habitat for steelhead relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of rearing habitat for steelhead relative to the CEQA conclusion.

H3_ELT/ESO_ELT

Sacramento River

Comparisons of CALSIM outputs of mean flow by month and water year type for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were used to evaluate effects of H3_ELT compared to Existing Conditions. Results for H3_ELT at Keswick were generally similar to those for Existing Conditions, except for September, in which flows were up to 34% higher and up to 24% lower, depending on water year type, and October and November, in which flows were up to 20% lower. The results for mean flows at Red Bluff were similar to those for flows at Keswick, except that the differences between H3_ELT and Existing Conditions were generally smaller. The most substantial effects on juvenile rearing habitats would occur from flow reductions in dry and critical water years, including those in September, as well as moderate reductions in dry and or critical years in August, October and November. Based on the overall infrequency and small size of these decreases, and negligible differences or beneficial increases in flow in most of the year, the flow reductions are not expected to have biologically meaningful negative effects on juvenile steelhead rearing conditions in the Sacramento River.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, mean water temperatures under H3_ELT would generally be similar to those under Existing Conditions, except during July through October at Keswick, when temperatures for critical years would range from 7% to 14% higher under H3_ELT, and for other water year types when temperatures would be up to 8% higher under H3_ELT.

SacEFT predicts that there would be a 2% increase in the percentage of years with good juvenile rearing habitat under H3_ELT compared to Existing Conditions (Table 11-4A-78). SacEFT predicts there would be a decrease of 26% in occurrence of years with "good" conditions for juvenile stranding risk (Table 11-4A-78). The increased stranding risk would contribute to the potential for juvenile mortality due to stranding.

Based on the incremental effects of reductions in mean monthly flows (up to 24% lower) for several months during drier water year types, including the warmer summer/ fall months of August through November, and increased risk of juvenile stranding (26%), effects of H3_ELT on flows would have biologically meaningful negative effects on juvenile rearing conditions in the Sacramento River.

Clear Creek

Comparisons of mean flows for Clear Creek were used to evaluate effects of H3_ELT relative to Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality. Effects of H3_ELT year-round would consist primarily of or small changes with respect to Existing Conditions, except that in critical water years during December through April mean flows would increase by 10%, in wet years during January flows would increase 40%, and in critical years during September they would fall 19%. The decreases in flow would not be of sufficient frequency and magnitude to cause biologically meaningful negative effects.

Evaluation of minimum instream flows for H3_ELT relative to Existing Conditions (Table 11-4A-84) indicates no effect (0%) for wet and above normal, and decreases for the remaining water year types (-50 to -70 cfs or -100%). These reductions corresponds to substantial decreases in total flow during drier water years based on relatively small quantities of flow (e.g., as low as 85 cfs in the summer months in drier water years, and more typically between 150 and 200 in other months). The reductions in minimum instream flows would affect juvenile rearing habitat and could increase stranding risk, particularly in drier water years.

No water temperature modeling was conducted in Clear Creek.

While effects of H3_ELT on mean monthly flow would consist predominantly of negligible effects, there would be moderate to substantial reductions in minimum instream flows, particularly during drier water years, that would affect juvenile rearing habitat and increase stranding risk in Clear Creek.

Feather River

The low-flow channel is the primary reach of the Feather River utilized by steelhead spawning and rearing. There would be no change in flows for H3_ELT relative to Existing Conditions in the low-flow channel (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Comparisons using CALSIM data by month and water year type for the Feather River at Thermalito (high-flow channel) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate variable effects of H3_ELT relative to Existing Conditions. H3_ELT would cause substantial changes in mean flows for a number of months and water year types. With some exceptions for specific water year types, there would be increases in mean flows of up to 140% during April through June, as well as for wetter years during July through September (up to 192% higher under H3_ELT)). However, for dry and/or critical years during July through September, flows would be up to 52% lower under H3_ELT than under Existing Conditions. H3_ELT would also cause reductions in flow during January through March, especially for below normal water years, of up to 48%, and during many other months and water year types. The flow changes would have a fairly broad range of effects on rearing habitat throughout the year, with reductions occurring in drier water years having the most adverse effects on juvenile rearing conditions.

Mean water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean water temperatures under H3_ELT would be similar (<5%) to those under Existing Conditions for all months and water year types,. In the high-flow channel, mean water temperatures under H3_ELT would be 5% and 6% higher than those under Existing Conditions during July of critical water years and August of dry water years, respectively, and would be similar for the remaining months and water year types.

Effects of H3_ELT on water temperature-related juvenile rearing conditions for steelhead in the Feather River were analyzed by comparing the percent of months between May through August over the 82-year CALSIM modeling period that exceed a 63°F temperature threshold in the low-flow channel (above Thermalito Afterbay) and by comparing the percent of months between October and April that exceed a 56°F threshold at Gridley. Results for the low-flow channel (above Thermalito Afterbay) and Gridley are presented for spring-run rearing and fall-run spawning and egg incubation in Impacts AQUA-59 and AQUA-76, respectively. In the low-flow channel and at Gridley, there would be no differences, small increases, and moderate to large increases (absolute difference), in the percent of months exceeding the threshold between H3_ELT and Existing Conditions. This comparison includes the effects of climate change.

The effects of H3_ELT on water temperature-related juvenile rearing conditions for steelhead in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 63°F NMFS threshold during May through August in the low-flow channel and the 56°F threshold during October through April at Gridley. Results for the low-flow channel (above Thermalito Afterbay) and Gridley are presented for spring-run rearing and fall-run spawning and egg incubation in Impacts AQUA-59 and AQUA-76, respectively. In the low-flow channel and at Gridley, there would be moderate increases in total degree-months (all water years combined) exceeding the temperature threshold during several months. These comparisons include the effects of climate change.

Mean May storage at Oroville would be similar or up to 12% lower under H3_ELT relative to Existing Conditions (Table 11-4A-45). Mean September Oroville storage under H3_ELT would be 19% to 29% lower than storage under Existing Conditions for wet, above normal and below normal water years, and would be similar for dry and critical water years (Table 11-4A-39).

Overall in the Feather River, effects of H3_ELT on mean flow would consist of substantial increases and decreases for various months and water year types. There would be relatively frequent, substantial flow reductions in drier water years that would affect juvenile rearing habitat conditions and contribute to stranding risk. Further, there would be moderate to large increases in the exceedance of temperature thresholds in the low-flow channel and at Gridley.

American River

CALSIM outputs were used to compare mean flows by month and water year type for H3_ELT for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality. Comparisons of H3_ELT to Existing Conditions indicate highly variable results, with moderately lower or higher flows for many months and water year types. There would be relatively large reductions in flow (up to 52%) for all water year types during August, September, and November, with the largest reductions occurring in the drier water year types. Flows in June would increase 25% in dry water years and would decrease up to 36% in critical and wet water years. The prevalent, substantial reductions inflow, particularly during drier water years, would have biologically meaningful negative effects on juvenile rearing conditions in the American River.

Mean water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT would be 6% to 7% higher than those under Existing Conditions during October of all but critical water years, but would be similar in the remaining months and water year types.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4A-85). The percent of months under H3_ELT would be greater by up to 57% (absolute difference) than those under Existing Conditions during all months examined.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4A-86). Total degree-months exceeding the threshold under H3_ELT would be 32 to 220 degree-months greater than those under Existing Conditions.

These results indicate that effects of H3_ELT on flows and water temperatures would affect juvenile steelhead rearing conditions in the American River throughout most of the year, particularly during drier water years.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows would generally be similar under H3_ELT relative to Existing Conditions except during February and March, when flows would be up to 29% lower (dry water year type).

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the year-round juvenile steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H3_ELT and Existing Conditions.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under Existing Conditions except during June through August, when flows would be up to 23% lower.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions during January through May and October and November, with exceptions depending on water year type, would be up to 28% greater than flows under Existing Conditions during December, and up to 35% lower than flows under Existing Conditions during June through September.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT/HOS_ELT

Sacramento River

Year-round flows in the Sacramento River at Keswick under H4_ELT would generally be similar to flows under Existing Conditions except during September, when flows would be 28% and 53% higher in wet and above normal water years, respectively, and 20% and 14% lower in dry and critical water years, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would also be up to 19% lower in November of dry and critical year types. Differences in mean flows between H4_ELT and Existing conditions at Red Bluff would be similar to but smaller than those at Keswick, except during October, in which mean flow would be up to 16% lower.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H4_ELT and Existing Conditions for any month or water year types at either location.

Clear Creek

Year-round flows in the Clear Creek under H4_ELT would generally be similar to flows under Existing Conditions, except that in critical water years during December through April mean flows would increase 10%, and in wet years during January flows would increase 40%. (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek.

Feather River

Year-round flows in the Feather River above Thermalito Afterbay (low-flow channel) under H4_ELT would be the same as flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the Feather River below Thermalito Afterbay (high-flow channel) under H4_ELT would generally be similar to or up to 509% greater than flows under Existing Conditions during April through June, and would generally be lower than flows under Existing Conditions (up to 54% lower) during July and August, as well as September of below normal and dry water years. During September of wet, above normal, and critical water years and August of critical years, flows under H4_ELT would be up to 166% higher than flows under Existing Conditions. During the other six months of the year, flows under H4_ELT and Existing Conditions would generally be similar, with many exceptions for individual water year types.

Mean water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations there would be no differences (<5%) in mean water temperatures for any month or water year type.

The analysis evaluating the percent of months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be a number of small to moderate increases in the percent of months exceeding the NMFS temperature thresholds underH4_ELT relative to Existing Conditions in the low flow channel and at Gridley. These comparisons include the effects of climate change.

The analysis evaluating the total degree-months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be small to moderate negative effects of H4_ELT relative to Existing Conditions in August in the low flow channel and October and November at Gridley, and no, small or positive effects in the other months at both locations. These comparisons include the effects of climate change.

Mean May storage at Oroville would be up to 19% lower under H4_ELT relative to Existing Conditions except in critical years, in which storage would be 15% greater (Table 11-4A-45). Mean September Oroville storage under H4_ELT would be about 24% lower than storage under Existing

Conditions for wet, above normal and below normal water years, 32% greater for critical years, and similar for dry years (Table 11-4A-39).

American River

Year-round flows in the American River at the confluence with the Sacramento River under H4_ELT would generally be similar to flows under Existing Conditions during October and December through April, with minor exceptions, and would be up to 47% lower during May through September and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H4_ELT would be 6% to 7% higher than those under Existing Conditions during October of all but critical water years, and would be similar in the remaining months and water year types.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4A-87). The percent of months under H4_ELT would be greater by up to 37% (absolute difference) than those under Existing Conditions during all months examined.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4A-88). Total degree-months (all water years combined) exceeding the threshold under H4_ELT would be 32 to 168 degree-months greater than those under Existing Conditions for all months.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows would generally be similar under H4_ELT relative to Existing Conditions, but with some flow reductions (up to 29%), especially for dry and critical water years during February and March.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the year-round juvenile steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures throughout the year.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be up to 23% lower during June through August, depending on water year type, than flows under Existing Conditions and would generally be similar in other months, with minor exceptions.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions during January through May and October and November, with minor exceptions. Flows would generally be lower (up to 34% lower) during June through September, primarily in wet, above normal, and below normal water year types, and would be up to 28% higher in December of the same three water year types.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Under Alternative 4A, there are flow reductions in the Feather, American, Stanislaus, San Joaquin, and Mokelumne Rivers and temperature increases in the Sacramento, Feather, American, and Stanislaus Rivers that would lead to reductions in quantity and quality of fry and juvenile steelhead rearing habitat relative to Existing Conditions. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce rearing habitat and substantially reduce the number of steelhead as a result of fry and juvenile mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, *Effects and Mitigation Approaches*, in the Draft EIR/EIS, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 4A on flows would be small and infrequent in the Sacramento River, Clear Creek, and Mokelumne River. Effects in the Feather and American rivers would be variable, but overall effects are expected to be slightly beneficial. Despite the increased flow variations, water temperatures in the Sacramento, Feather, American, and Stanislaus Rivers would not be affected by Alternative 4A. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, the impact would be less than significant and no mitigation is required.

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

In general, the effects of Alternative 4A on steelhead migration conditions relative to the NAA_ELT would not be adverse.

Upstream of the Delta

H3_ELT/ESO_ELT

Sacramento River

Juveniles

Sacramento River flow upstream of Red Bluff during the juvenile steelhead migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) is used to represent flow conditions in the mainstem of the upper river below Keswick Dam. Mean flows under H3_ELT during this period would generally be similar to flows under NAA_ELT, except during November, during which flows would be 6% to 18% lower than flows under NAA_ELT. These reductions would not have a biologically meaningful effect on steelhead juvenile migration because they would occur during only one of eight months of the period and are small to moderate in magnitude.

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Overall, these results indicate that H3_ELT would not have biologically meaningful effects on juvenile migration conditions.

Adults

Instream flows upstream of Red Bluff were compared monthly over the period from September through March under H3_ELT and NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT during this period would generally be similar to flows under NAA_ELT, except during November, during which flows would be up to 18% lower than flows under NAA_ELT. These reductions would not have a biologically meaningful effect on steelhead adult migration because they would occur during only one of seven months of the period and are small to moderate in magnitude.

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Kelts

Mean Sacramento River flows upstream of Red Bluff under H3_ELT during the March through April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the*

Fish Analysis) would generally be similar to flows under NAA_ELT. Therefore, H3_ELT would not affect kelt migration in the Sacramento River.

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Overall in the Sacramento River, these results indicate that H3_ELT would not have biologically meaningful effects on juvenile, adult, or kelt steelhead migration in the Sacramento River.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows in Clear Creek at Whiskeytown were evaluated for the juvenile steelhead migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to flows under NAA_ELT throughout the period. These results indicate that H3_ELT would not affect flow conditions for juvenile steelhead migration in Clear Creek.

Adults

Flows in Clear Creek at Whiskeytown were evaluated for the September through March adult steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to or greater than flows under NAA_ELT throughout the period. These results indicate that H3_ELT would not affect flow conditions for adult steelhead migration in Clear Creek.

Kelts

Flows in Clear Creek at Whiskeytown were evaluated for the March and April kelt steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would be similar to or greater than flows under NAA_ELT for both months of the period. These results indicate that H3_ELT would not affect flow conditions for kelt steelhead migration in Clear Creek.

Overall in Clear Creek, these results indicate that effects of H3 on flows would not affect juvenile, adult, or kelt steelhead migration.

Feather River

Juveniles

Flows in the Feather River at Thermalito Afterbay (high-flow channel) and at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the high-flow channel under H3_ELT would generally be similar to or up to 30% greater than flows under

NAA_ELT during the period. Increases in flow would have a beneficial effect on migration conditions, particularly in drier water years during some months.

Flows under H3_ELT in the Feather River at the confluence with the Sacramento River during October through May would generally be similar to flows under NAA_ELT, with minor exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated reduction would not have biologically meaningful effects on juvenile steelhead migration conditions.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Overall, there would be no biologically meaningful effects H3 on juvenile migration conditions in the Feather River.

Adults

Flows in the Feather River at Thermalito Afterbay (high-flow channel) and at the confluence with the Sacramento River were evaluated during the September through March adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in the high-flow channel under H3_ELT would generally be similar to or up to 30% greater than flows under NAA_ELT except during September. During September, flows would be up to 43% lower for all water year types except critical, in which flows would be 52% greater. These flow reductions would be limited to one month of the seven month migration period and would, therefore, not have a biologically meaningful effect on adult steelhead migration conditions. Mean flows in the Feather River at the confluence with the Sacramento River under H3_ELT would generally be similar to or greater than flows under NAA_ELT, except during September, in which flows would be up to 27% lower for all but critical water years and would be 14% higher for critical years. The flow reductions would be isolated and would, therefore, not have a biologically meaningful effect on adult steelhead migration conditions.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Kelts

Flows in the Feather River at the Thermalito Afterbay and at the confluence with the Sacramento River were evaluated during the March and April kelt migration period. Flows at Thermalito under H3_ELT during March and April would generally be similar to or, in dry and critical water years, up to 16% greater than flows under NAA_ELT. Flows at the confluence with the Sacramento River would generally be similar to those under NAA_ELT. These results indicate that H3_ELT would not affect kelt steelhead migration conditions in the Feather River.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in* *the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in either month or any water year type of the period.

Overall in the Feather River, H3_ELT would not have biologically meaningful effects on juvenile, adult, or kelt steelhead migration.

American River

Juveniles

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for the juvenile steelhead migration period (October through May). Mean flows under H3_ELT would generally be similar to flows or up to 25% greater than flows under NAA_ELT, except during November, in which flows would be up to 15% lower depending on water year type. Appreciable differences in flow would be too infrequent to have biologically meaningful effects on juvenile steelhead migration.

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Based on its generally small and infrequent effects on mean flow and negligible effects on water temperature, H3_ELT would not affect juvenile steelhead migration in the American River.

Adults

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for the September through March adult migration period. Flows under ELT would generally be similar to or up to 25% greater than flows under NAA_ELT, except during September and November, in which flows would be up to 25% lower, depending on month and water year type. These reductions would be too infrequent to cause biologically meaningful effects on adult steelhead migration.

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Kelts

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for the March through April kelt migration period. Mean flows under H3_ELT would be similar to flows under NAA_ELT during this period for all water year types.

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in* *the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type of the period.

Overall in the American River, the effects of H3_ELT on flows would not affect juvenile, adult, or kelt migration conditions.

Stanislaus River

Mean flows in the Stanislaus River at the confluence with the San Joaquin River for H3_ELT are essentially no different from flows under NAA_ELT for any month. Therefore, there would be no effect of H3_ELT on juvenile, adult, or kelt migration in the Stanislaus River.

Further, mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River for H3_ELT are not different from flows under NAA_ELT for any month. Therefore, there would be no effect of H3_ELT on juvenile, adult, or kelt migration in the Stanislaus River.

San Joaquin River

Mean flows in the San Joaquin River at Vernalis for H3_ELT are little different from flows under NAA_ELT for any month. Therefore, there would be no effect of H3_ELT on juvenile, adult, or kelt migration in the San Joaquin River.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Mean flows in the Mokelumne River at the Delta for H3_ELT are not different from flows under NAA_ELT for any month. Therefore, there would be no effect of H3_ELT on juvenile, adult, or kelt migration in the Mokelumne River.

Water temperature modeling was not conducted in the Mokelumne River.

H4_ELT /HOS_ELT

Sacramento River

Juveniles

Mean flows under H4_ELT in the Sacramento River upstream of Red Bluff during the October through May juvenile steelhead migration period would generally be similar to flows under NAA_ELT, except during November, in which flows would be lower for all water year types (9% to 15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not have a biologically meaningful effect on steelhead juvenile migration because they would occur during only one of eight months of the period and are small to moderate in magnitude.

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Adults

Mean flows under H4_ELT in the Sacramento River upstream of Red Bluff during the September through March adult steelhead migration period would generally be similar to flows under NAA_ELT, except during November, in which flows would be 9% to 15% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not have a biologically meaningful effect on steelhead adult migration because they would occur during only one of eight months of the period and are small to moderate in magnitude.

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Kelts

Mean flows under H4_ELT in the Sacramento River upstream of Red Bluff during the March through April adult steelhead migration period would be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Mean flows under H4_ELT in Clear Creek at Whiskeytown during the October through May juvenile migration period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Mean flows under H4_ELT in Clear Creek at Whiskeytown during the September through March adult migration period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Kelts

Mean flows under H4_ELT in Clear Creek at Whiskeytown during the March through April kelt migration period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Juveniles

Mean flows under H4_ELT in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to flows under NAA_ELT during October through March, with a few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows during April and May would be greater (up to 548% greater at Thermalito Afterbay location) than flows under NAA_ELT except in critical water years, for which flows would be similar.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Adults

Mean flows under H4_ELT in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the September through March adult migration period would generally be similar to flows under NAA_ELT, except during September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). During September of critical water years, mean flow under H4_ELT at Thermalito Afterbay would be 52% higher and at the confluence with the Sacramento River it would be 34% higher During September of the other water year types, mean flows at the two locations would be up to 60% and 38% lower, respectively.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Kelts

Mean flows under H4_ELT in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to or up to 18% greater than flows under NAA_ELT during March and up to 548% higher than flows under NAA_ELT during April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

American River

Juveniles

Mean flows under H4_ELT in the American River at the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to flows under

NAA_ELT except during October of below normal and critical water years, in which flows under H4_ELT would be 17% and 24% higher, respectively(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Adults

Mean flows under H4_ELT in the American River at the confluence with the Sacramento River during the September through March adult migration period would generally be similar to flows under H3_ELT except during September of below normal years, in which flows would be 22% lower, and October of below normal and critical water years, in which flows would be 17% and 24% higher (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Kelts

Mean flows under H4_ELT in the American River at the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Stanislaus River

Mean flows in the Stanislaus River at the confluence with the San Joaquin River for H4_ELT are essentially the same as flows under NAA_ELT in all months. Therefore, there would be no effect of H4_ELT on juvenile, adult, or kelt migration in the Stanislaus River.

Further, mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River for H4_ELT are not different from flows under NAA_ELT for any month. Therefore, there would be no effect of H4_ELT on juvenile, adult, or kelt migration in the Stanislaus River.

San Joaquin River

Mean flows in the San Joaquin River at Vernalis for H4_ELT are little different from flows under NAA_ELT for all months. Therefore, there would be no effect of H4_ELT on juvenile, adult, or kelt migration in the San Joaquin River.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Mean flows in the Mokelumne River at the Delta for H4_ELT are not different from flows under NAA_ELT for any month. Therefore, there would be no effect of H4_ELT on juvenile, adult, or kelt migration in the Mokelumne River.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Sacramento River

Juveniles

Alternative 4A operations would generally reduce OMR reverse flows under all flow scenarios, with a corresponding increase in net positive downstream flows, during the outmigration period of steelhead through the interior Delta channels (Appendix B, Supplemental Modeling for Alternative 4A). Conditions under Scenario H4_ELT would further improve overall average OMR flows relative to other flow scenarios under Alternative 4A. These improved net positive downstream flows would be substantial benefits of the proposed operations.

As noted under Predation Associated with Entrainment above, predation at the north Delta would be increased due to the construction of the proposed SWP/CVP water export facilities on the Sacramento River. It is assumed that per capita steelhead predation losses would be similar to those predicted for spring-run Chinook salmon, although slightly reduced because of the larger size of steelhead outmigrants. Bioenergetics modeling predicts a predation loss of about 0.2% of the juvenile spring-run population (Table 11-4A-26).

Based on DPM results for spring-run Chinook salmon (Impact AQUA-60 for Alternative 4A), changes in steelhead survival relative to NAA_ELT would be expected to be limited under Alternative 4A. Also, steelhead juveniles are larger than Chinook salmon juveniles in general, and therefore may be less vulnerable to predation during migration. The DPM analysis of Alternative 4A on juvenile spring-run Chinook salmon migration suggests a potential adverse effect of small magnitude. As noted for spring-run Chinook salmon, this adverse effect would be minimized through the bypass flow criteria and real-time operations outlined above, as well as inclusion within Alternative 4A of specific important conservation measures. These conservation measures include *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of spring-run Chinook salmon juveniles into the low-survival interior Delta. Therefore the effect on juvenile steelhead outmigration success through the Delta under Alternative 4A would not be adverse.

Adults

The upstream adult steelhead migration occurs from September–March, peaking during December-February. The steelhead kelt downstream migration occurs from January–April. The proportion of Sacramento River water in the Delta under Alternative 4A would be similar (8% or less difference) to NAA_ELT throughout the adult steelhead upstream migration (Table 11-4A-89). Under

Alternative 4A's Scenario H3_ELT, mean monthly Sacramento River flows at Rio Vista averaged over all water years would be reduced compared to NAA_ELT, ranging from 46% less in September to 7.5% less in December. For H4_ELT, the range is from about 1% less in April to 30% less in October and November. These differences are less than those observed under Alternative 1A and so, because the effect under Alternative 1A would not be adverse, Alternative 4A would also not have an adverse effect on adult and kelt steelhead migration through the Delta.

San Joaquin River

Juveniles

The only changes to San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. There are no flow changes associated with Alternative 4A Alternative 4A would have no effect on steelhead migration success through the Delta from the perspective of changing inflows into the Delta. However, juvenile steelhead migration success would be aided by the inclusion in the water conveyance facilities of an operable barrier at the head of Old River, which would keep flow and fish in the mainstem San Joaquin River.

Adults

Alternative 4A Scenario H3_ELT would slightly increase the proportion of San Joaquin River water in the Delta in September through March by 1.3 to 4.4 % (compared to NAA_ELT) (Table 11-4A-89). The proportion of San Joaquin River water under Scenario H3_ELT would be similar or slightly more than NAA_ELT. Conditions under Scenario H4_ELT are expected to increase the proportion of San Joaquin River water (relative to the change under Scenario H3_ELT) because it would involve fewer exports from the north Delta during spring.

Table 11-4A-89. Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Adult Steelhead Migration Period for Alternative 4A

Month	EXISTING CONDITIONS	NAA_ELT	H3_ELT	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Sacramento River					
September	60	65	61	0	-4
October	60	64	65	5	1
November	60	64	63	3	-1
December	67	67	65	-1	-1
January	76	75	73	-2	-2
February	75	74	69	-6	-4
March	78	77	69	-9	-8
San Joaquin River					
September	0.3	0.2	1.7	1.4	1.5
October	0.2	0.2	3.5	3.4	3.3
November	0.4	0.8	5.2	4.8	4.4
December	0.9	1.0	2.9	2.0	1.9
January	1.6	1.7	2.9	1.3	1.3
February	1.4	1.5	3.6	2.2	2.2
March	2.6	2.6	5.7	3.1	3.1
	Shading indicates 10% or greater absolute difference.				

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NEPA Effects: Upstream of the Delta, these modeling results indicate that the effect is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. Effects of Alternative 4A in all locations analyzed would consist primarily of negligible effects on mean monthly flow and water temperatures for the juvenile, adult, and kelt migration periods. In the Feather River, higher flows during spring months may provide some benefits to migrating steelhead. Effects of Alternative 4A on upstream water temperatures would be negligible.

Near-field effects of Alternative 4A NDD on Sacramento River steelhead related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating steelhead, although there is high uncertainty regarding the overall effects. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 12% mortality above current baseline levels). Environmental Commitment 15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, as described in the adaptive management and monitoring program in Section 4.1, several pre-construction surveys to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Similarly, Alternative 4A also includes investigations to better understand factors affecting juvenile through-Delta migration (as described in the adaptive management and monitoring program in Section 4.1) and includes biologically-based triggers to inform real-time operations of the NDD, intended to provide adequate migration conditions for downstream-migrating juvenile salmonids. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of predation-related mortality expected from near-field effects at the NDD remains highly uncertain.

As noted for other salmonids, two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area, although these modeling results focused on juvenile Chinook salmon as opposed to steelhead. As noted for winter-run and spring-run Chinook salmon above, the elements of Alternative 4A related to reduced interior Delta entry (Environmental Commitment 16) and reduced south Delta entrainment may offset the far-field effects of reduced flow. As noted for the various Chinook salmon runs, the overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and will be investigated as part of the adaptive management and monitoring program.

Adverse effects of the water conveyance facilities operations at the NDD would be minimized through the bypass flow criteria and real-time operations described for other salmonids (e.g., winter-run Chinook salmon), as well as inclusion within Alternative 4A of specific important conservation measures: *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of juvenile salmonids into the low-survival interior Delta.

CEQA Conclusion: In general, Alternative 4A would reduce the quantity and quality of migration habitat for steelhead relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of migration habitat for steelhead relative to Existing Conditions.

Upstream of the Delta

H3_ELT/ESO_ELT

Sacramento River

Juveniles

Flows in the Sacramento River just upstream of Red Bluff Diversion Dam were evaluated for the juvenile migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to those under Existing Conditions, except during October and November, in which flows would be up to 16% lower than those under Existing Conditions. These reductions in flow would be too small and infrequent to have biologically meaningful negative effects on migration conditions.

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water*

Quality Model and Reclamation Temperature Model Results Utilized in the Fish Analysis). There would be no differences (<5%) in mean water temperature between Existing Conditions.

Adults

Mean flows under H3_ELT during the adult migration period (September through March) would generally be similar to those under Existing Conditions, except during September through November October, in which flows would be up to 22% lower than those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) The changes in flow due to H3_ELT would be frequent enough (3 of 7 months), large enough (up to 22% lower), and occur during all water year types to be considered biologically meaningful negative effects on adult migration conditions.

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in all months except September and October, in which temperatures under H3_ELT would be 6% greater than those under Existing Conditions.

Kelts

Mean flows under H3_ELT during the kelt migration period (March and April) would be similar to those under Existing Conditions for all water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period.

Overall in the Sacramento River, H3_ELT would not affect flow or water temperature conditions for juvenile, adult, or kelt steelhead migration.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows under H3_ELT in Clear Creek at Whiskeytown during the October through May juvenile migration period would generally be similar to flows under Existing Conditions, except for 40% higher flow in January of wet years and 10% higher flows in December through April of critical water years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows under H3_ELT in Clear Creek at Whiskeytown during the September through March adult migration period would generally be similar to flows under Existing Conditions, except for 40% higher flow in January of wet water years, 10% higher flows in December through March of critical years, and 19% lower flow in September of critical years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Kelts

Flows under H3_ELT in Clear Creek at Whiskeytown during the March through April kelt migration period would generally be similar to flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall in Clear Creek, H3_ELT would not affect flow or water temperature conditions for juvenile, adult, or kelt steelhead migration.

Feather River

Juveniles

Mean flows were evaluated in the Feather River at Thermalito Afterbay during the October through May juvenile migration period. Flows under H3_ELT would be similar to flows under Existing Conditions during October through December and March, up to 48% lower than flows under Existing Conditions during January and February, and up to 33% greater than flows under Existing Conditions during April and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows at the confluence with the Sacramento River under H3_ELT would generally be similar to those under Existing Conditions throughout the period.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in all months and water year types of the migration period.

Adults

Mean flows were examined in the Feather River at Thermalito Afterbay during the September through March adult migration period. Flows under H3_ELT would be up to 192% greater than flows under Existing Conditions during September, similar to flows under Existing Conditions during October through December and March, and up to 48% lower than flows under Existing Conditions during January and February (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The mean flows at the confluence with the Sacramento River under H3_ELT would generally be similar or up to 19% lower than those under Existing Conditions during November through March and similar or up to 21% higher during October, while flows in September would range from 28% lower to 100% higher, depending on water year type.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in all months and water year types of the period.

Kelts

Mean flows under H3_ELT in the Feather River at Thermalito Afterbay during the March through April kelt migration period would be similar to flows under Existing Conditions during March and up to 29% higher than flows under Existing Conditions during April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows for March and April at the confluence with the Sacramento River would generally be similar between H3_ELT and Existing Conditions.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period.

Overall in the Feather River, the effect of H3_ELT on flows would include frequent substantial reductions in flows that would affect juvenile and adult migration conditions, particularly in drier water years, but would generally not affect kelt migration.

American River

Juveniles

Mean flows under H3_ELT in the American River at the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to or up to 15% higher than flows under Existing Conditions, except during November, January, and May, in which flows would be up to 24% lower under H3_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT would be no different (<5%) from those under Existing Conditions, except in October, for which the water temperatures would 5% to 6% higher for all but critical water years.

Adults

Flows under H3_ELT in the American River at the confluence with the Sacramento River during the September through March adult migration period would generally be similar to or up to 15% higher than flows under Existing Conditions, except during September, November, and January, in which flows would be up to 47% lower (September of critical water years) than under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT would be no different (<5%) from those under Existing Conditions, except in October, for which the water temperatures would 5% to 6% higher for all but critical water years.

Kelts

Flows under H3_ELT in the American River at the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to flows under Existing

Conditions, except for March of critical water years, in which the mean flow would be 12% lower under H3_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H3_ELT would be no different (<5%) from those under Existing Conditions.

Overall in the American River, the effect of H3_ELT on flows would include frequent moderate reductions in flows that would affect juvenile and adult migration conditions, particularly in drier water years, but would generally not affect kelt migration

Stanislaus River

Juveniles

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions during October through January and up to 29% lower than flows under Existing Conditions during February through May.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the October through May steelhead juvenile downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H3_ELT and Existing Conditions.

Adults

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to or up to 29% lower (February of critical water years) than flows under Existing Conditions depending on month and water year type.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H3_ELT and Existing Conditions.

Kelt

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows during the period under H3_ELT would be up to 23% over than flows under Existing Conditions.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H3_ELT and Existing Conditions.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Juveniles

Flows in the San Joaquin River at Vernalis were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions, with minor exceptions.

Adults

Flows in the San Joaquin River at Vernalis were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions, with minor exceptions.

Kelt

Flows in the San Joaquin River at Vernalis were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions, with minor exceptions.

Mokelumne River

Water temperature modeling was not conducted in the Mokelumne River.

Juveniles

Flows in the Mokelumne River at Delta were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be lower than flows under Existing Conditions during April and May (up to 11% lower), similar to flows under Existing Conditions during October, November, and January through March, and higher than flows under Existing Conditions during December (up to 28% higher).

Adults

Flows in the Mokelumne River at Delta were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions, except during December, in which mean flow would be up to 28% higher, and during September, when flows would be up to 22% lower.

Kelt

Flows in the Mokelumne River at Delta were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT would generally be similar to flows under Existing Conditions during both months of the period.

H4_ELT /ESO_ELT

Sacramento River

Juveniles

Flows in the Sacramento River just upstream of Red Bluff Diversion Dam were evaluated for the juvenile migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to those under Existing Conditions.

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results Utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period.

Adults

Mean flows under H4_ELT during the adult migration period (September through March) would generally be similar to those under Existing Conditions except during September, in which flows would be up to 49% higher for wet and above normal water years and up to 18% lower for dry and critical water years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The changes in flow would be too infrequent to have biologically meaningful negative effects on migration conditions.

Mean temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period.

Kelts

Mean flows under H4_ELT during the kelt migration period (March and April) would generally be similar to those under Existing Conditions for all water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month or water year type in the period.

Overall in the Sacramento River, H4_ELT would not affect flow or water temperature conditions for juvenile, adult, or kelt steelhead migration.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows under H4_ELT in Clear Creek at Whiskeytown during the October through May juvenile migration period would generally be similar to flows under Existing Conditions, except for 40% higher flow in January of wet years, 10% higher flows in December through April of critical water years, and other minor exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows under H4_ELT in Clear Creek at Whiskeytown during the September through March adult migration period would generally be similar to flows under Existing Conditions, except for 40% higher flow in January of wet water years, 10% higher flows in December through March of critical years, and other minor exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Kelts

Flows under H4_ELT in Clear Creek at Whiskeytown during the March through April kelt migration period would generally be similar to flows under Existing Conditions, except for 13% higher flows in March of below normal water years and 10% higher flows in March and April of critical water years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall in Clear Creek, H4_ELT would not affect flow or water temperature conditions for juvenile, adult, or kelt steelhead migration.

Feather River

Juveniles

Mean flows under H4_ELT in the Feather River at Thermalito Afterbay during the October through May juvenile migration period would generally be lower (up to 36% lower) than flows under Existing Conditions during October through March and would be much higher for all water year types except critical during April and May (up to 509% higher) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flow for April with all water years combined would be 92% greater than that under Existing Conditions. The flows at the confluence with the Sacramento River under H4_ELT would generally be similar or up to 26% lower (December of critical water years) than those under Existing Conditions during October through March and up to 112% higher in April and May.

Mean temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in all months and water year types of the migration period.

Adults

Mean flows under H4_ELT in the Feather River at Thermalito Afterbay during the September through March adult migration period would generally be lower (up to 36% lower) than flows under Existing Conditions during October through March (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows in September under H4_ELT would be up to 166% higher for wet, above normal and critical water years, and up to 49% lower for below normal and dry water years. The flows at the confluence with the Sacramento River under H4_ELT would generally be similar or up to 26% lower than those under Existing Conditions during October through March, while flows in September would range from 29% lower to 87% higher depending on water year type.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in all months and water year types of the period.

Kelts

Mean flows under H4_ELT in the Feather River at Thermalito Afterbay during the March and April kelt migration period would range from 22% lower to 16% higher in March and from 4% to 509% higher in April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows at the confluence with the Sacramento River for March would generally be similar between H4_ELT and Existing Conditions, while flows in April would be up to 112% higher under H4_ELT.

Mean water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period.

Overall in the Feather River, the effect of H4_ELT on flows would include persistent and/or substantial reductions in flows that would affect juvenile and adult migration conditions, particularly in drier water years.

American River

Juveniles

Mean flows under H4_ELT in the American River at the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to or up to 15% higher than flows under Existing Conditions, except during November and May, in which flows would be up to 25% lower under H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H4_ELT would be no different (<5%) from those under Existing Conditions, except in October, for which the water temperatures would 5% to 6% higher for all but critical water years.

Adults

Flows under H4_ELT in the American River at the confluence with the Sacramento River during the September through March adult migration period would generally be similar to or up to 15% higher than flows under Existing Conditions, except during September and November, in which flows would be up to 47% lower (September of critical water years) than under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H4_ELT would be no different (<5%) from those under Existing Conditions, except in October, for which the water temperatures would 5% to 6% higher for all but critical water years.

Kelts

Flows under H4_ELT in the American River at the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to flows under Existing Conditions, except for March of critical years, during which the mean flow would be 12% lower under H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under H4_ELT would be no different (<5%) from those under Existing Conditions.

Overall in the American River, reductions inflows would be too small and infrequent to affect migration conditions for steelhead.

Stanislaus River

Juveniles

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions during October through January and up to 29% lower than flows under Existing Conditions during February through May.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the October through May steelhead juvenile downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H4_ELT and Existing Conditions.

Adults

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions during September through January and up to 29% lower than flows under Existing Conditions during February and March.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H4_ELT and Existing Conditions.

Kelt

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be lower (by up to 23%) than flows under Existing Conditions in both months.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H4_ELT and Existing Conditions.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Juveniles

Flows in the San Joaquin River at Vernalis were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions, except during March and April (up to 12% lower).

Adults

Flows in the San Joaquin River at Vernalis were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be similar to flows under Existing Conditions, except during March (up to 12% lower)

Kelt

Flows in the San Joaquin River at Vernalis were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be lower than flows under Existing Conditions (up to 12% lower)

Mokelumne River

Water temperature modeling was not conducted in the Mokelumne River.

Juveniles

Flows in the Mokelumne River at Delta were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be lower than flows under Existing Conditions during April and May (up to 11% lower), similar to flows under Existing Conditions during October, November, and January through March, and higher than flows under Existing Conditions during December (up to 28% higher).

Adults

Flows in the Mokelumne River at Delta were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would generally be lower than flows under Existing Conditions during September (up to 22% lower), similar to flows under Existing Conditions during October, November, and January through March, and higher than flows under Existing Conditions during December (up to 28% higher).

Kelt

Flows in the Mokelumne River at Delta were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H4_ELT would be similar to flows under Existing Conditions during March and up to 7% lower than flows under Existing Conditions during April.

Through-Delta

Based on DPM results for spring-run Chinook salmon, which do not assume any adjustments in operations based on fish presence, steelhead survival would not be expected to decrease more than 1%. Assuming similar effects on steelhead, Alternative 4A would have a minimal effect on steelhead migration success through the Delta. Therefore, the impact on juvenile steelhead migration through the Delta would be small, particularly given the inclusion in Alternative 4A of Environmental Commitments 6, 15, and 16 (see additional discussion in the *Summary of CEQA Conclusion* below).

The proportion of Sacramento River water in the Delta under Alternative 4A Scenario H3_ELT would be similar to Existing Conditions (<10% difference) during the entire adult steelhead upstream migration (Table 11-4A-89). As discussed in more detail for Alternative 4, because of the overall similarity in olfactory cues and Rio Vista flows between Alternative 1A and Alternative 4A during the entire adult and kelt migration periods, effects on migration success would be expected to be similar to Alternative 1A. Olfactory cues and flows in the San Joaquin River basin would be improved or similar to Alternative 1A and Existing Conditions. Overall, the impact to steelhead adult and kelt migration under Alternative 4A is considered negligible.

Summary of CEQA Conclusion

Under Alternative 4A, there would be reductions in flow in the Sacramento, Feather, American, Stanislaus, and Mokelumne Rivers that would lead to biologically meaningful reductions in juvenile and adult migration conditions, thereby reducing survival relative to Existing Conditions. Reduced migration conditions would delay or eliminate successful migration necessary to complete the steelhead life cycle. Alternative 4A would not affect migration conditions for steelhead in Clear Creek or the San Joaquin River. Water temperatures under Alternative 4A would generally be similar to those under Existing Conditions in all rivers examined. There would be minimal effects on through-Delta migration conditions because changes in juvenile survival and adult olfactory cues would be small. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce migration conditions for steelhead.

However, this interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, *Effects and Mitigation Approaches*, in the Draft EIR/EIS, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to differ from one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA_ELT, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be negligible effects on mean monthly flow and water temperatures for the juvenile, adult, and kelt migration periods. Effects of. Near-field effects of Alternative 4A NDD on Sacramento River steelhead related to impingement and predation associated with the intake structures could result in negative effects on juvenile migrating steelhead, although there is high uncertainty regarding overall effects.

As noted for other salmonids such as winter-run Chinook salmon, similar or slightly lower survival than for Existing Conditions based on the water conveyance facilities operations would be offset by the inclusion of bypass flow criteria, real-time operational adjustments, *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 15 Localized Reduction of Predatory Fishes*, and *Environmental Commitment 16 Nonphysical Barriers*. Overall, it is concluded that the impact to steelhead would be less than significant and no mitigation would be required.

Restoration Measures (Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

As described for winter-run Chinook salmon, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4A and Alternative 1A. The mechanisms of impacts of habitat restoration discussed for winter-run Chinook salmon would be similar for steelhead. However, as noted for Alternative 1A, juvenile steelhead migrants are typically older and larger than Chinook salmon migrants, making them less susceptible to effects from restoration construction activities. As larger migrants, steelhead pass through the river more quickly, resulting in lower risks of exposure to increased turbidity, methylmercury, accidental spills, disturbed contaminated sediments, or predation.

The following impacts are those presented under Alternative 4A and Alternative 1A that are anticipated to be similar in nature for Alternative 4A, but would occur to a lesser extent because of the reduced extent of the restoration measures under Alternative 4A.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

The effects of construction of restoration measures on steelhead under Alternative 4A are similar in nature to those discussed in more detail under Alternative 1A: temporary increases in turbidity; increased exposure to mercury and methylmercury; accidental spills; disturbance of contaminated sediments; in-water work activities; and predation. In-water and shoreline restoration construction activities may result in short-term effects on steelhead through direct disturbance, short-term water quality impacts, and increased exposure to contaminants associated with the incidental disturbance of contaminated sediments. Overall and as noted for Alternative 1A, the effect of restoration construction activities on the bioavailability of contaminants is expected to be minimal, as they would likely be localized, sporadic, and of low magnitude. Implementation of the environmental commitments described in Appendix 3B, *Environmental Commitments*, would minimize or eliminate effects on steelhead. The relevant environmental commitments are: *Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; and Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*. Pertinent details of these plans are provided under Impact AQUA-1 for delta smelt under Alternative 1A. Given the greatly reduced extent of restoration under Alternative 4A relative to Alternative 1A, the effects of construction of restoration measures on steelhead would be expected to be less than for Alternative 1A.

***NEPA Effects*:** The effects of short-term construction activities would not be adverse to winter-run Chinook salmon. Implementation of the environmental commitments described in Appendix 3B, *Environmental Commitments*, would minimize or eliminate effects on steelhead. The relevant environmental commitments are: *Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; and Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*. Pertinent details of these plans are provided under Impact AQUA-1.

***CEQA Conclusion*:** As discussed for Alternative 1A, habitat restoration activities could result in short-term effects on steelhead but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce steelhead habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

As also noted for winter-run Chinook salmon, Alternative 4A habitat restoration actions could result in the disturbance or mobilization of upland and aquatic contaminants that could affect steelhead. As noted above, steelhead tend to pass through the Delta more quickly than other salmonids such as winter-run Chinook salmon, so that any overlap with contaminant effects of restoration measures would be limited. A detailed analysis of the potential effects based on the larger extent of tidal habitat restoration proposed under Alternative 4A can be found in the *BDCP Effects Analysis – Appendix 5D*, *Contaminants (hereby incorporated by reference)*. Potential impacts on steelhead from effects of methylmercury, selenium, copper, ammonia, and pesticides associated with habitat restoration activities would be similar to those discussed for delta smelt (see Impact AQUA-8). Within the relatively small extent of habitat restored under *Environmental Commitment 4 Tidal Natural Communities Restoration*, it is anticipated that any potential effects of methylmercury on steelhead will be addressed through implementation of Environmental Commitment 12. Environmental Commitment 12 is intended to minimize methylmercury exposure associated with restoration measures for juvenile Chinook salmon. Additional analysis and tools may be developed to further reduce methylmercury exposure as the habitat restoration conservation measures are refined and analyzed in site-specific documents.

NEPA Effects: The effect of restoration measures on chemical contaminants is not adverse to steelhead with respect to selenium, copper, ammonia, pesticides, and methylmercury (with implementation of Environmental Commitment 12).

CEQA Conclusion: Alternative 4A restoration actions are likely to result in slightly increased production, mobilization, and bioavailability of methylmercury. However, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury from restoration areas. Therefore, the impact of contaminants is considered less than significant because it would not substantially affect steelhead either directly or through habitat modifications. Consequently, no mitigation would be required.

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

Restored habitat under *Environmental Commitment 4 Tidal Natural Communities Restoration* and *Environmental Commitment 6 Channel Margin Enhancement* is intended to offset habitat loss/modification caused by construction and operation of the water facilities proposed under Alternative 4A.

NEPA Effects: The effects of restored habitat conditions on steelhead would not be adverse because they would provide potentially suitable habitat for steelhead.

CEQA Conclusion: As described above, habitat restoration would be undertaken to offset loss/modification of habitat from water facility construction and operation. The effects of restored habitat conditions on steelhead would be less than significant. Consequently, no mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

As noted for winter-run Chinook salmon, Alternative 4A includes three other Environmental Commitments, which are reduced in their extent relative to the Conservation Measures included in other Alternatives (e.g., Alternative 1A and Alternative 4). While the extent of these measures is reduced compared to these alternatives, the nature of the mechanisms for steelhead remains the same.

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (Environmental Commitment 12)

The impact discussion for winter-run Chinook salmon (Impact AQUA-46) is also applicable to steelhead.

NEPA Effects: The effects of methylmercury management on steelhead would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As noted for winter-run Chinook salmon, effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts on steelhead would be less than significant. Consequently, no mitigation is required.

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (Environmental Commitment 15)

Environmental Commitment 15 Localized Reduction of Predatory Fish would involve efforts to reduce predation by predatory fish at the proposed north Delta intakes and at the south Delta export facilities, including Clifton Court Forebay.

NEPA Effects: To the extent that localized predator control efforts of *Environmental Commitment 15 Localized Reduction of Predatory Fish* reduce the local abundance of fish predators at the north Delta diversions and near the south Delta export facilities (e.g., in Clifton Court Forebay), it is possible, but not assured, that there would be some reduction in losses to predation of juvenile steelhead (predation of adults is not a concern). This is of relevance given the potential effects on steelhead juveniles because of operations of the NDD (see Impact AQUA-93). Due to the uncertainty in the effectiveness of Environmental Commitment 15, there would be no demonstrable effect of this conservation measure on steelhead.

CEQA Conclusion: Due to the uncertainties associated with this Environmental Commitment, there would be no demonstrable effect on steelhead. This impact is considered less than significant. Consequently, no mitigation would be required.

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (Environmental Commitment 16)

As noted for winter-run Chinook salmon, under Alternative 4A, an NPB at the divergence of Georgiana Slough from the Sacramento River would be intended to guide juvenile salmonid fish such as steelhead away from Georgiana Slough and the interior Delta, wherein survival is relatively low compared to the Sacramento River (Singer et al. 2013). As noted for spring-run Chinook salmon, exploration with the DPM of the potential effects of an NPB at this location suggests that with effectiveness similar to that observed during a pilot study in 2011 (Perry et al. 2012), through-Delta survival of juvenile Chinook salmon would not differ greatly between Alternative 4A and Existing Conditions or NAA_ELT (see Table 5.C.5.3-41 in the *BDCP Effects Analysis Appendix 5.C hereby incorporated by reference*). These results, which are assumed to also be applicable to steelhead given similar life histories, suggest that Environmental Commitment 16 could offset negative effects of the water conveyance facilities. As discussed for Alternative 1A, the physical structure of an NPB may provide habitat for piscivorous fish in the area and increase localized predation risk.

NEPA Effects: The effects of NPB would not be adverse because it is intended to improve migration survival.

CEQA Conclusion*:* As discussed above, the NPB at the divergence of Georgiana Slough from the Sacramento River has the potential to reduce the proportion of steelhead entering the low-survival interior Delta. The impacts of *Environmental Commitment 16 Nonphysical Fish Barriers* are expected to be less than significant. Consequently, no mitigation would be required.

Sacramento Splittail

Construction and Maintenance of Water Conveyance Facilities

The discussion of potential effects to delta smelt from construction and maintenance of the water conveyance facilities under Alternative 4A is also relevant to Sacramento splittail. As discussed for Alternative 1A, various life stages of Sacramento splittail would have the potential to overlap construction and maintenance to varying degrees (Table 11-8).

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

The potential effects of construction of the water conveyance facilities on Sacramento splittail would be the same as described for Alternative 4 (Impact AQUA-109). This section provides additional detail on underwater noise impacts which are also applicable to Impact AQUA-109 in Alternative 4.

Table 11-8 presents the life stages of Sacramento splittail and the months of their potential presence in the north, east, and south Delta during the proposed in-water construction window (June 1–October 31). Under Alternative 4A, underwater noise generated by impact pile driving in or near open waters of the Delta can reach levels associated with potential injury of fish, including Sacramento splittail. The potential exists for relatively large numbers of young-of-the-year to occur in the vicinity of pile driving activities at the north Delta intakes, barge unloading facilities, Clifton Court Forebay, and Head of Old River operable barrier as larvae and juveniles disperse from upstream spawning and early rearing areas (riparian margins and floodplains) to the estuary in April-August. However, because of the relatively small area of open water affected by noise exceeding the injury thresholds (Table 4.3.7-1 under Delta Smelt), the limited duration of pile driving activities (Table 4.3.7-1 under Delta Smelt), and the lack of suitable rearing habitat in the affected areas, adverse effects would be limited to a small proportion of the population. Implementation of Mitigation Measures AQUA-1a and AQUA-1b would further reduce these impacts. No significant population-level effects are expected.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-109, the effect would not be adverse for Sacramento splittail. Implementation of the measures described in Appendix 3B, *Environmental Commitments*, such as *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan* would guide rapid and effective response in the case of inadvertent spills of hazardous materials. Construction would not be expected to increase predation rates relative to baseline conditions. Construction will result in both temporary and permanent alteration of rearing and migratory habitats used by splittail. However, Alternative 4A includes Environmental Commitment 4 to restore tidal habitat and Environmental Commitment 6 to restore channel margin habitat. Underwater noise produced by impact pile driving could result in adverse effects on splittail that occur in areas subject to noise levels exceeding the interim injury threshold for fish smaller than 2 grams (183 dB $SEL_{cumulative}$). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce these potential effects depending on the degree to which they can be implemented (see below).

CEQA Conclusion: As described in Alternative 4, Impact AQUA-109, the impact of the construction of the water conveyance facilities on splittail would not be significant except for construction noise associated with pile driving. Construction of Alternative 4A involves several elements with the potential to affect splittail. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*).

Implementation of Mitigation Measures AQUA-1a and AQUA-1b would potentially reduce noise impacts to less than significant levels. The extent to which these measures can be implemented is unknown at this time. Significant impacts may be unavoidable if these measures cannot be implemented to a sufficient degree to substantially reduce the amount of impact driving or the noise levels produced by impact driving.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4A would be the same as those described for Alternative 4, Impact AQUA-110. Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect splittail. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on splittail from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1. As concluded in Alternative 4, Impact AQUA-110, the impact would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-110, the impact of the maintenance of water conveyance facilities on Sacramento splittail would be less than significant and no mitigation is required. Once constructed, Alternative 4A structures and facilities will require ongoing periodic maintenance that includes in-water work activities with the potential to affect splittail. These activities include periodic cleaning and replacement of screens, trash racks, and associated machinery and dredging to maintain intake capacity. These activities will produce disturbance and underwater noise, and may generate turbidity or other water quality effects. In general, the likelihood of adverse effects on splittail from maintenance activities would be avoided and minimized through the same methods and rationale described for Impact AQUA-1.

Operations of Water Conveyance Facilities

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Water Exports from SWP/CVP South Delta Facilities

The salvage of splittail is considered an indicator of reproductive success more than of relative impact (Sommer et al. 1997); in contrast to other EIR/EIS alternatives for which juvenile splittail salvage was predicted using a historical relationship between Yolo Bypass inundation and salvage density at CVP and SWP, the analysis of splittail salvage for Alternative 4A used the per capita method, which evaluates how changes in exports would affect entrainment potential independent of other factors (This method is fully described in *BDCP Effects Analysis, Appendix 5B – Entrainment; Section 5.B.5.4.5 hereby incorporated by reference*). The per capita method was used because Yolo Bypass inundation is not included in the method, thus allowing an appropriate comparison between NAA_ELT (for which Yolo Bypass improvements would occur, but were not modeled) and H3_ELT (for which Yolo Bypass improvements would also occur as part of a program separate from Alternative 4A, and which was included in the modeling). The per capita rate of juvenile splittail entrainment under H3_ELT, which is an index of entrainment risk of an individual splittail and is directly related to the amount of water exported, averaged across all years would be reduced 37% for juveniles (Table 11-4A-91) and 54% for adults (Table 11-4A-92) compared to NAA_ELT. Adult entrainment and juvenile per capita entrainment are anticipated to be reduced in all water year types due to lower south Delta exports. Because Sacramento River and OMR flows are higher under the H4_ELT flow scenario for Alternative 4A compared to NAA_ELT, this scenario is expected to decrease entrainment loss at the south Delta more so than for the H3_ELT scenario.

Table 11-4A-91. Differences Between Model Scenarios in Juvenile Sacramento Splittail Entrainment Index[a] (Per Capita Method) at the SWP and CVP Salvage Facilities for Alternative 4A (Scenario H3_ELT) (See *BDCP Effects Analysis, Appendix 5B – Entrainment, Section 5B.6.1.7.1)*

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-1,036,669 (-52%)	-928,107 (-49%)
Above Normal	-54,102 (-41%)	-42,647 (-35%)
Below Normal	-1,789 (-18%)	-1,201 (-13%)
Dry	-579 (-29%)	-306 (-18%)
Critical	-611 (-46%)	-456 (-39%)
All Years	-234,987 (-43%)	-180,132 (-37%)

Shading indicates entrainment increased 10% or more.

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

[a] Estimated annual number of fish lost. Average (May–July).

Table 11-4A-92. Differences Between Model Scenarios in Adult Sacramento Splittail Entrainment Index[a] (salvage density method) at the SWP and CVP Salvage Facilities for Alternative 4A (Scenario H3_ELT) (See *BDCP Effects Analysis, Appendix 5B – Entrainment, Section 5B.6.1.7.1)*

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-2,790 (-70%)	-2,986 (-72%)
Above Normal	-3,294 (-68%)	-3,258 (-68%)
Below Normal	-1,352 (-40%)	-1,344 (-40%)
Dry	-680 (-28%)	-616 (-26%)
Critical	-594 (-18%)	-494 (-15%)
All Years	-1,875 (-54%)	-1,916 (-54%)

Shading indicates entrainment increased 10% or more.

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

[a] Estimated annual number of fish lost. Average (December–March).

Water Exports from SWP/CVP North Delta Intake Facilities

The north Delta intakes would be screened, and all splittail except larvae and juveniles less than 22 mm long would be excluded from entrainment (*BDCP Effects Analysis – Appendix 5B Entrainment, Section 5.B.6.2.4, hereby incorporated by reference*). Potential impacts would be minimized by the adaptive management plan under Alternative 4A, including monitoring of the new screens effectiveness and corrective measures if needed. This monitoring would be focused on listed species such as delta smelt and winter-run and spring-run Chinook salmon, but the temporal overlap of splittail early life stages with these species occurrence as larvae or juveniles near the north Delta intakes would result in de facto management for splittail. Although entrainment of smaller life stages at the north Delta intakes is likely to occur during lower flow years when floodplain inundation is less, the bulk of reproduction occurs when floodplains are inundated, which would occur more often under NAA_ELT and Alternative 4A because of Yolo Bypass improvements; splittail emerging from the Yolo Bypass at its downstream terminus in the Cache Slough subregion would not be susceptible to north Delta intake entrainment. In addition, the north Delta intakes would divert considerably less water in drier years, so that the risk of entrainment by the north Delta intakes would be less at times when there would be more juvenile splittail likely to be susceptible to entrainment, having not been spawned in the Yolo Bypass or other floodplains.

Predation Associated with Entrainment

Per-capita entrainment-related predation loss of splittail at the south Delta facilities is not expected to be greater under Alternative 4A than NAA_ELT because predicted per capita entrainment is lower due to lower south Delta exports. The predation loss would be lower under Scenario H4_ELT than under Scenario H3_ELT. However, because predation of entrained splittail is not currently considered to be an important driver of splittail population dynamics, this variation in the predicted impact in both Alternative 4A subscenarios is not considered to be adverse to splittail in either of these operational scenarios.

Predation at the north Delta would be increased due to the installation of the proposed water export facilities on the Sacramento River, with three intakes for Alternative 4A. These losses would be offset by the reduction in entrainment and predation loss at the SWP/CVP south Delta intakes, habitat restoration under Environmental Commitment 6, and reduction in potential predation under Environmental Commitment 15. Further, as described for Alternative 1A and as noted for Alternative 4, the fishery agencies concluded that the predation was not a factor currently limiting splittail abundance. In addition, as described above for entrainment at the north Delta intakes, the importance of floodplain inundation (particularly the Yolo Bypass) and the resulting emigration of juvenile splittail to the Delta downstream of the intakes, plus the relatively low diversions from the north Delta intakes in drier years when floodplains would be less available, suggests a limited effect of predation.

NEPA Effects: In conclusion, the effect from entrainment and predation loss under Alternative 4A would not be adverse, because while predation loss of splittail would be potentially increased at the north Delta facilities, it would be offset by substantial reductions in per capita entrainment and associated predation at the south Delta facilities compared to the NAA_ELT actions, as well as other conservation measures (Environmental Commitment 6, Environmental Commitment 15, and potentially Environmental Commitment 16).

CEQA Conclusion: Operational activities associated with reduced south Delta water exports would result in an overall decrease in the proportion of splittail population entrained for all water year types. As discussed above, although entrainment of smaller life stages at the north Delta intakes is likely to occur during lower flow years when floodplain inundation is less, the bulk of reproduction occurs when floodplains are inundated, which would occur more often under NAA_ELT and Alternative 4A because of Yolo Bypass improvements; splittail emerging from the Yolo Bypass at its downstream terminus in the Cache Slough subregion would not be susceptible to north Delta intake entrainment. Also, as discussed above, there would be less water diverted from the north Delta intakes in drier years in which splittail reproduction was more focused in non-floodplain areas, which would limit the potential for entrainment by the north Delta intakes. Under Scenario H3_ELT, estimated juvenile entrainment (Per Capita method) and hence pre-screen predation losses would be 43% lower and adult entrainment and pre-screen predation losses would be 54% lower than Existing Conditions. Per capita entrainment and related predation loss at the south Delta would be further reduced under Scenario H4_ELT compared to Existing Conditions. The impact and conclusion for predation associated with entrainment would be the same as described above.

In conclusion, the impact of Alternative 4A from entrainment and predation loss would be less than significant because of improvements in overall proportional entrainment, and no mitigation is required.

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

Sacramento splittail spawn in floodplains and channel margins and in side-channel habitat upstream of the Delta, primarily in the Sacramento River and Feather River. Floodplain spawning overwhelmingly dominates production in wet years. During low-flow years when floodplains are not inundated, spawning in side channels and channel margins would be much more critical.

In general, Alternative 4A would have little to no effect on splittail spawning habitat relative to the NAA_ELT because improvements to the Yolo Bypass would occur under the NAA_ELT and therefore would not differentiate Alternative 4A from NAA_ELT. There would be negligible effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River, with beneficial effects from moderate to substantial increases in mean monthly flow for some months and water year types for each location. There would be negligible negative effects on water temperatures in the Feather River and a beneficial effect from a decrease in exposure to critical high water temperatures.

H3_ELT/ESO_ELT

Floodplain Habitat

Effects of H3_ELT on floodplain spawning habitat were evaluated for Yolo Bypass. Note that, in contrast to other Alternatives, Alternative 4A does not include improvements to Yolo Bypass such as modification of the Fremont Weir; these improvements are assumed to occur as part of NAA_ELT (and therefore also are included in Alternative 4A, but are not as a result of the alternative). As described for Alternative 4, effects in Yolo Bypass were evaluated using a habitat suitability approach based on water depth (2 m threshold) and inundation duration (minimum of 30 days). Effects of flow velocity were ignored because flow velocity was generally very low throughout the modeled area for most conditions, with generally 80 to 90% of the total available area having flow velocities of 0.5 foot per second or less (a reasonable critical velocity for early life stages of splittail; Young and Cech 1996), and because habitat heterogeneity in the flooded Yolo Bypass is high (Sommer et al. 2005).

There would be little to no difference in floodplain habitat availability or acreage between NAA_ELT and Alternative 4A because Yolo Bypass improvements would be present in both (Table 11-4A-93; Table 11-4A-94).

Table 11-4A-93. Differences in Frequencies of Inundation Events (for 82-Year Simulations) of Different Durations on the Yolo Bypass under Different Scenarios and Water Year Types, February through June, from 15 2-D and Daily CALSIM II Modeling Runs

Number of Days of Continuous Inundation	Change in Number of Inundation Events for Each Scenario	
	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
30–49 Days		
Wet	-4	Little to no difference[a]
Above Normal	0	Little to no difference[a]
Below Normal	4	Little to no difference[a]
Dry	1	Little to no difference[a]
Critical	1	Little to no difference[a]
50–69 Days		
Wet	-5	Little to no difference[a]
Above Normal	0	Little to no difference[a]
Below Normal	1	Little to no difference[a]
Dry	0	Little to no difference[a]
Critical	0	Little to no difference[a]
≥70 Days		
Wet	8	Little to no difference[a]
Above Normal	2	Little to no difference[a]
Below Normal	1	Little to no difference[a]
Dry	0	Little to no difference[a]
Critical	0	Little to no difference[a]

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

[a] The inclusion of Yolo Bypass improvements was not modeled for NAA_ELT, but would be expected to result in minimal differences in the number of inundation events between NAA_ELT and H3_ELT.

Table 11-4A-94. Change in Splittail Weighted Habitat Area (HUs[c] and percent) in Yolo Bypass from Existing Biological Conditions to Alternative 4A by Water Year Type from 15 2-D and Daily CALSIM II Modeling Runs

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	1,123 (73%)	Little to no difference[b]
Above Normal	715 (62%)	Little to no difference[b]
Below Normal	337 (257%)	Little to no difference[b]
Dry	8 (NA[a])	Little to no difference[b]
Critical	5 (NA[a])	Little to no difference[b]

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

[a] NA percent differences could not be computed because no splittail weighted habitat occurred in the bypass for NAA_ELT and Existing Conditions in those years (dividing by 0).

[b] The inclusion of Yolo Bypass improvements was not modeled for NAA_ELT, but would be expected to result in minimal differences in the weighted habitat area between NAA_ELT and H3_ELT.

[c] HUs = Habitat Units. HUs were computed as the product of habitat acreage and a Habitat Suitability Index (based on water depth) that ranges from 0 to 1, where maximum suitability = 1. Therefore, HUs are always less than or equal to habitat acreage.

As noted for Alternative 4, a potential effect of Yolo Bypass improvements is changes in inundation of the Sutter Bypass as a result of increased flow diversion at the modified Fremont Weir. Because modification of the Fremont Weir would occur under Alternative 4A and the NAA_ELT, there would be little to no difference in inundated acreage in the lower Sutter Bypass between H3_ELT and NAA_ELT (Table 11-4A-95). Therefore, H3_ELT would not affect splittail spawning and rearing habitat in the Sutter Bypass relative to NAA_ELT.

Table 11-4A-95. Differences (and Percent Change) in Daily Average (December–June) Lower Sutter Bypass Inundation (acres)

Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet	-35 (-1.5)	Little to no difference[a]
Above Normal	55 (4.1)	Little to no difference[a]
Below Normal	-26 (-7.8)	Little to no difference[a]
Dry	-4 (-2.8)	Little to no difference[a]
Critical	1 (2.8)	Little to no difference[a]
All	1 (0.1)	Little to no difference[a]

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

[a] The inclusion of Yolo Bypass improvements was not modeled for NAA_ELT, but would be expected to result in minimal differences in the lower Sutter Bypass inundation between NAA_ELT and H3_ELT.

Channel Margin and Side-Channel Habitat

In addition to spawning on floodplains, splittail spawning and larval and juvenile rearing also occur in channel margin and side-channel habitat upstream of the Delta. These habitats are likely to be especially important during dry years, when flows are too low to inundate the floodplains (Sommer et al. 2007). Side-channel habitats are affected by changes in flow because greater flows cause more flooding, thereby increasing availability of such habitat, and because rapid reductions in flow dewater the habitats, potentially stranding splittail eggs and rearing larvae. Effects of the alternative on flows in years with low flows are expected to be most important to the splittail population because in years of high flows, when most production comes from floodplain habitats, the upstream side-channel habitats contribute relatively little production. However, as noted by Sommer (1997), splittail have high fecundity and so can respond rapidly to improvements in environmental conditions (e.g., floodplain inundation), so that very high recruitment occurs in years with floodplain inundation.

Effects on channel margin and side-channel habitat were evaluated by comparing flow conditions for the Sacramento River at Wilkins Slough and the Feather River at the confluence with the Sacramento River for the time-frame February through June. These are the most important months for splittail spawning and larval rearing (Sommer pers. comm.), and juveniles likely emigrate from the side-channel habitats during May and June if conditions become unfavorable.

Differences between model scenarios for monthly average flows during February through June by water-year type were determined for the Sacramento River at Wilkins Slough and for the Feather River at the confluence.

Flows under H3_ELT relative to NAA_ELT in the Sacramento River at Wilkins Slough were compared for the February through June spawning period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Modeling results indicate that H3_ELT would have primarily negligible effects (<5%) during February through April and May. During June, flows would be up to 16% greater under H3_ELT than under NAA_ELT). Due to the low magnitude and frequency of flow changes during June, this increase is not expected to have a biologically meaningful effect on splittail spawning conditions. Modeling results also show that Sacramento splittail spawning temperature tolerances would not be exceeded in the Sacramento River under Alternative 4A.

Flows in the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) during February through June under H3_ELT would generally be similar to or greater than flows under NAA_ELT. Flows under H3_ELT during April, May, and June would be up to 77% greater than flows under NAA_ELT, which, due to the high magnitude and frequency of change, would be a beneficial effect to splittail. These flow increases would substantially increase the amount of channel margin and side channel habitat available for splittail spawning during the majority of the spawning period.

Simulated daily and monthly water temperatures in Sacramento River at Hamilton City and Feather River at the confluence with the Sacramento River, respectively, were used to investigate the potential effects of H3_ELT on the suitability of water temperatures for splittail spawning and egg incubation. A range of 45°F to 75°F was selected as the suitable range for splittail spawning and egg incubation.

There would be no biologically meaningful difference (>5% absolute scale) between NAA_ELT and H3_ELT in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F regardless of water year type (Table 11-4A-96). In the Feather River, there would be differences between NAA_ELT and H3_ELT in temperatures below 45°F. There would be a 6% reduction in the exceedance above the 75°F threshold for above normal water years but due to the low magnitude and frequency of this reduction, it is not expected to have a biologically meaningful effect on splittail.

Table 11-4A-96. Difference (Percent Difference) in Percent of Days or Months[a] during February to June in Which Temperature Would Be below 45°F or above 75°F in the Sacramento River at Hamilton City and Feather River at the Confluence with the Sacramento River[b]

	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Sacramento River at Hamilton City		
Temperatures below 45°F		
Wet	-2.8 (-60%)	0 (0%)
Above Normal	-2.8 (-60%)	0 (0%)
Below Normal	-2.7 (-53%)	-0.2 (-8%)
Dry	-1.4 (-47%)	0 (0%)
Critical	-1.1 (-54%)	0 (0%)
All	-2.2 (-55%)	0 (0%)
Temperatures above 75°F		
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)
Feather River at Sacramento River Confluence		
Temperatures below 45°F		
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)
Temperatures above 75°F		
Wet	2.3 (NA)	0 (0%)
Above Normal	1.8 (NA)	-5.5 (-76%)
Below Normal	1.4 (NA)	-4.3 (-75%)
Dry	3.4 (77%)	-2.2 (-22%)
Critical	6.6 (396%)	0 (0%)
All	3.0 (243%)	-2.0 (-32%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.
[a] Days were used in the Sacramento River and months were used in the Feather River.
[b] Based on the modeling period of 1922 to 2003.

These results indicate that H3_ELT would cause no negative effects on splittail spawning conditions in channel margin and side-channel habitats resulting from changes in flow and water temperatures. Effects of H3_ELT on mean monthly flow would consist of negligible effects or increases in flow (increases up to 12% in the Sacramento River and to 77% in the Feather River) for some months and water year types in the spawning period that would have beneficial effects on rearing conditions. There would be negligible or beneficial project-related effects on exceedance of critical water temperatures in the Sacramento River, and a beneficial effect from a decrease (up to-6%) in exposure to critical high water temperatures in the Feather River.

Stranding Potential

As indicated above and as described for Alternative 4, rapid reductions in flow can dewater channel margin and side-channel habitats, potentially stranding splittail eggs and rearing larvae. Yolo Bypass improvements would occur under the NAA_ELT and therefore would exist under Alternative 4A, but there would be little to no difference in stranding potential between Alternative 4A and NAA_ELT.

H4_ELT/HOS_ELT

Floodplain Habitat

Floodplain habitat conditions for splittail under H4_ELT would be similar to conditions under H3_ELT, and would not differ from NAA_ELT because Yolo Bypass improvements are assumed to occur independently of Alternative 4A and therefore would be part of Alternative 4A as well as NAA_ELT.

Channel Margin and Side-Channel Habitat

Flows under H4_ELT in the Sacramento River at Wilkins Slough during February through June would be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Feather River at the Sacramento River confluence under H4_ELT would be up to 119% higher than under NAA_ELT, a benefit to splittail. Flows at these two locations are representative of the reach of these rivers where splittail spawn on wetted channel margin and side channels.

There would be no biologically meaningful difference (<5% difference on an absolute scale) between NAA_ELT and H4_ELT in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F regardless of water year type (Table 11-4A-97). In the Feather River, there would be differences between NAA_ELT and H4_ELT in temperatures below 45°F. There would be a 6% reduction in the exceedance above the 75°F threshold for above normal water years under H4_ELT relative to NAA_ELT, but no other differences.

Table 11-4A-97. Difference (Percent Difference) in Percent of Days or Months[a] during February to June in Which Temperature Would Be below 45°F or above 75°F in the Sacramento River at Hamilton City and Feather River at the Confluence with the Sacramento River[b]

	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Sacramento River at Hamilton City		
Temperatures below 45°F		
Wet	-2.8 (-60%)	0 (0%)
Above Normal	-2.8 (-60%)	0 (0%)
Below Normal	-2.6 (-51%)	-0.1 (-4%)
Dry	-1.4 (-47%)	0 (0%)
Critical	-1.1 (-54%)	0 (0%)
All	-2.2 (-55%)	0 (0%)
Temperatures above 75°F		
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)
Feather River at Sacramento River Confluence		
Temperatures below 45°F		
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)
Temperatures above 75°F		
Wet	3.8 (NA)	1.5 (702%)
Above Normal	5.5 (NA)	-1.8 (-25%)
Below Normal	1.4 (NA)	-4.3 (-75%)
Dry	5.6 (126%)	0 (0%)
Critical	5 (300%)	-1.6 (-19%)
All	4.2 (340%)	-0.8 (-13%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

[a] Days were used in the Sacramento River and months were used in the Feather River.

[b] Based on the modeling period of 1922 to 2003.

Stranding Potential

As noted for H3_ELT, because the improvements to Yolo Bypass such as Fremont Weir modifications would occur under the NAA_ELT and therefore would exist under Alternative 4A, there would be no difference in stranding potential between H4_ELT and NAA_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. The effects of H3_ELT on splittail spawning would consist of negligible effects and beneficial effects in some months on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough generally <5% change in flow) and the Feather River (increases in mean monthly flow up to 119%), and negligible or beneficial effects on water temperatures in the Sacramento and Feather Rivers (<5% change).

CEQA Conclusion: In general, Alternative 4A would have no effect on splittail spawning habitat relative to Existing Conditions. There would be negligible flow- and temperature-related effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River. Yolo Bypass improvements (e.g., modification of Fremont Weir) would occur irrespective of Alternative 4A, but are not included in Existing Conditions, so there would be generally beneficial effects to splittail coinciding with the implementation of Alternative 4A (but not as a result of Alternative 4A).

H3_ELT/ESO_ELT

Floodplain Habitat

As noted elsewhere in the analysis of Alternative 4A for splittail, increases in floodplain habitat because of Fremont Weir modifications during Yolo Bypass improvements are assumed to occur independently of Alternative 4A and would be part of NAA_ELT as well as Alternative 4A. Comparisons of splittail weighted inundation frequencies for H3_ELT and Existing Conditions show relatively small increases in drier years under H3_ELT. In wet years, there are reductions under H3_ELT in the frequencies of the shorter inundation periods and an increase in the frequency of the longest inundation periods (70 days or more) because a number what would be shorter inundation periods under Existing Conditions merge to produce longer inundation periods under H3_ELT (Table 11-4A-93).The availability of suitable spawning habitat would be greater under H3_ELT than under Existing Conditions (Table 11-4A-94), with increases of between 5 and 979 Habitat Units (HUs; see footnote in Table 11-5A-61) of suitable spawning habitat depending on water year type. Increased HUs for wet, above normal, and below normal water years are predicted to be 73%, 62%, and 257%, respectively for H3_ELT. Comparisons for dry and critical water years indicate project-related increases of 8 and 5 HUs of suitable spawning habitat, respectively, compared to 0 HUs for Existing Conditions. There would generally be no or small differences (8% lower in below normal years) in splittail spawning and rearing habitat in the Sutter Bypass under H3_ELT relative to Existing Conditions (Table 11-4A-95). These results indicate that under H3_ELT the extent of suitable spawning habitats would be up to 257% greater than under Existing Conditions, although the difference would not be as a result of implementation of Alternative 4A, but instead from separate Yolo Bypass improvements that are assumed to take place regardless of Alternative 4A.

Channel Margin and Side-Channel Habitat

Flows were compared between H3_ELT and Existing Conditions for the Sacramento River at Wilkins Slough (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) during February through June Flows under H3_ELT would generally not differ (<5%) from those under Existing Conditions during February through May although flows during June would be up to 18% higher under H3_ELT. Due to the low magnitude and frequency of flow changes during June, this increase is not expected to have a biologically meaningful effect on splittail spawning conditions.

Results for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) show variable effects of H3_ELT depending on month and water year type. Results for all months except April include negligible effects (<5%), small to large increases in mean monthly flow (to 71%), and small to moderate decreases (up to -15%). During April. Flows would be generally similar between H3_ELT and Existing Conditions. Based on a prevalence of negligible (<5%) or beneficial effects on flow (increases to 71%), and isolated decreases that would be of small magnitude, these results indicate that effects of Alternative 4A on flow would not have biologically meaningful negative effects on splittail spawning conditions in channel margin and side-channel habitats in the Feather River.

Simulated daily and monthly water temperatures in Sacramento River at Hamilton City and Feather River at the confluence with the Sacramento River, respectively, were used to investigate the potential effects of H3_ELT on the suitability of water temperatures for splittail spawning and egg incubation. A range of 45°F to 75°F was selected as the suitable range for splittail spawning and egg incubation.

There would be no biologically meaningful difference (>5% absolute scale) between Existing Conditions and H3_ELT in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F regardless of water year type (Table 11-4A-96). In the Feather River, there would be differences between Existing Conditions and H3_ELT in temperatures below 45°F. There would be a 7% increase in the exceedance above the 75°F threshold under H3_ELT relative to Existing Conditions in critical water years, but no other differences.

Stranding Potential

As noted for other alternatives, and due to a lack of quantitative tools and historical data to evaluate possible stranding effects, the following provides a narrative summary of potential effects in relation to stranding potential. The Yolo Bypass is exceptionally well-drained because of grading for agriculture, which likely helps limit stranding mortality of splittail. Moreover, water stage decreases on the bypass are relatively gradual (Sommer et al. 2001). Stranding of Sacramento splittail in perennial ponds on the Yolo Bypass does not appear to be a problem under Existing Conditions (Feyrer et al. 2004). Yolo Bypass improvements (occurring independently of Alternative 4A) would be designed, in part, to further reduce the risk of stranding by allowing water to inundate certain areas of the bypass to maximize biological benefits, while keeping water away from other areas to reduce stranding in isolated ponds. Actions to increase the frequency of Yolo Bypass inundation that are separate from Alternative 4A but that would coincide with Alternative 4A would increase the frequency of potential stranding events in relation to Existing Conditions. For splittail, an increase in inundation frequency would also increase the production of Sacramento splittail in the bypass. While total stranding losses may be greater under Alternative 4A than under Existing Conditions (although not as a result of Alternative 4A), the total number of splittail would be expected to be greater under Alternative 4A (again, not as a result of Alternative 4A, but coincident with it).

In the Yolo Bypass, Sommer et al. (2005) found these potential losses are offset by the improvement in rearing conditions. Henning et al. (2006) also noted the potential for stranding risk as wetlands desiccate and oxygen concentrations decline, but the seasonal timing of use by juveniles may decrease these risks. Sommer et al. (2005) addressed the question of stranding and concluded the potential improvements in habitat capacity outweighed the potential stranding problems that may exist in some years. Overall, these effects are less than significant.

H4_ELT/HOS_ELT

Floodplain Habitat

Floodplain habitat conditions for splittail under H4_ELT would be similar to conditions under H3_ELT, and would not differ from NAA_ELT because Yolo Bypass improvements are assumed to occur independently of Alternative 4A and therefore would be part of Alternative 4A as well as NAA_ELT.

Channel Margin and Side-Channel Habitat

Flows under H4_ELT in the Sacramento River at Wilkins Slough during February through June would generally be similar to flows under Existing Conditions with some increases (up to 11%) and decreases (up to 12%) depending on month and water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Feather River at the Sacramento River confluence under H4_ELT would generally be similar to those under Existing Conditions between February and May and up to 77% higher during June, a benefit to splittail.

There would be no biologically meaningful difference (>5% absolute scale) between Existing Conditions and H4_ELT in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F regardless of water year type (Table 11-4A-97). In the Feather River, there would be differences between Existing Conditions and H4_ELT in temperatures below 45°F. There would be a 6% increase in the exceedance above the 75°F threshold for above normal water and dry years under H4_ELT relative to Existing Conditions, but no other differences. These increases are not expected to cause a biologically meaningful negative effect to splittail due to their low magnitude and frequency.

Summary of CEQA Conclusion

Collectively, these results indicate that the impact is not significant because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. There would be negligible effects of the alternative on flow and water temperatures in channel margin habitats and side channels. Floodplain inundation and stranding potential would be greater than the CEQA baseline, but not as a result of Alternative 4A, and the net result would be expected to be beneficial. No mitigation is necessary.

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

H3_ELT/ESO_ELT

Because both Alternative 4A and NAA_ELT are assumed to include Yolo Bypass improvements including Fremont Weir modification, there would be little to no difference in the quantity and quality of rearing habitat in the Yolo Bypass. There would be no effect on rearing conditions in channel margin and side-channel habitats due to negligible changes in mean monthly flow and water temperatures during most of the rearing period in the Sacramento River and the Feather River.

Floodplains are important rearing habitats for juvenile splittail during periods of high flows when areas like the Yolo Bypass are inundated. During low flows when floodplains are not inundated, splittail rear in side-channel and channel margin habitat. Therefore, the previous impact discussion applies to rearing as well as spawning habitat for splittail for H3_ELT. The small and infrequent changes to flow under H3_ELT described above would also not substantially affect splittail rearing habitat conditions.

H4_ELT/HOS_ELT

Because flows and water temperatures under H4_ELT would be similar to those under H3_ELT, conclusions for H4_ELT are similar to those under H3_ELT.

NEPA Effects: Based on the analyses above, the effect of Alternative 4 on splittail rearing habitat is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of mortality.

CEQA Conclusion: In general, there would be no effect of Alternative 4A on splittail rearing habitat relative to Existing Conditions.

H3_ELT/ESO_ELT

As described above, floodplains are important rearing habitats for juvenile splittail during periods of high flows when areas like the Yolo Bypass are inundated. Alternative 4A would not result in changes in floodplain habitat, although there would be a greater extent of floodplain habitat available coincident with implementation of Alternative 4A because of Yolo Bypass improvements (e.g., Fremont Weir modification) that would occur regardless of Alternative 4A but that are not current present under Existing Conditions. During low flows when floodplains are not inundated, splittail rear in side-channel and channel margin habitat. Therefore, the previous impact discussion applies to rearing as well as spawning habitat for splittail for H3_ELT.

H4_ELT/HOS_ELT

Because flows and water temperatures under H4_ELT would be similar to those under H3_ELT, conclusions for H4_ELT are similar to those under H3_ELT.

Summary of CEQA Conclusion

Based on the analyses above, the impact of Alternative 4 on splittail rearing habitat is not significant because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of mortality. There would be negligible effects of the alternative on flow and water temperatures in channel margin habitats and side channels. Floodplain inundation and stranding potential would be greater than the CEQA baseline but not as a result of Alternative 4A. No mitigation is necessary.

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

Upstream of the Delta

In general, Alternative 4A would not affect migration conditions for juvenile or adult splittail in the Sacramento River or the Feather River relative to the NAA_ELT based on negligible or beneficial effects on mean monthly flow during the migration period and negligible effects on exposure to critical water temperatures in the Feather River. Adults migrate upstream primarily in December through March and juvenile migrate primarily in April through July (Moyle et al. 2004).

H3_ELT/ESO_ELT

The effects of H3_ELT on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. There would be no effect of H3_ELT on channel margin and side-channel habitat in either location because there would be negligible changes in mean monthly flow and water temperatures compared to NAA_ELT.

H4_ELT/HOS_ELT

The effects of H4_ELT on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. These effects would be similar to those for H3_ELT.

Through-Delta

Alternative 4A would generally improve OMR reverse flows during the period of juvenile splittail migration through the Delta under all flow scenarios. Modeled OMR flows under Alternative 4A would be reduced slightly in May compared to other months under all flow scenarios, but flows would still be less negative than under NAA_ELT. Modeled OMR flows would be increased in June and July under Alternative 4A flow scenarios compared to baseline conditions (NAA_ELT). Based on the modeling, overall OMR flows improve during the splittail migration period. For juvenile splittail migrating down the Sacramento River past the north Delta intakes, migration flows downstream of the north Delta intakes under Alternative 4A generally would be somewhat reduced relative to NAA_ELT, which could reduce splittail survival in the more riverine reaches (as seen for juvenile Chinook salmon; Perry 2010). As noted in the analysis of entrainment potential above, the greatest proportion of juvenile splittail would be expected to be emigrating from the Yolo Bypass in years when it is inundated (a more frequent occurrence under NAA_ELT and Alternative 4A because of Fremont Weir modifications) and therefore these juveniles would enter the Delta in its further downstream, tidal reaches in the Cache Slough subregion, where riverine flow-related migration influences would be very small relative to tidal flow influences.

NEPA Effects: The effect of Alternative 4A is not adverse because it would not substantially reduce or degrade migration habitat or substantially reduce the number of fish as a result of mortality.

CEQA Conclusion: Overall, the effects of water operations on migration conditions for Sacramento splittail are less than significant.

Upstream of the Delta

In general, effects of Alternative 4A would have no effect on splittail migration conditions relative to Existing Conditions due to a lack of effects to flows and water temperatures in the Sacramento River and the Feather River during the splittail migration period.

H3_ELT/ESO_ELT

Effects of H3_ELT on splittail migration conditions are the same as described for channel margin and side-channel habitats in Impact AQUA-112.

H4_ELT/HOS_ELT

The effects of H4_ELT on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. These effects would be similar to those for H3_ELT.

Through-Delta

Average modeled OMR flows would be greater under Scenario H3_ELT than the CEQA baseline during the majority of the juvenile splittail migration through the Delta. OMR flow conditions under Scenario H4 would further improve migration conditions for juvenile splittail. For juvenile splittail migrating down the Sacramento River past the north Delta intakes, migration flows downstream of the north Delta intakes under Alternative 4A generally would be somewhat reduced relative to NAA_ELT, which could reduce splittail survival in the more riverine reaches (as seen for juvenile Chinook salmon; Perry 2010). As noted in the analysis of entrainment potential above, the greatest proportion of juvenile splittail would be expected to be emigrating from the Yolo Bypass in years when it is inundated (a more frequent occurrence under NAA_ELT and Alternative 4A because of Fremont Weir modifications) and therefore these juveniles would enter the Delta in its further downstream, tidal reaches in the Cache Slough subregion, where riverine flow-related migration influences would be very small relative to tidal flow influences. The greater availability of the Yolo Bypass under Alternative 4A compared to Existing Conditions would improve migration conditions for splittail that are able to access the Bypass. Therefore the impact on splittail migration survival is concluded to be less than significant.

Summary of CEQA Conclusion

The impact is less than significant because it would not substantially reduce suitable migration habitat or substantially reduce the number of fish as a result of mortality and no mitigation is necessary. There would be negligible effects of the alternative on flow and water temperatures in channel margin habitats and side channels. Floodplain inundation and stranding potential would be greater than the CEQA baseline but not as a result of Alternative 4A. No mitigation is necessary.

Restoration Measures (Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

As described for other covered fishes, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A. The mechanisms of impacts of habitat restoration discussed for winter-run Chinook salmon generally would be similar for splittail, which could overlap restoration measure effects. However, because the extent of restoration is limited to offsetting losses from construction of water facilities under the water conveyance facilities, any such effects would be greatly limited compared to Alternative 1A and 4, for example.

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

As noted for Alternative 1A's discussion of Impact AQUA-115, in-water and shoreline construction activities (e.g., riprap removal and levee breaching; shoreline excavation and recontouring) could increase turbidity, but splittail are tolerant of such increases. In addition, implementation of the environmental commitments described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments,* of the Draft EIR/EIS (*Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; and Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*), would minimize or eliminate any potential negative effects on splittail from construction of the restoration measures.

NEPA Effects**:** The effects of short-term construction activities would not be adverse to splittail. Implementation of the environmental commitments described in Appendix 3B, *Environmental Commitments*, would minimize or eliminate effects on splittail. The relevant environmental commitments are: *Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; and Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*. Pertinent details of these plans are provided under Impact AQUA-1.

CEQA Conclusion**:** As discussed for Alternative 1A, habitat restoration activities could result in short-term effects on splittail but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce splittail habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

As noted in the more detailed analysis of Impact AQUA-116 for Alternative 1A, potential impacts on Sacramento splittail from effects of methylmercury, selenium, copper, ammonia, and pesticides associated with habitat restoration activities would be similar to those discussed in detail for delta smelt (see Impact AQUA-8) except that Sacramento splittail is a benthic forager so the release of sediment borne contaminants may result in greater effects for this species. Alternative 4A would restore 59 acres of tidal wetlands that have the potential to temporarily increase contaminant exposure to fish in the Delta. Additionally, depending on the specific site conditions of the restoration, benthic grazers that bioaccumulate selenium, which splittail feed on, may colonize and increase the potential for splittail exposure to selenium. However, this restoration and its potential contaminant effects would be negligible given the very small area that would be restored.

NEPA Effects: As noted for other species, while Alternative 4A habitat restoration actions may result in a very small increase in production, mobilization, and bioavailability of methylmercury, selenium, copper, and pesticides in the aquatic system, any such releases would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation of these contaminants in splittail. Overall, the effects of contaminants associated with restoration measures would not be adverse for splittail.

CEQA Conclusion: Habitat restoration under Alternative 4A may result in increased production, mobilization, and bioavailability of contaminants in the aquatic system, but these would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation in splittail. For methylmercury, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury in the limited restoration areas. Regarding selenium, the amount of restoration (59) acres would have a negligible effect on the potential for benthic grazers to colonize and bioaccumulate selenium that could be consumed by splittail and substantially affect them. Therefore, the impact of contaminants is considered less than significant because it would not substantially affect splittail either directly or through habitat modifications. Consequently, no mitigation would be required.

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

Restored habitat under *Environmental Commitment 4 Tidal Natural Communities Restoration* and *Environmental Commitment 6 Channel Margin Enhancement* is intended to offset habitat loss/modification caused by construction and operation of the water facilities proposed under Alternative 4A.

NEPA Effects: The effects of restored habitat conditions on splittail would not be adverse because restoration is intended to provide habitat benefits for splittail.

CEQA Conclusion: As described above, habitat restoration would be undertaken to offset loss/modification of habitat from water facility construction and operation. The effects of restored habitat conditions on splittail would be less than significant. Consequently, no mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

As noted for other covered species, Alternative 4A includes three other Environmental Commitments, which are reduced in their extent relative to the Conservation Measures included in other Alternatives (e.g., Alternative 1A and Alternative 4). While the extent of these measures is reduced compared to these alternatives, the nature of the mechanisms for splittail remains the same.

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (Environmental Commitment 12)

The impact discussion for winter-run Chinook salmon (Impact AQUA-46) is also applicable to splittail because they have similar potential to be exposed to methylmercury in the Delta.

NEPA Effects: The effects of methylmercury management on splittail would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As noted for winter-run Chinook salmon, effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts on splittail would be less than significant. Consequently, no mitigation is required.

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (Environmental Commitment 15)

NEPA Effects: Potential impacts on Sacramento splittail from predator removal at the north Delta intakes and at the south Delta export facilities is expected to slightly reduce the predation rates on Sacramento splittail. However and as concluded for Alternative 1A (Impact AQUA-121), because the affected proportion of the population would be very small this effect would not be detectable. There would not be an adverse effect on splittail.

CEQA Conclusion: Because the proportion of the population affected by Environmental Commitment 15 would be very small and not measurable, there would be a less than significant impact to splittail. Consequently, no mitigation would be required.

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (Environmental Commitment 16)

As described for Alternative 1A, although the NPB at the divergence of Georgiana Slough from the Sacramento River under Alternative 4A would be constructed and operated to benefit salmonids, Sacramento splittail are likely to also be deterred by the NPB based on their hearing ability and strong swimming ability as young juveniles. This would reduce the risk of predation for juvenile splittail by reducing their entry into the low-survival interior Delta.

NEPA Effects: The NPB also has the potential to attract predatory fish, which often hold around underwater human-made structure. Therefore, there is a slightly increased risk of predation for juvenile Sacramento splittail in the area immediately around the NPB. However, the structure is intended to promote successful survival of salmonids and designs are being tested to minimize any risk of predation associated with the structure. Additionally, the 2011 pilot study of the NPB at Georgiana Slough did not find that predation near the NPB was more frequent than predation farther from the NPB (DWR 2012). As such, the overall effects of NPB would not be adverse.

CEQA Conclusion: As described for Alternative 1A, the first months of the juvenile Sacramento splittail migration to the Delta overlap with the latter portion of the main juvenile salmonid outmigration period during which the NPB would be implemented. Deterrence away from the interior Delta would reduce the risk of predation for juvenile splittail, although the NPB also has the potential to attract predatory fish, which often hold around underwater human-made structures. Therefore, there is a slightly increased risk of predation for juvenile Sacramento splittail in the area immediately around the NPB. However the overall impacts of the NPB are expected to be less than significant on Sacramento splittail because they would reduce entry into the low-survival interior Delta, where entrainment and predation potential increases. Consequently, no mitigation would be required.

Green Sturgeon

Construction and Maintenance of Water Conveyance Facilities

The discussion of potential effects to delta smelt from construction and maintenance of the water conveyance facilities under Alternative 4A is also relevant to green sturgeon. Adult and juvenile green sturgeon would have the potential to encounter construction and maintenance because of their presence in the Delta for considerable periods of time (Table 11-8).

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

The potential effects of construction of the water conveyance facilities on green sturgeon or their designated critical habitat would be the same as described for Alternative 4 (Impact AQUA-127). This section provides additional detail on underwater noise impacts which are also applicable to Impact AQUA-127 in Alternative 4.

Table 11-8 presents the life stages of green sturgeon and months of their potential presence in the north, east, and south Delta during the proposed in-water construction window (June 1–October 31). Based on the proposed timing of pile driving activities and the occurrence of sensitive life stages of the covered species in the affected reaches, green sturgeon are considered most vulnerable to pile driving impacts because of their potential year-round presence in the plan area.

Under Alternative 4A, impact pile driving could result in exposure of juvenile and adult green sturgeon to underwater noise levels exceeding the injury thresholds at a number of construction sites where in-water pile driving is proposed. The potential for exposure of adults and juveniles to pile driving noise is highest in the north Delta (Sacramento River in the vicinity of the three proposed intakes) which serves as the primary migration route utilized by adults to access upstream spawning areas, and the primary migration route for juveniles entering the Delta from natal rearing areas in the upper Sacramento River. Restricting impact pile driving to June 1 to October 31 avoids the peak periods of upstream migration of adults (late February to early May) although some adults may migrate through the Delta as late as June or July. Some adults may also be exposed to pile driving noise during their outmigration; outmigration of tagged adults has been observed during summer (June–August) and late fall or winter (November-December) coincident with increases in flow from the first significant rain events (Heublein et al. 2009). Juvenile and sub-adult green sturgeon may be present in the Delta year-round and therefore subject to pile driving noise during pile driving activities at the proposed intakes, barge landings, and other in-water structures. Following the larval rearing period, young-of-the-year juveniles enter the Delta where they continue to rear for up to three years before entering the ocean. Fish salvage data collected at the state and federal water export facilities in the southern Delta indicate that juvenile green sturgeon in the Delta range in length from 100 to 600 mm, with most being greater than 200 mm (Adams et al. 2002, Beamesderfer et al. 2007).

Several factors likely reduce the potential for injury or mortality of adult and juvenile sturgeon during pile driving activities at the proposed intake structures. As described earlier, the estimated impact distances above are worst-case estimates based on impact driving in open water with no attenuation measures and an unimpeded underwater propagation path. To mitigate potential adverse effects, DWR proposes to use vibratory driving to the extent feasible to minimize both the area and duration of potentially harmful underwater noise levels associated with impact driving in open water outside the work window (Mitigation Measure AQUA-1a). In addition, construction of the intake facilities would be spread out over a period of five years, limiting the number of sites where pile driving will take place and the duration of impact driving in any given year (Table 4.3.7-1 under Delta Smelt). Although pile driving activities could occur 42 to 55 days per season at each intake location, in-water pile driving will not be continuous and limited to daylight hours only, resulting in 12-16 hour periods each day for migrating fish to pass the construction sites undisturbed.

Several aspects of green sturgeon life history and biology also affect the potential for injury or mortality of adult and juvenile green sturgeon to pile driving noise. All in-water pile driving will be performed after June 1 and before October 31, avoiding the primary upstream and downstream migration periods of pre- and post-spawning adults. Adult sturgeon are large (>19 kilograms) and presumably much less vulnerable to pile driving noise than smaller fish (approximately 2 grams or smaller) protected by the SPL and SEL injury criteria. In addition, adult sturgeon are highly mobile and thus able to rapidly avoid or swim away from areas of elevated noise. Their exposure would also be limited by their rapid migration rate; recent telemetry studies indicate that adult green sturgeon migrate rapidly to and from spawning areas in the upper Sacramento River, traversing the estuary and Delta in less than one week (Heublein et al. 2009). The behavioral responses of green sturgeon to pile driving noise are unknown but could include disruptions of normal migratory behavior and potential delays in migration. However, given the intermittent nature of pile driving and the daily cessation of pile driving at night, such delays are expected to be minor and not affect the ability of adults to successfully reach the spawning grounds.

Because of their relatively small body size, widespread distribution, and year-round presence in the Delta and estuary, juvenile and sub-adult green sturgeon are at higher risk of injury and mortality to pile driving noise than adults. Similar to adults, the potential for exposure to pile driving noise is highest in the North Delta (Sacramento River in the vicinity of the three proposed intakes) which serves as the primary migration route for young-of-the-year juveniles entering the Delta from natal rearing areas in the upper Sacramento River. Based on the size distribution of juveniles observed at the export facilities in the southern Delta, most juveniles entering the Delta would be expected to be actively swimming juveniles (>100 mm in length) capable of avoiding or swimming away from areas of elevated noise. Because juveniles spend the majority of their lives in deep brackish portions of the estuary before entering the ocean (Moyle 2002), the Sacramento River adjacent to the proposed intake locations likely serves primarily as a migratory corridor, reducing the duration of potential exposures of juveniles to pile driving sound. Another factor that may contribute to reducing the exposure of juveniles to pile driving noise would be the cessation of pile driving activities at night when juveniles appear to be most active and higher in the water column (Kynard et al. 2005).

A number of data sources suggest that the distribution of juvenile green sturgeon is widespread in the Delta and estuary, indicating that juvenile green sturgeon could be exposed to pile driving sounds at a number of construction sites in the Delta. In the absence of information on the movements and distribution of juveniles, potential impacts to the population can be generally assessed based on the proportion of total habitat subject to pile driving sounds. Under existing conditions, the Delta comprises an estimated 84,280 acres of subtidal aquatic habitat. Using this estimate as a measure of the total amount of potential foraging and rearing habitat available to juveniles, Table 4.3.7-2 shows the percentage of habitat that would be subjected to pile driving noise exceeding the injury thresholds during each year of pile driving activities.

Table 4.3.7-2. Potential underwater noise impact areas in each year of pile driving activities as a percentage of the total amount of subtidal aquatic habitat in the Delta (Alternative 4A).

Construction Year	Facilities/Structures	Potential Impact Area (acres)	Approximate Percentage of Subtidal Habitat
2	Intake 5 cofferdams	69	<0.1%
3	Intake 3 cofferdams Intake 5 foundation piles	153	0.2%
4	Intake 2 cofferdams Intake 3 foundation piles Intake 5 bridge piles	204	0.2%
5	Intake 2 foundation piles Intake 3 bridge piles Barge unloading facilities (5)	3,436	4.1%
6	Intake 2 bridge piles	45	<0.1%
7	HOR barrier cofferdams and foundation	36	<0.1%
8	CCF cofferdams	364	0.4%
9	CCF siphons	175	0.2%

These estimates represent a general order-of-magnitude estimate of the potential exposure of the population to pile driving noise. Thus, potential for exposure of the population to project pile driving noise is very low in most years. The exception is year 5 when an estimated 3,436 acres or 4.1% of the total amount of subtidal habitat would be subject to pile driving noise levels that could harm juvenile green sturgeon. This potential impact is due largely to the construction of six barge unloading facilities at various locations along the pipeline/tunnel alignment. Factors that may further limit exposure of the population to adverse effects include the short duration of pile driving activities at most locations (Table 4.3.7-1 under Delta Smelt). In addition, the total area of habitat available to juvenile green sturgeon expands beyond the Delta into the lower estuary and bays as juveniles grow and develop salinity tolerance. Juvenile typically achieve full tolerance by the end of their first year at sizes larger than 250 mm (Adams et al. 2002). Thus, there is a low likelihood of significant population-level effects on green sturgeon due to pile driving noise.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-127, the effect would not be adverse for green sturgeon. Implementation of the measures described in Appendix 3B, *Environmental Commitments*, such as *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan* would guide rapid and effective response in the case of inadvertent spills of hazardous materials. Construction will result in both temporary and permanent alteration of rearing and migratory habitats used by green sturgeon. However, Alternative 4A includes Environmental Commitment 4 to restore tidal habitat. The direct effects of underwater construction noise on green sturgeon that may be present could be adverse if sturgeon are exposed. However, considering the ability of green sturgeon to move away from the noise and migrate during the night or other times that pile driving is not occurring, the relatively few green sturgeon in the area of pile driving, and the implementation of Mitigation Measures AQUA-1a and AQUA-1b, that would minimize exposure, this effect would not be adverse.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-127, the impact of the construction of the water conveyance facilities on green sturgeon would not be significant except for construction noise associated with pile driving. Construction of Alternative 4A involves several elements with the potential to affect green sturgeon. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4A would be the same as those described for Alternative 4, Impact AQUA-128. As concluded in Alternative 4, Impact AQUA-128, the impact would not be adverse for green sturgeon.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-128, the impact of maintenance of water conveyance facilities on green sturgeon or their designated critical habitat would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

Water Exports

The potential entrainment effects under Alternative 4A would be the same as those under Alternative 4, which reflects the analysis for Alternative 1A. Operating new north Delta intakes and conveyance for SWP have the potential to avoid or reduce entrainment as described for Alternative 1A; there would be no adverse effect.

Scenario H3_ELT would substantially reduce entrainment of juvenile green sturgeon at the south Delta export facilities. Entrainment loss would be reduced 56% in wetter years and by 37% in drier years under Scenario H3_ELT compared to NAA_ELT (Table 11-4A-98). Entrainment losses of green sturgeon would be somewhat less under HOS_ELT. Under both the H3_ELT and H4_ELT scenarios, however, entrainment at the south Delta facilities would be substantially reduced compared to the NAA_ELT.

Table 11-4A-98. Juvenile Green Sturgeon Entrainment Index at the SWP and CVP Salvage Facilities—Differences (Absolute and Percentage) between Model Scenarios for Alternative 4A (Scenario H3_ELT)

	Absolute Difference (Percent Difference)	
Water Year Type[b]	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wet and Above Normal	-68 (-58%)	-62 (-56%)
Below Normal, Dry, and Critical	-21 (-43%)	-17 (-37%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

[a] Estimated annual number of fish lost, based on non-normalized data.

[b] Sacramento Valley water year-types.

Predation Associated with Entrainment

Entrainment-related predation loss of juvenile green sturgeon would not be greater under Alternative 4A and may be lower relative to baseline due to a reduction in entrainment loss. Conditions under Scenario H4_ELT would likely reduce predation loss relative to Scenario H3_ELT. The impact and conclusion for predation risk associated with NPB structures and the north Delta intakes would be the same as described for Alternative 1A (Impact AQUA-129).

NEPA Effects: In conclusion, the effect of Alternative 4A on entrainment and associated predation of green sturgeon would not be adverse and may provide modest benefit due to reduced losses at the south Delta facilities.

CEQA Conclusion: Similar to differences in south Delta entrainment described above for the NAA_ELT, there would be decreases in south Delta entrainment under H3_ELT relative to Existing Conditions (58% in wetter years; 43% in drier years; Table 11-4A-90). Therefore, the impact of the water operations on green sturgeon related to entrainment and associated predation losses would be less than significant and no mitigation would be required.

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

In general, Alternative 4A would not affect spawning and egg incubation habitat for green sturgeon relative to the NAA_ELT.

H3_ELT/ESO_ELT

Sacramento River

Mean flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation. Mean flows under H3_ELT would generally be similar to or up to 12% greater than flows under NAA_ELT for all months and water year types at both locations

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River*

Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

The number of days when temperatures exceeded the analysis criterion (i.e., 63°F identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period. The combination of number of days and degrees above the 63°F threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H3_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-99. There would be no substantial differences between NAA_ELT and H3_ELT in the number of years with each "level of concern".

Table 11-4A-99. Differences between Baseline and H3_ELT Scenarios in the Number of Years in Which Water Temperature Exceedances above 63°F are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Red	3 (75%)	0 (0%)
Orange	0 (0%)	0 (0%)
Yellow	1 (50%)	-1 (-25%)
None	-4 (-5%)	1 (1%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Total degree-days exceeding 63°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4A-100). Total degree-days (all water years combined) under H3_ELT would be 18% lower than under NAA_ELT during July and similar to the total under NAA_ELT in the remaining 4 months.

Table 11-4A-100. Differences between Baseline and H3_ELT Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
May	Wet	17 (131%)	0 (0%)
	Above Normal	0 (NA)	-2 (-100%)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	2 (NA)	1 (100%)
	All	19 (146%)	-1 (-3%)
June	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
July	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	129 (1613%)	-30 (-18%)
	All	129 (1613%)	-30 (-18%)
August	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	28 (NA)	-1 (-3%)
	Critical	610 (303%)	-56 (-6%)
	All	638 (317%)	-57 (-6%)
September	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	4 (NA)	3 (300%)
	Dry	137 (442%)	7 (4%)
	Critical	497 (186%)	-44 (-5%)
	All	638 (214%)	-34 (-4%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Feather River

Flows were examined in the Feather River between Thermalito Afterbay and during the February through June green sturgeon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows under H3_ELT at Thermalito would generally be similar to or up to 106% greater (June of below normal years) than flows under NAA_ELT, with minor exceptions. Differences at the confluence with the Sacramento River would generally be similar to but smaller than those at Thermalito. These results indicate that flows in the Feather River would increase overall under H3_ELT independent of climate change.

Mean water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) between NAA_ELT and H3_ELT in mean water temperatures for any month or water year type during the period.

Water temperature-related effects of H3_ELT on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures exceed a 64°F temperature threshold at Gridley (Table 11-4A-101). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. The percent of months exceeding the threshold during May and June under H3_ELT would generally be similar to or up to 26% lower (absolute difference) than that under NAA_ELT with few exceptions.

Table 11-4A-101. Differences between Baselines and H3_ELT in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 64°F Threshold, May through September

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3_ELT					
May	25 (77%)	16 (87%)	7 (75%)	9 (233%)	4 (150%)
June	2 (3%)	1 (1%)	-1 (-2%)	1 (2%)	-1 (-3%)
July	0 (0%)	0 (0%)	0 (0%)	9 (10%)	20 (29%)
August	0 (0%)	0 (0%)	7 (8%)	14 (17%)	19 (30%)
September	-9 (-13%)	-9 (-16%)	5 (17%)	14 (183%)	5 (200%)
NAA_ELT vs. H3_ELT					
May	-4 (-6%)	-1 (-3%)	-5 (-22%)	0 (0%)	0 (0%)
June	-1 (-1%)	-6 (-6%)	-14 (-15%)	-21 (-24%)	-26 (-36%)
July	0 (0%)	0 (0%)	0 (0%)	-1 (-1%)	4 (4%)
August	0 (0%)	0 (0%)	-1 (-1%)	-1 (-1%)	-1 (-2%)
September	10 (20%)	6 (16%)	5 (17%)	1 (6%)	-1 (-14%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Water temperature-related effects of H3_ELT on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-4A-102). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. Combining water years, total degree-months exceeding the threshold during May and June under H3_ELT would be 6% to 23% lower relative to NAA_ELT. Within months, total degree-months under H3_ELT would be similar or up to 45% lower than that under NAA_ELT depending on month and water year type. These results indicate that there would be a small to moderate benefit of H3_ELT to green sturgeon spawning and egg incubation temperature-related conditions in the Feather River.

Table 11-4A-102. Differences between Baselines and H3_ELT in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 64°F in the Feather River at Gridley, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
May	Wet	11 (183%)	0 (0%)
	Above Normal	4 (36%)	-4 (-21%)
	Below Normal	12 (150%)	-1 (-5%)
	Dry	16 (114%)	-1 (-3%)
	Critical	12 (71%)	-1 (-3%)
	All	55 (98%)	-7 (-6%)
June	Wet	12 (16%)	-32 (-27%)
	Above Normal	-6 (-12%)	-23 (-34%)
	Below Normal	-19 (-29%)	-37 (-45%)
	Dry	10 (11%)	-16 (-13%)
	Critical	21 (38%)	1 (1%)
	All	18 (5%)	-107 (-23%)
July	Wet	11 (7%)	6 (3%)
	Above Normal	5 (9%)	0 (0%)
	Below Normal	19 (28%)	4 (5%)
	Dry	46 (53%)	20 (18%)
	Critical	58 (73%)	32 (30%)
	All	139 (31%)	62 (12%)
August	Wet	5 (3%)	8 (5%)
	Above Normal	15 (33%)	7 (13%)
	Below Normal	25 (36%)	7 (8%)
	Dry	69 (101%)	26 (23%)
	Critical	18 (21%)	-8 (-7%)
	All	132 (30%)	40 (7%)
September	Wet	-26 (-67%)	7 (117%)
	Above Normal	-4 (-25%)	11 (1100%)
	Below Normal	6 (21%)	-7 (-17%)
	Dry	13 (46%)	2 (5%)
	Critical	20 (100%)	2 (5%)
	All	9 (7%)	15 (12%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

San Joaquin River

Flows in the San Joaquin River under H3_ELT would be similar to those under NAA_ELT throughout the March through June period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

H4_ELT /HOS_ELT

Sacramento River

Mean flows in the Sacramento River at Keswick and upstream of Red Bluff during the March through July spawning and egg incubation period for green sturgeon under H4_ELT would generally be similar to flows under NAA_ELT for all months and water year types at both locations (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

There would be no differences between NAA_ELT and H4_ELT in the number of years with each level of concern in the Sacramento River at Bend Bridge (Table 11-4A-103).

Table 11-4A-103. Differences between Baseline Scenarios and H1 and H4_ELT Scenarios in the Number of Years in Which Water Temperature Exceedances above 63°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Red	2 (50%)	-1 (-14%)
Orange	-1 (-100%)	-1 (-100%)
Yellow	-2 (-100%)	-4 (-100%)
None	1 (1%)	6 (9%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Total degree-days (all water year types combined) exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under H4_ELT during May through September would range from no different than to 54% lower than those under NAA_ELT for all months during the period (Table 11-4A-104). This represents a moderate benefit of H4_ELT to green sturgeon temperature-related spawning conditions in the Sacramento River.

Table 11-4A-104. Differences between Baseline Scenarios and H4_ELT in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
May	Wet	17 (131%)	0 (0%)
	Above Normal	1 (NA)	-1 (-50%)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	1 (NA)	0 (0%)
	All	19 (146%)	-1 (-3%)
June	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
July	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	69 (862.5%)	-90 (-54%)
	All	69 (863%)	-90 (-54%)
August	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	23 (NA)	-6 (-21%)
	Critical	352 (175%)	-314 (-36%)
	All	375 (187%)	-320 (-36%)
September	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	5 (NA)	4 (400%)
	Dry	112 (361%)	-18 (-11%)
	Critical	223 (84%)	-318 (-39%)
	All	340 (114%)	-332 (-34%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Feather River

Flows under H4_ELT in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June period would generally be similar to or up to 548% greater (April of below normal water years) than flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) between NAA_ELT and H4_ELT in any month or water year type during the period.

The percent of months exceeding the 64°F NMFS threshold during May and June under H4_ELT would be similar to or up to 28% lower (absolute difference) than that under NAA_ELT, representing a small to moderate benefit of H4_ELT (Table 11-4A-105).

Table 11-4A-105. Differences between Baselines and H4_ELT Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 64°F Threshold, May through September

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISITING CONDITIONS vs. H4_ELT					
May	0 (0%)	-2 (-13%)	0 (0%)	6 (167%)	2 (100%)
June	4 (4%)	5 (6%)	6 (8%)	14 (21%)	12 (26%)
July	0 (0%)	0 (0%)	0 (0%)	7 (8%)	22 (32%)
August	0 (0%)	0 (0%)	9 (9%)	19 (23%)	33 (54%)
September	-7 (-11%)	-6 (-11%)	2 (9%)	11 (150%)	4 (150%)
NAA_ELT vs. H4_ELT					
May	-28 (-47%)	-20 (-55%)	-12 (-56%)	-2 (-20%)	-1 (-20%)
June	0 (0%)	-2 (-3%)	-6 (-7%)	-9 (-10%)	-12 (-17%)
July	0 (0%)	0 (0%)	0 (0%)	-2 (-2%)	6 (7%)
August	0 (0%)	0 (0%)	0 (0%)	4 (4%)	14 (17%)
September	11 (22%)	9 (22%)	2 (9%)	-1 (-6%)	-2 (-29%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

Combining water years, total degree-months exceeding the 64°F NMFS threshold during the May and June spawning period under H4_ELT would be 5% to 29% lower relative to NAA_ELT. Within months, total degree-months under H4_ELT would be similar or up to 74% lower than that under NAA_ELT depending on water year type (Table 11-4A-106). These results indicate that there would be a small to moderate benefit of H4_ELT to green sturgeon spawning and egg incubation temperature-related conditions in the Feather River

Table 11-4A-106. Differences between Baselines and H1 and H4_ELT Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 64°F in the Feather River at Gridley, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
May	Wet	0 (0%)	-11 (-65%)
	Above Normal	-6 (-55%)	-14 (-74%)
	Below Normal	6 (75%)	-7 (-33%)
	Dry	17 (121%)	0 (0%)
	Critical	12 (71%)	-1 (-3%)
	All	28 (50%)	-34 (-29%)
June	Wet	40 (53%)	-4 (-3%)
	Above Normal	14 (27%)	-3 (-4%)
	Below Normal	4 (6%)	-14 (-17%)
	Dry	22 (23%)	-4 (-3%)
	Critical	20 (36%)	0 (0%)
	All	100 (29%)	-25 (-5%)
July	Wet	37 (22%)	32 (18%)
	Above Normal	29 (55%)	24 (41%)
	Below Normal	33 (49%)	18 (22%)
	Dry	58 (67%)	32 (29%)
	Critical	49 (62%)	23 (22%)
	All	207 (45%)	130 (24%)
August	Wet	43 (24%)	46 (26%)
	Above Normal	30 (67%)	22 (42%)
	Below Normal	36 (51%)	18 (20%)
	Dry	71 (104%)	28 (25%)
	Critical	20 (24%)	-6 (-5%)
	All	199 (45%)	107 (20%)
September	Wet	-14 (-36%)	19 (317%)
	Above Normal	3 (19%)	18 (1800%)
	Below Normal	20 (71%)	7 (17%)
	Dry	9 (32%)	-2 (-5%)
	Critical	20 (100%)	2 (5%)
	All	37 (28%)	43 (34%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

San Joaquin River

Flows under H4_ELT in the San Joaquin River during the March through June period would be very similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

No water temperature modeling was in the San Joaquin River.

NEPA Effects: Collectively, these modeling results indicate that there would not be adverse effects on green sturgeon spawning and egg incubation habitat because the amount of suitable habitat would not be substantially reduced. Flow and temperature conditions would generally be similar between Alternative 4A and the NEPA baseline in the Sacramento River and San Joaquin River and would be beneficial under Alternative 4A relative the NEPA baseline in the Feather River. Temperature conditions would be slightly improved under H4 relative to H3.

CEQA Conclusion: Collectively, the results of the Impact AQUA-130 CEQA analysis show that the difference between the CEQA baseline and Alternative 4A could be significant because, when compared to the CEQA baseline, the alternative would substantially reduce the quantity and quality of spawning and egg incubation habitat for green sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, the comparison to the NAA is a better approach because it isolates the effects of the alternative from those of sea level rise, climate change, and future water demand. Based on this identification of the actual increment of change attributable to the alternative, Alternative 4A would not affect the quantity and quality of spawning and egg incubation habitat for green sturgeon relative to the CEQA baseline.

H3_ELT /ESO_ELT

Sacramento River

Mean flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3_ELT would generally be similar to those under Existing Conditions at both locations, with minor exceptions. These results indicate that there would be no effect on flows in the Sacramento River under H3_ELT relative to Existing Conditions.

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period.

There would be 3 more years with a “red” NMFS level of concern in the Sacramento River at Bend Bridge under H3_ELT than under Existing Conditions (Table 11-4A-99).

Total degree-days exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under H3_ELT (for all water years combined) would be up to 1,613% higher than under Existing Conditions during the May through September period (Table 11-4A-100). The very high increase between Existing Conditions and H3_ELT on the relative scale (1,613%) is a mathematical artifact resulting from the small value of the divisor (i.e., degree-days for Existing Conditions). On an absolute scale, the increase of 129 degree days constitutes an increase of only 0.3 degrees on each day over the 82-year period, which is a small change.

Feather River

Flows were examined in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June green sturgeon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). At Thermalito, mean flows under H3_ELT would generally be similar to or up to 48% lower than those under Existing Conditions during February and March, and would generally be similar to or up to 140% greater than those under Existing Conditions during April through June. At the confluence with the Sacramento River, flows under H3_ELT would generally be similar to those under Existing Conditions in all months and water year types of the period, except June, in which flows under H3_ELT would be up to 28% higher. These results indicate that there would generally be lower flows in the Feather River under H3_ELT relative to Existing Conditions early in the spawning and egg incubation period and greater flows later in the period.

Mean water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between H3_ELT and Existing Conditions for any other month or water year type during the period.

Water temperature-related effects of H3_ELT on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures exceed a 64°F temperature threshold at Gridley (Table 11-4A-101). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. The percent of months exceeding the threshold during May and June under H3_ELT would be similar to or up to 25% greater (absolute difference) than that under Existing Conditions, representing a small to moderate negative effect of H3_ELT, although this comparison includes the effect of climate change.

Water temperature-related effects of H3_ELT on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-4A-102). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. Combining water years, total degree-months exceeding the threshold during May and June under H3_ELT would be 5% to 98% greater relative to Existing Conditions. Within months, total degree-months under H3_ELT would be similar or up to 183% higher than that under Existing Conditions depending on water year type. These results indicate that there would be a moderate negative effect of H3_ELT on green sturgeon spawning and egg incubation temperature-related conditions in the Feather River, although this comparison includes the effect of climate change.

San Joaquin River

Mean flows in the San Joaquin River under H3_ELT would generally be up to 16% lower than those under Existing Conditions throughout the March through June spawning and egg incubation period for green sturgeon except during May, in which there would be no differences in flows between H3_ELT and Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

No water temperatures modeling was conducted in the San Joaquin River.

H4_ELT /HOS_ELT

Sacramento River

Mean flows under H4_ELT in the Sacramento River at Keswick and upstream of Red Bluff during the March through July spawning and egg incubation period for green sturgeon would generally be similar to flows under Existing Conditions for all months and water year types in the period. (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period.

There would be 2 more years with a "red" NMFS level of concern in the Sacramento River at Bend Bridge under H4_ELT than under Existing Conditions (Table 11-4A-103).

Total degree-days exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under H4_ELT would be up to 863% higher than under Existing Conditions during the May through September period (Table 11-4A-104). On an absolute scale this increase is 69 degree days, which constitutes a small change relative to the 82-year period of record used for the analysis.

Feather River

Mean flows under H4_ELT in the Feather River at Thermalito Afterbay during the February through June period would generally be similar to or up to 19% lower than flows under Existing Conditions in February. (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). However, flows under H4_ELT during April through June would be up to 509% greater than flows under Existing Conditions. Flows would be variable during March, but generally similar between Existing Conditions and H4_ELT. Mean flows under H4_ELT at the confluence with the Sacramento River would generally be similar to or up to 112% greater than those under Existing Conditions.

Mean water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in any month or water year type during the period.

The percent of months exceeding the 64°F NMFS threshold during May and June under H4_ELT would be similar to or up to 14% greater than (absolute difference) that under Existing Conditions, representing a small negative effect of H4_ELT (Table 11-4A-105). This analysis includes climate change.

Combining water years, total degree-months exceeding the threshold during May and June under H4_ELT would be 29% to 50% greater relative to Existing Conditions. Within months, total degree-months under H4_ELT would be 55% lower to 121% higher than that under Existing Conditions depending on water year type (Table 11-4A-106). These results indicate that there would be a moderate to large negative effect of H4_ELT on green sturgeon spawning and egg incubation temperature-related conditions in the Feather River. This analysis includes the effect of climate change.

San Joaquin River

Flows in the San Joaquin River under H4_ELT would be similar to or up to 16% lower than those under Existing Conditions throughout the March through June spawning and egg incubation period for green sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

No water temperature modeling was in the San Joaquin River.

Summary of CEQA Conclusion

Under Alternative 4A, flows would generally not differ in the Sacramento River. However, flows would be lower under Alternative 4A in the Feather and San Joaquin rivers and water temperature conditions would be degraded in all rivers examined relative to Existing Conditions. Results would generally be consistent between H3 and H4. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of green sturgeon as a result of elevated exceedances above temperature thresholds.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flow and water temperature conditions under Alternative 4A would be similar to or better than those under NAA_ELT. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

In general, Alternative 4A would not affect the quantity and quality of green sturgeon larval and juvenile rearing habitat relative to the NAA_ELT.

Water temperature was used to determine the potential effects of alternatives on green sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

H3_ELT/ESO_ELT

Sacramento River

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Feather River

Mean water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Water temperature-related effects of H3_ELT on green sturgeon rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures exceed a 64°F temperature threshold at Gridley (Table 11-4A-101). The percent of months exceeding the threshold under H3_ELT would be similar to or up to 26% lower (absolute difference) than that under NAA_ELT during May and June, similar to that under NAA_ELT during July and August, and similar to or up to 10% greater than that under NAA_ELT during September.

Water temperature-related effects of H3_ELT on green sturgeon rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-4A-102). Combining water years, total degree-months exceeding the threshold under H3_ELT would be 6% to 23% lower relative to NAA_ELT during May and June and 7% to 112% higher during July through September. These results indicate that there would be both beneficial and negative temperature-related effects to green sturgeon rearing in the Feather River. However, the largest change in degree-months (62 degree-months during July) would equate to an increase of less than 0.8 degrees per month. Given the highly variable nature of the Feather River outside of the low-flow channel, this change is not expected to be biologically meaningful. In fact, it is not unexpected that this amount of change would occur daily on a diel cycle.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River, however flows in all months and water year types, based on CALSIM II, were the same or very similar between NAA_ELT and H3_ELT and H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), and therefore no temperature effects would occur as a result of Alternative 4A.

H4_ELT/HOS_ELT

Sacramento River

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Feather River

Mean water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

The percent of months exceeding the 64°F NMFS threshold under H4_ELT would be similar to or up to 28% lower (absolute difference) than that under NAA_ELT during May and June, and similar or up to 14% greater than that under NAA_ELT during July through September. (Table 11-4A-105).

Combining water years, total degree-months exceeding the 64°F NMFS threshold under H4_ELT would be 5% to 29% lower relative to NAA_ELT during May and June and 20% to 34% higher (relative scale) during July through September (Table 11-4A-106). These results indicate that there would be both beneficial and negative temperature-related effects of H4_ELT on green sturgeon rearing in the Feather River. However, the largest change in degree-months (130 degree-months during July) would equate to an increase of less than 1.6 degrees per month. Given the highly variable nature of the Feather River outside of the low-flow channel, this change is not expected to be biologically meaningful. In fact, it is not unexpected that this amount of change would occur daily on a diel cycle.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River, however flows in all months and water year types, based on CALSIM II, were the same or very similar between NAA_ELT and H3_ELT and H4_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), and therefore no temperature effects would occur as a result of Alternative 4A.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because it does not have the potential to substantially reduce the amount of suitable habitat. Water temperatures in the Sacramento and Feather rivers and exceedances of NMFS temperature thresholds in the Feather River under Alternative 4A would be similar to those under NAA_ELT. Although degree-months would be higher on a relative scale under Alternative 4A during some months, these changes would not be biologically meaningful when considering the high variation in water temperatures relative to these increases. These modeling results would generally be consistent among scenarios.

CEQA Conclusion: In general, Alternative 4A would reduce the quantity and quality of rearing habitat for larval and juvenile green sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA comparison, Alternative 4A would not affect the quantity and quality of rearing habitat for larval and juvenile green sturgeon relative to Existing Conditions.

Water temperature was used to determine the potential effects of Alternative 4A on green sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

H3_ELT /ESO_ELT

Sacramento River

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water*

Quality Model and Reclamation Temperature Model Results Utilized in the Fish Analysis). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT for any month or water year type of the period, except a 6% higher mean temperature for August of critical water years.

Feather River

Mean water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period, except during July of critical water years (7% higher under H3_ELT) and August of dry years (6% higher under H3_ELT).

Water temperature-related effects of H3_ELT on green sturgeon rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures would exceed a 64°F temperature threshold at Gridley (Table 11-4A-101). The percent of months exceeding the threshold under H3_ELT would generally be greater by up to 25% (absolute difference) than the percent under Existing Conditions during all months, except in September for the >1.0°F and >2.0°F exceedance categories, in both of which exceedances would be 9 percent lower under H3_ELT. These modeling results include the effects of climate change.

Water temperature-related effects of H3_ELT on green sturgeon rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-4A-102). Combining water years, total degree-months exceeding the threshold under H3_ELT would be 5% to 98% higher in all months. These results indicate that there would be negative temperature-related effects of H3_ELT on green sturgeon rearing in the Feather River. These modeling results include the effects of climate change.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

H4_ELT /HOS_ELT

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4_ELT during May through July and 5% lower during August and October.

Feather River

Mean water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period, except for 6% lower means under H4_ELT during July of critical water years and August of dry years.

The percent of months exceeding the 64°F NMFS threshold under H4_ELT would generally be greater by up to 33% than the percent under Existing Conditions during all months and water year types, except in September for the >1.0°F and >2.0°F exceedance categories, in which exceedances would be 7 and 6 percent lower, respectively, under H3_ELT (Table 11-4A-105). These modeling results include the effects of climate change.

Combining water years, total degree-months exceeding the 64°F NMFS threshold under H4_ELT would be 28% to 50% higher in all months (Table 11-4A-106). These results indicate that there would be negative temperature-related effects of H4 on green sturgeon rearing in the Feather River. These modeling results include the effects of climate change.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Summary of CEQA Conclusion

Under Alternative 4A, water temperatures would be similar in the Sacramento River, although the exceedance above NMFS temperature thresholds in the Feather River would be higher under Alternative 4A than those under the CEQA baseline, which could increase stress, mortality, and susceptibility to disease for larval and juvenile green sturgeon. These modeling results are consistent among scenarios. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce rearing habitat and substantially reduce the number of green sturgeon as a result of fry and juvenile mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 4A on water temperatures would be negligible and exceedances above thresholds would be similar between NAA_ELT and Alternative 4A. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact would be less than significant and no mitigation is required.

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

In general, effects of Alternative 4A on green sturgeon migration conditions relative to the NAA are not adverse.

Upstream of the Delta

H3_ELT/ESO_ELT

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick and Wilkins Slough and in the Feather River between Thermalito and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through June adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River mean flows at Keswick under H3_ELT would generally be up to 23% lower than flows under NAA_ELT during November, and similar to flows under NAA_ELT in the remaining months, with minor exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Sacramento River flows at Wilkins Slough under H3_ELT would generally be up to 20% lower than flows under NAA_ELT during September and November, up to 12% greater during May and June, and similar to flows under NAA_ELT in the remaining eight months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Differences between H3_ELT and NAA_ELT in Feather River mean flows at Thermalito would vary a great deal with month and water year type. In general, mean flows under H3_ELT would be up to 48% lower than flows under NAA_ELT during July through September, although flows in critical water years during August and September would be 23% and 25% higher (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The mean flows would generally be up to 106% greater during May and June, and similar to flows under NAA_ELT in the remaining seven months, with a number of exceptions.

Feather River flows at the confluence with the Sacramento River under H3_ELT would generally be up to 50% lower (critical water years) than flows under NAA_ELT during July through September, although flows in critical water years during August and September would be 21% and 14% higher (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The mean flows would generally be greater under H3_ELT during June (up to 77% greater) and similar to flows under NAA_ELT in the remaining eight months, with minor exceptions.

Given the benthic nature of green sturgeon and that flows in the Feather River would be consistent with the flow schedule provided by NMFS during the project planning process that is meant to better mimic the natural flow regime while providing adequate storage to meet downstream temperature and water quality requirements, the reductions in summer flows at both locations in the Feather River are not expected to have a substantial effect on green sturgeon.

Larval transport flows were also examined by utilizing the positive correlation between white sturgeon year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved green sturgeon larval transport that results in improved year class strength. However, there is high uncertainty about what the mechanism responsible for this relationship is because many flow variables correlate throughout the Central Valley. One hypothesis suggests that the correlation is caused by high flows in the upper river resulting in improved migration, spawning, and rearing conditions in the upper river. Another hypothesis suggests that the positive correlation is a result of higher flows through the Delta triggering more adult sturgeon to move up into the river to spawn. In addition, this correlation was developed using data collected in the absence of north Delta intakes. Also, there are temporal and spatial differences between green and white sturgeon larval presence that make using white sturgeon as a surrogate in this analysis highly uncertain and potentially not applicable (Murphy et al. 2011). In particular, unlike white sturgeon, during April and May, green sturgeon adults would be spawning and larvae would be rearing in the upper Sacramento River and Feather River. This mismatch in timing and location limits the confidence in using this as a surrogate for green sturgeon and suggests that year-class strength correlated with flow at another location upstream or during a different period, if at all.

Regardless, for lack of a known relationship for green sturgeon year-class strength, the results using white sturgeon as a surrogate for green sturgeon were examined here. Results for white sturgeon presented in Impact AQUA-150 below suggest that, using the positive correlation between Delta outflow and year class strength, green sturgeon year class strength would be lower under H3_ELT than those under NAA_ELT (up to 50% lower). Given the increased spring outflow in April and May under H4, it is expected that year-class strength would be similar or greater to NAA_ELT under H4_ELT.

H4_ELT /HOS_ELT

Year-round flows in the Sacramento River at Keswick under H4_ELT would be up to 20% lower than flows under NAA_ELT during November, and generally similar to flows under NAA_ELT in the remaining months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows at Wilkins Slough under H4_ELT would generally be similar to those under NAA_ELT except during August, September, and November, when flows would be up to 20% lower under H4_ELT.

Differences between H4_ELT and NAA_ELT in Feather River mean flows at Thermalito would vary a great deal with month and water year type. In general, mean flows under H4_ELT would be up to 60% lower than flows under NAA_ELT during July through September, although flows in critical water years during August and September would be 48% and 52% higher (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The mean flows under H4_ELT would generally be up to 548% greater flows under NAA_ELT during April through June, and similar in the remaining six months, with a number of exceptions.

Feather River flows at the confluence with the Sacramento River under H3_ELT would generally be up to 42% lower than flows under NAA_ELT during July through September, although flows in critical water years during August and September would be 42% and 34% higher (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The mean flows would generally be greater under H4_ELT during April through June (up to 119% greater) and similar to flows under NAA_ELT in the remaining six months, with minor exceptions.

Given the benthic nature of green sturgeon and that flows in the Feather River would be consistent with the flow schedule provided by NMFS during the Alternative 4a planning process that is meant to better mimic the natural flow regime while providing adequate storage to meet downstream temperature and water quality requirements, the reductions in summer flows at both locations in the Feather River are not expected to have a substantial effect on green sturgeon.

Through-Delta

As described for other species (e.g., Sacramento splittail in Impact AQUA-114), migration conditions in the southern Delta generally would be considerably improved relative to NAA_ELT, because of reduced frequency of reverse OMR flows. The range of Alternative 4A operations (i.e., H3_ELT and H4_ELT) includes a range of Delta outflows, as discussed below. The effect on green sturgeon would not be adverse.

NEPA Effects: Upstream flows (above north Delta intakes) are generally similar between Alternative 4A and NAA_ELT. However, due to the removal of water at the North Delta intakes, there are substantial differences in through-Delta flows between Alternative 4A and NAA_ELT. An examination of monthly average Delta outflow exceedances above 15,000 cfs, 20,000 cfs, and 25,000 cfs during April and May of wet and above-normal years was used to provide context for differences in through-Delta migration conditions, per recommendations by the Anadromous Fish Restoration Program (USFWS 1995) (see Table 11-4A-114 in the discussion of white sturgeon below). This showed that the percentage of months exceeding the above Delta outflow thresholds in April and May of wet and above normal years was appreciably lower than NAA_ELT for Alternative 4A's H3_ELT scenario, but was similar or considerably greater than NAA_ELT for Alternative 4A's H4_ELT scenario. As noted for Alternative 4, analysis of white sturgeon year-class strength (USFWS 1995), used here as a surrogate for green sturgeon, found a positive correlation between year class strength and Delta outflow during April and May. However, this conclusion was reached in the absence of north Delta intakes and the exact mechanism that causes this correlation is not known at this time. One hypothesis suggests that the correlation is caused by high flows in the upper river resulting in improved migration, spawning, and rearing conditions in the upper river. Another hypothesis suggests that the positive correlation is a result of higher flows through the Delta triggering more adult sturgeon to move up into the river to spawn. It is also possible that some combination of these factors are working together to produce the positive correlation between high flows and sturgeon year-class strength.

The scientific uncertainty regarding which mechanisms are responsible for the positive correlation between year class strength and river/Delta flow will be addressed through targeted research and monitoring to be conducted in the years leading up to the initiation of north Delta facilities operations as described in the adaptive management and monitoring section in Section 4.1. These investigations will inform decisions regarding Delta outflow within the range of H3_ELT/H4_ELT operations such that the effect on green sturgeon Delta flow conditions would not be adverse. This, combined with similarities in upstream flow conditions between Alternative 4A and NAA_ELT, indicate that Alternative 4A would not be adverse to migration conditions for green sturgeon.

CEQA Conclusion: In general, Alternative 4A would reduce the quantity and quality of migration habitat for green sturgeon in upstream locations relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA comparison, Alternative 4A would not affect the quantity and quality of migration habitat for green sturgeon.

Upstream of the Delta

H3_ELT/ESO_ELT

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick and Wilkins Slough and in the Feather River between Thermalito and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through July adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River flows at Keswick under H3_ELT would generally be up to 24% lower than flows under Existing Conditions during August, September, and November of dry and critical water years and up to 34% higher during September of wet and above normal water years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). In the other months and water year types, the mean flows would generally be similar between H3_ELT and Existing Conditions, with several exceptions. Mean flows at Wilkins Slough under H3_ELT would generally be up to 24% lower than flows under Existing Conditions during August, September, and November of dry and critical water years and up to 33% higher during September of wet and above normal water years. Mean flow in June would be up to 18% higher under H3_ELT, and flows would be similar in other months and water year types.

For Delta outflow, the percent of months exceeding outflow thresholds under H3_ELT would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (4% to 50% lower on a relative scale) (see Table 11-4A-114 below).

Feather River flows at Thermalito Afterbay under H3_ELT would generally be up to 52% lower than flows under Existing Conditions during January, February, and July, higher than flows under Existing Conditions during April through June and September, and similar to flows under Existing Conditions during the remaining months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flow under H3_ELT at the confluence with the Sacramento River would generally be up to 140% greater than flows under Existing Conditions during February, June, and September, up to 55% lower than flows under Existing Conditions during July, and similar to flows under Existing Conditions during the remaining months.

H4_ELT /HOS_ELT

Year-round flows were examined in the Sacramento River at Keswick and Wilkins Slough. Flows at Keswick under H4_ELT would generally be similar to flows under Existing Conditions, except during September and November, in which mean flows would be up to 20% lower, and during February, in which flows would be up to 12% higher. Flows at Wilkins Slough would generally be similar to flows under Existing Conditions except during September and October, in which flows would be up to 21% lower, and during July, in which flows would be up to 8% greater. (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Year-round flows in the Feather River below Thermalito Afterbay (high-flow channel) and at the confluence under H4_ELT would generally be similar to or up to 36% lower than flows under Existing Conditions during January through March, and up to 55% lower during July through

September, although flow would be up to 55% higher during critical water years in August and September, (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). During April through June, mean flow under H4_ELT would be up to 509% greater than flow under Existing Conditions. During September, mean flow under H4_ELT would be up to 49% lower in below normal and dry water years and up to 166% higher in wet, above normal, and critical water years. Reductions in flows in the Feather River would be persistent and large enough to have biologically meaningful effects to green sturgeon migration.

Through-Delta

Given the improved OMR flows and the range of Delta outflows under Alternative 4A's H3_ELT and H4_ELT that would be refined through the Adaptive Management Program to avoid negative impacts to green sturgeon (see NEPA Effects discussion above), the potential impact of Alternative 4A on in-Delta conditions for green sturgeon is considered less than significant, and no mitigation would be required.

Summary of CEQA Conclusion

Under Alternative 4A, there would be frequent small to large reductions in flows in the Sacramento and Feather Rivers upstream of the Delta that would reduce the ability of all three life stages of green sturgeon to migrate successfully. Exceedance of Delta outflow thresholds would be lower under Alternative 4A's H3_ELT scenario than under Existing Conditions, but would be similar or greater than under Existing Conditions for the H4_ELT scenario. Note that there is high uncertainty that year class strength is due to Delta outflow or if both year class strength and Delta outflows co-vary with another unknown factor. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce upstream migration conditions for green sturgeon.

However, this interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA_ELT, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be negligible effects on green sturgeon migration conditions in upstream areas. Within the Plan Area, the Adaptive Management Program will evaluate water operations through the adaptive management and monitoring program as described in Section 4.1 and ensure the impacts of water operations on migration conditions for green sturgeon are less than significant. Therefore, this impact is found to be less than significant and no mitigation is required.

Restoration Measures (Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

As described for other covered fishes, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A. The mechanisms of impacts of habitat restoration discussed for winter-run Chinook salmon generally would be similar for green sturgeon. Because green sturgeon may inhabit the Delta year-round, they would be more likely to encounter any effects from restoration measures. However, because the extent of restoration is limited to offsetting losses from construction of the water conveyance facilities, any such effects would be greatly limited compared to Alternative 1A and 4, for example.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

As noted for Alternative 1A's discussion of Impact AQUA-133, in-water and shoreline construction activities (e.g., riprap removal and levee breaching; shoreline excavation and recontouring) could increase turbidity, but green sturgeon are tolerant to such increases and implementation of the environmental commitments described under Impact AQUA-1 for delta smelt and in Appendix 3B, Environmental Commitments (Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; and Disposal of Spoils, Reusable Tunnel Material, and Dredged Material), would minimize or eliminate effects on green sturgeon.

***NEPA Effects*:** The effects of short-term construction activities would not be adverse to green sturgeon because environmental commitments would limit the potential for construction-related effects.

***CEQA Conclusion*:** As discussed for Alternative 1A, habitat restoration activities could result in short-term effects on green sturgeon but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce green sturgeon habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

The factors influencing the potential effects of contaminants from restored areas on green sturgeon are discussed in the analysis of Impact AQUA-134 under Alternative 1A. Because the extent of habitat restoration under Alternative 4A is considerably reduced relative to Alternative 1A, any effects from contaminants also would be considerably reduced.

NEPA Effects: While Alternative 4A habitat restoration actions may result in a very small increase production, mobilization, and bioavailability of methylmercury, selenium, copper, and pesticides in the aquatic system, any such releases would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation of these contaminants in green sturgeon. Alternative 4A would restore 59 acres of tidal wetlands that, depending on the specific site conditions of the restoration, may result in the colonization of benthic grazers that bioaccumulate selenium. As sturgeon are benthic feeders, the increased habitat for grazers may result in increased exposure to selenium. However, the small amount of area to be restored would not result in a substantial change in exposure potential. Overall, the effects of contaminants associated with restoration measures would not be adverse for green sturgeon.

CEQA Conclusion: Habitat restoration under Alternative 4A may result in increased production, mobilization, and bioavailability of contaminants in the aquatic system, but these would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation in green sturgeon. For methylmercury, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury in the limited restoration areas. Therefore, the impact of contaminants is considered less than significant because it would not substantially affect green sturgeon either directly or through habitat modifications. Consequently, no mitigation would be required.

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

Restored habitat under *Environmental Commitment 4 Tidal Natural Communities Restoration* and *Environmental Commitment 6 Channel Margin Enhancement* is intended to offset habitat loss/modification caused by construction and operation of the water facilities proposed under Alternative 4A.

NEPA Effects: The effects of restored habitat conditions on green sturgeon would not be adverse because restoration is intended to provide habitat benefits for green sturgeon.

CEQA Conclusion: As described above, habitat restoration would be undertaken to offset loss/modification of habitat from water facility construction and operation. The effects of restored habitat conditions on green sturgeon would be less than significant. Consequently, no mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

As noted for other covered species, Alternative 4A includes three other Environmental Commitments, which are reduced in their extent relative to the Conservation Measures included in other Alternatives (e.g., Alternative 1A and Alternative 4A). While the extent of these measures is reduced compared to these alternatives, the nature of the mechanisms for green sturgeon remains the same.

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (Environmental Commitment 12)

The impact discussion for winter-run Chinook salmon (Impact AQUA-46) is also applicable to green sturgeon.

NEPA Effects: The effects of methylmercury management on green sturgeon would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As noted for winter-run Chinook salmon, effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts on green sturgeon would be less than significant. Consequently, no mitigation is required.

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (Environmental Commitment 15)

Alternative 4A includes a predator removal program similar to Conservation Measure 15 included in Alternative 1A, although the environmental commitment under Alternative 4A is reduced in scope to focus solely on the north and south Delta export locations, whereas Alternative 1A would include predator removal at these and other potential hotspots. As described under Alternative 1A, it is possible, but not assured, that there would be some reduction in predation losses of green sturgeon under *Environmental Commitment 15 Localized Reduction of Predatory Fish*. As described for Alternative 1A, there is uncertainty in the potential efficacy of Environmental Commitment 15 and also uncertainty in the importance of predation to juvenile green sturgeon, given the likely limited period of vulnerability to predation in the Delta. Due to these uncertainties, there would be no demonstrable effect of this conservation measure on green sturgeon. As noted for Alternative 1A, there is a very small risk of sturgeon by-catch during implementation of Environmental Commitment 15, but the number of green sturgeon affected is expected to be very low.

NEPA Effects: Consistent with the analysis for Alternative 1A and reflecting the above discussion, the overall effect would not be adverse because few, if any, sturgeon would be affected.

CEQA Conclusion: Consistent with the analysis for Alternative 1A and reflecting the above discussion, the impact is considered less than significant. Consequently, no mitigation would be required.

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (Environmental Commitment 16)

As described for winter-run Chinook salmon, under Alternative 4A, an NPB at the divergence of Georgiana Slough from the Sacramento River would be implemented to guide juvenile salmonids away from Georgiana Slough and the interior Delta, wherein survival is relatively low compared to the Sacramento River (Perry et al. 2010). As described in the *BDCP Effects Analysis*, the effects of an NPB at this location would be expected to have little to no effect on green sturgeon because of their position in the water column (near the river bottom, whereas an NPB at this location would be likely to function in the upper half of the water column; DWR 2012) and their physiology (limited hearing ability in the range employed by the NPB's acoustic deterrence stimuli; see section 5C.5.3.9 in *BDCP Effects Analysis Appendix 5.C* and section 5.B.6.1.11.1 *BDCP Effects Analysis Appendix 5.B, both hereby incorporated by reference*).

NEPA Effects: Consistent with the analysis for Alternative 1A and reflecting the above discussion, the overall effect would not be adverse because green sturgeon are unlikely to encounter the NPB, which would not be located near the channel bottom and because green sturgeon have limited hearing within the range of acoustic sound generated by the NPB.

CEQA Conclusion: Consistent with the analysis for Alternative 1A and reflecting the above discussion, the impact is considered less than significant. Consequently, no mitigation would be required.

White Sturgeon

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

The potential effects of construction of the water conveyance facilities on white sturgeon would be the same as those described for Alternative 4, Impact AQUA-145. This section provides additional detail on underwater noise impacts which are also applicable to Impact AQUA-145 in Alternative 4.

Table 11-8 presents the life stages of white sturgeon and months of their potential presence in the north, east, and south Delta during the proposed in-water construction window (June 1–October 31). Under Alternative 4A, white sturgeon adults and juveniles occur year-round in the Delta and therefore could be exposed to pile driving noise during construction of the proposed intakes, barge unloading facilities, CCF cofferdams, CCF siphons, and Head of Old River operable barrier. Larvae may also be exposed to pile driving noise but are generally at lower risk than juveniles and adults because of only minor spatial and temporal overlap with in-water pile driving activities. Because the majority of the population spawns in the Sacramento River, adults, larvae, and juveniles are most likely to encounter pile driving noise at the proposed intake locations in the north Delta as they migrate or disperse to and from upstream spawning areas. Similar to green sturgeon, adult white sturgeon are large (>15 kilograms) and less susceptible to noise from impact driving, and are able to avoid injurious exposure to underwater noise from pile driving. They may experience short delays in migration upon encountering pile driving noise; however, pile driving would occur only intermittently through a portion of the day, and minor migration delays are not expected to affect their ability to successfully reach the spawning grounds.

Because of their relatively small body size, larvae and juvenile white sturgeon are at higher risk of injury or mortality from pile driving noise. Juveniles are most likely to encounter pile driving noise because of their widespread distribution and year-round presence in the Delta. Although juvenile white sturgeon are capable of actively avoiding pile driving noise and other in-water disturbances, some may be injured or killed if they remain in the areas subject to cumulative SELs exceeding the injury thresholds (Table 4.3.7-1 under Delta smelt). In the absence of information on the movements and distribution of juveniles, potential impacts to the population can be generally assessed based on the proportion of total habitat subject to pile driving sounds. Under existing conditions, the Delta comprises an estimated 84,280 acres of subtidal aquatic habitat. Using this estimate as a measure of the total amount of potential foraging and rearing habitat available to juveniles, Table 4.3.7-2 shows the percentage of habitat that would be subjected to pile driving noise exceeding the injury thresholds during each year of pile driving activities.

These estimates represent a general order-of-magnitude estimate of the potential exposure of the population to pile driving noise. Thus, potential for exposure of the population to project pile driving noise is very low in most years. The exception is year 5 when an estimated 3,436 acres or 4.1% of the total amount of subtidal habitat would be subject to pile driving noise levels that could harm juvenile sturgeon. This potential impact is due largely to the construction of six barge unloading facilities at various locations along the pipeline/tunnel alignment. Factors that may further limit exposure of the population to adverse effects include the short duration of pile driving activities at most locations (Table 4.3.7-1 under Delta Smelt). In addition, the total area of habitat available to juvenile white sturgeon expands beyond the Delta into Suisun and San Pablo Bays as juveniles grow and develop salinity tolerance, further reducing the probability of encountering pile driving noise.

Based on these considerations and the implementation of Mitigation Measures AQUA-1a and AQUA-1b, there is a low likelihood of significant population-level effects on white sturgeon due to pile driving noise.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-145, the effect would not be adverse for white sturgeon. Implementation of the measures described in Appendix 3B, *Environmental Commitments*, such as *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan* would guide rapid and effective response in the case of inadvertent spills of hazardous materials. Construction will result in both temporary and permanent alteration of rearing and migratory habitats used by white sturgeon. However, Alternative 4A includes Environmental Commitment 4 to restore tidal habitat. The direct effects of underwater construction noise on white sturgeon that may be present could be adverse if sturgeon are exposed. However, considering the ability of white sturgeon to move away from the noise and migrate during the night or other times that pile driving is not occurring, the relatively few white sturgeon in the area of pile driving, and the implementation of Mitigation Measures AQUA-1a and AQUA-1b,that would minimize exposure, this effect would not be adverse.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-145, the impact of the construction of the water conveyance facilities on white sturgeon would not be significant except for construction noise associated with pile driving. Construction of Alternative 4A involves several elements with the potential to affect white sturgeon. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4A would be the same as those described for Alternative 4, Impact AQUA-146. As concluded in Alternative 4, Impact AQUA-146, the impact would not be adverse for white sturgeon.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-146, the impact of the maintenance of water conveyance facilities on white sturgeon would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Water Exports

The potential effects of the water operations under Alternative 4A would be the same as those described for green sturgeon (see Impact AQUA-129), which is a reduction in entrainment at the south Delta facilities, and avoidance or reduction of entrainment at the proposed north Delta diversion facilities. As concluded in Impact AQUA-129, the impact of Alternative 4A on white sturgeon would not be adverse.

Predation Associated with Entrainment

The potential effects would be the same as described for green sturgeon in Alternative 4A (see Impact AQUA-129).

NEPA Effects: In conclusion, the effect of Alternative 4A operations on entrainment and associated predation of white sturgeon would not be adverse and may provide modest benefit due to reduced losses at the south Delta facilities.

CEQA Conclusion: As described above for green sturgeon (Impact AQUA-129) the impact of water operations on white sturgeon would be less than significant and no mitigation would be required.

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

In general, Alternative 4A would not affect spawning and egg incubation habitat for white sturgeon relative to the NAA_ELT. Alternative 4A would provide flow-related benefits to white sturgeon spawning in the Feather River.

H3_ELT/ESO_ELT

Sacramento River

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon. Mean flows under H3_ELT would generally be similar to those under NAA_ELT throughout the spawning and egg incubation period at both locations (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

The number of days at Hamilton City on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-4A-13). The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H3_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-107. For the 61°F threshold, there would be 5 fewer (14% fewer) "red" years under H3_ELT than under NAA_ELT. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between NAA_ELT and H3_ELT.

Table 11-4A-107. Differences between Baselines and H3_ELT in the Number of Years in Which Water Temperature Exceedances above the 61°F and 68°F Thresholds Are Within Each Level of Concern, Sacramento River at Hamilton City, March through June

Level of Concern	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
61°F threshold		
Red	23 (288%)	-5 (-14%)
Orange	4 (27%)	-2 (-10%)
Yellow	-12 (-39%)	2 (12%)
None	-15 (-54%)	5 (63%)
68°F threshold		
Red	0 (NA)	0 (NA)
Orange	0 (NA)	0 (NA)
Yellow	1 (NA)	-1 (-100%)
None	-1 (-1%)	1 (1%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4A-108, Table 11-4A-109). Total degree-days exceeding the 61°F threshold under H3_ELT would be 2 degree-day (67%) greater than those under NAA_ELT during March, which would not be biologically meaningful. During April through June, total degree days above 61°F would be 2 to 373 (1% to 11%) lower under H3_ELT than under NAA_ELT. These totals would not be biologically meaningful to white sturgeon considering that the daily reduction in temperature would be <0.2 degrees (2542 and 2460 total days during May and June, respectively over the 82-year modeling period. Total degree-days exceeding the 68°F threshold would be similar between NAA_ELT and H3_ELT, except during May, in which exceedances would be 10 degree-days (33%) fewer under H3_ELT.

Table 11-4A-108. Differences between Baseline and H3_ELT Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 61°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	2 (NA)	2 (NA)
	Dry	3 (NA)	0 (0%)
	Critical	0 (NA)	0 (NA)
	All	5 (NA)	2 (67%)
April	Wet	18 (150%)	0 (0%)
	Above Normal	15 (150%)	0 (0%)
	Below Normal	16 (267%)	-4 (-15%)
	Dry	47 (92%)	4 (4%)
	Critical	2 (200%)	-2 (-40%)
	All	98 (123%)	-2 (-1%)
May	Wet	478 (144%)	-1 (0%)
	Above Normal	123 (56%)	-113 (-25%)
	Below Normal	227 (123%)	-42 (-9%)
	Dry	209 (103%)	-105 (-20%)
	Critical	219 (108%)	-7 (-2%)
	All	1,256 (110%)	-268 (-10%)
June	Wet	425 (74%)	-65 (-6%)
	Above Normal	151 (50%)	-56 (-11%)
	Below Normal	177 (84%)	-70 (-15%)
	Dry	203 (61%)	-127 (-19%)
	Critical	181 (48%)	-55 (-9%)
	All	1,137 (63%)	-373 (-11%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Table 11-4A-109. Differences between Baseline and H3_ELT Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 68°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Mar	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Apr	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
May	Wet	9 (129%)	0 (0%)
	Above Normal	3 (NA)	-10 (-77%)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	1 (NA)	0 (0%)
	All	13 (186%)	-10 (-33%)
Jun	Wet	2 (NA)	0 (0%)
	Above Normal	-1 (-100%)	-2 (-100%)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	1 (NA)	0 (0%)
	All	2 (200%)	-2 (-40%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

Feather River

Flows in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean flows at Thermalito Afterbay under H3_ELT would generally be similar to or greater by up to 30% greater than those under NAA_ELT, with some exceptions. Mean flows at the confluence with the Sacramento River under H3_ELT would be similar to flows under NAA_ELT, with minor exceptions.

Mean water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period. Mean water temperatures would not differ (<5%) between NAA_ELT and H3_ELT at either location throughout the period.

San Joaquin River

Flows in the San Joaquin River at Vernalis under H3_ELT during February through May would be little different from flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted for the San Joaquin River.

H4_ELT /HOS_ELT

Sacramento River

Flows under H4_ELT in the Sacramento River at Wilkins Slough and Verona during February to May would generally be similar to flows under NAA_ELT except during April and May at Verona, in which flows would be up to 36% and 25% higher, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

The number of days when temperatures exceeded the analysis criterion (i.e., 61°F optimal and 68°F lethal threshold identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period. The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H4_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-110. For the 61°F threshold, there would be 1 more (3% increase) "red" year and 3 fewer (14% reduction) "orange" years under H4_ELT than under NAA_ELT, which would not be biologically meaningful. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between NAA_ELT and H4_ELT.

Table 11-4A-110. Differences between Baselines and H4_ELT Scenario in the Number of Years in Which Water Temperature Exceedances above the 61°F and 68°F Thresholds are within Each Level of Concern, Sacramento River at Hamilton City, March through June

Level of Concern	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
61°F threshold		
Red	29 (363%)	1 (3%)
Orange	3 (20%)	-3 (-14%)
Yellow	-14 (-45%)	0 (0%)
None	-18 (-64%)	2 (25%)
68°F threshold		
Red	0 (NA)	0 (NA)
Orange	0 (NA)	0 (NA)
Yellow	1 (NA)	-1 (-50%)
None	-1 (-1%)	1 (1%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4A-111, Table 11-4A-112). Total degree-days exceeding the 61°F threshold under H4_ELT would be 2 degree-days (67%) greater than those under NAA_ELT during March and 3 degree-days (2%) greater during April, which would not be biologically meaningful. During the May and June, there would be reductions of 152 degree-days (6%) and 29 degree-days (1%) between NAA_ELT and H4_ELT in total degree-days exceeding the 61°F threshold. Total degree-days exceeding the 68°F threshold would be similar between NAA_ELT and H4_ELT for all four months.

Table 11-4A-111. Differences between Baselines and H4_ELT in Total Degree-Days (°F-days) by Month and Water Year Type for Water Temperature Exceedances above 61°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	2 (NA)	2 (NA)
	Dry	3 (NA)	0 (0%)
	Critical	0 (NA)	0 (NA)
	All	5 (NA)	2 (67%)
April	Wet	18 (150%)	0 (0%)
	Above Normal	14 (140%)	-1 (-4%)
	Below Normal	20 (333%)	0 (0%)
	Dry	49 (96%)	6 (6%)
	Critical	2 (200%)	-2 (-40%)
	All	103 (129%)	3 (2%)
May	Wet	488 (147%)	9 (1%)
	Above Normal	158 (72%)	-78 (-17%)
	Below Normal	273 (148%)	4 (1%)
	Dry	267 (132%)	-47 (-9%)
	Critical	186 (92.1%)	-40 (-9%)
	All	1,372 (120%)	-152 (-6%)
June	Wet	487 (84%)	-3 (0%)
	Above Normal	265 (87%)	58 (11%)
	Below Normal	237 (112%)	-10 (-2%)
	Dry	325 (97%)	-5 (-1%)
	Critical	167 (45%)	-69 (-11%)
	All	1,481 (82%)	-29 (-1%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Table 11-4A-112. Differences between Baselines and H4_ELT in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 68°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
April	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
May	Wet	9 (129%)	0 (0%)
	Above Normal	12 (NA)	-1 (-8%)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	1 (NA)	0 (0%)
	All	22 (314%)	-1 (-3%)
June	Wet	2 (NA)	0 (0%)
	Above Normal	4 (400%)	3 (150%)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	1 (NA)	0 (0%)
	All	7 (700%)	3 (60%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

Feather River

Mean flows under H4_ELT in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February to May would be similar to or up to 518% greater than flows under NAA_ELT at Thermalito and up to 12% greater at the confluence.

Mean water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period. Mean monthly water temperatures would not differ between NAA_ELT and H4_ELT at either location throughout the period.

San Joaquin River

Mean monthly flows in the San Joaquin River at Vernalis under H4_ELT during February through May would be similar to those under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted for the San Joaquin River.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. Flows under Alternative 4A would generally be higher in the Feather River relative to the NAA_ELT and generally similar to flows under the NAA_ELT in the Sacramento and San Joaquin Rivers. Alternative 4A would not affect temperatures in any river during the white sturgeon spawning and egg incubation period. Results would generally be similar between H3_ELT and H4_ELT.

CEQA Conclusion: Collectively, the results of the Impact AQUA-148 CEQA analysis show that the difference between the CEQA baseline and Alternative 4A could be significant because, when compared to the CEQA baseline, the alternative would substantially reduce the quantity and quality of spawning and egg incubation habitat for white sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, the comparison to the NAA_ELT is a better approach because it isolates the effects of the alternative from those of sea level rise, climate change, and future water demand. Based on this identification of the actual increment of change attributable to the alternative, Alternative 4A would not affect the quantity and quality of spawning and egg incubation habitat for white sturgeon relative to the Existing Conditions.

H3_ELT /ESO_ELT

Sacramento River

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). At Wilkins Slough, mean flows under H3_ELT would generally be similar to those under Existing Conditions. At Verona, mean flow under H3_ELT for most of the months and water year types would be slightly lower (less than 10% lower) than flows under Existing Conditions during February and April, and similar during March and May.

Mean water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period

The number of days when temperatures exceeded the analysis criterion (i.e., 61°F optimal and 68°F lethal threshold identified in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period. The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H3_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-107. For the 61°F threshold, there would be 23 more (288% increase) "red" years under H3_ELT than under Existing Conditions. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between Existing Conditions and H3_ELT.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4A-108, Table 11-4A-109). Total degree-days exceeding the 61°F threshold under H3_ELT would be 5 degree-days (percent change unable to be calculated due to division by 0) to 1,256 degree-days (110%) higher depending on month. Total degree-days exceeding the 68°F threshold would not differ between Existing Conditions and H3_ELT during March and April. During May and June, total degree-days would be 13 (186%) and 2 (200%) degree-days higher under H3_ELT, although these small absolute differences would not have a biologically meaningful effect on white sturgeon.

Feather River

Flows in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Differences in mean flows between H3_ELT and Existing Conditions at Thermalito Afterbay would vary greatly during the period. Mean flows during February and March would be up to 48% lower under H3_ELT in below normal and dry water years and would be similar or moderately higher in other water year types, while in April and May they would be up to 33% higher depending on water year type. Mean flows at the confluence with the Sacramento River under H3_ELT would generally be similar to or greater than flows under Existing Conditions, except in below normal years during February and March (14% and 15% lower, respectively). These results indicate that there would be some reductions in flows in the Feather River under H3_ELT relative to Existing Conditions.

Mean water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures would not differ (<5%) between Existing Conditions and H3_ELT at either location throughout the period.

San Joaquin River

Mean flows under H3_ELT were examined in the San Joaquin River at Vernalis during February through May. Flows under H3_ELT during March and April would be up to 12% lower than those under Existing Conditions, whereas flows under H3_ELT during February and May would be similar to those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted for the San Joaquin River.

H4_ELT/HOS_ELT

Sacramento River

Mean flows under H4_ELT in the Sacramento River at Wilkins Slough and Verona during February to May would generally be similar to or lower than flows under Existing Conditions, except during April and May at Verona, in which flows under H4_ELT would be up to 30% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water*

Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period.

The number of days when temperatures exceeded the analysis criterion (i.e., 61°F optimal and 68°F lethal threshold identifies in Table 11-4A-13) by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period. The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4A-14. Differences between baselines and H4_ELT in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4A-110. For the 61°F threshold, there would be 29 more (363% increase) "red" years under H4_ELT than under Existing Conditions. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between Existing Conditions and H4_ELT.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4A-108, Table 11-4A-109). Total degree-days exceeding the 61°F threshold under H4_ELT would be 5 degree-days (percent change unable to be calculated due to division by 0) to 1,481 degree-days (82%) higher depending on month. Total degree-days exceeding the 68°F threshold would not differ between Existing Conditions and H4_ELT during March and April. During May and June, total degree-days under H4_ELT would be 22 (314%) and 7 (700%) degree-days higher, although these small absolute differences would not have a biologically meaningful effect on white sturgeon.

Feather River

Mean flows under H4_ELT in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the February to May would generally be similar to or up to 22% lower than flows under Existing Conditions during February and March and would be up to 509% greater than flows under Existing Conditions during April and May, except for critical water years in which flows would be similar for the two scenarios. (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would not differ between Existing Conditions and H4_ELT at either location throughout the period.

San Joaquin River

Mean flows under H4_ELT in the San Joaquin River would generally be similar or up to 12% lower than flows under Existing Conditions.

Summary of CEQA Conclusion

Under Alternative 4A, there would be small to moderate, persistent reductions in flows in the Sacramento, Feather, and San Joaquin Rivers that would cause biologically meaningful effects to white sturgeon spawning and egg incubation habitat. Further, there would be increases in exceedances of NMFS temperature thresholds in the Sacramento River that would cause a biologically meaningful effect to white sturgeon spawning and egg incubation. Results would generally be consistent between H3_ELT and H4_ELT. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce the quantity and quality of suitable spawning and egg incubation habitat.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows under Alternative 4A would generally be higher in the Feather River and generally similar in the Sacramento and San Joaquin Rivers. Alternative 4A would not affect temperatures in any river during the white sturgeon spawning and egg incubation period. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

In general, Alternative 4A would not affect quantity and quality of white sturgeon larval and juvenile rearing habitat relative to the NAA_ELT.

Water temperature was used to determine the potential effects of alternatives on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

H3_ELT/ESO_ELT

Mean water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period.

Mean water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and H3_ELT in any month or water year type throughout the period

Water temperatures were not modeled in the San Joaquin River.

H4_ELT /HOS_ELT

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and H4_ELT in any month or water year type throughout the period.

Water temperatures were not modeled in the San Joaquin River.

NEPA Effects: These modeling results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. There would be no differences in water temperatures between Alternative 4A and the NAA_ELT. Results would be similar between H3_ELT and H4_ELT.

CEQA Conclusion: In general, Alternative 4A would not affect the quantity and quality of white sturgeon larval and juvenile rearing habitat relative to Existing Conditions.

Water temperature was used to determine the potential effects of alternatives on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

H3_ELT /ESO_ELT

Mean water in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H3_ELT in any month or water year type throughout the period.

Mean water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures would be similar between Existing Conditions and H3_ELT during all months and water year types except July of critical water years and August of dry years, in which the means would be 7% and 6% higher, respectively, under H3_ELT.

Water temperatures were not modeled in the San Joaquin River.

H4_ELT/HOS_ELT

Mean water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and H4_ELT in any month or water year type throughout the period.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures would be similar between Existing Conditions and H4_ELT during all months and water year types except July of dry and critical water years, in which temperatures under H4_ELT would be 5% and 6% higher, and August of dry years, in which the temperature would be 6% higher.

Water temperatures were not modeled in the San Joaquin River.

Summary of CEQA Conclusion

These modeling results indicate that the effect is less than significant because it does not have the potential to substantially reduce the amount of suitable habitat and no mitigation is required. There would be few differences in water temperatures between Alternative 4A and the CEQA baseline. Results would be similar between H3_ELT and H4_ELT.

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

In general, effects of Alternative 4A on white sturgeon migration conditions relative to NAA_ELT are not adverse.

Upstream of the Delta

H3_ELT/ESO_ELT

Analyses for white sturgeon focused on the Sacramento River (North Delta to RM 143—i.e., Wilkins Slough and Verona CALSIM nodes). Larval transport flows were represented by the average number of months per year that exceeded thresholds of 17,700 cfs (Wilkins Slough) and 31,000 cfs (Verona) (Table 11-4A-113). Exceedances of the 17,700 cfs threshold for Wilkins Slough and the 31,000 cfs threshold at Verona under H3_ELT would generally be similar to those under NAA_ELT. Despite some large relative difference (up to 25%), the changes on an absolute scale would be small (up to 0.2 fewer months per year).

Table 11-4A-113. Difference and Percent Difference in Number of Months in Which Flow Rates Exceed 17,700 and 5,300 cfs in the Sacramento River at Wilkins Slough and 31,000 cfs at Verona

	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Wilkins Slough, 17,700 cfs[a]		
Wet	-0.1 (-4%)	0 (0%)
Above Normal	0.1 (6%)	0 (0%)
Below Normal	-0.1 (-25%)	0 (0%)
Dry	0 (0%)	0 (0%)
Critical	0 (0%)	0 (0%)
Wilkins Slough, 5,300 cfs[b]		
Wet	0 (-1%)	-0.1 (-1%)
Above Normal	-0.3 (-4%)	0 (0%)
Below Normal	-0.2 (-4%)	0.1 (3%)
Dry	-0.1 (-1%)	0 (0%)
Critical	0 (0%)	-0.1 (-2%)
Verona, 31,000 cfs[a]		
Wet	-0.4 (-16%)	-0.2 (-8%)
Above Normal	0 (0%)	0 (0%)
Below Normal	-0.1 (-29%)	-0.1 (-17%)
Dry	-0.1 (-40%)	-0.1 (-25%)
Critical	0 (NA)	0 (NA)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

NA = could not be calculated because the denominator was 0.

[a] Months analyzed: February through May.

[b] Months analyzed: November through May.

The effects of changes in flow for white sturgeon under Alternative 4A was also examined by utilizing the positive correlation between year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved transport (e.g., for white sturgeon larvae or other early life stages) that results in improved year class strength. An examination of monthly average Delta outflow exceedances above 15,000 cfs, 20,000 cfs, and 25,000 cfs during April and May of wet and above-normal years was used to provide context for differences in through-Delta migration conditions, per recommendations by the Anadromous Fish Restoration Program (USFWS 1995). The percentage of months exceeding flow thresholds under H3_ELT would generally be lower than those under NAA_ELT (up to 50% lower) (Table 11-4A-114). These results indicate that, using the positive correlation between Delta outflow and year class strength, year class strength generally would be lower under H3_ELT.

Table 11-4A-114. Difference and Percent Difference in Percentage of Months in Which Average Delta Outflow is Predicted to Exceed 15,000, 20,000, and 25,000 Cubic Feet per Second (cfs) in April and May of Wet and Above-Normal Water Years

Flow	Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
April					
15,000 cfs	Wet	-4 (-4%)	-4 (-4%)	4 (4%)	4 (4%)
	Above Normal	-17 (-18%)	-17 (-18%)	(0%)	(0%)
20,000 cfs	Wet	-8 (-9%)	-8 (-9%)	15 (18%)	15 (18%)
	Above Normal	-33 (-44%)	-33 (-44%)	8 (11%)	8 (11%)
25,000 cfs	Wet	-19 (-24%)	-19 (-24%)	12 (14%)	12 (14%)
	Above Normal	-17 (-29%)	-17 (-29%)	25 (43%)	25 (43%)
May					
15,000 cfs	Wet	-12 (-13%)	-12 (-13%)	8 (9%)	8 (9%)
	Above Normal	-33 (-40%)	-25 (-33%)	(0%)	8 (11%)
20,000 cfs	Wet	-27 (-32%)	-15 (-21%)	-4 (-5%)	8 (11%)
	Above Normal	-17 (-40%)	-8 (-25%)	25 (60%)	33 (100%)
25,000 cfs	Wet	-19 (-28%)	-12 (-19%)	-8 (-11%)	(0%)
	Above Normal	-17 (-50%)	-17 (-50%)	(0%)	(0%)
April/May Average					
15,000 cfs	Wet	-8 (-8%)	-4 (-4%)	4 (4%)	8 (8%)
	Above Normal	-17 (-17%)	-17 (-17%)	(0%)	(0%)
20,000 cfs	Wet	-15 (-17%)	-15 (-17%)	8 (9%)	8 (9%)
	Above Normal	-17 (-25%)	-8 (-14%)	17 (25%)	25 (43%)
25,000 cfs	Wet	-19 (-24%)	-12 (-16%)	(0%)	8 (11%)
	Above Normal	-17 (-33%)	-17 (-33%)	25 (50%)	25 (50%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).

For juveniles, flows in the Sacramento River at Verona were examined during the year-round migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows at Verona under H3_ELT would be lower by up to 22% relative to NAA_ELT during July, September and November, greater by up to 35% greater during June, and similar in the remaining eight months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For adults, the average number of months per year during the November through May adult migration period in which flows in the Sacramento River at Wilkins Slough exceed 5,300 cfs was determined (Table 11-4A-113). The average number of months exceeding 5,300 cfs under H3_ELT would be similar to the number of months under NAA_ELT.

H4_ELT/HOS_ELT

Year-round flows under H4_ELT in the Sacramento River at Verona would be similar to those under NAA_ELT, except during June, in which mean flows under H4_ELT would be up to 35% higher, during July through September and November, in which flows would be up to 22% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For H4_ELT, the percentage of months exceeding the USFWS's (1995) recommended Delta outflow thresholds in April and May of wet and above normal years was similar or considerably greater than NAA_ELT (Table 11-4A-114). These results indicate that, using the positive correlation between Delta outflow and year class strength, year class strength generally would be similar or greater under H4_ELT relative to NAA_ELT.

Through-Delta

As described for other species (e.g., Sacramento splittail in Impact AQUA-114), migration conditions in the southern Delta generally would be considerably improved relative to NAA_ELT, because of reduced frequency of reverse OMR flows. The range of Alternative 4A operations (i.e., H3_ELT and H4_ELT) includes a range of Delta outflows, as described above (see Table 11-4A-114), which is discussed further below.

NEPA Effects: Upstream flows (above north Delta intakes) would generally be similar between Alternative 4A and NAA_ELT. As noted for green sturgeon and described above, due to the removal of water at the North Delta intakes, there are substantial differences in through-Delta flows between Alternative 4A and NAA_ELT. The percentage of months exceeding the USFWS (1995) Delta outflow thresholds in April and May of wet and above normal years was appreciably lower than NAA_ELT for Alternative 4A's H3_ELT scenario, but was similar or considerably greater than NAA_ELT for Alternative 4A's H4_ELT scenario (Table 11-4A-114). As noted for Alternative 4 and in the analysis of green sturgeon, the exact mechanism for the correlation between white sturgeon year-class strength and Delta outflow is not known at this time.

The scientific uncertainty regarding which mechanisms are responsible for the positive correlation between year class strength and river/Delta flow will be addressed through targeted research and monitoring to be conducted in the years leading up to the initiation of north Delta facilities operations as described in the adaptive management and monitoring program in Section 4.1 to inform decisions regarding Delta outflow such that the effect on white sturgeon Delta flow conditions would not be adverse. This uncertainty and the associated adaptive management and monitoring program, combined with similarities in upstream flow conditions between Alternative 4A and NAA_ELT, indicate that Alternative 4A would not be adverse to migration conditions for white sturgeon.

CEQA Conclusion: In general, Alternative 4A would reduce the quantity and quality of migration habitat for white sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of migration habitat for white sturgeon.

Upstream of the Delta

H3_ELT/ESO_ELT

The number of months per year with exceedances above the 17,700 cfs threshold for Wilkins Slough under H3_ELT would be similar to those under Existing Conditions on the relative scale (%), except in below normal years (25% lower) (Table 11-4A-113). The number of months per year exceeding

31,000 cfs at Verona under H3_ELT would be up to 40% lower than those under Existing Conditions. All of these changes would be small to moderate on the absolute scale (up to 0.4 fewer months per year).

For Delta outflow, the percent of months exceeding outflow thresholds under H3_ELT would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (4% to 50% lower on a relative scale) (Table 11-4A-114).

For juveniles, flows in the Sacramento River at Verona were examined during the year-round migration period. In general, mean flows under H3_ELT would be similar or lower relative to Existing Conditions during January through May and July through December, with the largest reductions in flow (up to 31% lower) during July through September. Flows under H3_ELT would be higher (up to 50%) during June of above normal, below normal, and dry water years and during September of wet and above normal water years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For adult migration, the average number of months per year exceeding 5,300 cfs at Wilkins Slough under H3_ELT would be similar to or slightly lower than the number of months under Existing Conditions (up to 4% lower) (Table 11-4A-113).

H4_ELT/HOS_ELT

Year-round flows under H4_ELT in the Sacramento River at Verona would be similar to or up to 43% greater than flows under Existing Conditions during April through June, September, and December, and up to 28% lower than flows under Existing Conditions in the remaining 7 months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Through-Delta

Given the improved OMR flows and the range of Delta outflows under Alternative 4A's H3_ELT and H4_ELT that would be refined to avoid negative impacts to green sturgeon (see NEPA Effects discussion above), the potential impact of Alternative 4A on in-Delta conditions for white sturgeon is considered less than significant, and no mitigation would be required.

Summary of CEQA Conclusion

Under Alternative 4A, the exceedance of flow thresholds in the Sacramento River would be lower than under Existing Conditions. Exceedance of Delta outflow thresholds would be lower under Alternative 4A's H3_ELT scenario than under Existing Conditions, but would be similar or greater than under Existing Conditions for the H4_ELT scenario, although there is high uncertainty that year class strength is due to Delta outflow or if both year class strength and Delta outflows are co-varying with another unknown factor. Juvenile migration flows in the Sacramento River at Verona would be up to 31% lower in six (for H3_ELT) or seven (for H4_ELT) of 12 months relative to Existing Conditions. These reduced flows would have a substantial effect on the ability to migrate downstream, delaying or slowing rates of successful migration downstream and increasing the risk of mortality. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce migration conditions for white sturgeon.

However, this interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA_ELT, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be negligible effects on upstream flows.

In addition and as noted for green sturgeon, Real Time Operations described for the water conveyance facilities allow for optimization of short-term adjustments. This will ensure that the impacts of water operations on migration conditions for white sturgeon are less than significant. The adaptive management and monitoring program will evaluate water operations to ensure the impacts of water operations on migration conditions for white sturgeon are less than significant. Therefore, this impact is found to be less than significant and no mitigation is required.

Restoration Measures (Environmental Commitment 2, Environmental Commitment 4–Environmental Commitment 7, and Environmental Commitment 10)

As described for other covered fishes, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A. The mechanisms of impacts of habitat restoration discussed for winter-run Chinook salmon generally would be similar for white sturgeon. As noted for green sturgeon, white sturgeon may inhabit the Delta year-round and would be more likely to encounter any effects from restoration measures. However, because the extent of restoration is limited to offsetting losses from construction of the water conveyance facilities, any such effects would be greatly limited compared to Alternative 1A and 4, for example.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

The discussion of Impact AQUA-133 for green sturgeon also is applicable to white sturgeon.

***NEPA Effects*:** The effects of short-term construction activities would not be adverse to white sturgeon because environmental commitments would limit the potential for construction-related effects.

***CEQA Conclusion*:** As discussed for Alternative 1A, habitat restoration activities could result in short-term effects on white sturgeon but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce white sturgeon habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

The discussion of Impact AQUA-134 for green sturgeon also is applicable to white sturgeon.

NEPA Effects: While Alternative 4A habitat restoration actions may result in a very small increase production, mobilization, and bioavailability of methylmercury, selenium, copper, and pesticides in the aquatic system, any such releases would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation of these contaminants in white sturgeon. Alternative 4A would restore 59 acres of tidal wetlands that, depending on the specific site conditions of the restoration, may result in the colonization of benthic grazers that bioaccumulate selenium. As sturgeon are benthic feeders, the increased habitat for grazers may result in increased exposure to selenium. However, the small amount of area to be restored would not result in a substantial change in exposure potential. Overall, the effects of contaminants associated with restoration measures would not be adverse for white sturgeon.

CEQA Conclusion: Habitat restoration under Alternative 4A may result in increased production, mobilization, and bioavailability of contaminants in the aquatic system, but these would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation in white sturgeon. For methylmercury, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury in the limited restoration areas. Therefore, the impact of contaminants is considered less than significant because it would not substantially affect white sturgeon either directly or through habitat modifications. Accordingly, no mitigation would be required.

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

Restored habitat under *Environmental Commitment 4 Tidal Natural Communities Restoration* and *Environmental Commitment 6 Channel Margin Enhancement* is intended to offset habitat loss/modification caused by construction and operation of the water facilities proposed under Alternative 4A.

NEPA Effects: The effects of restored habitat conditions on white sturgeon would not be adverse because restoration is intended to provide habitat benefits for white sturgeon.

CEQA Conclusion: As described above, habitat restoration activities could result in short-term effects on white sturgeon, primarily as a result of increased potential for contaminated sediments to enter the water column. However, these effects are likely to be localized, sporadic, and of low magnitude. Adverse effects during restoration would be avoided by limiting the frequency, duration, and spatial extent of in-water work and implementing the commitments described in detail under Impact AQUA-1 and in Appendix 3B, *Environmental Commitments*. The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce white sturgeon habitat, restrict its range or interfere with its movement. Additionally, there would be substantial long-term net benefits of habitat restoration. Consequently, no additional mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

As noted for other covered species such as green sturgeon, Alternative 4A includes three other Environmental Commitments, which are reduced in their extent relative to the Conservation

Measures included in other Alternatives (e.g., Alternative 1A and Alternative 4). While the extent of these measures is reduced compared to these alternatives, the nature of the mechanisms for white sturgeon remains the same.

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (Environmental Commitment 12)

The impact discussion for winter-run Chinook salmon (Impact AQUA-46) is also applicable to white sturgeon.

NEPA Effects: The effects of methylmercury management on white sturgeon would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As noted for winter-run Chinook salmon, effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts on white sturgeon would be less than significant. Consequently, no mitigation is required.

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (Environmental Commitment 15)

The discussion of Impact AQUA-139 for green sturgeon also is applicable to white sturgeon.

NEPA Effects: The overall effect would not be adverse because it is unlikely that the targeted predators prey on white sturgeon and because the white sturgeon bycatch is expected to be minimal.

CEQA Conclusion: Consistent with the analysis for Alternative 1A, the impact is considered less than significant because it is unlikely that the targeted predators prey on white sturgeon and because the white sturgeon bycatch is expected to be minimal. Consequently, no mitigation would be required.

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (Environmental Commitment 16)

The discussion of Impact AQUA-140 for green sturgeon also is applicable to white sturgeon.

NEPA Effects: The overall effect would not be adverse because the NPB would not be located in the same portion of the channel that white sturgeon are expected to occur and because their hearing ability is low within the range of sound that the NPB generates.

CEQA Conclusion: Consistent with the analysis for Alternative 1A, the impact is considered less than significant because the NPB would not be located in the same portion of the channel that white sturgeon are expected to occur and because their hearing ability is low within the range of sound that the NPB generates. Consequently, no mitigation would be required.

Pacific Lamprey

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

The potential effects of construction of the water conveyance facilities on Pacific lamprey would be the same as those described for Alternative 4, Impact AQUA-163. This section provides additional detail on underwater noise impacts which are also applicable to Impact AQUA-163 in Alternative 4.

Table 11-8 presents the life stages of Pacific lamprey and months of their potential presence in the north, east, and south Delta during the proposed in-water construction window (June 1–October 31). Potential impacts of pile driving noise on Pacific lamprey are different from other fish species. In a study of hearing in sturgeon and lamprey, Popper (2005) found that lamprey do not have the typical hearing structures of other fish. Although there have been no studies to determine responses of lamprey to sound (Popper 2005), ammocoetes are partially buried in the substrate, and the substrate dampens vibrations and noise. As a result, at least some life stages of Pacific lamprey may be less susceptible to injury from impact pile driving than other fish species.

Under Alternative 4A, adult, ammocoete, and macropthalmia life stages could be present in the vicinity of the proposed in-water pile driving locations (intakes, barge unloading facilities, CCF cofferdams, CCF siphons, and Head of Old River operable barrier) during in-water pile driving activities. While adults would primarily occur between June and July and macropthalmia in June, ammocoetes would occur throughout the year. However, the abundance of ammocoetes is low at all in-water pile driving sites. Adults are considered moderately abundant in June and July near the intakes, but of low abundance in the east and south Delta where barge landings would be located. Macropthalmia would be primarily migrating downstream, and during only a portion of the in-water construction period. Therefore their exposure to pile driving sound levels would likely be limited.

Given the likely low numbers in the east and south Delta, the relatively small areas affected by underwater noise in the east and south Delta, and the intermittent nature of pile driving activities, exposure of Pacific lamprey to potentially harmful pile driving noise is expected to be limited to a small proportion of the total population. Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the magnitude of these effects. Overall, underwater construction noise would be expected to adversely affect small numbers of Pacific lamprey and not result in significant population-level effects.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-163, the effect would not be adverse for Pacific lamprey. Implementation of the measures described in Appendix 3B, *Environmental Commitments*, such as *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan* would guide rapid and effective response in the case of inadvertent spills of hazardous materials. This species' natural tolerance to turbidity, would likely avoid the risk of any adverse turbidity effects resulting from project construction. Construction would not be expected to increase predation rates relative to baseline conditions. Construction will result in both temporary and permanent alteration of rearing and migratory habitats used by Pacific lamprey. However, Alternative 4A includes Environmental Commitment 4 to restore tidal habitat. The direct effects of underwater construction noise on Pacific lamprey that may be present could be adverse if they are exposed. However, implementation of Mitigation Measures AQUA-1a and AQUA-

1b, combined with the in-water work window that would minimize exposure, would reduce the potential for effects from underwater noise and this effect would not be adverse.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-163, the impact of the construction of the water conveyance facilities on Pacific lamprey would not be significant except for construction noise associated with pile driving. Construction of Alternative 4A involves several elements with the potential to affect Pacific lamprey. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4A would be the same as those described for Alternative 4, Impact AQUA-164. As concluded in Alternative 4, Impact AQUA-164, the impact would not be adverse for Pacific lamprey.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-164, the impact of the maintenance of water conveyance facilities on Pacific lamprey would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

Water Exports

The potential entrainment impacts of Alternative 4A on Pacific lamprey and river lamprey would be similar to Alternative 4 for operating SWP/CVP south Delta export facilities and the proposed new SWP/CVP North Delta intakes (Impact AQUA-165). Alternative 4A operational criteria are designed to avoid or reduce potential entrainment and the effect would not be adverse.

The analysis of Pacific lamprey and river lamprey entrainment at the SWP/CVP south Delta export facilities is combined because the salvage facilities do not distinguish between the two lamprey species. Under Scenario H3_ELT, average annual entrainment of lamprey at the south Delta export facilities would be substantially reduced by about 45% (Table 11-4A-115) across all year types compared to the NAA_ELT. Entrainment losses would be further reduced under Scenario H4_ELT compared to NAA_ELT. Therefore, Alternative 4A would not have adverse effects on lamprey.

Predation Associated with Entrainment

Entrainment-related predation loss of lamprey at the south Delta facilities would not be greater under this Alternative compared to the NNA-ELT and would be lower due to a reduction in entrainment loss. Conditions under Scenario H4_ELT would decrease predation loss relative to NAA_ELT and Scenario H3_ELT. Predation at the north Delta would be increased due to the installation of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta facilities is unknown because of the lack of knowledge about their distribution and population abundances in the Delta.

NEPA Effects: Overall, the effect of entrainment and entrainment-related predation would not be adverse because entrainment, and predation associated with entrainment, would be reduced under Alternative 4A.

CEQA Conclusion: Annual entrainment losses of lamprey would be decreased under Scenario H3_ELT by 45% relative to Existing Conditions, and would be further decreased under Scenario H4_ELT. Lamprey predation loss at the south Delta facilities would not be increased relative to Existing Conditions and may be decreased due to reduction entrainment losses. Predation at the north Delta would be increased due to the installation of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta facilities is unknown because of the lack of knowledge about their distribution and population abundances in the Delta. Overall, the effect of predation loss on lamprey under Alternative 4A would be similar or lower than existing conditions, consistent with the change in entrainment. Overall, the impacts of Alternative 4A water operations to Pacific lamprey are considered less than significant because they would reduce entrainment and potentially entrainment-related predation. Consequently, no mitigation would be required.

Table 11-4A-115. Lamprey Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities for Alternative 4A (Scenario H3_ELT)

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
All Years	-1,526 (-45%)	-1,504 (-45%)

Note: Negative numbers indicate lower values under Alternative 4A (i.e., the calculations are based on Alternative 4A minus the baseline).
[a] Estimated annual number of fish lost, based on non-normalized data.

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

In general, Alternative 4A would not affect the quality and quantity of spawning and egg incubation habitat for Pacific lamprey relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flow-related impacts to Pacific lamprey spawning habitat were evaluated by estimating effects of flow alterations on egg exposure, called redd dewatering risk, and effects on water temperature. Rapid reductions in flow can dewater redds leading to mortality. Locations for each river used in the dewatering risk analysis were based on available literature, personal conversations with agency experts, and spatial limitations of the CALSIM II model, and include the Sacramento River at Keswick, Sacramento River at Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and the American River at Nimbus Dam and at the confluence with the Sacramento River. Pacific lamprey spawn in these rivers between January and August so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage). Water temperature results from the SRWQM and the Reclamation Temperature Model were used to assess the exceedances of water temperatures under all model scenarios in the upper Sacramento, Trinity, Feather, and American rivers.

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, and substrate) of river lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, January to August.

There would be minimal differences between H3_ELT and NAA_ELT in exposure to flow reductions in all rivers except for a small (10%) increase in the Feather River at Thermalito Afterbay (Table 11-4A-116). These results indicate that H3_ELT would not have biologically meaningful effects on Pacific lamprey redd cohorts in all locations analyzed because the difference represents only 2 percent (11 out of 656) of total hypothetical redd cohorts.

Table 11-4A-116. Differences between Model Scenarios in Dewatering Risk of Pacific Lamprey Redd Cohorts[a]

Location	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Sacramento River at Keswick	13 (24%)	1 (-2%)
Sacramento River at Red Bluff	15 (28%)	5 (8%)
Trinity River downstream of Lewiston	-1 (-1%)	1 (1%)
Feather River at Thermalito Afterbay	-26 (-17%)	11 (10%)
American River at Nimbus Dam	27 (32%)	5 (5%)
American River at Sacramento River Confluence	31 (33%)	8 (7%)

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%. Positive values indicate a higher value in H3_ELT than in Existing Conditions or NAA_ELT.

Significant reduction in survival of eggs and embryos of Pacific lamprey were observed at 22°C (71.6°F; Meeuwig et al. 2005). Therefore, in the Sacramento River, this analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) using daily data from SRWQM. For other rivers, the analysis predicted the number of consecutive 2 month periods during which at least one month exceeds 22°C (71.6°F) using monthly averaged data from the Reclamation temperature model. Each individual day or month starts a new “egg cohort” such that there are 19,928 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from January 1 through August 31, and 648 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Exact spawning locations of Pacific lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

In most locations, egg cohort exposure would not differ between NAA_ELT and H3_ELT (Table 11-4A-117). However, the number of cohorts exposed under H3_ELT would be 92% lower than those under NAA_ELT in the Trinity River at Lewiston. Also, the number of cohorts exposed under H3_ELT would be 93% greater than those under NAA_ELT in the Feather River below Thermalito Afterbay. Although a 92% reduction and a 93% increase appear substantial, these values represent only 23 and 37 egg cohorts, respectfully, or 3.5% and 5.7% of the 648 total hypothetical cohorts. Therefore, these increases and decreases in egg cohort exposure are small relative to the total population. As a result, they would not have a biologically meaningful effect.

Table 11-4A-117. Differences (Percent Differences) between Model Scenarios in Pacific Lamprey Egg Cohort Temperature Exposure[a]

Location	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	506 (NA)	23 (5%)
Trinity River at Lewiston	0 (0%)	-23 (-92%)
Trinity River at North Fork	0 (NA)	0 (0%)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	53 (221%)	37 (93%)
American River at Nimbus	42 (382%)	2 (4%)
American River at Sacramento River Confluence	96 (171%)	2 (1%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	23 (1150%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey egg cohorts experiencing water temperatures above 71.6°F during January to August on at least one day during a 49-day incubation period in the Sacramento River or for at least one month during a 2-month incubation period for in other rivers each model scenario. Positive values indicate a higher value in H3_ELT than in EXISTING CONDITIONS or NAA_ELT.

H4_ELT/HOS

Flows during January through August under H4_ELT would generally be similar to or greater than flows under H3_ELT in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H4_ELT in these rivers and results for H4_ELT would be the same as those for H3_ELT.

In the Feather River at Thermalito Afterbay, there would be 23 more cohorts (20%) exposed to a 50% month over month drop in flow rate under H4_ELT relative to NAA_ELT (Table 11-4A-118). Although relatively large, this value represents <4% of the population of ammocoetes (23 out of 648 total cohorts). Therefore, it is not expected that this increase in exposure would have a biologically meaningful effect to the population.

Table 11-4A-118. Differences between Model Scenarios in Dewatering Risk of Pacific Lamprey Redd Cohorts in the Feather River at Thermalito Afterbay[a]

Measurement	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Difference (Percent Difference)	-14 (-9%)	23 (20%)

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%. Positive values indicate a higher value in H4 than in Existing Conditions or NAA_ELT.

Water temperatures would not differ between H4_ELT and H3_ELT and, therefore, no egg cohort temperature analyses were conducted. Overall, results for H4_ELT would be similar to those for H3_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because Alternative 4A would not have substantial effects on spawning and egg incubation habitat for Pacific lamprey. There would be no biologically meaningful differences in flow reductions that increase redd dewatering risk between the NAA_ELT and H3_ELT at all locations evaluated. Also, there would be increases and decreases in exposure risk of eggs to elevated temperatures but would not have a biologically meaningful effect due to their small absolute values relative to total egg cohort sizes. These modeling results are consistent between H3_ELT and H4_ELT.

CEQA Conclusion: Collectively, the results of the Impact AQUA-166 CEQA analysis show that there would be no effect of Alternative 4A on Pacific lamprey spawning and egg incubation habitat relative to the CEQA baseline.

H3_ELT/ESO_ELT

Effects of H3_ELT on month-over-month flow reduction compared to Existing Conditions consist of negligible effects (<5% difference) in the Trinity River, a decrease in egg cohorts exposed to flow reductions (-17%) in the Feather River, and moderate to substantial increases in exposures in the Sacramento River and American River (Table 11-4A-116). Changes would be most substantial for the American River (increased risk of dewatering exposure to 27 cohorts or 32% at Nimbus Dam, and 31 cohorts or 33% at the confluence). In the Sacramento River, there would be increased exposure to flow reductions for 13 cohorts or 24% at Keswick, and to 15 cohorts or 28% at Red Bluff. These results indicate that effects of Alternative 4A on flow would not negatively affect Pacific lamprey redd dewatering risk in the Feather River and Trinity River. Further, an increase of 13 to 31 cohorts out of 656 cohorts would represent fewer than 5 percent of total redd cohorts. Therefore, Alternative 4A would not affect dewatering risk in the Sacramento River or the American River.

The number of egg cohorts exposed to 22°C (71.6°F) under H3_ELT would be greater than that under Existing Conditions in at least one location in all rivers, except the Trinity River (Table 11-4A-117). In the American River, the difference in the number of cohorts exposed would represent 6 to 15 percent of total cohorts.

H4_ELT/HOS

Flows during January through August under H4_ELT would generally be similar to or greater than flows under H3_ELT in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H4_ELT in these rivers and results for H4_ELT would be the same as those for H3_ELT.

In the Feather River at Thermalito Afterbay, there would be 14 fewer cohorts (9%) exposed to a 50% month over month drop in flow rate under H1 relative to NAA_ELT (Table 11-4A-118). Although relatively large, this value represents <5% of the population of ammocoetes. Therefore, it is not expected that this decrease in exposure would have a biologically meaningful effect to the population.

Water temperatures under H4_ELT would be similar to those under H3_ELT for all rivers examined. Therefore, no additional cohort temperature exposure analyses were conducted for H4_ELT. Overall, results for H4_ELT would be similar to those for H3_ELT.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impacts to Pacific lamprey spawning and egg incubation conditions would be less than significant. There would be no increases in exposure to redd dewatering that would affect more than 5 percent of the population in all rivers. Temperature exposure in the American River at the Sacramento River confluence would affect 15 percent more cohorts under H3_ELT, but there would be no other differences that would have a biologically meaningful effect to Pacific lamprey in any of the other 9 locations evaluated. Therefore, the impact is less than significant and no mitigation is required.

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

In general, the effect of Alternative 4A on Pacific lamprey rearing habitat would be negligible relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flow-related impacts to Pacific lamprey rearing habitat were evaluated by estimating of the frequency of rapid flow reductions in ammocoete rearing areas. Rapid reductions in flow can strand ammocoetes, leading to mortality. Comparisons of effects were made for ammocoete cohorts in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River. An ammocoete remains relatively immobile in the sediment in the same location for 5 to 7 years, after which it migrates downstream. During the upstream rearing period there is potential for ammocoete stranding from rapid reductions in flow.

The analysis of ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (January through August) and spend 7 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than a given flow reduction (50%–90% in 5% increments)at any time during the seven-year period.

Comparisons of month-over-month flow reductions for the Sacramento River at Keswick (Table 11-4A-119) indicate that H3_ELT would have either no effect (0%) or negligible effects (<5%) on cohort exposures to all flow reductions. These results indicate that there would be no difference in Pacific lamprey stranding risk between H3_ELT and NAA_ELT in the Sacramento River at Keswick.

Table 11-4A-119. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

	Percent Difference[a]

-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

Results of comparisons for the Sacramento River at Red Bluff (Table 11-4A-120) indicate that there would be no or negligible changes in flow reductions. These results indicate that there would no effect of H3_ELT on Pacific lamprey ammocoete exposure to flow reductions in the Sacramento River at Red Bluff.

-85%	0	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

Comparisons for the Trinity River indicate that there would be no or small (5%) differences in cohort exposure between NAA_ELT and H3_ELT for all flow reductions evaluated (Table 11-4A-121). These results indicate that there would be no biologically meaningful effects of H3_ELT on Pacific lamprey stranding risk in the Trinity River.

Table 11-4A-121. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Trinity River at Lewiston

[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

In the Feather River at Thermalito Afterbay, there would be no difference in ammocoete cohort exposure at the 50% through 75% flow reductions (Table 11-4A-122). For the 80% through 90% flow reductions, ammocoete exposure would be 1% to 64% lower, which would have a beneficial effect on ammocoete rearing. These results indicate that there will be beneficial effects of H3_ELT on Pacific lamprey ammocoete rearing in the Feather River.

-85%	-19	-30
-90%	-64	-64

[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

Comparisons for the American River at Nimbus Dam (Table 11-4A-123) and at the confluence with the Sacramento River (Table 11-4A-124) have similar results. There would be no or negligible differences in cohort exposure between NAA_ELT and H3_ELT for the 50% to 70% flow reductions range and the 85% to 90% flow reductions range. There would be higher cohort exposure under H3_ELT relative to NAA_ELT at Nimbus Dam at the 75% flow reduction (7% higher) and at the confluence with the Sacramento River at the 75% (12% higher) and 80% (23% higher) flow reductions. At the confluence with the Sacramento River, there would be no differences in cohort exposure for all flow reduction levels except the 85% level, at which exposure would be 33% greater under H3_ELT. These results indicate that there would generally be no effect of H3_ELT on stranding risk in the American River with few small exceptions that would be infrequent and would therefore not result in biologically meaningful effects.

-90%	104	0

[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

To evaluate water temperature-related effects of H3_ELT on Pacific lamprey ammocoetes, we examined the predicted number of ammocoete "cohorts" that experience water temperatures greater than 71.6°F for at least one day in the Sacramento River (because daily water temperature data are available) or for at least one month in the Feather, American, Stanislaus, and Trinity rivers over a 7 year period, the maximum likely duration of the ammocoete life stage (Moyle 2002). Each individual day or month starts a new "cohort" such that there are 18,244 cohorts for the Sacramento River, corresponding to 82 years of ammocoetes being "born" every day each year from January 1 through August 31, and 593 cohorts for the other rivers using monthly data over the same period.

The number of ammocoete cohorts exposed to temperatures greater than 71.6°F would be similar between NAA_ELT and H3_ELT in most of the rivers (Table 11-1A-125). Ammocoetes in the Feather River at Thermalito Afterbay would experience a 15% increase in exposure to temperatures greater than 71.6°F, although there would be no difference relative to the NAA at the fish dam. Overall, the effects would be minimal to the Pacific lamprey population.

Table 11-4A-125. Differences (Percent Differences) between Model Scenarios in Pacific Lamprey Ammocoete Cohorts Exposed to Temperatures Greater than 71.6°F in at Least One Day or Month

Location	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Sacramento River at Keswick[b]	0 (NA)	0 (NA)
Sacramento River at Hamilton City[b]	7,721 (NA)	476 (7%)
Trinity River at Lewiston	56 (NA)	0 (0%)
Trinity River at North Fork	56 (NA)	0 (0%)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	164 (43%)	70 (15%)
American River at Nimbus	265 (137%)	-14 (-3%)
American River at Sacramento River Confluence	151 (35%)	9 (2%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	283 (505%)	0 (0%)

NA = could not be calculated because the denominator was 0.
[a] Positive values indicate a higher value in H3_ELT than in EXISTING CONDITIONS or NAA_ELT.
[b] Based on daily data; all other locations use monthly data; 1922–2003.

H4_ELT/HOS

There would be generally no differences in mean flows year-round between H4_ELT and H3_ELT in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between NAA_ELT and H4_ELT at the 50% through 80% flow reductions (Table 11-4A-126). For the 85% and 90% flow reductions, ammocoete exposure under H4_ELT would be 9 and 53% higher, respectively. The 85% and 90% flow reductions would occur rarely: 19 and 7 times under NAA_ELT and 22 and 10 times, respectively under H4_ELT throughout the 985 total months evaluated. Therefore, these reductions would affect a small proportion of the population. As a result, these results indicate that there would be no biologically meaningful effect of H4_ELT on stranding risk.

Table 11-4A-126. Percent Difference between Baselines and H4_ELT Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Feather River at Thermalito Afterbay

Percent Flow Reduction	Percent Difference[a]	
	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
-50%	0	0
-55%	0	0
-60%	0	0
-65%	0	0
-70%	0	0
-75%	0	0
-80%	0	2
-85%	25	9
-90%	53	53

[a] Negative values indicate reduced cohort exposure under H4_ELT.

There would generally be no differences in mean water temperatures year-round between H4_ELT and H3_ELT in any river examined. As a result, no additional ammocoete cohort exposure analyses were conducted for H4_ELT. Results of these analyses for H4_ELT would be the same as those for H3_ELT.

Overall, these results indicate that results for H4_ELT would generally be similar to those under H3_ELT except for an increase in ammocoete stranding risk exposure in the Feather River at 85% and 90% flow reductions under H4_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. There would generally be negligible effects or beneficial effects of H3_ELT on Pacific lamprey ammocoete stranding risk in all rivers evaluated. There would be minimal differences in exposure risk of ammocoetes to elevated temperatures within each river evaluated.

CEQA Conclusion: In general, Alternative 4A would reduce the quantity and quality of rearing habitat for Pacific lamprey relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of rearing habitat for Pacific lamprey relative to NAA_ELT.

H3_ELT/ESO_ELT

Comparisons of H3_ELT to Existing Conditions for the Sacramento River at Keswick indicate negligible changes (<5%) in occurrence of flow reductions for all flow reduction categories, with the exception of a 104% increase in occurrence of month-over-month flow reductions of 85% (Table 11-4A-119). Comparisons for the Sacramento River at Red Bluff indicate no effect (0%) or negligible effects (<5%) for all flow reduction categories with the exception of 10% and 23% increases in exposure for the 75% and 80% flow reduction events, respectively (Table 11-4A-120). Based on the fact that increases in exposure would only be substantial for one or two flow reduction categories depending on location, H3_ELT would not be expected to have biologically meaningful negative effects on spawning success in the Sacramento River but would contribute incrementally to regional effects.

Increases from Existing Conditions to H3_ELT of 20–34% are predicted for egg cohort exposed to flow reductions from 75% to 90% for the Trinity River (Table 11-4A-121); the percentages correspond generally to increased occurrences from approximately 350 events for Existing Conditions to approximately 450 events for H3_ELT. Despite the prevalence of increased exposure risk to the higher flow reduction events, the percentage of cohorts exposed to stranding risk is relatively small compared to the total number of cohorts and therefore effects on rearing success in the Trinity River would not be biologically meaningful but would contribute incrementally to regional effects.

Comparisons for the Feather River at Thermalito Afterbay (Table 11-4A-122) indicate that there would be negligible (<5%) differences in exposure of Pacific lamprey ammocoete cohorts to all flow reductions except the 85% and 90% reductions, in which exposure would be 19% and 64% lower under H3_ELT. This suggests that flow conditions would improve for Pacific lamprey ammocoetes under H3_ELT.

Comparisons for the American River at Nimbus Dam (Table 11-4A-123) and at the confluence with the Sacramento River (Table 11-4A-124) indicate an increase in exposure risk to stranding between 70% and 85% or 90% for H3_ELT compared to Existing Conditions; predicted increases ranged from 34 to 238% for Nimbus Dam and from 7 to 223% for the confluence. These persistent and substantial increases in exposures to larger flow reduction events would have biologically meaningful effects on Pacific lamprey ammocoete cohort stranding and therefore spawning success in the American River.

The number of ammocoete cohorts exposed to 71.6°F under H3_ELT would be higher than those under Existing Conditions in most locations examined, except in the Sacramento River at Keswick, in the Feather River at the Fish Barrier Dam, and the Stanislaus River at Knights Ferry (Table 11-4A-125).

H4_ELT/HOS

There would be generally no differences in mean flows year-round between H4_ELT and H3_ELT in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between Existing Conditions and H4_ELT at the 50% through 80% flow reductions (Table 11-4A-126). For the 85% and 90% flow reductions, ammocoete exposure under H4_ELT would be 25% and 53% higher, respectively. These results indicate that there would generally be no effect of H4_ELT on stranding risk with exceptions that very high flow reductions that would not be common enough to have biologically meaningful effects.

There would generally be no differences in mean water temperatures year-round between H4_ELT and H3_ELT in any river examined. As a result, no additional ammocoete cohort exposure analyses were conducted for H4_ELT. Results of these analyses for H4_ELT would be the same as those for H3_ELT.

Overall, these results indicate that results for H4_ELT would generally be similar to those under H3_ELT.

Summary of CEQA Conclusion

Under Alternative 4A, the risk of redd dewatering would increase to some degree under some flow reductions in the Sacramento and Trinity rivers, and substantially in the American River at Nimbus Dam (increases from 34% to 238%). Flow reductions would increase the risk of ammocoete stranding and desiccation in these rivers. There would be a beneficial effect from decreased occurrence of flow reduction events (=reduced ammocoete stranding risk) in the Feather River (-19% to -64% for the 85% and 90% flow reduction categories) but this effect would not offset the more substantial reductions in the other locations. There would be an increase in exposure to critical water temperatures in most locations examined. Increased exposure to higher water temperatures would increase stress and mortality of ammocoetes. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce rearing habitat and substantially reduce the number of Pacific lamprey as a result of fry and juvenile mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur in 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would generally be negligible effects or beneficial effects of Alternative 4A on Pacific lamprey ammocoete stranding risk in all rivers evaluated. There would be increase and decreases in exposure risk of ammocoetes to elevated temperatures within each river evaluated that would balance out such that there would be no net effect on Pacific lamprey ammocoetes. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions).

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

In general, the effect of Alternative 4A on Pacific lamprey migration conditions would be negligible relative to the NAA_ELT.

H3_ELT/ESO_ELT

After 5 to7 years, Pacific lamprey ammocoetes migrate downstream and become macropthalmia (juveniles) once they reach the Delta. Migration generally is associated with large flow pulses in winter months (December through March) (USFWS unpublished data) meaning alterations in flow have the potential to affect downstream migration conditions. The effects of H3_ELT water operations on seasonal migration flows for Pacific lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the likely migration pathways of Pacific lamprey during the likely macropthalmia migration period (December through May) were examined for the Sacramento River at Rio Vista and Red Bluff, the Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

The adult Pacific lamprey upstream migration period occurs between January and June. CALSIM II flow outputs were examined during these periods for each model scenario.

Sacramento River

Macropthalmia

Flows the Sacramento River at Rio Vista (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the December to May macropthalmia migration period. Flows under H3_ELT would generally be lower by up to 24% under H3_ELT relative to NAA_ELT. Based on the prevalence of moderate decreases in flow in drier water years for much of migration period, H3_ELT would affect Pacific lamprey macropthalmia migration conditions at this location. In the Sacramento River upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), flows under H3_ELT during December through May would be similar to or up to 9% greater than flows under NAA_ELT.

Adults

Flows in the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the January to June adult migration period. Flows under H3_ELT would be similar to or up to 9% greater than flows under NAA_ELT. These results indicate that H3_ELT would generally not affect adult migration conditions in the Sacramento River.

Feather River

Macropthalmia

Flows in the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the December to May macropthalmia migration period. Flows under H3_ELT during would generally be similar to or greater (up to 12% greater) than flows under NAA_ELT. These results indicate that effects of H3_ELT on macropthalmia migration flows in the Feather River would generally be negligible.

Adults

Flows in the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the January through June adult migration period. Flows under H3_ELT would generally be similar to flows under NAA_ELT during January through May and greater by up to 77% during June. These results indicate that H3_ELT would have no effect or a beneficial effect on adult migration conditions in the Feather River.

American River

Macropthalmia

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the December through May macropthalmia migration period. Flows under H3_ELT would generally be similar to flows under NAA_ELT with few small exceptions. These results indicate that H3_ELT would not have negative effects on macropthalmia migration conditions in the American River.

Adults

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the January to June adult migration period. Flows under H3_ELT during January through May would generally be similar to flows under NAA_ELT with few small exceptions. Flows under H3_ELT during June would generally be greater by up to 25% than flows under NAA_ELT. These results indicate that H3_ELT would have no effect or a beneficial effect on adult migration conditions in the American River.

H4_ELT/HOS

Flows at Rio Vista would be up to 12% lower under H4_ELT relative to NAA_ELT during December through April and there would be no differences during May. Flows in the Sacramento River upstream of Red Bluff under H4_ELT during the December through May macropthalmia migration period would generally be similar to flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), indicating that migration conditions for macropthalmia in this reach would be unaffected under. Flows in the Sacramento River at Red Bluff under H4_ELT during the January through June migration period would generally be similar to flows under NAA_ELT. Overall, flows at Rio Vista under H4_ELT would be slightly lower on average than flows under NAA_ELT and flows would not differ between NAA_ELT and H4_ELT at Red Bluff.

Flows in the Feather River at the confluence with the Sacramento River under H4_ELT during the December through May macropthalmia migration period would generally be similar to or greater than (up to 119% greater) flows under H3_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), indicating that migration conditions for macropthalmia would be improved under H4_ELT relative to NAA_ELT in the Feather River. Flows under H4_ELT during the January through June adult migration period would generally be similar to or greater than (up to 119% greater) flows under H3_ELT, indicating that migration conditions for adults would also be improved under H4_ELT relative to NAA_ELT in the Feather River.

Flows in the American River at the confluence with the Sacramento River under H4_ELT during the December through May macropthalmia migration period and the January through June adult migration period would generally be similar to or greater than flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

These results indicate that there would be small negative effects of Alternative 4A on lamprey migration flows in the Sacramento River, moderately large benefits in the Feather River, and no effect in the American River.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it would not substantially reduce or degrade migration habitat or substantially reduce the number of fish as a result of mortality. There would be small to moderate negative effects of Alternative 4A on lamprey migration flows in the Sacramento River at Rio Vista, no effect (under H3_ELT) or moderately large benefits (under H4_ELT) in the Feather River, and no effect in the Sacramento River at Red Bluff and in the American River. Combined, these effects would not result in adverse effects on migration conditions for Pacific lamprey.

CEQA Conclusion: In general, Alternative 4A would not reduce the quantity and quality of migration habitat for Pacific lamprey relative to Existing Conditions.

H3_ELT/ESO_ELT

Sacramento River

Macropthalmia

Comparisons of mean monthly flow rates for H3_ELT to Existing Conditions in the Sacramento River at Rio Vista (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate that flows would be up to 47% lower under H3_ELT compared to Existing Conditions.

Comparisons for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate negligible effects (<5%) or small increases or decreases in flow (up to 10%) under H3_ELT that would not have biologically meaningful effects on migration conditions relative to Existing Conditions.

Adults

Comparisons of mean monthly flow for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January through June for H3_ELT relative to Existing Conditions indicate that for most months and water year types, flows under H3_ELT would be similar to (<5% difference) or greater than flows under Existing Conditions, with some increases and decreases in mean monthly flow that would not have biologically meaningful effects on migration.

Feather River

Macropthalmia

Comparisons for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate variable effects of H3_ELT relative to Existing Conditions by month and water year type, with negligible effects (<5%), moderate increases in flow (to 18%) that would be beneficial for migration conditions, with occasional occurrences of moderate decreases in flow to -19%. These results indicate that the effects of H3_ELT on flows would not have negative effects on macropthalmia migration in the Feather River.

Adults

Comparisons of mean monthly flow for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January to June indicate variable effects of H3_ELT relative to Existing Conditions depending on the month and water year type, with primarily negligible effects (<5%), small to substantial increases in flow (to 71%) that would have a beneficial effect on migration conditions, and occasional small to moderate decreases in flow (up to 19%). Based on the prevalence of negligible effects and increases in flow which would have a beneficial effect on migration conditions, and only occasional reductions in flow of small to moderate magnitude, these results indicate that effects of H3_ELT on flow would not have biologically meaningful negative effects on adult migration conditions in the Feather River.

American River

Macropthalmia

Comparisons for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate variable effects of H3_ELT relative to Existing Conditions, with negligible effects (<5%) during April, increases (up to 15%) during February and March that would be beneficial on migration conditions, and decreases (up to -18%) during January and May. Due to the low magnitude and frequency of increases and decreases in flow, these differences would not have biologically meaningful positive or negative effects on macropthalmia migration conditions in the American River.

Adults

Comparisons of mean monthly flow for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January to June indicate variable effects of H3_ELT relative to Existing Conditions, with negligible effects (<5%), increases (up to 15%) that would be beneficial on migration conditions, and decreases (to -35%). Based on the balance of increases and decreases in flows, these results indicate that effects of H3_ELT on flow would not have biologically meaningful negative effects on adult migration conditions in the American River.

H4_ELT/HOS

Flows in the Sacramento River at Rio Vista during the December through May macropthalmia migration period under H4_ELT would be mostly lower by up to 17% than flows under Existing Conditions. Flows upstream of Red Bluff under H4_ELT during December through May would generally be similar to or greater than (up to 9% greater) flows under NAA_ELT (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), indicating that migration conditions for Pacific lamprey macropthalmia would be largely unaffected by H4_ELT. Flows in the Sacramento River at Red Bluff under H4_ELT during the January through June migration period would generally be similar to or greater than (up to 9% greater) flows under NAA_ELT, indicating that migration conditions for adults would be largely unaffected by H4_ELT.

Flows in the Feather River at the confluence with the Sacramento River under H4_ELT during the December through May macropthalmia migration period would generally be similar to or greater than (up to 112% greater) flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), indicating that migration conditions for macropthalmia would be similar to or improved under H4_ELT. Flows in the Feather River at the confluence with the Sacramento River under H4_ELT during the January through June migration period would generally be similar to or greater than (up to 112% greater) flows under Existing Conditions, except during June in which flows under H4_ELT would be up to 28% lower. Overall, flows in the Feather River would be higher under H4_ELT than those under Existing Conditions during the adult migration period.

Differences in flows in the American River at the confluence with the Sacramento River under H4_ELT during the December through May macropthalmia migration period and the January through June adult migration period would generally be similar. Flows under H4_ELT would be similar to those under Existing Conditions during December, March, and April, higher during January, February, and March, and lower during May and June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Due to the wide variation in results, it is concluded that the effects will not be negative.

These results indicate that the effects of H4_ELT on Pacific lamprey migration conditions would generally be similar to those under Existing Conditions.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the effect is less than significant because it would not substantially reduce or degrade migration habitat or substantially reduce the number of fish as a result of mortality. There would be small to moderate negative effects of Alternative 4A on lamprey migration flows in the Sacramento River at Rio Vista, no effect (under H3_ELT) or moderately large benefits (under H4_ELT) in the Feather River, and no effect in the Sacramento River at Red Bluff and in the American River. Combined, these effects would not have a population level effect on Pacific lamprey. Therefore, the impact is less than significant and no mitigation is required.

Restoration Measures (Environmental Commitments 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

As described for other covered fishes, Alternative 4A includes a greatly reduced extent of restoration measures relative to Alternative 4 and Alternative 1A. The mechanisms of impacts of habitat restoration discussed for other covered species such as winter-run Chinook salmon generally would be similar for Pacific lamprey. Pacific lamprey would have the potential to encounter restoration-related effects. However, because the extent of restoration is limited to offsetting losses from construction of the water conveyance facilities, any such effects would be greatly limited compared to Alternative 1A and 4, for example.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

As noted for Alternative 1A's discussion of Impact AQUA-133, in-water and shoreline construction activities (e.g., riprap removal and levee breaching; shoreline excavation and recontouring) could increase turbidity, but Pacific lamprey are tolerant to such increases and implementation of the environmental commitments described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments* (Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; and Disposal of Spoils, Reusable Tunnel Material, and Dredged Material), would minimize or eliminate effects on Pacific lamprey.

NEPA Effects: The effects of short-term construction activities would not be adverse to Pacific lamprey because environmental commitments would limit the potential for construction-related effects.

CEQA Conclusion: As discussed for Alternative 1A, habitat restoration activities could result in short-term effects on Pacific lamprey but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental*

Commitments). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce Pacific lamprey habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

The factors influencing the potential effects of contaminants from restored areas on Pacific lamprey are discussed in the analysis of Impact AQUA-170 under Alternative 1A. Because the extent of habitat restoration under Alternative 4A is considerably reduced relative to Alternative 1A, any effects from contaminants also would be considerably reduced.

NEPA Effects: As noted for other covered fishes, while Alternative 4A habitat restoration actions may result in a very small increase production, mobilization, and bioavailability of methylmercury, selenium, copper, and pesticides in the aquatic system, any such releases would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation of these contaminants in Pacific lamprey. Overall, the effects of contaminants associated with restoration measures would not be adverse for Pacific lamprey.

CEQA Conclusion: As noted for other covered fishes, habitat restoration under Alternative 4A may result in increased production, mobilization, and bioavailability of contaminants in the aquatic system, but these would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation in Pacific lamprey. For methylmercury, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury in the limited restoration areas. Therefore, the impact of contaminants is considered less than significant because it would not substantially affect Pacific lamprey either directly or through habitat modifications. Consequently, no mitigation would be required.

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

Restored habitat under *Environmental Commitment 4 Tidal Natural Communities Restoration* and *Environmental Commitment 6 Channel Margin Enhancement* is intended to offset habitat loss/modification caused by construction and operation of the water facilities proposed under Alternative 4A.

NEPA Effects: The effects of restored habitat conditions on Pacific lamprey would not be adverse restoration could provide habitat benefits for lamprey.

CEQA Conclusion: As described above, habitat restoration would be undertaken to offset loss/modification of habitat from water facility construction and operation. The effects of restored habitat conditions on Pacific lamprey would be less than significant. Consequently, no mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

As noted for other covered species, Alternative 4A includes three other conservation measures, which are reduced in their extent relative to other Alternatives (e.g., Alternative 1A and Alternative 4). While the extent of these measures is reduced compared to these alternatives, the nature of the mechanisms for Pacific lamprey remains the same.

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (Environmental Commitment 12)

The impact discussion for winter-run Chinook salmon (Impact AQUA-46) is also applicable to Pacific lamprey.

NEPA Effects: The effects of methylmercury management on Pacific lamprey would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As noted for winter-run Chinook salmon, effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts on Pacific lamprey would be less than significant. Consequently, no mitigation is required.

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (Environmental Commitment 15)

It is possible, but not assured, that there would be some reduction in predation losses of Pacific lamprey under *Environmental Commitment 15 Localized Reduction of Predatory Fish*; for Alternative 4A, such efforts would be focused at the NDD and at the south Delta export facilities. There is uncertainty in the potential efficacy of Environmental Commitment 15 and also uncertainty in the importance of predation to Pacific lamprey. Due to these uncertainties, there would be no demonstrable effect of this conservation measure on Pacific lamprey.

NEPA Effects: Consistent with the analysis for Alternative 1A and reflecting the above discussion, the overall effect would not be adverse.

CEQA Conclusion: Consistent with the analysis for Alternative 1A and reflecting the above discussion, the impact is considered less than significant. Consequently, no mitigation would be required.

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (Environmental Commitment 16)

As described for winter-run Chinook salmon, under Alternative 4A, an NPB at the divergence of Georgiana Slough from the Sacramento River would be implemented to guide juvenile salmonids away from Georgiana Slough and the interior Delta, wherein survival is relatively low compared to the Sacramento River (Perry et al. 2010). As described in the *BDCP Effects Analysis*, the effects of an NPB at this location would be expected to have little to no effect on Pacific lamprey because of their physiology (limited hearing ability in the range employed by the NPB's acoustic deterrence stimuli; see section 5C.5.3.9 in *BDCP Effects Analysis Appendix 5.C* and section 5.B.6.1.11.1 *BDCP Effects Analysis Appendix 5.B, both hereby incorporated by reference*). As noted in the discussion of Impact AQUA-180 for Alternative 1A, the NPB may attract piscivorous predators but the additional predation on Pacific lamprey is expected to be low.

NEPA Effects: The overall effect of the NPB on Pacific lamprey would not be adverse because of their limited hearing ability in the range employed by the NPB's acoustic deterrence stimuli.

CEQA Conclusion: Consistent with the analysis for Alternative 1A and reflecting the above discussion, the impact of the NPB on Pacific lamprey is considered less than significant because of their limited hearing ability in the range employed by the NPB's acoustic deterrence stimuli. Consequently, no mitigation would be required.

River Lamprey

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

The potential effects of construction of water conveyance facilities on river lamprey would be the same as those described for Alternative 4 Impact AQUA-181. This section provides additional detail on underwater noise impacts which are also applicable to Impact AQUA-181 in Alternative 4.

Table 11-8 presents the life stages of river lamprey and months of their potential presence in the north, east, and south Delta during the proposed in-water construction window (June 1–October 31). Little is known about the distribution and abundance of river lamprey, but salvage records at the south Delta export facilities indicate that they could be present in the Delta during this period. It is assumed that the discussion above for Pacific lamprey generally applies to river lamprey. Thus, underwater construction noise could adversely affect small numbers of river lamprey but would not result in significant population-level effects.

NEPA Effects: As concluded for Alternative 4, Impact AQUA-181, the effect would not be adverse for river lamprey. Implementation of the measures described in Appendix 3B, *Environmental Commitments*, such as *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan* would guide rapid and effective response in the case of inadvertent spills of hazardous materials. This species' natural tolerance to turbidity would likely avoid the risk of any adverse turbidity effects resulting from project construction. Construction would not be expected to increase predation rates relative to baseline conditions. Construction will result in both temporary and permanent alteration of rearing and migratory habitats used by river lamprey. However, Alternative 4A includes Environmental Commitment 4 to restore tidal habitat. The direct effects of underwater construction noise on river lamprey that may be present could be adverse if river lamprey are exposed. However, implementation of Mitigation Measures AQUA-1a and AQUA-1b, combined with the in-water work window that would minimize exposure, would reduce the potential for effects from underwater noise and this effect would not be adverse.

CEQA Conclusion: As described in Alternative 4, Impact AQUA-181, the impact of the construction of water conveyance facilities on river lamprey would not be significant except for construction noise associated with pile driving. Construction of Alternative 4A involves several elements with the potential to affect river lamprey. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A (see Impact AQUA-182) except that only three intakes would need to be maintained under Alternative 4 rather than five under Alternative 1A, resulting in less impacts. As concluded in Alternative 1A, Impact AQUA-182, the impact would not be adverse for river lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-182, the impact of the maintenance of water conveyance facilities on river lamprey would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

Water Exports

The impact on entrainment of river lamprey at water operations facilities in the south and north Delta is expected to be the same as described for Pacific lamprey (see Impact AQUA-165). Entrainment losses at the south Delta facilities would be reduced for both flow scenarios under Alternative 4A compared to NAA_ELT. The potential impacts at the proposed new north Delta intakes are unknown since little is known about the river lamprey life history in the Delta.

Predation Associated with Entrainment

Entrainment-related predation loss of lamprey at the south Delta facilities would not be greater under this Alternative compared to the NAA_ELT and may be lower due to a reduction in entrainment loss. Conditions under Scenario H4_ELT would decrease predation loss relative to NAA_ELT and Scenario H3_ELT. Predation at the north Delta would be increased due to the installation of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta facilities is unknown because of the lack of knowledge about their distribution and population abundances in the Delta.

NEPA Effects: Overall, the effect of entrainment and entrainment-related predation would not be adverse because entrainment, and predation associated with entrainment, would be reduced under Alternative 4A.

CEQA Conclusion: As described above for Pacific lamprey (which is assumed to have the same entrainment effects as river lamprey), annual entrainment losses of lamprey would be substantially reduced under both flow scenarios for Alternative 4A relative to existing biological conditions. Lamprey predation loss at the south Delta facilities would not be increased relative to Existing Conditions and may be decreased due to reduction entrainment losses. The impact of predation loss at the north Delta is unknown, since there is little available knowledge on the distribution and abundance in the Delta, especially in the vicinity of the proposed new north Delta intakes. Overall, the impacts of Alternative 4A water operations to river lamprey are considered less than significant because they would reduce entrainment and potentially entrainment-related predation. No mitigation would be required.

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

In general, the effect of Alternative 4A would be negligible relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flow-related impacts to river lamprey spawning habitat were evaluated by estimating effects of flow alterations on redd dewatering risk as described for Pacific lamprey with appropriate time-frames for river lamprey incorporated into the analysis. The same locations were analyzed as for Pacific lamprey: the Sacramento River at Keswick and Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and the American River at Nimbus Dam and at the confluence with the Sacramento River. River lamprey spawn in these rivers between February and June so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage).

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, and substrate) of river lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, as described for Pacific lamprey, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, February to June.

There would be negligible differences between H3_ELT and NAA_ELT in exposure to flow reductions in all rivers except for a small decrease (8% lower) in the American River at Nimbus Dam (Table 11-4A-127). These results indicate that H3_ELT would not have biologically meaningful effects on river lamprey redd cohorts predicted to experience a month-over-month change in flow of greater than 50% in all locations analyzed.

Table 11-4A-127. Differences between Model Scenarios in Dewatering Risk of River Lamprey Redd Cohorts[a]

Location	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Sacramento River at Keswick	3 (9%)	0 (0%)
Sacramento River at Red Bluff	4 (11%)	1 (3%)
Trinity River downstream of Lewiston	-2 (-3%)	0 (0%)
Feather River below Thermalito Afterbay	-3 (-4%)	-3 (-4%)
American River at Nimbus	4 (7%)	-5 (-8%)
American River at Sacramento River confluence	12 (20%)	0 (0%)

[a] Difference and percent difference between model scenarios in the number of river lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%. Positive values indicate a higher value in H3_ELT than in Existing Conditions or NAA_ELT.

River lamprey generally spawn between February and June (Beamish 1980; Moyle 2002). Using Pacific lamprey as a surrogate, eggs are assumed to hatch in 18-49 days depending on water temperature (Brumo 2006) and are, therefore, assumed to be present during roughly the same period and locations as spawners. Moyle et al. (1995) indicate that river lamprey "adults need… temperatures [that] do not exceed 25°C," although there is no mention of thermal requirements for eggs in this or any existing literature. Meeuwig et al. (2005) reported that, for Pacific lamprey eggs, significant reductions in survival were observed at 22°C (71.6°F). Therefore, for this analysis, both temperatures, 22°C (71.6°F) and 25°C (77°F), were used as upper thresholds of river lamprey eggs. The analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) or 25°C (77°F) using daily data from USRWQM. For other rivers, the analysis predicted the number of consecutive two-month periods during which at least one month exceeds 22°C (71.6°F) or 25°C (77°F) using monthly averaged data from the Bureau's temperature model. Each individual day or month starts a new "egg cohort" such that there are 12.320 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from February 1 through June 30, and 405 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Spawning locations of river lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

For both thresholds, there would be few differences in egg cohort exposure between NAA_ELT and H3_ELT among all sites (Table 11-4A-128). In most cases, absolute differences account for <5% of the total number of cohorts. The two exceptions are for the 71.6 °F threshold in the Feather River at Thermalito Afterbay (7% absolute increase) and for the 77 °F threshold in American River at the Sacramento River Confluence (11% absolute decrease). However, due to the low magnitude and frequency, there would be no population level effects of this increase and decrease in temperature exposure to river lamprey eggs.

Table 11-4A-128. Differences (Percent Differences) between Model Scenarios in River Lamprey Egg Cohort Temperature Exposure[a]

Location	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
Temperatures above 71.6°F		
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	100 (NA)	-1 (-1%)
Trinity River at Lewiston	0 (NA)	0 (NA)
Trinity River at North Fork	1 (NA)	0 (0%)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	11 (122%)	7 (54%)
American River at Nimbus	12 (240%)	-2 (-11%)
American River at Sacramento River Confluence	18 (64%)	-11 (-19%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	11 (1100%)	0 (0%)
Temperatures above 77°F		
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	0 (NA)	0 (NA)
Trinity River at Lewiston	0 (NA)	0 (NA)
Trinity River at North Fork	0 (NA)	0 (NA)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	2 (NA)	2 (NA)
American River at Nimbus	1 (NA)	0 (0%)
American River at Sacramento River Confluence	3 (NA)	0 (0%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Difference and percent difference between model scenarios in the number of river lamprey egg cohorts experiencing water temperatures above 71.6°F and 77°F during February through June on at least one day during a 49-day incubation period in the Sacramento River or for at least one month during a 2-month incubation period in other rivers for each model scenario. Positive values indicate a higher value in H3_ELT than in EXISTING CONDITIONS or NAA_ELT.

H4_ELT/HOS

Flows during January through August under H4_ELT would generally be similar to or greater than flows under H3_ELT in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H4_ELT in these rivers and results for H4_ELT would be the same as those for H3_ELT.

In the Feather River at Thermalito Afterbay, there would be 23 more cohorts (20%) exposed to a 50% month over month drop in flow rate under H4_ELT relative to NAA_ELT (Table 11-4A-129). This change of 23 cohorts out of 410 cohorts equated to ~6% of all cohorts, which is not considered substantial to the population.

Table 11-4A-129. Differences between Model Scenarios in Dewatering Risk of River Lamprey Redd Cohorts[a]

Location	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
Feather River at Thermalito Afterbay	-14 (-9%)	23 (20%)

[a] Difference and percent difference between model scenarios in the number of river lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%. Positive values indicate a higher value in H1 or H4_ELT than in Existing Conditions or NAA_ELT.

Water temperatures would not differ between H4_ELT and H3_ELT and, therefore, no egg cohort temperature analyses were conducted. Overall, results for H4_ELT would be similar to those for H3_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. Effects of Alternative 4A on river lamprey redd dewatering risk and exposure risk of eggs to elevated water temperatures would be small or negligible for all locations analyzed.

CEQA Conclusion: Collectively, the results of the Impact AQUA-166 CEQA analysis show that the difference between the CEQA baseline and Alternative 4A is less than significant.

H3_ELT/ESO_ELT

Dewatering risk during the river lamprey spawning period from February to June would generally be similar to slightly higher under H3_ELT relative to Existing Conditions (Table 11-4A-127). The largest difference would be in the American River at the Sacramento River confluence (12 cohorts, or 20% increase). An increase in 12 cohorts of the 410 total cohorts would represent <3% of total cohorts. As a result, it is concluded that this increase would not represent a biological meaningful effect to river lamprey.

Egg cohort temperature exposure results are reported in Table 11-4A-128. There would be either negligible differences or an increase in exposure of egg cohorts (11 to 18 cohorts, or 64% to 1,100%) under H3_ELT relative to Existing Conditions to temperatures above 71.6°F in the Feather River, American River, and Stanislaus River and an increase of up to 100 cohorts in the Sacramento River. However, none of these increases would compose more than 5% of the 410 total ammocoete cohort count and, therefore, would not be biologically relevant to the species. There would be negligible differences in the number of cohorts exposed to temperatures above 77°F under H3_ELT relative to Existing Conditions.

H4_ELT/HOS

Flows during February through June under H4_ELT would generally be similar to or greater than flows under H3_ELT in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H4_ELT in these rivers and results for H4_ELT would be the same as those for H3_ELT.

In the Feather River at Thermalito Afterbay, there would be 14 (9%) more cohorts (Table 11-4A-129). This increase would be too small to have a biologically meaningful effect on river lamprey.

Water temperatures under H4_ELT would be similar to those under H3_ELT for all rivers examined. Therefore, no additional cohort temperature exposure analyses were conducted for H4_ELT.

Overall, results for H4_ELT would be similar to those for H3_ELT.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the effect is less than significant because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. Effects of Alternative 4A on river lamprey redd dewatering risk and exposure risk of eggs to elevated water temperatures would be small or negligible for all locations analyzed. No mitigation is necessary.

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

In general, the effect of Alternative 4A would be negligible relative to the NAA_ELT.

H3_ELT/ESO_ELT

Flow-related impacts to river lamprey rearing habitat were evaluated by estimating of the frequency of rapid flow reductions in ammocoete rearing areas. Rapid reductions in flow can strand ammocoetes, leading to mortality. Comparisons of effects were made for ammocoete cohorts, as described for Pacific lamprey, in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River.

As for Pacific lamprey, the analysis of river lamprey ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (February through June) and spend 5 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than the flow reduction at any time during the period.

Comparisons of H3_ELT to NAA_ELT for the Sacramento River at Keswick (Table 11-4A-130) indicate that there would be no effect (0%) or negligible effects (≤5%) attributable to H3_ELT in all flow reduction categories.

Table 11-4A-130. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
-50%	0	0
-55%	2	0
-60%	6	5
-65%	1	-4
-70%	0	-5
-75%	4	3
-80%	7	0
-85%	111	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

Results of comparisons for the Sacramento River at Red Bluff indicates that H3_ELT would have negligible effects (<5%) in all but the 55% flow increase category, which would cause a 6% increase in cohort exposure (Table 11-4A-131). Overall, this indicates that there would be minimal effect on ammocoete exposure.

Table 11-4A-131. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Red Bluff

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
-50%	0	2
-55%	6	6
-60%	4	-2
-65%	-2	-3
-70%	2	0
-75%	19	0
-80%	23	0
-85%	0	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

Comparisons for the Trinity River indicate that there would be no or negligible differences in ammocoete cohorts exposed flow reductions between H3_ELT and NAA_ELT for all flow reduction categories except 80-90%, which would be 5 to 11% higher under H3_ELT (Table 11-4A-132).

Table 11-4A-132. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Trinity River at Lewiston

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
-50%	0	0
-55%	0	0
-60%	0	0
-65%	0	0
-70%	0	0
-75%	27	0
-80%	30	5
-85%	33	6
-90%	49	11

[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

In the Feather River at Thermalito Afterbay, there would be no difference in ammocoete cohort exposure at the 50% through 75% flow reductions (Table 11-4A-133). For the 80% through 90% flow reductions, ammocoete exposure would be 5% to 64% lower, which due to the low frequency with which 85% and 90% reductions in flow would occur, would not be frequent enough to have a biologically meaningful effect on river lamprey ammocoete rearing. These results indicate that there will be no effects of H3_ELT on river lamprey ammocoete rearing in the Feather River.

Table 11-4A-133. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Feather River at Thermalito Afterbay

[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

Comparisons for the American River at Nimbus Dam (Table 11-4A-134) and at the confluence with the Sacramento River (Table 11-4A-135) have similar results. There would be no or negligible differences in cohort exposure between NAA_ELT and H3_ELT for most flow reduction categories. There would be higher cohort exposure under H3_ELT relative to NAA_ELT at Nimbus Dam at the 75% and 80% flow reductions (19% and 22% higher, respectively) and at the confluence with the

Sacramento River at the 80% and 85% flow reductions (9% and 32% higher, respectively) flow reductions. These results indicate that there would generally be no effect of H3_ELT on stranding risk in the American River with few small exceptions that would not be common enough to have biologically meaningful effects.

[a] Negative values indicate reduced cohort exposure, a benefit of H3_ELT.

Because the thermal tolerance of river lamprey ammocoetes is unknown, the thermal tolerance of Pacific lamprey ammocoetes of 22°C (71.6°F) and of river lamprey adults of 25°C (77°F) (Moyle et al. 1995) was used. River lamprey ammocoetes rear upstream for 3–5 years (Moyle 2002). To be conservative, this analysis assumed a maximum ammocoete duration of 5 years. Each individual day or month starts a new "cohort" such that there are 18,730 cohorts for the Sacramento River, corresponding to 82 years of ammocoetes being "born" every day each year from January 1 through August 31, and 380 cohorts for the other rivers using monthly data over the same period.

There would be differences in the number of ammocoete cohorts exposed to temperatures greater than the thresholds in most of the rivers, particularly for the 77°F threshold (Table 11-4A-136). However, each river with an increase in exposure would also have a site with a decrease in exposure of similar magnitude, except in the Feather River for the 77°F threshold. Overall, the increases and decreases are expected to balance out within rivers such that there would be no overall effect on river lamprey ammocoetes.

Table 11-4A-136. Differences (Percent Differences) between Model Scenarios in River Lamprey Ammocoete Cohorts Exposed to Temperatures in the Feather River Greater than 71.6°F and 77°F in at Least One Month

Location	EXISTING CONDITIONS vs. H3_ELT	NAA_ELT vs. H3_ELT
71.6°F Threshold		
Sacramento River at Keswick[b]	0 (NA)	0 (NA)
Sacramento River at Hamilton City[b]	5775 (NA)	-11 (-0.2%)

Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Positive values indicate a higher value in H3_ELT than in EXISTING CONDITIONS or NAA_ELT.

[b] Based on daily data; all other locations use monthly data; 1922–2003.

H4_ELT/HOS

There would be generally no differences in mean flows year-round between H4_ELT and H3_ELT in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between NAA_ELT and H4_ELT at the 50% through 80% flow reductions (Table 11-4A-137). For the 85% and 90% flow reductions, ammocoete exposure under H4_ELT would be 14% and 47% higher, respectively.

Table 11-4A-137. Percent Difference between Baselines and H4_ELT Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Feather River at Thermalito Afterbay

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H4_ELT	NAA_ELT vs. H4_ELT
-50%	0	0
-55%	0	0
-60%	0	0
-65%	0	0
-70%	0	0
-75%	0	0
-80%	2	5
-85%	22	14
-90%	57	47

[a] Negative values indicate reduced cohort exposure under H4_ELT.

There would generally be no differences in mean water temperatures year-round between H4_ELT and H3_ELT in any river examined. As a result, no additional ammocoete cohort exposure analyses were conducted for H4_ELT. Results of these analyses for H4_ELT would be the same as those for H3_ELT.

Overall, these results indicate that results for H4_ELT would generally be similar to those under H3_ELT except for an increase in ammocoete stranding risk exposure in the Feather River at 85% and 90% flow reductions under H4_ELT. The 85% and 90% flow reductions would occur rarely—19 and 7 times under NAA_ELT and 22 and 10 times, respectively—under H4_ELT, throughout the 985 months evaluated. Therefore, these reductions would affect a small proportion of the population. These results indicate that there would be no biologically meaningful effect of H4_ELT on stranding risk.

NEPA Effects: These modeling results indicate the effect would not be adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish through ammocoete mortality. Project-related effects on flow reductions and effects on water temperatures in all locations analyzed would be negligible and would not affect river lamprey ammocoete stranding risk and rearing success because the changes would not be large enough or frequent enough to be biologically meaningful.

CEQA Conclusion: In general, Alternative 4A would reduce the quantity and quality of rearing habitat for river lamprey relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of rearing habitat for river lamprey relative to NAA_ELT.

H3_ELT/ESO_ELT

Comparisons of H3_ELT to Existing Conditions for the Sacramento River at Keswick indicate negligible effects (<5%) or small increases (to 7%) for ammocoete cohort exposures to flow reductions from 50% to 80% and 90%, and a more substantial increase in exposure (111%) to 85% flow reduction events (Table 11-4A-130). Comparisons for the Sacramento River at Red Bluff indicate similar results with negligible effects (<5%) or small increases in exposure (to 6%) for 50% to 70% and 85% to 90% flow reduction categories, and a more substantial increases in exposure (19% to 23%) in the 80% and 85% flow reduction categories, respectively (Table 11-4A-131). Based on the prevalence of small and negligible effects, the effects of a more substantial increase in flow reductions in a single flow reduction category would not be considered biologically meaningful to river lamprey in the Sacramento River.

Comparisons for the Trinity River between H3_ELT and Existing Conditions indicated no effect (0%) for the lower flow reduction categories up to 70%, and increases in occurrence ranging from 27% to 49% for the 75% through 90% flow reduction categories (Table 11-4A-132). The prevalence of increased occurrence of higher-magnitude flow reductions would affect river lamprey ammocoete stranding in the Trinity River.

Comparisons for the Feather River between H3_ELT and Existing Conditions indicated no effect (0%) or reductions in frequency of occurrence for all flow reduction categories, with 7% to 61% reductions in cohorts exposed to 80% to 90% flow reduction events (Table 11-4A-133). Due to the low frequency with which 85% and 90% reductions in flow would occur, would not be frequent enough to have a biologically meaningful effect on river lamprey ammocoete rearing.

Comparisons for the American River at Nimbus Dam (Table 11-4A-134) and at the confluence with the Sacramento River (Table 11-4A-135) between H3_ELT and Existing Conditions indicate a 45% to 292% increased chance of occurrence of flow reductions between 70 and 85% under H3_ELT compared to NAA_ELT at Nimbus Dam and a 20% to 270% increased chance of occurrence of flows reductions between 70% and 85% at the confluence with the Sacramento River. The prevalence of increased occurrence of higher-magnitude flow reductions would constitute a biologically meaningful effect on river lamprey ammocoete stranding in the American River.

The number of ammocoete cohorts exposed to 71.6°F under H3_ELT (including climate change) would be up to 620% higher than those under Existing Conditions in most locations examined (Table 11-A1-136). The number of ammocoete cohorts exposed to 77°F would be similar between Existing Conditions and H3_ELT in the Sacramento, Trinity, and Stanislaus Rivers, but 50 to 80 cohorts higher in the Feather and American Rivers (percent differences could not be calculated because there would be 0 cohorts under Existing Conditions).

H4_ELT/HOS

There would be generally no differences in mean flows year-round between H4_ELT and H3_ELT in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between Existing Conditions and H4_ELT at the 50% through 80% flow reductions (Table 11-4A-137). There would be 22% and 57% more cohorts exposed to 85% and 90% flow reductions, respectively, under H3_ELT relative to Existing Conditions.

There would generally be no differences in mean water temperatures year-round between H4_ELT and H3_ELT in any river examined. As a result, no additional ammocoete temperature cohort exposure analyses were conducted for H4_ELT. Results of these analyses for H4_ELT would be the same as those for H3_ELT.

Overall, these results indicate that results for H4_ELT would generally be similar to those under H3_ELT.

Summary of CEQA Conclusion

Under Alternative 4A, there would be moderate to substantial persistent increases in occurrence of flow reduction events for Alternative 4A with respect to Existing Conditions for the Trinity River (up to 49%) and the American River at Nimbus Dam (up to 292%) and at the confluence with the Sacramento River (up to 270%) that would increase river lamprey ammocoete stranding risk and therefore rearing success for these locations. There would be a beneficial effect from reduced occurrence of flow reductions in the Feather River (up to 61% reduction) but this effect would not be sufficient to offset the negative effects from increased occurrence of flow reductions at the other locations. Further, stranding risk under H4_ELT in the Feather River would be higher than those under H3_ELT, such that the benefits under H3_ELT would not occur under these H4_ELT. There would also be increases under Alternative 4A in ammocoete cohort exposure to critical water temperatures in the Feather and American rivers that would have effects on rearing success through ammocoete mortality. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce rearing habitat and substantially reduce the number of river lamprey as a result of fry and juvenile mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, project-related effects on flow reductions and effects on water temperatures in all locations analyzed would be negligible and would not affect river lamprey ammocoete stranding risk and rearing success. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 4A and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, the impact is less than significant and no mitigation is required.

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

In general, the effect of Alternative 4A on river lamprey migration conditions would be negligible relative to the NAA_ELT.

H3_ELT/ESO_ELT

After 3 to 5 years, river lamprey ammocoetes migrate downstream and become macropthalmia once they reach the Delta. River lamprey migration generally occurs September through November (USFWS unpublished data). The effects of H3_ELT on seasonal migration flows for river lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the likely migration pathways of river lamprey during the likely migration period (September through November) were examined to predict how H3_ELT may affect migration flows for outmigrating macropthalmia. Analyses were conducted for the Sacramento River at Red Bluff, Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

The adult river lamprey upstream migration period also occurs between September and June. Therefore, results presented below represent effects to the migration of both macropthalmia and adult river lamprey. CALSIM II flow outputs were examined during these periods for each model scenario.

Sacramento River

Mean monthly flow rates for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the September to November river lamprey macropthalmia and adult migration periods. Flows under H3_ELT would generally be similar to or up to 18% lower than flows under NAA_ELT during September and November and similar to flows under NAA_ELT during October. Because of the relatively small magnitude, reduced flows during November are not likely to cause biologically meaningful effects on river lamprey migration.

Feather River

Flows in the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the September to November river lamprey macropthalmia and adult migration periods. Flows under H3_ELT would generally be up to 27% lower than flows under NAA_ELT during September, up to 17% higher than flows under NAA_ELT during October, and similar to flows under NAA_ELT during November. Based on occurrence of negligible effects or increases in flow that would have a beneficial effect on migration conditions, with decreases predicted for wetter water years when effects on migration conditions would not be as critical, these results indicate that effects of NAA_ELT on flows would not have biologically meaningful negative effects on migration conditions in the Feather River.

American River

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the September through November macropthalmia and adult migration periods. Flows under H3_ELT would be lower than flows under NAA_ELT during September and November and similar to flows during October. These results indicate that project-related effects would include small to moderate decreases in flow under H3_ELT for some months and water year types.

H4_ELT/HOS

Flows under H4_ELT in the Sacramento River at Red Bluff would be similar to flows under NAA_ELT during September and October and up to 15% lower during November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT in the Feather River at the confluence with the Sacramento River would generally be up to 38% lower than flows under H3_ELT in September and mixed (higher, lower, and similar) during October and November. Flows under H4_ELT in the American River at the confluence with the Sacramento River would generally be lower than those under NAA_ELT but up to 22% during September and November and similar during October. These results indicate that project-related effects would include small to moderate decreases in flow under H4_ELT for some months and water year types.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. H3_ELT would primarily have negligible effects (<5%), small increases or decreases in flow, or decreases in wetter water year types and/or during a limited portion of the migration period that would not have negative effects on migration conditions. There would be beneficial effects from moderate increases in flow for some months and water year types in the Feather River (to 34%) and American River (to 24%); however, the beneficial effect would be partially offset by flow reductions during other months of the migration periods. Flows under H4_ELT would be similar to those under H3_ELT.

CEQA Conclusion: In general, Alternative 4A would reduce the quantity and quality of migration habitat for river lamprey relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 4A would not affect the quantity and quality of migration habitat for river lamprey.

H3_ELT/ESO_ELT

For the Sacramento River at Red Bluff, comparisons of mean monthly flow rate for H3_ELT to Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate that flows under H3_ELT would be up to 22% lower than those under Existing Conditions during October and November. During September, flows would be higher in wetter years and lower in drier years.

Comparisons for the Feather River at the confluence with the Sacramento River indicate (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate highly variable effects of H3_ELT relative to Existing Conditions depending on month and water year type. Combining all water year types, flows would be 28% higher during September, 8% lower during October, and 5% lower during November.

Comparisons for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for September through November indicate reductions in flows in September and November of up to 47% and variable changes of 11% lower to 15% higher during October depending on water year type. Overall, these results show that flows would be reduced in the American River during this period relative to Existing Conditions.

H4_ELT/HOS

Flows under H4_ELT in the Sacramento River at Red Bluff would be similar to or greater than flows under Existing Conditions during September through November, although highly variable during September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4_ELT in the Feather River at the confluence with the Sacramento River would be higher and lower than flows under Existing Conditions depending on month and water year type, but lower overall. Flows under H4_ELT in the American River at the confluence with the Sacramento River would generally be up to 47% lower than flows under Existing Conditions. Overall, migration conditions for river lamprey under H4_ELT would be less favorable than conditions under Existing Conditions.

Summary of CEQA Conclusion

Under Alternative 4A, there would be moderate and persistent flow reductions for substantial portions of the river lamprey macropthalmia migration period in the American River, and less persistent and smaller magnitude flow reductions in the Sacramento River and Feather River. These flow reductions would affect juvenile migration success, increase straying, and delay access to the ocean. If in fact, lamprey use these cues to find natal spawning grounds, these flow reductions may also affect adult migration success, including a reduction in the ability for adults to sense olfactory cues. There would be beneficial effects from increases in flow for some months and water year types in each location. However, this effect would not be sufficient to offset the negative effects of flow reductions for the remainder of the migration period and/or in other water year types, particularly drier water year types when effects of flow reductions would be more critical. Flows under H4_ELT would be less favorable than those under H3_ELT. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 4A could be significant because the alternative could substantially reduce migration conditions for river lamprey.

However, this interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA_ELT, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would generally be negligible effects on mean monthly flow and water temperatures for river lamprey migration periods at all locations analyzed. Therefore, this impact is less than significant and no mitigation is required,

Restoration Measures (Environmental Commitment Environmental Commitment 4, Environmental Commitment 6, Environmental Commitment 7, and Environmental Commitment 10)

The discussion of the effects of restoration measures for Pacific lamprey is also applicable to river lamprey.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Refer to Impact AQUA-169 under Pacific lamprey for a discussion of the effects of construction of restoration measures on river lamprey.

NEPA Effects**:** The effects of short-term construction activities would not be adverse to river lamprey because environmental commitments would limit the potential for construction-related effects.

CEQA Conclusion**:** As discussed for Alternative 1A, habitat restoration activities could result in short-term effects on river lamprey but would be localized, sporadic, and of low magnitude; such effects would be avoided by limiting the frequency, duration, and spatial extent of in-water work and with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments*). The potential impact of habitat restoration activities is considered less than significant because it would not substantially reduce river lamprey habitat, restrict its range, or interfere with its movement. No additional mitigation would be required.

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Refer to Impact AQUA-169 under Pacific lamprey for a discussion of the effects of contaminants associated with restoration measures on river lamprey, which are assumed to have similar potential for exposure and effects of exposure for contaminant-related effects.

NEPA Effects: As noted for other covered fishes, while Alternative 4A habitat restoration actions may result in a very small increase production, mobilization, and bioavailability of methylmercury, selenium, copper, and pesticides in the aquatic system, any such releases would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation of these contaminants in river lamprey. Overall, the effects of contaminants associated with restoration measures would not be adverse for river lamprey.

CEQA Conclusion: As noted for other covered fishes, habitat restoration under Alternative 4A may result in increased production, mobilization, and bioavailability of contaminants in the aquatic system, but these would be short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation in river lamprey. For methylmercury, implementation of *Environmental Commitment 12 Methylmercury Management* would help to minimize the increased mobilization of methylmercury in the limited restoration areas. Therefore, the impact of contaminants is considered less than significant because it would not substantially affect river lamprey either directly or through habitat modifications. Consequently, no mitigation would be required.

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

Refer to Impact AQUA-170 under Pacific lamprey for a discussion of the effects of restored habitat conditions on river lamprey.

NEPA Effects: The effects of restored habitat conditions on river lamprey would not be adverse because restoration could provide habitat benefits for lamprey.

CEQA Conclusion: As described in the discussion for Pacific lamprey, habitat restoration would be undertaken to offset loss/modification of habitat from water facility construction and operation. The effects of restored habitat conditions on river lamprey would be less than significant. Consequently, no mitigation would be required.

Other Environmental Commitments (Environmental Commitment 12, Environmental Commitment 15, and Environmental Commitment 16)

The discussion of the effects of other conservation measures for Pacific lamprey is also applicable to river lamprey.

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (Environmental Commitment 12)

Refer to Impact AQUA-46 under winter-run Chinook salmon for a discussion of the effects of methylmercury management on river lamprey.

NEPA Effects: The effects of methylmercury management on river lamprey would not be adverse because it is expected to reduce overall methylmercury levels resulting from habitat restoration.

CEQA Conclusion: As noted for winter-run Chinook salmon, effects of *Environmental Commitment 12 Methylmercury Management* within the areas restored under Alternative 4A are expected to reduce overall methylmercury levels resulting from habitat restoration. Because it is designed to improve water quality and habitat conditions, impacts on river lamprey would be less than significant. Consequently, no mitigation is required.

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (Environmental Commitment 15)

Refer to Impact AQUA-175 under Pacific lamprey for a discussion of the effects of predator management on river lamprey.

NEPA Effects: Consistent with the analysis for Alternative 1A and reflecting the above discussion for Pacific lamprey, which is expected to have similar predators, the overall effect would not be adverse.

CEQA Conclusion: Consistent with the analysis for Alternative 1A and reflecting the discussion for Pacific lamprey, the impact is considered less than significant. Consequently, no mitigation would be required.

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (Environmental Commitment 16)

Refer to Impact AQUA-176 under Pacific lamprey for a discussion of the effects of nonphysical fish barriers on river lamprey.

NEPA Effects: The overall effect of the NPB on Pacific lamprey would not be adverse because of their limited hearing ability in the range employed by the NPB's acoustic deterrence stimuli.

CEQA Conclusion: Consistent with the analysis for Alternative 1A and reflecting the above discussion, the impact of the NPB on Pacific lamprey is considered less than significant because of their limited hearing ability in the range employed by the NPB's acoustic deterrence stimuli. Consequently, no mitigation would be required.

Non-Covered Aquatic Species of Primary Management Concern

Construction and Maintenance of Water Conveyance Facilities

The effects of construction and maintenance of the water conveyance facilities under Alternative 4A would be similar in nature for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-1 under delta smelt for a discussion of the types of effects of construction of water conveyance facilities that are relevant to non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of water conveyance facilities under Alternative 4A would the same as those for Alternative 4. Implementation of the measures described in Appendix 3B, *Environmental Commitments*, such as *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan* would guide rapid and effective response in the case of inadvertent spills of hazardous materials. Construction would not be expected to increase predation rates relative to baseline conditions. Construction will result in both temporary and permanent alteration of rearing and migratory habitats. However, Alternative 4A includes Environmental Commitment 4 to restore tidal habitat and Environmental Commitment 6 to restore channel margin habitat. The direct effects of underwater construction noise on species that may be present could be adverse if they are exposed. However, implementation of Mitigation Measures AQUA-1a and AQUA-1b, combined with the in-water work window that would minimize exposure, would reduce the potential for effects from underwater noise and this effect would not be adverse.

Consistent with the conclusion for Alternative 4, Impact AQUA-1, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for non-covered aquatic species of primary management concern.

CEQA Conclusion: Consistent with the conclusion for Alternative 4, Impacts AQUA-1 and AQUA-199, the impact of the construction of the water conveyance facilities on non-covered aquatic species of primary management concern would not be significant except for construction noise associated with pile driving. Construction of Alternative 4A involves several elements with the potential to affect these fish species. However, these turbidity and hazardous material spill effects will be effectively avoided and/or minimized through implementation of environmental commitments (see Impact AQUA-1 and Appendix 3B, *Environmental Commitments*: *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; *Fish Rescue and Salvage Plan*; and *Barge Operations Plan*). Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4A would be the same as those described for Alternative 4 (which draws on the analysis of Alternative 1A, Impact AQUA-2). California bay shrimp would not be affected because they do not occur in the vicinity and Sacramento-San Joaquin roach and hardhead are unlikely to be affected because their primary distributions are upstream. Consequently, the effects would not be adverse.

CEQA Conclusion: Consistent with the conclusion for Alternative 4, Impact AQUA-2 and Impact AQUA-200, the impact of the maintenance of water conveyance facilities on non-covered species of primary management concern would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

The effects of water operations of the water conveyance facilities under Alternative 4A include a detailed analysis of the following species.

- Striped bass
- American shad
- Threadfin shad
- Largemouth bass
- Sacramento tule perch
- Sacramento-San Joaquin roach – California species of special concern
- Hardhead – California species of special concern

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

A revised analysis of Impact AQUA-201 for all alternatives, including Alternative 4A, is provided in Chapter 11, Section 11.3.5, in Appendix A. The analysis below for Alternative 4A draws on that analysis.

Striped Bass
