- C.38. Sacramento River at Mallard Slough Salinity
- C.39. Sacramento River at Port Chicago Salinity

Introduction

This section provides model CALSIM II and DSM2 model simulation results for alternatives evaluated for the BDCP EIR/EIS. Sections provided for each parameter include figures and tables in various formats to provide the reader with tools for multiple ways of analysis.

Different types of presentations are explained below:

- **Probability of Exceedance Plots:** Probability of exceedance plots provide the frequency of occurrence of values of a parameter that exceed a reference value. For this appendix, the calculation of exceedance probability is done by ranking the data. For example, for Shasta storage end of September exceedance plot, Shasta storage values at the end of September for each simulated year are sorted in ascending order. The smallest value would have a probability of exceedance of 100% since all other values would be greater than that value; and the largest value would have a probability of exceedance of 0%. All the values are plotted with probability of exceedance on the x-axis and the value of the parameter on the y-axis. Following the same example, if for one scenario, Shasta end of September of 2,000 TAF corresponds to 80% probability; it implies that Shasta end-of September storage is higher than 2,000 TAF in 80% of the years under the simulated conditions.
- **Monthly Pattern Plots:** Monthly pattern plots provide average values for a parameter for each month of the year. The averaging may be done on a long-term basis; which means that it is being averaged over the full number of simulated years, or it may be done for a set of simulated years that have a certain year type. In this appendix, year types are determined using the Sacramento Valley 40-30-30 Index developed by the State Water Resources Control Board (SWRCB). In this appendix, for year type based averages, the year type for each simulated year is assumed to be the classification of the year under current climate conditions. This type of plot is used to obtain insight to the monthly variation of phenomenon throughout the year.
- **Long Term Average Summary and Year Type Based Statistics Summary Tables:** These tables provide parameter values for each 10% increment of exceedance probability (rows) for each month (columns) as well as long-term and year-type averages (using the Sacramento Valley 40-30-30 Index developed by the SWRCB for current climate) for each month. For a few parameters, such as Delta outflow, annual total or average values are added to the tables (for volume and rates, respectively).
- **Long Term Average Summary and Dry and Critical Year Type Based Summary Tables:** these tables are primarily used to report average annual SWP and CVP deliveries for each hydrologic region. Values are averaged either for all the years (long-term) or for dry and critical years (using the Sacramento Valley 40-30-30 Index developed by the SWRCB for current climate). This table is also provided in a format that summarizes SWP and CVP agricultural and municipal and industrial deliveries to the north and south of Delta.
- **Long Term Average Summary for SWP Table A and Article 21 Deliveries:** This table provides firm and intermittent SWP deliveries on a long-term average basis.

- Long Term Average Summary for Total Delta Exports: This plot consists of stacked bars for north and south Delta exports to present the long-term and dry and critical year average (using the Sacramento Valley 40-30-30 Index developed by the SWRCB for current climate) for Delta exports.

All plots and tables are prepared to accommodate following comparisons:

- No Action Alternative at late-long term (with climate change and sea level rise) compared to existing conditions
- Alternatives at late-long term (with climate change and sea level rise) compared to existing conditions
- Alternatives at late-long term (with climate change and sea level rise) compared to the No Action Alternative at late-long term (with climate change and sea level rise)

Appropriate Use of Model Results

The physical models developed and applied in the BDCP analysis are generalized and simplified representations of a complex water resources system. A brief description of appropriate use of the model results to compare two scenarios or to compare against threshold values or standards is presented below.

Absolute vs. Relative Use of the Model Results

The models are not predictive models (in how they are applied in this project), and therefore the results cannot be considered as absolute with and within a quantifiable confidence interval. The model results are only useful in a comparative analysis and can only serve as an indicator of condition (e.g. compliance with a standard) and of trend (e.g. generalized impacts).

Appropriate Reporting Time-Step

Due to the assumptions involved in the input data sets and model logic, care must be taken to select the most appropriate time-step for the reporting of model results. Sub-monthly (e.g. weekly or daily) reporting of model results is inappropriate for all models and the results should be presented on a monthly basis.

Statistical Comparisons are Preferred

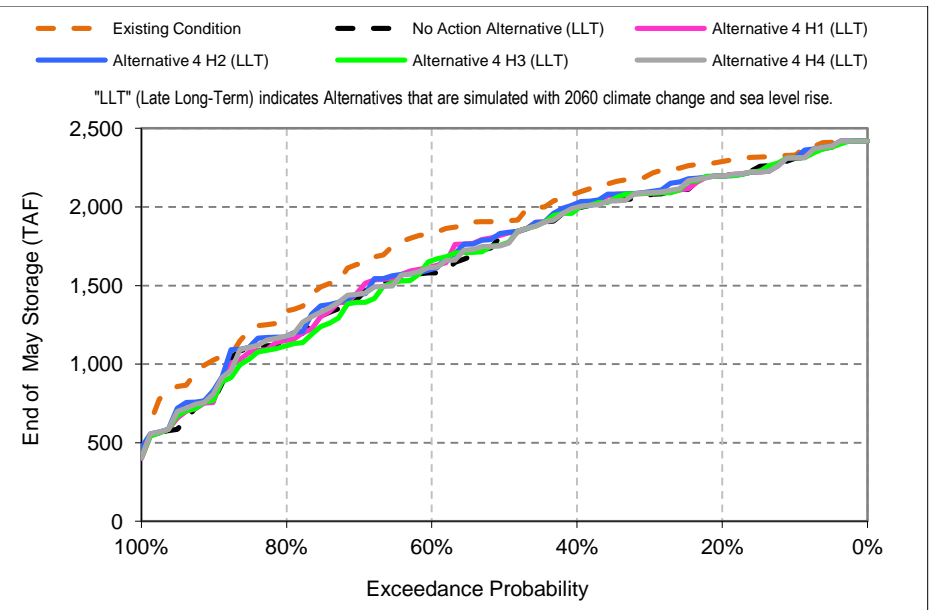

Absolute differences computed at a point in time between model results from an alternative and a baseline to evaluate impacts is an inappropriate use of model results (e.g. computing differences between the results from a baseline and an alternative for a particular day or month and year within the period of record of simulation). Likewise computing absolute differences between an alternative (or a baseline) and a specific threshold value or standard is an inappropriate use of model results. Statistics computed based on the absolute differences at a point in time (e.g. average of monthly differences) are an inappropriate use of model results. By computing the absolute differences in this way, disregards the changes in antecedent conditions between individual scenarios and distorts the evaluation of impacts of a specific action.

Reporting seasonal patterns from long-term averages and water year type averages is appropriate. Statistics computed based on long-term and water year type averages are an appropriate use of model results. Computing differences between long-term or water year type averages of model results from two scenarios are appropriate. Care should be taken to use the

appropriate water year type for presenting water year type average statistics of model results (e.g. D1641 Sacramento River 40-30-30 or San Joaquin River 60-20-20 based on assumed with or without climate modifications). Water year types are based on the current climate and hydrologic conditions and are not modified for the late-long term level of climate and hydrology.

The most appropriate presentation of monthly and annual model results is in the form of probability distributions and comparisons of probability distributions (e.g. cumulative probabilities). If necessary, comparisons of model results against threshold or standard values should be limited to comparisons based on cumulative probability distributions.

a Based on the 82-year simulation period

b As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999) calculated for current and future climate.

Positive differences highlighted in red indicate eastward movement of X2 position

"LLT" (Late Long-Term) indicates Alternatives that are simulated with 2060 climate change and sea level rise.

Alternative 4 H2 represents the enhanced spring delta outflow scenario of Alternative 4.

Notes:

1. Long Term is the average quantity for the period of Oct 1921 - Sep 2003.
2. Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of Oct 1921 - Sep 2003.
3. "LLT" (Late Long-Term) indicates Alternatives that are simulated with 2060 climate change and sea level rise.

Table C-13-22-2. CALSIM II Summary Reporting Metrics, Long-Term Average and Dry and Critical Year Averages

					Alternative 6A,6B,6C (LLT)	No Action Alternative (LLT)	Alternative 6A,6B,6C (LLT) minus No Action Alternative (LLT)
Water Supply Reliability							
North of Delta							
CVP Ag	Contract Delivery (annual average; does not include Exchange contractors)	(TAF/year)	Long Term Dry and Critical	142 32	161 44	-19 -12

Notes:

1. Long Term is the average quantity for the period of Oct 1921 - Sep 2003.
2. Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of Oct 1921 - Sep 2003.
3. "LLT" (Late Long-Term) indicates Alternatives that are simulated with 2060 climate change and sea level rise.

Note: "LLT" (Late Long-Term) indicates Alternatives that are simulated with 2060 climate change and sea level rise.

a Based on the 82-year simulation period

b As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999)
