Comparisons for the American River at the confluence with the Sacramento River for September through November indicate reductions in flow for all water year types in September (44% to 58%) and November (19% to 38%), but flow increases in all water years during October (5% to 45%). The overall predominance of decreased flows for Alternative 1A compared to Existing Conditions would affect migration conditions, with substantial decreases for dry and critical years in September (44 and 52%, respectively) and November (38 and 19%, respectively).

Overall, these results indicate that Alternative 1A would cause decreases in mean monthly flow during substantial portions of the river lamprey macropthalmia migration period in the Sacramento River (to -21%), Feather River (to -27%), and American River (to -58%), compared to Existing Conditions.

Adults

Effects of Alternative 1A on flow during the adult migration period, September through November, would be the same as described for the macropthalmia migration period, September through November, above.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-186 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 1A could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Reductions in flows during substantial portions of the macropthalmia and adult migration periods in the Sacramento and American Rivers would reduce migration ability of both life stages. For macropthalmia, reduced migration ability would increase straying risk and delay initiation of the oceanic life stage. For adults, reduced flows would reduce the ability to sense olfactory cues if adults use such cues to return to natal spawning grounds.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 1A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 1A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 1A. This indicates that the differences between Existing Conditions and Alternative 1A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 1A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration conditions for river lamprey. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Temporary Increases in Turbidity

As with Pacific lamprey (see Impact AQUA-169), river lamprey are tolerant of turbid water conditions and are unlikely to be affected by temporary increases in turbidity during restoration construction. Implementing the environmental commitments described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments* (*Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan; Fish Rescue and Salvage Plan*; and *Barge Operations Plan*), would minimize the potential for turbidity to affect river lamprey.

Increased Exposure to Mercury

The conversion of subtidal, unvegetated conditions to vegetated wetlands could enhance the cycling of mercury into biota by increasing the conversion of mercury to methylated mercury. The overall effect of increased bioavailability of methylmercury on lamprey is likely to be of low magnitude and localized (see discussion for delta smelt under Impact AQUA-7). With implementation of *CM12 Methylmercury Management*, the potential effects of increased mobilization on lamprey at the restoration sites are expected to be minimized. However, the cycling of mercury is a complicated process, and is difficult to predict based on existing information.

Accidental Spills

The potential risks of accidental spills (see the discussion for delta smelt under Impact AQUA-7) would be minimized by implementing the environmental commitments *Environmental Training; Stormwater Pollution Prevention Plan; Erosion and Sediment Control Plan; Hazardous Materials Management Plan; Spill Prevention, Containment, and Countermeasure Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material; and Barge Operations Plan;* see Appendix 3B, *Environmental Commitments* and Impact AQUA-1). Specifically, the *Spill Prevention, Containment, and Countermeasure Plan* will be implemented to minimize the risk of spills occurring and to provide for rapid and effective response to contain any accidental spills.

Disturbance of Contaminated Sediments

Runoff and resuspension of contaminants could cause short-term, localized increases in the concentrations of contaminants in and near restoration sites (see discussion for delta smelt under Impact AQUA-7). The potential impacts of toxics on lamprey would be minimized to the extent possible by timing construction activities so that vulnerable early life stages of fish are not present. Although lamprey ammocoetes would likely be present during the in-water work window, implementation of environmental commitments (see Appendix 3B) (*Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan; Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*; and *Barge Operations Plan*) would minimize exposure levels. Pertinent details of these plans are provided under Impact AQUA-1 for delta smelt. Because of the expected periodic and temporary nature of toxicity spikes and the timing of activities relative to species' presence, the potential effects would be minimized.

In-Water Work Activities

Restoration construction activities could temporarily produce noise levels and disturbances that could affect nearby lamprey. Such activities are not expected to elevate underwater noise above the threshold sound pressure levels established for fish (see discussion for delta smelt under Impact AQUA-1). Any changes in disturbance levels would be minor and temporary, and unlikely to affect lamprey. Potential effects of in-water activity would be minimized by implementation of the environmental commitments described under Impact AQUA-1 and in Appendix 3B, *Environmental Commitments*, including *Erosion and Sediment Control Plan*; *Dispose of Spoils, Reusable Tunnel Material, and Dredged Material*; and *Barge Operations Plan*. Pertinent details of these plans are provided under Impact AQUA-1 for delta smelt.

Predation

Although there is low certainty regarding their behavior in the Delta, lamprey macrothalmia likely use the Delta primarily as a migration corridor, as evidenced by low catches in beach seines in back sloughs and higher catches in beach seines in mainstem sampling (U.S. Fish and Wildlife Service 2013). Only a small proportion of the proposed habitat restoration would be located along major migration corridors, such as the mainstem Sacramento and San Joaquin rivers, in the West and South Delta ROAs. Therefore, it is presumed that lamprey will not spend large amounts of time in the vicinity of restored tidal marsh or floodplain habitat while they are being constructed. Additionally any in-water work may cause predatory fish to temporarily avoid those locations reducing the predation potential. Therefore, predation is not expected to increase, and the effect would not be adverse.

Summary

In-water and shoreline construction activities associated with habitat restoration would be scheduled to occur when the least number of river lamprey are expected in or near the restoration sites. Such activities would include riprap removal and levee breaching, and shoreline excavation and re-contouring. River lamprey are tolerant to increases in turbidity, which might occur during shoreline restoration construction activities. Implementation of the environmental commitments described in Appendix 3B, *Environmental Commitments*, would minimize or eliminate effects on river lamprey (see Impact AQUA-181) by reducing the amount of turbidity and guiding the rapid and effective response in case of inadvertent spills of hazardous materials. These environmental commitments are *Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan*; and *Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*. Pertinent details of these plans are provided under Impact AQUA-1 for delta smelt and Appendix 3B, *Environmental Commitments*. As a result, the effects of short-term restoration construction activities would not be adverse to river lamprey.

While implementation of these environmental commitments would minimize or eliminate short-term effects occurring during restoration construction, long-term effects could also occur. For example, removing or breaching levees would result in the expansion of floodplain habitat, and more frequent inundation these areas, potentially promoting conversion of mercury to methylated mercury, and runoff containing agricultural-related toxins such as copper and organochlorine pesticides. However, the overall effect of increased bioavailability of methylmercury and other pollutants on river lamprey is likely to be of low magnitude, periodic and localized. In addition, potential increases would be minimized to the extent possible because of implementation of *CM12 Methylmercury Management* (see Impact AQUA-181).

NEPA Effects: For the reasons described above, the effect would not adversely affect river lamprey populations.

CEQA Conclusion: In-water and shoreline construction activities associated with habitat restoration would be scheduled to occur when the least number of river lamprey would be expected to occur in or near the restoration sites. River lamprey are tolerant to increases in turbidity, which might occur during shoreline restoration construction activities, and implementation of the environmental commitments described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments* (*see Environmental Training*; *Stormwater Pollution Prevention Plan*; *Erosion and Sediment Control Plan*; *Hazardous Materials Management Plan*; *Spill Prevention, Containment, and Countermeasure Plan*; and *Disposal of Spoils, Reusable Tunnel Material, and Dredged Material*), would minimize or eliminate the potential for turbidity, accidental spills, resuspension of contaminated sediments, or construction noise to affect river lamprey. Therefore, this impact is considered less than significant for river lamprey because it would not substantially reduce available habitat, or restrict the range or movement of river lamprey. Consequently, no mitigation would be required.

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

A complete analysis can be found in the *BDCP Effects Analysis – Appendix D*, *Contaminants (hereby incorporated by reference)*. The effects of contaminants on river lamprey associated with project operations and habitat restoration are expected to be similar to that for Pacific lamprey (Impact AQUA-170).

NEPA Effects: Alternative 1A actions are likely to result in increased production, mobilization, and bioavailability of methylmercury, selenium, copper, and pesticides in the aquatic system. However, any such releases would be sporadic, short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation in river lamprey. Implementation of *CM12 Methylmercury Management* would also help to minimize the increased mobilization of methylmercury at restoration areas. The effects of contaminants on river lamprey associated with restoration measures would not be adverse, while the overall effects of the restored habitat are expected to be beneficial.

CEQA Conclusion: Alternative 1A actions are likely to result in increased production, mobilization, and bioavailability of methylmercury, selenium, copper, and pesticides in the aquatic system. However, any such releases would be sporadic, short-term and localized, and would be unlikely to result in measurable increases in the bioaccumulation in river lamprey. Implementation of *CM12 Methylmercury Management* would also help to minimize the increased mobilization of methylmercury at restoration areas. Therefore, the impact of contaminants would be less than significant because it would not substantially affect river lamprey either directly or through habitat modifications and, with restoration, would be beneficial in the long-term. Consequently, no mitigation would be required

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

Refer to Impact AQUA-171 under Pacific lamprey for a discussion of the effects or restored habitat conditions on river lamprey.

Other Conservation Measures (CM12–CM19 and CM21)

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (CM12)

Refer to Impact AQUA-172 under Pacific lamprey for a discussion of the effects of methylmercury management on river lamprey.

Impact AQUA-191: Effects of Invasive Aquatic Vegetation Management on River Lamprey (CM13)

The following analysis is based on the more detailed analysis included in *BDCP Effects Analysis – Appendix F, Biological Stressors, Section F.1.1 Invasive Aquatic Vegetation, Section F.4 Invasive Aquatic Vegetation, and F.5.3.2.3 Nonnative Aquatic Vegetation Control (Conservation Measure 13) (hereby incorporated by reference)*.

NEPA Effects: A general analysis of the effects on covered fish species has been conducted that was described above for delta smelt (see Impact AQUA-11). Potential impacts on river lamprey from IAV control during operations are similar to those discussed above for Pacific lamprey (see Impact AQUA-173). The control of IAV with implementation of *CM13 Invasive Aquatic Vegetation Control* is expected to maintain or improve turbidity conditions that could benefit river lamprey rearing conditions. The control of IAV would also increase the amount of rearing habitat, as well as access to the habitat and potential increases in food availability. Therefore, the effects of IAV control are expected to provide an overall benefit to river lamprey.

CEQA Conclusion: The control of IAV should provide a modest net benefit to river lamprey during operations through chemical and mechanical treatment and is considered a beneficial impact by reducing predation mortality, increasing food availability, and increasing rearing habitat. The impact is expected to be beneficial, consequently, no mitigation would be required.

Impact AQUA-192: Effects of Dissolved Oxygen Level Management on River Lamprey (CM14)

Refer to Impact AQUA-174 under Pacific lamprey for a discussion of the effects of oxygen level management on river lamprey.

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (CM15)

Refer to Impact AQUA-175 under Pacific lamprey for a discussion of the effects of predator management on river lamprey.

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (CM16)

Refer to Impact AQUA-176 under Pacific lamprey for a discussion of the effects of nonphysical fish barriers on river lamprey.

Impact AQUA-195: Effects of Illegal Harvest Reduction on River Lamprey (CM17)

Refer to Impact AQUA-177 under Pacific lamprey for a discussion of illegal harvest reduction on river lamprey.

Impact AQUA-196: Effects of Conservation Hatcheries on River Lamprey (CM18)

Refer to Impact AQUA-178 under Pacific lamprey for a discussion of conservation hatcheries on river lamprey.

Impact AQUA-197: Effects of Urban Stormwater Treatment on River Lamprey (CM19)

Refer to Impact AQUA-179 under Pacific lamprey for a discussion of urban stormwater treatment on river lamprey.

Impact AQUA-198: Effects of Removal/Relocation of Nonproject Diversions on River Lamprey (CM21)

Refer to Impact AQUA-180 under Pacific lamprey for a discussion of removal/relocation of nonproject diversions on river lamprey.

Non-Covered Aquatic Species of Primary Management Concern

The non-covered fish and aquatic species identified as special status by state or federal agencies, or that are of particular ecological, recreational, or commercial importance are listed below.

- Striped bass
- American shad
- Threadfin shad
- Largemouth bass
- Sacramento tule perch
- Sacramento-San Joaquin roach – California species of special concern
- Hardhead – California species of special concern – California species of special concern
- California bay shrimp

Striped bass, American shad, and largemouth bass are all sport fish species and were introduced into rivers for that purpose. All three species are regulated by CDFW for recreational fishing. Roach, hardhead, and Sacramento tule perch are native fish species that are important to the aquatic ecosystem. Threadfin shad are nonnative fish species that were introduced as forage fish for game fish. All of these fish species could be present during construction activities for intakes and barge landings, although it is unlikely that roach or hardhead would be affected as they reside primarily within tributary streams and their primary distributions are upstream of the action area. California bay shrimp occur in San Francisco and San Pablo bays, Suisun Bay and Suisun Marsh, and the western delta in low salinity waters.

Construction and Maintenance of CM1

The effects of construction and maintenance of CM1 under Alternative 1A would be similar for all non-covered species depending on abundance within the area; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-1 under delta smelt for a discussion of the effects of construction of water conveyance facilities on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of water conveyance facilities would be similar to those described there. California bay shrimp would not be affected because they do not occur in the vicinity. Similarly, it is unlikely that roach or hardhead would be affected, as they reside primarily within tributary streams, upstream of the construction areas. Consequently, the effects would not be adverse.

CEQA Conclusion: As described in Impact AQUA-1 under Alternative 1A for delta smelt, the impact of the construction of water conveyance facilities would not be significant on non-covered aquatic species of primary management concern except potentially for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-2 under delta smelt for a discussion of the effects of maintenance of water conveyance facilities on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of maintenance of water conveyance facilities would be similar to those described there. California bay shrimp would not be affected because they do not occur in the vicinity. Consequently, the effects would not be adverse. Similarly, it is unlikely that roach or hardhead would be affected as they occur primarily in tributary streams and upstream of the maintenance areas.

CEQA Conclusion: As described above, these impacts would be less than significant.

Water Operations of CM1

The effects of water operations of CM1 under Alternative 1A include analysis of the following species:

- Striped Bass
- American Shad
- Threadfin Shad

- Largemouth Bass
- Sacramento Tule Perch
- Sacramento-San Joaquin roach – California species of special concern
- Hardhead – California species of special concern
- California bay shrimp

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-3 under delta smelt for a discussion of the effects of water operations on entrainment of non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of water operations would be similar to those described there, although there are some caveats for each species. Striped bass larvae could be entrained at the water diversion facilities in both the north and south Delta, although larval entrainment is not thought to have population consequences due to the large fecundity of individual females and the fact that population levels do not correspond to numbers of adults (Moyle 2002). Largemouth bass are nest builders and typically build their nests in quiet, low flow backwaters and are unlikely to be entrained at facilities. Both shad species are very similar in morphology at the larval stage to Delta smelt and entrainment would be similar. The difference lies in the larval and early juvenile distribution which would create more opportunities for interaction with diversion facilities, although it is not thought that entrainment is a limiting factor for any of these species. Tule perch is a live bearing surf perch usually found in heavy cover or rip-rap and are unlikely to be affected, as the population is widespread and is not easily entrained, and on average it makes up only a fraction of all species salvaged at the south Delta facilities. California bay shrimp do not occur in freshwater and would not be affected, and it is unlikely that hardhead or roach would be affected, because their distributions are almost exclusively in upstream areas. Consequently, the effects would not be adverse.

CEQA Conclusion: As described above, these impacts would be less than significant.

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

Striped Bass

In general, Alternative 1A would slightly improve the quality and quantity of upstream habitat conditions for striped bass relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing, although striped bass distribution occurs below Red Bluff Diversion Dam which would exclude striped bass from the upper Sacramento and Clear Creek (Moyle 2002). Striped bass are also not known to occur in the Trinity River (Moyle 2002) Striped bass are broadcast spawners not needing substrate like salmon for egg incubation. The eggs are slightly heavier that water but any amount of current will suspend the eggs off the bottom, thus the lowering of current will not affect viability of embryos.

Striped bass are not thought to occur above Red Bluff in the Sacramento River and are not known from the Trinity River or Clear Creek.

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be substantially greater (up to 219% greater) than flows under NAA during April through June (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would always be greater than flows under NAA regardless of water year type (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Striped bass are known to migrate upstream until temperatures reach 59°F and then spawn, thus in low temperature years they migrate upstream farther then when temperatures are warmer. It is unlikely that striped bass would spawn under less than minimal temperature needs for embryo development, thus temperature is not a likely stressor on striped bass embryo development. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be lower than the percentage under NAA in all water years (Table 11-1A-89). The percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in below normal and critical water year types and slightly higher in all other types (up to 11% higher). Striped bass spawning distribution is known to occur below Red Bluff, (Moyle 2002).

In the Trinity River below Lewiston Reservoir, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water years except critical years compared to NAA (7% higher) (Table 11-1A-89). Striped bass are not known to occur in the Trinity River (Moyle 2002).

Table 11-1A-89. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures Are outside the 59°F to 68°F Water Temperature Range for Striped Bass Spawning, Embryo Incubation, and Initial Rearing[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	-13 (-14%)	9 (11%)
	Above Normal	-12 (-13%)	6 (7%)
	Below Normal	-19 (-20%)	2 (2%)
	Dry	-15 (-16%)	6 (7%)
	Critical	-23 (-27%)	-1 (-1%)
	All	-16 (-17%)	5 (7%)
Trinity River below Lewiston Reservoir	Wet	0 (0%)	0 (0%)
	Above Normal	-3 (-3%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	-2 (-2%)	0 (0%)
	Critical	-17 (-17%)	6 (7%)
	All	-3 (-3%)	1 (1%)
Feather River below Thermalito Afterbay	Wet	0 (0%)	-5 (-12%)
	Above Normal	-18 (-40%)	-15 (-56%)
	Below Normal	-12 (-28%)	-14 (-46%)
	Dry	-2 (-4%)	2 (4%)
	Critical	11 (29%)	-3 (-6%)
	All	-3 (-8%)	-6 (-15%)
American River below Nimbus Dam	Wet	-27 (-54%)	-8 (-33%)
	Above Normal	-15 (-45%)	-6 (-33%)
	Below Normal	-19 (-53%)	-5 (-29%)
	Dry	-2 (-7%)	-11 (-43%)
	Critical	14 (42%)	6 (12%)
	All	-12 (-33%)	-6 (-23%)
Stanislaus River below New Melones Dam	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)
	Critical	-3 (-3%)	0 (0%)
	All	0 (0%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be lower than the percentage under NAA in all water years except critical years (16% higher) (Table 11-1A-89). The percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year types.

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside the range would be lower than the percentage under NAA in all water years except critical years (12% higher compared to NAA) (Table 11-1A-89).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water years (Table 11-1A-89).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 1A would not cause a substantial reduction in striped bass spawning, incubation, or initial rearing habitat. Flows in all rivers examined during the April through June spawning, incubation, and initial rearing period under Alternative 1A would generally be similar to or greater than flows under the NAA. Overall, there would be flow increases in all waterways except Trinity River and Clear Creek. The percentage of months outside the 59°F to 68°F water temperature range would generally be lower under Alternative 1A than under the NAA. The increased frequency in months outside the temperature range in the Sacramento River would not be of sufficient magnitude to have a population level effect on striped bass.

CEQA Conclusion: In general, Alternative 1A would slightly improve the quality and quantity of upstream habitat conditions for striped bass relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

Striped bass are not thought to occur above Red Bluff in the Sacramento River and are not known to occur in the Trinity River or Clear Creek.

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (28% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal years during April (6% lower) and wet and critical years during June (24% and 31% lower, respectively), but generally lower, by up to 24%, during May (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see AQUA-76, -77, and -78 under Chinook salmon fall-/late-fall run ESU). The analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality.

Striped bass are known to migrate upstream until temperatures reach 59°F and then spawn, thus in low temperature years they migrate upstream farther then when temperatures are warmer. It is unlikely that striped bass would spawn under less than minimal temperature needs for embryo development, thus temperature is not a likely stressor on striped bass embryo development. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be lower than the percentage under Existing Conditions in all water years except critical years (29% higher) (Table 11-1A-89).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside the range would be lower than the percentage under Existing Conditions in all water years except critical years (42% higher) (Table 11-1A-89).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under Existing Conditions in all water years (Table 11-1A-89).

Collectively, these results indicate that the impact would not be significant because Alternative 1A would not cause a substantial reduction in spawning, incubation, and initial rearing habitat of striped bass. Therefore, no mitigation is necessary. Flows in all rivers except the San Joaquin and Stanislaus rivers during the April through June spawning, incubation, or initial rearing period under Alternative 1A would generally be similar to or greater than flows under Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 1A, although this effect would not be biologically meaningful to striped bass. The percentage of months outside the 59°F to 68°F water temperature range would generally be lower under Alternative 1A than under CEQA baseline, particularly in the American River (up to 54% reduction in percentage of months).

American Shad

In general, Alternative 1A would slightly improve the quality and quantity of upstream habitat conditions for American shad relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning. It is unlikely that the lesser amount of flow will impact the migration ability of American shad. Given their much smaller body size and their known use of much smaller streams (e.g., Cosumnes River), plus their use of broadcast spawning it is unlikely that lowered flow would have a negative effect on them in this way.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under NAA during April through June (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Although American shad juveniles do appear in screw trap data at Red Bluff the numbers are very small. For example, four American shad were caught in 2000 out of over 889,000 fish caught (Gaines and Martin 2001).

In the Trinity River below Lewiston Reservoir, flows under A1A_LLT would generally be similar to or greater than flows under NAA during April through June except in above normal years during

April compared (11% lower)(Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Although American shad juveniles do appear in screw trap data at Willow Creek the numbers are very small. For example one American shad was caught by screw trap at Willow Creek in 2007 (Pinnix et al. 2010).

American shad are not known from Clear Creek.

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be substantially greater (up to 219% greater) than flows under NAA during April through June (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be greater than flows under NAA regardless of water year type (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see AQUA-76, -77, and -78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. The range of 60°F to 70°F is the spawning range in general of American shad in the Sacramento River. The spawning temperature range does not imply that temperatures below this would be stressful to migrating shad. Male shad migrate to spawning areas much earlier than females with much lower temperatures with no apparent migration stress or mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in most water year types and slightly higher in wet and dry water year types (7% and 5% higher, respectively). Although American shad juveniles do appear in screw trap data at Red Bluff the numbers are very small. For example, four American shad were caught in 2000 out of over 889,000 fish caught (Gaines and Martin 2001).

In the Trinity River below Lewiston Reservoir, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water years (Table 11-1A-90). In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-90).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside the 60°F to 70°F water temperature range would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-90).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to the percentage under NAA in all water year types (Table 11-1A-90).

Table 11-1A-90. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures Are outside the 60°F to 70°F Water Temperature Range for American Shad Adult Migration and Spawning[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	-9 (-9%)	6 (7%)
	Above Normal	-8 (-8%)	4 (4%)
	Below Normal	-15 (-15%)	-1 (-1%)
	Dry	-8 (-8%)	4 (5%)
	Critical	-18 (-20%)	0 (0%)
	All	-11 (-11%)	3 (4%)
Trinity River below Lewiston Reservoir	Wet	0 (0%)	0 (0%)
	Above Normal	-3 (-3%)	0 (0%)
	Below Normal	-2 (-2%)	0 (0%)
	Dry	-2 (-2%)	0 (0%)
	Critical	-11 (-11%)	0 (0%)
	All	-3 (-3%)	0 (0%)
Feather River below Thermalito Afterbay	Wet	-5 (-11%)	0 (0%)
	Above Normal	-3 (-8%)	-12 (-36%)
	Below Normal	0 (0%)	-7 (-23%)
	Dry	-2 (-5%)	-7 (-20%)
	Critical	3 (8%)	-3 (-7%)
	All	-2 (-5%)	-5 (-13%)
American River below Nimbus Dam	Wet	-32 (-56%)	0 (0%)
	Above Normal	-24 (-57%)	-6 (-33%)
	Below Normal	-21 (-50%)	-5 (-22%)
	Dry	-6 (-21%)	-4 (-18%)
	Critical	14 (63%)	-6 (-15%)
	All	-16 (-40%)	-3 (-14%)
Stanislaus River below New Melones Dam	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)
	Critical	0 (0%)	0 (0%)
	All	0 (0%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 1A would not cause a substantial reduction in American shad spawning or adult migration. Flows in all rivers examined during the April through June adult migration and spawning period under Alternative 1A would generally be similar to or greater than flows under NAA. Overall, there would be flow increases in all waterways except Trinity River and Clear Creek. The percentage of months outside the 60°F to 70°F water temperature range would generally be lower under Alternative 1A than under NAA in all waterways examined.

CEQA Conclusion: In general, Alternative 1A would slightly improve the quality and quantity of upstream habitat conditions for American shad relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning. It is unlikely that the lesser amount of flow will impact the migration ability of American shad. Given their much smaller body size and their known use of much smaller streams (e.g., Cosumnes River), plus their use of broadcast spawning it is unlikely that lowered flow would affect them in this way.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Although American shad juveniles do appear in screw trap data at Red Bluff the numbers are very small. For example, four American shad were caught in 2000 out of over 889,000 fish caught (Gaines and Martin 2001).

In the Trinity River below Lewiston Reservoir, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Although American shad juveniles do appear in screw trap data at Willow Creek the numbers are very small. For example, one American shad was caught by screw trap at Willow Creek in 2007 (Pinnix et al. 2010).

American shad are not known from Clear Creek.

In the American River at Nimbus Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal years during April (6% lower) and wet and critical years during June (24% and 31% lower, respectively), but generally lower, by up to 24%, during May (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. The range of 60°F to 70°F is the spawning range in general of American shad in the Sacramento River. The spawning temperature range does not imply that temperatures below this would be stressful to migrating shad. Male shad migrate to spawning areas much earlier than females with much lower temperatures with no apparent migration stress or mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be lower than the percentage under Existing Conditions in all water years (Table 11-1A-90). Although American shad juveniles do appear in screw trap data at Red Bluff the numbers are very small. For example, four American shad were caught in 2000 out of over 889,000 fish caught (Gaines and Martin 2001).

In the Trinity River below Lewiston Reservoir, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under Existing Conditions in all water year types (Table 11-1A-90). Although American shad juveniles do appear in screw trap data at Willow Creek the numbers are very small. For example, one American shad was caught by screw trap at Willow Creek in 2007 (Pinnix et al. 2010).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under Existing Conditions in all water years except critical years (8% higher) (Table 11-1A-90).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside of the 60°F to 70°F water temperature range would be similar to or lower than the percentage under Existing Conditions in all water years except critical years (63% higher) (Table 11-1A-90).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to the percentage under Existing Conditions in all water year types (Table 11-1A-90).

Collectively, these results indicate that the impact would not be significant because Alternative 1A would not cause a substantial reduction in American shad adult migration or spawning habitat, and no mitigation is necessary. Flows in all rivers examined, except the San Joaquin and Stanislaus rivers during the April through June adult migration and spawning period under Alternative 1A, would generally be similar to or greater than flows under Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 1A, although this effect would not be biologically meaningful to American shad. The percentage of months outside the 60°F to 70°F water temperature range would generally be similar to or lower under Alternative 1A than under the CEQA baseline, particularly in the Sacramento and American rivers (up to 57% reduction) (Table 11-1A-90).

Threadfin Shad

In general, Alternative 1A would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to the NAA. The primary distribution of threadfin shad is within the Delta and lower rivers and in reservoirs. Threadfin shad that are seen in tributaries and the mainstem Sacramento River are produced in reservoirs and transported downstream during high flows. Threadfin shad are not migrating upstream to spawn in these areas, and may persist in these downstream areas during times of low flow. It is likely that there is a pattern of reintroduction that allows threadfin shad to persist in these upstream areas. Threadfin shad use floating objects such as vegetation and wood to spawn on so it is unlikely that their spawning habitat would be reduced (Moyle 2002).

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during April through August threadfin shad spawning period. Lower flows could reduce the quantity and quality of instream habitat (backwaters) available for spawning. Threadfin shad are just transient in these upstream areas as they are being flushed out of reservoirs downstream.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under NAA during April through July except in below normal and dry years during July (8% lower for both), and up to 19% lower during August (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Although the numbers are small as indicated by screw trap catches at Red Bluff Diversion Dam where 1,260 threadfin shad were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Threadfin shad are not known from the Trinity River system (Pinnix et al. 2010).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than flows under NAA throughout the period, except in critical years during June (8% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Threadfin shad are not known from Clear Creek screw trap data (Gaines and Martin 2001; Greenwald et al. 2003; Earley et al. 2008a, 2008b, 2009, 2010).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally greater during April through June (up to 219% greater) and generally be lower than those under NAA during July and August (up to 51% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally lower than flows under NAA during July and August (up to 30% lower), greater during May and June (up to 31% greater), and similar between NAA and A1A_LLT during April.

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay spawning in these areas. According to Moyle (2002) the peak of spawning occurs at a temperature of 68°F, although spawning has been observed to occur from 57°F to 64°F. This makes it likely that threadfin shad can spawn successfully at much lower temperatures than 68°F, although their survival is higher at hatching ≥.8 at above 66°F (Betsill and Avyle 1997). Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-91). Although numbers are small as indicated by screw trap catches at Red Bluff Diversion Dam where 1,260 threadfin shad were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Threadfin shad are not known from the Trinity River system (Pinnix et al. 2010).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be higher than the percentage under NAA in wet, above, and below normal water years (up to 9% higher) (Table 11-1A-91).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT below the 68°F water temperature threshold would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-91).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT below the 68°F water temperature threshold would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-91).

Table 11-1A-91. Difference and Percent Difference in the Percentage of Months in Which April–August Water Temperatures Fall below the 68°F Water Temperature Threshold for Threadfin Shad Spawning[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)
	Critical	-16 (-16%)	0 (0%)
	All	-2 (-2%)	0 (0%)
Trinity River below Lewiston Reservoir	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)

	Dry	0 (0%)	0 (0%)
	Critical	-2 (-2%)	0 (0%)
	All	0 (0%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 1A would not cause a substantial reduction in spawning habitat. Flows in all rivers examined during the April through August spawning period under Alternative 1A would generally be similar to or greater than flows under the NAA, except during July and August in the Sacramento, Feather, and American rivers. Lower flows during these months in these rivers are not of sufficient magnitude or frequency to have a biologically meaningful effect on threadfin shad. The percentage of months below the spawning temperature threshold would generally be lower under Alternative 1A relative to the NAA.

CEQA Conclusion: In general, Alternative 1A would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during April through August spawning period. Lower flows could reduce the quantity and quality of instream habitat (backwaters) available for spawning. However, this is unlikely to affect threadfin shad as they spawn on floating objects such as vegetation or wood which would float up or down with the flow regime (Moyle 2002).

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT during April through June would generally be similar to or greater than flows under Existing Conditions, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A1A_LLT during July and August would generally be lower than flows under Existing Conditions by up to 24%. Although numbers are small as indicated by screw trap catches at Red Bluff Diversion Dam where 1,260 threadfin shad were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Threadfin shad are not known from the Trinity River system (Pinnix et al. 2010).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would nearly always be similar to or greater than flows under Existing Conditions throughout the period, except in critical years during August (17% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Threadfin shad are not known from Clear Creek screw trap data (Gaines and Martin 2001; Greenwald et al. 2003; Earley et al. 2008a, 2008b, 2009, 2010).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater (up to 204% greater) than flows under Existing Conditions during April through June and lower (up to 56% lower) during July and August (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be similar to flows under Existing Conditions during April and June with some exceptions (up to 31% lower), and lower during May, July, and August (up to 49% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay spawning in these areas. According to Moyle (2002) the peak of spawning occurs at a temperature of 68°F, although spawning has been observed to occur from 57°F to 64°F. This makes it likely that threadfin shad can spawn successfully at much lower temperatures than 68°F, although their larval survival rate is higher (0.6 vs. 0.8) at above 66°F (Betsill and Avyle 1997). Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under Existing Conditions in all water year types (Table 11-1A-91). Although numbers are small as indicated by screw trap catches at Red Bluff Diversion Dam where 1,260 threadfin shad were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Threadfin shad are not known from the Trinity River system (Pinnix et al. 2010).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT below the 68°F water temperature threshold would be lower than the percentage under Existing Conditions in all water year types (Table 11-1A-91).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT below the 68°F water temperature threshold would be similar to or lower than the percentage under Existing Conditions in all water year types (Table 11-1A-91).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT below the 68°F water temperature threshold would be similar to or lower than the percentage under Existing Conditions in all water year types (Table 11-1A-91).

Collectively, these results indicate that the impact would be less than significant because Alternative 1A would not cause a substantial reduction in habitat, and no mitigation is necessary. Flows in all rivers examined during the April through August spawning period under Alternative 1A would generally be similar to or greater than flows under Existing Conditions, except during summer months in the Sacramento, Feather, and American rivers. Lower flows during these months in the Sacramento and Feather rivers would not be of sufficient magnitude or frequency to cause a biologically meaningful effect on threadfin shad. Lower flows in the American River would occur during the majority of the period, but, due to the spatial diversity and movement ability of threadfin shad, these reductions are not expected to have a biologically meaningful effect on threadfin shad. The percentage of months outside all temperature thresholds are generally lower under Alternative 1A than under Existing Conditions, indicating that there would be a net temperature-related benefit of Alternative 1A to threadfin shad.

Largemouth Bass

In general, Alternative 1A would not affect the quality and quantity of upstream habitat conditions for largemouth bass relative to the NAA. The primary distribution of largemouth bass is in the central and south Delta, although they do occur in slower moving parts of the rivers, their tributaries and reservoirs. Given this fact it is unlikely that upstream flows and temperatures will have a discernible effect on largemouth bass population numbers.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could increase the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, CALSIM II Model

Results utilized in the Fish Analysis). Although few largemouth bass are expected to occur in this area, as indicated by screw trap catches at Red Bluff Diversion Dam where 185 largemouth bass were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

In the Trinity River below Lewiston Reservoir, flows under A1A_LLT would generally be similar to or greater than flows under NAA during March through June, except in above normal years during April (11% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Largemouth bass were not found in Trinity River screw trap data (Pinnix et al. 2010), but are apparently found in low numbers when washed down from upstream reservoirs (USFWS and Hoopa Valley Tribe 1999).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than flows under NAA during March through June, except in critical years during June (8% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Largemouth bass are caught in rotary screw traps in low numbers mostly in the fry form (Gaines and Martin 2001) most likely washed down from Whiskeytown Reservoir or local farm ponds. It is unlikely that these largemouth bass rear and spawn except in the lowest velocity areas of lower Clear Creek where they are most likely flushed out of the system by high flow events (Moyle 2002).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would be substantially greater (up to 219% greater) than flows under NAA during March through June (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be similar to or greater than flows under NAA throughout the period, except in dry and critical years during March (9% and 8% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success. Although Kelley (1968) found no difference in incubation survival of largemouth bass eggs in the temperature range of 55°F to 75°F. Thus it is unlikely that there would be reduced spawning success because of low temperatures. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in below normal and critical water years and higher in all other water year types (up to 8% higher) (Table 11-1A-92). Although numbers are small as indicated by screw trap catches at Red Bluff Diversion Dam where 185 largemouth were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

In the Trinity River below Lewiston Reservoir, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water years except critical years (5% higher) (Table 11-1A-92). Largemouth bass were not found in Trinity River screw trap data (Pinnix et al. 2010), but are apparently found in low numbers when washed down from upstream reservoirs (U.S. Fish and Wildlife Service and Hoopa Valley Tribe 1999).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-92).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside the 59°F to 75°F water temperature range would be similar to or lower than the percentage under NAA in all water years except critical years (8% higher) (Table 11-1A-92).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-92).

Table 11-1A-92. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures Are outside the 59°F to 75°F Water Temperature Range for Largemouth Bass Spawning[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT

	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)
	Critical	-2 (-2%)	0 (0%)
	All	0 (0%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

CEQA Conclusion: In general, Alternative 1A would reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to Existing Conditions. Although at most this would be a minor effect as largemouth bass are not abundant in this area and the main distribution of this species abundance is found downstream of this area.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Although numbers are small as indicated by screw trap catches at Red Bluff Diversion Dam where 185 largemouth bass were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

In the Trinity River below Lewiston Reservoir, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March and critical years during May (6% lower in both) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Largemouth bass were not found in Trinity River screw trap data (Pinnix et al. 2010), but are apparently found in low numbers when washed down from upstream reservoirs (U.S. Fish and Wildlife Service and Hoopa Valley Tribe 1999).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would always be similar to or greater than flows under Existing Conditions during March through June (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Largemouth bass are caught in rotary screw traps in low numbers mostly in the fry form (Gaines and Martin 2001) most likely washed down from Whiskeytown Reservoir or local farm ponds. It is unlikely that these largemouth bass rear and spawn except in the lowest velocity areas of lower Clear Creek where they are most likely flushed out of the system by high flow events (Moyle 2002).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be substantially greater (up to 204% greater) than flows under Existing Conditions during March through June, except in below normal years during March (31% lower) and wet years during May (28% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during March, April, and June, except in critical years during March and June (8% and 31% lower, respectively), above normal years during April (6% lower) and wet years during June (24% lower). Flows under A1A_LLT in May would generally be up to 24% lower than those under Existing Conditions (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success. Kelley (1968) found no difference in incubation survival of largemouth bass eggs in the temperature range of 55°F to 75°F. This would seem to make it unlikely that there would be reduced spawning success because of low temperatures. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be lower than the percentage under Existing Conditions in all water years (Table 11-1A-92). Although numbers are small as indicated by screw trap catches at Red Bluff Diversion Dam where 185 largemouth bass were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Trinity River below Lewiston Reservoir, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under Existing Conditions in all water year types (Table 11-1A-92). Largemouth bass were not found in Trinity River screw trap data (Pinnix et al. 2010), but are apparently found in low numbers when washed down from upstream reservoirs (U.S. Fish and Wildlife Service and Hoopa Valley Tribe 1999).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be lower than the percentage under Existing Conditions in all water years except critical years (8% higher) (Table 11-1A-92).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside of the 59°F to 75°F water temperature range would be lower than the percentage under Existing Conditions in all water years (Table 11-1A-92).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under Existing Conditions in all water year types (Table 11-1A-92).

Sacramento Tule Perch

In general, Alternative 1A would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round Sacramento tule perch presence. Lower flows could reduce the quantity and quality of instream habitat available for rearing. Sacramento tule perch are well adapted to high and low flows of the natural hydrograph in California streams (Baltz and Moyle 1982). It is unlikely that flows going up or down 10 percent or more would have a great impact on this species as it is well adapted to the wet winters and dry summers of the natural California climate. Also, Sacramento tule perch are a deep-bodied and laterally compressed fish, which is a body form not conducive to maintaining position in high velocity current without great effort (Cech et al. 1990). Unless lower flows increase high velocity habitat there is likely to be no effect on Sacramento tule perch, which prefer lower velocity high oxygenated habitats (Moyle and Baltz 1985).

Upstream of Red Bluff, Sacramento River flows under A1A_LLT in August, September, and November would be lower than flows under NAA (up to 44% lower), and generally similar to or greater than flows during the rest of the year, with some exceptions (up to 11% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Numbers as indicated by screw trap catches at Red Bluff Diversion Dam are small where 77 tule perch were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Sacramento tule perch are not found in the Trinity River (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during June and September (8% and 13% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Numbers of Sacramento tule perch caught in screw traps are low with an average of less than 2 caught over an 8-year period (Gaines and Martin 2001; Greenwald et al. 2003; Earley et al. 2008a, 2008b, 2009, 2010).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater than those under NAA during October through June (up to 219% greater) and lower during July through September (up to 86% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be greater than flows under NAA during May, June, and October (up to 37% greater), generally lower during July through September (up to 47% lower), and generally similar during the remaining months (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months exceeding water temperature thresholds of 72°F and 75°F for the year-round occurrence of all life stages of Sacramento tule perch was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quantity and quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT above the 72°F threshold would be similar to the percentage under NAA in all water years except critical years (16% higher) (Table 11-1A-93). These relative differences, however, represent very low percentages of years (<1%). Therefore, these differences would not be biologically meaningful to Sacramento tule perch. Numbers as indicated by screw trap catches at Red Bluff Diversion Dam are small where 77 Sacramento tule perch were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Sacramento tule perch are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT above the 72°F threshold would be higher than the percentage under NAA in all water year types (up to 700% higher) (Table 11-1A-93).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT above the 72°F threshold would be higher than the percentage under NAA in almost all water year types (up to

150% higher) (Table 11-1A-93). These relative differences, however, represent very low percentages of years (<3%). Therefore, these differences would not be biologically meaningful to Sacramento tule perch.

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT above the 72°F threshold would be similar to the percentage under NAA in all water year types (Table 11-1A-93).

Table 11-1A-93. Difference and Percent Difference in the Percentage of Months in Which Year-Round Water Temperatures Exceed 72°F and 75°F Water Temperature Thresholds for Sacramento Tule Perch Occurrence[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
72°F Threshold

	All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 1A would not cause a substantial reduction in rearing habitat. Flows under Alternative 1A in all rivers examined throughout the year are generally similar to or greater than flows under the NAA, except during summer months in the Feather River and half the year in the American River. These reductions in flows, however, would not result in an overall biologically meaningful effect on Sacramento tule perch. The percentages of years outside all temperature thresholds under Alternative 1A are generally similar to the percentages under the NAA. Some increases in percentage of years outside temperature ranges under Alternative 1A would occur, but they would generally be small (<5% on an absolute scale) and would not affect Sacramento tule perch habitat at a population level.

CEQA Conclusion: In general, Alternative 1A would not reduce the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round Sacramento tule perch presence. Lower flows could reduce the quantity and quality of instream habitat available for rearing. Sacramento tule perch are well adapted to high and low flows of the natural hydrograph in California streams (Baltz and Moyle 1982). It is unlikely that flows going up or down 10 percent or more would have a great impact on this species as it is well adapted to the wet winters and dry summers of the natural California climate. Also, Sacramento tule perch are a deep-bodied and laterally compressed fish, a body form not conducive for maintaining position in high velocity current area without great effort (Cech et al. 1990). Unless lower flows increase high velocity habitat there is likely to be no effect on Sacramento tule perch, which prefer lower velocity high oxygenated habitats (Moyle and Baltz 1985).

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during all months but July through September and November, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A1A_LLT during July through September and November would be lower than flows under Existing Conditions (up to 24% lower). Numbers as indicated by screw trap catches at Red Bluff Diversion Dam are small where 77 tule perch were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Sacramento tule perch are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August and September (17% and 38% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Numbers of Sacramento tule perch caught in screw traps are low with an average of less than 2 tule perch caught over an 8-year period (Gaines and Martin 2001; Greenwald et al. 2003; Earley et al. 2008a, 2008b, 2009, 2010).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater than those under Existing Conditions during February through June, October, and December (up to 204% greater), lower during July through September (up to 56% lower), and similar during November and January (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally greater than flows under Existing Conditions during February, March, and October (up to 42% greater), lower during January, May, July through September, and November through December (up to 53% lower), and generally similar during the rest of the year (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months exceeding water temperatures of 72°F and 75°F for the year-round occurrence of all life stages of Sacramento tule perch was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in Clear Creek or the San Joaquin River.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT above the 72°F threshold would be similar to the percentage under Existing Conditions in all water years (Table 11-1A-93). Numbers as indicated by screw trap catches at Red Bluff Diversion Dam are small where 77 tule perch were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Sacramento tule perch are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT above the 72°F threshold would be similar to or higher than the percentage under Existing Conditions in all water year types (up to 333% higher) (Table 11-1A-93).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT above the 72°F threshold would be similar to or higher than the percentage under Existing Conditions in almost all water year types (up to 414% higher) (Table 11-1A-93). The relative differences predicted in wet, above normal, and below normal years, however, represent low percentages of years (<3%). Therefore, these differences would not be biologically meaningful to Sacramento tule perch.

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT above the 72°F threshold would be similar to the percentage under Existing Conditions in all water year types (Table 11-1A-93).

Collectively, the results of the Impact AQUA-202 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 1A could be significant because the alternative could substantially reduce the amount of suitable habitat, contrary to the NEPA conclusion set forth above. There would be small to moderate flow-related effects and temperature-related effects of Alternative 1A on Sacramento tule perch in the American and Feather rivers. Flow reductions and increases in exceedances above temperature thresholds would have a biologically meaningful effect on the population. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 1A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 1A indicates that flows in the locations and during the months analyzed above would generally be similar between future conditions without BDCP and Alternative 1A. This indicates that the differences between Existing Conditions and Alternative 1A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 1A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for Sacramento tule perch. This impact is found to be less than significant and no mitigation is required.

The NEPA and CEQA conclusions differ for this impact statement because they were determined using two unique baselines. The NEPA conclusion was based on the comparison of A1A_LLT with NAA and the CEQA conclusion was based on the comparison of A1A_LLT with Existing Conditions. These baselines differ in two ways. First, the NAA includes the Fall X2 standard in wet above normal water years whereas Existing Conditions do not. Second, the NAA is assumed to occur during the late long-term implementation period whereas the CEQA baseline is assumed to occur during existing climate conditions. Therefore, differences in model outputs between the CEQA baseline and the Alternative 1A are due to both the alternative and future climate change.

Sacramento-San Joaquin Roach

In general, Alternative 1A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows might reduce the quantity and quality of instream habitat available for spawning. In a study of roach over a whole season Moyle and Baltz (1985) found them in habitats with flows averaging 0.2 m/s but ranging from 0.025m/s to 0.38 m/s. Roach are typically considered a foothill stream species and it is unlikely that their population numbers are dependent on the Sacramento River and large tributaries (Moyle 2002).

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Numbers as indicated by screw trap catches at Red Bluff Diversion Dam are small where 275 Sacramento-San Joaquin roach were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Sacramento-San Joaquin roach are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than flows under NAA during March through June, except in critical years during June (8% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Numbers of Sacramento-San Joaquin roach caught in screw traps are low with an average of less than 45 caught over a 9-year period (Gaines and Martin 2001; Greenwald et al. 2003; Earley et al. 2008a, 2008b, 2009, 2010).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would be substantially greater (up to 219% greater) than flows under NAA during March through June (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be similar to or greater than flows under NAA throughout the period, except in dry and critical years during March (9% and 8% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek. The Sacramento River and its large tributaries are most likely not the primary habitat of Sacramento-San Joaquin roach. It is more likely that they are washed into these bigger streams from smaller tributaries which would likely be warmer than the below dam releases that are made for salmonid fishes.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be lower than the percentage under NAA in all water year types (Table 11-1A-94). Numbers as indicated by screw trap catches at Red Bluff Diversion Dam are small where 275 Sacramento-San Joaquin roach were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Sacramento-San Joaquin roach are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year types except below normal years (7% higher) (Table 11-1A-94).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT below the 60.8°F water temperature threshold would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-94).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to the percentage under NAA in all water year types (Table 11-1A-94).

Table 11-1A-94. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures Fall below the 60.8°F Water Temperature Threshold Range for the Initiation of Sacramento-San Joaquin Roach Spawning[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	-5 (-5%)	2 (3%)
	Above Normal	-3 (-3%)	4 (4%)
	Below Normal	-8 (-8%)	-1 (-1%)
	Dry	-3 (-3%)	2 (2%)
	Critical	-10 (-10%)	-1 (-1%)
	All	-5 (-5%)	1 (1%)
Trinity River below Lewiston Reservoir	Wet	0 (0%)	0 (0%)
	Above Normal	-2 (-2%)	0 (0%)
	Below Normal	-2 (-2%)	0 (0%)
	Dry	-3 (-3%)	0 (0%)
	Critical	-8 (-8%)	0 (0%)
	All	-2 (-2%)	0 (0%)
Feather River below Thermalito Afterbay	Wet	-13 (-19%)	0 (0%)
	Above Normal	-7 (-13%)	0 (0%)
	Below Normal	-2 (-4%)	4 (7%)
	Dry	-13 (-23%)	-1 (-3%)
	Critical	-19 (-33%)	-4 (-11%)
	All	-11 (-19%)	0 (-1%)
American River below Nimbus Dam	Wet	-22 (-32%)	0 (0%)
	Above Normal	-20 (-33%)	0 (0%)
	Below Normal	-23 (-36%)	0 (0%)
	Dry	-18 (-36%)	1 (4%)
	Critical	-15 (-30%)	0 (0%)
	All	-20 (-34%)	0.3 (1%)
Stanislaus River below New Melones Dam	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)
	Critical	0 (0%)	0 (0%)
	All	0 (0%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

CEQA Conclusion: In general, Alternative 1A would reduce the quality and quantity of upstream habitat relative to Existing Conditions, although these mainstem river changes are not likely affect Sacramento-San Joaquin roach, which occur primarily in tributary areas.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning. In a study of roach over a whole season Moyle and Baltz (1985) found them in habitats with flows averaging 0.2 m/s but ranging from 0.025m/s to 0.38 m/s. Roach are typically considered a foothill stream species and it is unlikely that their population numbers are dependent on the Sacramento River and large tributaries (Moyle 2002).

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Numbers as indicated by screw trap catches at Red Bluff Diversion Dam are small where 275 Sacramento-San Joaquin roach were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Sacramento-San Joaquin roach are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would always be similar to or greater than flows under Existing Conditions during March through June (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Numbers of Sacramento-San Joaquin roach caught in screw traps are low with an average of less than 45 caught over a 9-year period (Gaines and Martin 2001; Greenwald et al. 2003; Earley et al. 2008a, 2008b, 2009, 2010).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be substantially greater (up to 204% greater) than flows under Existing Conditions during March through June, except in below normal years during March (31% lower) and wet years during May (28% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during March, April, and June, except in critical years during March and June (8% and 31% lower, respectively), above normal years during April (6% lower) and wet years during June (24% lower). Flows under A1A_LLT in May would generally be up to 24% lower than those under Existing Conditions (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek. The Sacramento River and its large tributaries are most likely not the primary habitat of Sacramento-San Joaquin roach. It is more likely that they are washed into these bigger streams from smaller tributaries which would likely be warmer than the below dam releases that are made for salmonid fishes.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT below the threshold would be lower than the percentage under Existing Conditions in all water years (Table

11-1A-94). Numbers as indicated by screw trap catches at Red Bluff Diversion Dam are small where 275 Sacramento-San Joaquin roach were caught out of a total of 857,727 total fish caught (Gaines and Martin 2001).

Sacramento-San Joaquin roach are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT below the threshold would be lower than the percentage under Existing Conditions in all water year types (Table 11-1A-94).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT below the threshold would be lower than the percentage under Existing Conditions in all water years (Table 11-1A-94).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT below the threshold would be similar to the percentage under Existing Conditions in all water year types (Table 11-1A-94).

Hardhead

In general, Alternative 1A would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under NAA throughout the period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Hardhead are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would always to be similar to flows under NAA throughout the period regardless of water year type (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be substantially greater (up to 219% greater) than flows under NAA throughout the period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would be similar to or greater than flows under NAA during April. During May, flows under A1A_LLT would generally be greater than flows under NAA (up to 28% greater) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see AQUA-76, -77, and -78 under Chinook salmon fall-

/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year except wet and dry years (5% and 9% higher, respectively) (Table 11-1A-95).

Hardhead are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be lower than the percentage under NAA in all water year (Table 11-1A-95).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside the 59°F to 75°F water temperature range would be similar to or lower than the percentage under NAA in all water years except critical years (6% higher) (Table 11-1A-95).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to the percentage under NAA in all water year types (Table 11-1A-95).

Table 11-1A-95. Difference and Percent Difference in the Percentage of Months during April–May in Which Water Temperatures Are outside the 59°F to 64°F Water Temperature Range for Hardhead Spawning[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	-10 (-11%)	4 (5%)
	Above Normal	-13 (-14%)	2 (2%)
	Below Normal	-15 (-16%)	0.5 (1%)
	Dry	-6 (-6%)	8 (9%)
	Critical	-15 (-16%)	0 (0%)
	All	-11 (-12%)	3 (4%)
Trinity River below Lewiston Reservoir	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)
	Critical	0 (0%)	0 (0%)
	All	0 (0%)	0 (0%)
Feather River below Thermalito Afterbay	Wet	-6 (-9%)	-8 (-14%)
	Above Normal	-27 (-43%)	-18 (-50%)
	Below Normal	4 (8%)	-18 (-38%)
	Dry	-8 (-15%)	-3 (-6%)
	Critical	-8 (-15%)	-8 (-18%)
	All	-8 (-14%)	-10 (-21%)
American River below Nimbus Dam	Wet	-27 (-37%)	-4 (-8%)
	Above Normal	18 (40%)	0 (0%)
	Below Normal	4 (7%)	-4 (-7%)
	Dry	14 (29%)	-3 (-5%)
	Critical	38 (100%)	4 (6%)
	All	3 (6%)	-2 (-3%)
Stanislaus River below New Melones Dam	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)
	Critical	0 (0%)	0 (0%)
	All	0 (0%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

CEQA Conclusion: In general, Alternative 1A would reduce the quality and quantity of upstream habitat conditions for hardhead relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the period, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Hardhead are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would always be similar to or greater than flows under Existing Conditions throughout the period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the period, except in wet years during May (28% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would be similar to or greater than flows under Existing Conditions during April except in above normal years (6% lower) and generally up to 24% lower than flows under Existing Conditions during May (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT below the threshold would be lower than the percentage under Existing Conditions in all water years (Table 11-1A-95).

Hardhead are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT below the threshold would be lower than the percentage under Existing Conditions in all water years except below normal years (8% higher) (Table 11-1A-95).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT below the threshold would be higher than the percentage under Existing Conditions in almost all water years (up to 100% higher) (Table 11-1A-95).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT below the threshold would be similar to the percentage under Existing Conditions in all water year types (Table 11-1A-99).

California Bay Shrimp

NEPA Effects: For California bay shrimp the overall flows and temperature within the estuary would be neutral or slightly improved with respect to spawning. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on spawning conditions for California bay shrimp would not be significant and no mitigation is required.

Impact AQUA-203: Effects of Water Operations on Rearing Habitat of Non-Covered Aquatic Species of Primary Management Concern

Refer to Impact AQUA-5 under delta smelt and Impact AQUA-41 under Chinook salmon for a discussion of the effects of water operations on rearing habitat of non-covered species of primary management concern. Although there are minor differences the effects are similar. Although Delta smelt and Chinook salmon are used for the purpose of comparing changes in flow and temperature it is recognized that non-covered species may use habitat differently and may respond differently to these changes. The conclusion from these comparisons for AQUA-5 and AQUA-41 of adverse from comparisons with Delta smelt and Chinook salmon are likely not adverse for non-covered species because of range, different uses of habitat, and differing temperature tolerance.

Striped Bass

NEPA Effects: Refer to Impact AQUA-5 under delta smelt and Impact AQUA-41 under Chinook salmon for a discussion of the effects of water operations on rearing habitat for striped bass. The potential effects would be similar to those described there. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on striped bass rearing habitat would be less than significant.

American Shad

NEPA Effects: Refer to Impact AQUA-5 under delta smelt and Impact AQUA-41 under Chinook salmon for a discussion of the effects of water operations on rearing habitat for American shad. The potential effects would be similar to those described there. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on American shad rearing habitat would be less than significant.

Threadfin Shad

NEPA Effects: Refer to Impact AQUA-5 under delta smelt and Impact AQUA-41 under Chinook salmon for a discussion of the effects of water operations on rearing habitat for threadfin shad. The potential effects would be similar to those described there. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on threadfin shad rearing habitat would be less than significant.

Largemouth Bass

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat (backwaters) available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under NAA during April through July and October, with some exceptions (up to 14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A1A_LLT during August, September, November, and July would be lower, by up to 42%, than NAA depending on month, water year type, and time period.

In the Trinity River below Lewiston Reservoir, flows under A1A_LLT would generally be similar to or greater than flows under NAA during the April through November period with some exceptions (up to 42% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Largemouth bass were not found in Trinity River screw trap data (Pinnix et al. 2010), but are apparently found in low numbers when washed down from upstream reservoirs (U.S. Fish and Wildlife Service and Hoopa Valley Tribe 1999).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during June and September (8% and 13% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be lower than those under NAA during July through September (up to 86% lower) and generally greater during April through June and October through November (up to 219% greater), with some exceptions (up to 28% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be lower than flows under NAA during July through September (up to 47% lower), greater during May, June, and October (up to 36% greater), and similar during April and November, with some exceptions (up to 17% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures would not exceed 88°F under NAA or A1A_LLT in any of the rivers examined (Table 11-1A-96). As a result, there would be no difference in the percentage of months in which the 88°F water temperature threshold is exceeded between Alternative 1A and the NAA.

Table 11-1A-96. Difference and Percent Difference in the Percentage of Months during April–November in Which Water Temperatures Exceed the 88°F Water Temperature Threshold for Juvenile Largemouth Bass Rearing[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Trinity River below Lewiston Reservoir	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
American River below Nimbus Dam	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Stanislaus River below New Melones Dam	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round adult largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT during August, September, and November would be lower than flows under NAA (up to 44% lower), and generally similar to or greater than flows under NAA during the rest of the year, with some exceptions (up to 11% lower). (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Trinity River below Lewiston Reservoir, flows under A1A_LLT would generally be similar to or greater than flows under NAA with some exceptions (up to 11% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Largemouth bass were not found in Trinity River screw trap data (Pinnix et al. 2010), but are apparently found in low numbers when washed down from upstream reservoirs (U.S. Fish and Wildlife Service and Hoopa Valley Tribe 1999).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during June and September (8% and 13% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater than those under NAA during October through June (up to 219% greater) and lower during July through September (up to 86% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be greater than flows under NAA during May, June, and October (up to 37% greater), generally lower during July through September (up to 47% lower), and generally similar during the remaining months (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures would not exceed 88°F under NAA or A1A_LLT in any of the waterways examined (Table 11-1A-97). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between Alternative 1A and the NAA.

Table 11-1A-97. Difference and Percent Difference in the Percentage of Months in Which Year-Round Water Temperatures Exceed the 86°F Water Temperature Threshold for Adult Largemouth Bass Survival[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Trinity River below Lewiston Reservoir	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
American River below Nimbus Dam	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Stanislaus River below New Melones Dam	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 1A would not cause a substantial reduction in juvenile and adult rearing or spawning habitat. Flows in all rivers examined during the year under Alternative 1A are generally similar to or greater than flows under the NAA in most months. Flows in July through September are generally lower in the Feather River high flow channel and in the American River below Nimbus Dam, although these reductions would not be biologically meaningful to the largemouth bass population due to the high mobility and diverse distribution of largemouth bass in the Central Valley. The percentage of months outside all temperature thresholds in all locations examined under Alternative 1A are generally similar to or lower than under the NAA.

CEQA Conclusion: In general, Alternative 1A would reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to Existing Conditions.

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions in all months but July through September and November with some exceptions (up to 14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows during July through September and November under A1A_LLT would be up to 24% lower than flows under Existing Conditions.

In the Trinity River below Lewiston Reservoir, flows under A1A_LLT during April through November would generally be similar to or greater than flows under Existing Conditions throughout the period with some exceptions (up to 42% lower), except during October and November (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A1A_LLT during October and November would be up to 25% lower than flows under Existing Conditions. Largemouth bass were not found in Trinity River screw trap data (Pinnix et al. 2010), but are apparently found in low numbers when washed down from upstream reservoirs (USFWS and Hoopa Valley Tribe 1999).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the April through November period, except in critical years during August and September (17% to 38% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater (up to 204% greater) than flows under Existing Conditions during April through June and October, lower (up to 56% lower) during July through September, and similar during November (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during April, June, and October, with some exceptions (up to 31% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A1A_LLT during the rest of the period would be lower by up to 53% and.

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

The analysis indicates that there would be no temperature-related effects in in the Sacramento, Trinity, American, and Stanislaus rivers during the April through November period. Water temperatures would not exceed 88°F under Existing Conditions or A1A_LLT in all waterways examined (Table 11-1A-97). As a result, there would be no difference in the percentage of months in which the 88°F water temperature threshold is exceeded between Alternative 1A and Existing Conditions.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round adult largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during all months but July through September and November, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A1A_LLT during July through September and November would be lower than flows under Existing Conditions (up to 24% lower).

In the Trinity River below Lewiston Reservoir, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year with some exceptions (up to 42% lower), except during October through December when it would generally be lower (up to 25% lower during both months) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Largemouth bass were not found in Trinity River screw trap data (Pinnix et al. 2010), but are apparently found in low numbers when washed down from upstream reservoirs (USFWS and Hoopa Valley Tribe 1999).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August and September (17% and 38% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater than those under Existing Conditions during February through June, October, and December (up to 204% greater), lower during July through September (up to 56% lower), and similar during November and January (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally greater than flows under Existing Conditions during February, March, and October (up to 42% greater), lower during January, May, July through September, and November through December (up to 53% lower), and generally similar during the rest of the year (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures would not exceed 86°F under Existing Conditions or A1A_LLT in all waterways examined (Table 11-1A-97). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between Alternative 1A and Existing Conditions.

Collectively, the results of the Impact AQUA-202 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 1A could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat, contrary to the NEPA conclusion set forth above. There would be small to moderate flow-related effects and temperature-related effects of Alternative 1A on Sacramento tule perch in the American and Feather rivers. Flow reductions and increases in exceedances above temperature thresholds would have a biologically meaningful effect on the population. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 1A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 1A indicates that flows in the locations and during the months analyzed above would generally be similar between future conditions without BDCP and Alternative 1A. This indicates that the differences between Existing Conditions and Alternative 1A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 1A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for Sacramento tule perch. This impact is found to be less than significant and no mitigation is required.

The NEPA and CEQA conclusions differ for this impact statement because they were determined using two unique baselines. The NEPA conclusion was based on the comparison of A1A_LLT with NAA and the CEQA conclusion was based on the comparison of A1A_LLT with Existing Conditions. These baselines differ in two ways. First, the NAA includes the Fall X2 standard in wet above normal water years whereas Existing Conditions do not. Second, the NAA is assumed to occur during the late long-term implementation period whereas the CEQA baseline is assumed to occur during existing climate conditions. Therefore, differences in model outputs between the CEQA baseline and the Alternative 1A are due primarily to both the alternative and future climate change.

Sacramento Tule Perch

NEPA Effects: Refer to Impact AQUA-5 under delta smelt and Impact AQUA-41 under Chinook salmon for a discussion of the effects of water operations on rearing habitat for Sacramento tule perch. The potential effects would be similar to those described there. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on Sacramento tule perch rearing habitat would be less than significant.

Sacramento-San Joaquin Roach

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach rearing period. Lower flows could reduce the quantity and quality of instream habitat available for rearing. The Sacramento River and its large tributaries are most likely not the primary habitat of Sacramento-San Joaquin roach. It is more likely that they are washed into these bigger streams from smaller tributaries which would likely be warmer than the below dam releases that are made for salmonid fishes.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT during August, September, and November would be lower than flows under NAA (up to 44% lower), and generally similar to or greater than flows under NAA during the rest of the year, with some exceptions (up to 11% lower). (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Sacramento-San Joaquin roach are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during June and September (8% and 13% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater than those under NAA during October through June (up to 219% greater) and lower during July through September (up to 86% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be greater than flows under NAA during May, June, and October (up to 37% greater), generally lower during July through September (up to 47% lower), and generally similar during the remaining months (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76–through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures would not exceed 86°F under NAA or A1A_LLT in any of the waterways examined (Table 11-1A-98). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between Alternative 1A and NAA.

Table 11-1A-98. Difference and Percent Difference in the Percentage of Months in Which Year-Round Water Temperatures Exceed the 86°F Water Temperature Range for Sacramento-San Joaquin Roach Survival[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Trinity River below Lewiston Reservoir	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
American River below Nimbus Dam	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Stanislaus River below New Melones Dam	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 1A would not cause a substantial reduction in spawning and juvenile and adult Sacramento-San Joaquin roach rearing habitat. Flows under Alternative 1A in all rivers examined throughout the year are generally similar to or greater than flows under the NAA, except during July through September are generally lower in the Feather River high flow channel and in the American River below Nimbus Dam, although these reductions would not be biologically meaningful to the roach population. The percentage of months outside temperature thresholds are generally similar to or lower under Alternative 1A than under NAA. In addition, Sacramento-San Joaquin roach occur primarily in tributary habitat areas, where there would be little or no effects from Alternative 1A water operations.

CEQA Conclusion: In general, Alternative 1A would reduce the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach rearing period. Lower flows could reduce the quantity and quality of instream habitat available for rearing. The Sacramento River and its large tributaries are most likely not the primary habitat of Sacramento-San Joaquin roach. It is more likely that they are washed into these bigger streams from smaller tributaries which would likely be warmer than the below dam releases that are made for salmonid fishes.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during all months but July through September and November, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A1A_LLT during July through September and November would be lower than flows under Existing Conditions (up to 24% lower).

Sacramento-San Joaquin roach are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August and September (17% and 38% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater than those under Existing Conditions during February through June, October, and December (up to 204% greater), lower during July through September (up to 56% lower), and similar during November and January (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally greater than flows under Existing Conditions during February, March, and October (up to 42% greater), lower during January, May, July through September, and November through December (up to 53% lower), and generally similar during the rest of the year (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76–through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures would not exceed 86°F under Existing Conditions or A1A_LLT in any of the waterways examined (Table 11-1A-98). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between Alternative 1A and Existing Conditions.

Collectively, these results indicate that the impact would not be significant because Alternative 1A would cause a substantial reduction in Sacramento-San Joaquin roach spawning habitat or juvenile and adult rearing habitat, as these occur primarily in tributary habitat areas. However, flows would be substantially lower during the majority of the year-round juvenile and adult rearing period in the American River and in one third of the period in the Feather River. Flows in other rivers would not have biologically meaningful effects.

Hardhead

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT during August, September, and November would be lower than flows under NAA (up to 44% lower), and generally similar to or greater than flows under NAA during the rest of the year, with some exceptions (up to 11% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Hardhead are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam). Flows under A1A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during June and September (8% and 13% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater than those under NAA during October through June (up to 219% greater) and lower during July through September (up to 86% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally be greater than flows under NAA during May, June, and October (up to 37% greater), generally lower during July through September (up to 47% lower), and generally similar during the remaining months (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76– through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead rearing was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-99).

Hardhead are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be lower than the percentage under NAA in all water year types except below normal years (6% higher) (Table 11-1A-99).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside the 59°F to 75°F water temperature range would be similar to or lower than the percentage under NAA in all water year types (Table 11-1A-99).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to the percentage under NAA in all water year types (Table 11-1A-99).

Table 11-1A-99. Difference and Percent Difference in the Percentage of Months in Which Year-Round Water Temperatures Are outside the 65°F to 82.4°F Water Temperature Range for Juvenile and Adult Hardhead Occurrence[a]

Location	Water Year Type	EXISTING CONDITIONS vs. A1A_LLT	NAA vs. A1A_LLT
Sacramento River upstream of Red Bluff	Wet	0 (0%)	0 (0%)
	Above Normal	-1 (-1%)	0 (0%)
	Below Normal	-1 (-1%)	-1 (-1%)
	Dry	-4 (-4%)	0 (0%)
	Critical	-14 (-15%)	-1 (-1%)
	All	-3 (-3%)	0 (0%)
Trinity River below Lewiston Reservoir	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	-1 (-1%)	0 (0%)
	Dry	-1 (-1%)	0 (0%)
	Critical	-9 (-9%)	-1 (-1%)
	All	-2 (-2%)	0 (0%)
Feather River below Thermalito Afterbay	Wet	-5 (-7%)	-2 (-3%)
	Above Normal	-9 (-13%)	-5 (-7%)
	Below Normal	-7 (-9%)	4 (6%)
	Dry	-7 (-10%)	0.5 (1%)
	Critical	-8 (-11%)	-1 (-1%)
	All	-7 (-9%)	-1 (-1%)
American River below Nimbus Dam	Wet	-20 (-25%)	1 (1%)
	Above Normal	-17 (-24%)	0 (0%)
	Below Normal	-17 (-24%)	1 (1%)
	Dry	-13 (-20%)	0 (-1%)
	Critical	-13 (-21%)	0 (0%)
	All	-17 (-23%)	0 (0%)
Stanislaus River below New Melones Dam	Wet	0 (0%)	0 (0%)
	Above Normal	0 (0%)	0 (0%)
	Below Normal	0 (0%)	0 (0%)
	Dry	0 (0%)	0 (0%)
	Critical	-1 (-1%)	0 (0%)
	All	0 (0%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 1A would not cause a substantial reduction in spawning and juvenile and adult hardhead rearing. Flows under Alternative 1A in all rivers examined throughout the year are generally similar to or greater than flows under the NAA, except during summer months in the Feather and half the year in the American rivers. These reductions in flows, however, would not cause an overall biologically meaningful effect on hardhead due to the high mobility and diverse distribution of hardhead in the Central Valley. The percentages of years outside all temperature thresholds in all locations examined under Alternative 1A are generally lower than under the NAA.

CEQA Conclusion: In general, Alternative 1A would reduce the quality and quantity of upstream habitat conditions for hardhead relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions during all months but July through September and November, except in wet years during May (14% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A1A_LLT during July through September and November would be lower than flows under Existing Conditions (up to 24% lower).

Hardhead are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In Clear Creek at Whiskeytown Dam, flows under A1A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August and September (17% and 38% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the Feather River at Thermalito Afterbay, flows under A1A_LLT would generally be greater than those under Existing Conditions during February through June, October, and December (up to 204% greater), lower during July through September (up to 56% lower), and similar during November and January (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

In the American River at Nimbus Dam, flows under A1A_LLT would generally greater than flows under Existing Conditions during February, March, and October (up to 42% greater), lower during January, May, July through September, and November through December (up to 53% lower), and generally similar during the rest of the year (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Flow rates in the San Joaquin and Stanislaus rivers would be the same as described above for covered fish species under Alternative 1A (see Impacts AQUA-76 through 78 under Chinook salmon fall-/late-fall run ESU). That analysis indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months in which year-round in-stream temperatures would be outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead rearing was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

In the Sacramento River upstream of Red Bluff, the percentage of months under A1A_LLT outside the range would be similar to or lower than the percentage under Existing Conditions in all water year types (Table 11-1A-99).

Hardhead are not found in Trinity River screw trap data (Pinnix et al. 2010), or within the Klamath Province (Moyle 2002).

In the Feather River below Thermalito Afterbay, the percentage of months under A1A_LLT outside the range would be lower than the percentage under Existing Conditions in all water year types (Table 11-1A-99).

In the American River below Nimbus Dam, the percentage of months under A1A_LLT outside the range would be lower than the percentage under Existing Conditions in all water year types (Table 11-1A-99).

In the Stanislaus River below New Melones Dam, the percentage of months under A1A_LLT outside the range would be similar to the percentage under Existing Conditions in all water year types (Table 11-1A-99).

Collectively, these results indicate that the impact would be significant because Alternative 1A would cause a substantial reduction in hardhead habitat. Flows would be substantially lower during the majority of the year-round juvenile and adult rearing period in the American River and in one third of the period in the Feather River. Flows in other rivers would not have biologically meaningful effects on hardhead. The percentages of years outside the temperature thresholds are generally lower under Alternative 1A than under Existing Conditions, except for the 59–64°F spawning temperature range in the American River. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less than significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available.

The NEPA and CEQA conclusions differ for this impact statement because they were determined using two unique baselines. The NEPA conclusion was based on the comparison of A1A_LLT with NAA and the CEQA conclusion was based on the comparison of A1A_LLT with Existing Conditions. These baselines differ in two ways. First, the NAA includes the Fall X2 standard in wet above normal water years whereas the CEQA Existing Conditions do not. Second, the NAA is assumed to occur during the late long-term implementation period whereas the CEQA baseline is assumed to occur during existing climate conditions. Therefore, differences in model outputs between the CEQA baseline and the Alternative 1A are due primarily to both the alternative and future climate change.

California Bay Shrimp

NEPA Effects: For California bay shrimp the overall flows and temperature within the estuary would be neutral or slightly improved with respect to rearing. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on rearing conditions for California bay shrimp would not be significant and no mitigation is required.

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

Striped Bass

NEPA Effects: Refer to Impact AQUA-6 under delta smelt and Impact AQUA-42 under Chinook salmon for a discussion of the effects of water operations on migration conditions for striped bass. The potential effects would be similar to those described there. The potential effects would be similar to those described, although the primary mechanisms of effect are likely to be changes in water flow, and related water temperatures, which could alter adult spawning migration timing. In addition, newly hatched larvae drift with the currents, so changes in flow would affect the rate of downstream movement, resulting in potential changes in food availability, predation rates, and available suitable habitat. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on striped bass migration conditions would be less than significant.

American Shad

NEPA Effects: Refer to Impact AQUA-6 under delta smelt and Impact AQUA-42 under Chinook salmon for a discussion of the effects of water operations on migration conditions for American shad. The potential effects would be similar to those described there. The potential effects would be similar to those described, although the primary mechanism of effect would be changes in flow, which could affect adult and juvenile migration timing and migration rates. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on American shad migration conditions would be less than significant.

Threadfin Shad

NEPA Effects: Threadfin shad are non-migratory fish within the Delta, so they do not use the Delta as migration habitat. Therefore, Alternative 1A would have no effect on their movements within the Delta.

CEQA Conclusion: As described above, threadfin shad are non-migratory, so flow changes under Alternative 1A would have no impact on their movements within the Delta. Therefore, no mitigation is required.

Largemouth Bass

NEPA Effects: Largemouth bass are non-migratory fish within the Delta. Therefore they do not use the Delta as migration habitat corridor. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes under Alternative 1A would not affect largemouth movements within the Delta. No mitigation would be required.

Sacramento Tule Perch

NEPA Effects: Similar with largemouth bass, Sacramento tule perch are a non-migratory species and do not use the Delta as a migration corridor as they are a resident Delta species. There would be no effect.

CEQA Conclusion: As described immediately above, flow movements would not affect Sacramento tule perch movements within the Delta. No mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: Sacramento-San Joaquin roach are non-migratory, and the overall flows and temperature in upstream rivers during spawning would be similar to those described under Alternative 1A, Impact AQUA-202 for spawning. As described there, the flows would slightly improve the upstream spawning conditions relative to the NAA, but would have no effect on Sacramento-San Joaquin roach movement in the Delta.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for Sacramento-San Joaquin roach would not be significant and no mitigation is required.

Hardhead

NEPA Effects: For hardhead the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 1A, Impact AQUA-202 for spawning. As described there, the flows would slightly improve the upstream conditions relative to the NAA. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for hardhead would not be significant and no mitigation is required.

California Bay Shrimp

NEPA Effects: For California bay shrimp the overall flows and temperature in the estuary associated with migration would be similar to those described under Alternative 1A, Impact AQUA-202 for spawning. As described there, the flows would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for California bay shrimp would not be significant and no mitigation is required.

Restoration Measures (Conservations Measures 2, 4–7, and 10)

The effects of restoration measures under Alternative 1A would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-7 under delta smelt a discussion of the effects of construction of restoration measures on non-covered species of primary management concern. The potential effects would be similar to those described there. These effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of the construction of restoration measures would be less than significant.

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-8 under delta smelt a discussion of the effects of contaminants associated with restoration measures on non-covered species of primary management concern. The potential effects would be similar to those described there. These effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of contaminants associated with restoration measures would be less than significant.

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-9 under delta smelt a general discussion of the effects of restored habitat conditions on non-covered species of primary management concern. Although there are minor differences the effects are similar including for food production and export. Striped bass use Suisun Bay and the lower San Joaquin River so restored habitat in those locations would be of direct benefit. Largemouth bass do not use the Yolo Bypass and that restored habitat would have no direct benefit for them. Sacramento-San Joaquin roach do not use Yolo Bypass or the main river channels so those habitat improvements would not benefit them. Hardhead are primarily upstream of the Delta or in the lowermost main tributary channels so habitat improvements would have minimal benefit for them. Similarly, Sacramento perch would mainly benefit from restoration of tidal marsh habitat which would increase food resources. Threadfin shad use the estuarine zone so the increased acreage and improved quality of estuarine habitat would benefit them. California bay shrimp use the estuarine zone within Suisun Marsh so the increased acreage and improved quality of habitat would benefit them. Downstream transport of food resources into the Bay would also benefit California bay shrimp.

CEQA Conclusion: As described immediately above, the impacts of restored habitat conditions would range from no impact, to slightly beneficial, to beneficial.

Other Conservation Measures (CM12–CM19 and CM21)

The effects of other conservation measures under Alternative 1A would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (CM12)

NEPA Effects: Refer to Impact AQUA-10 under delta smelt a discussion of the effects of methylmercury management on non-covered species of primary management concern The potential effects would be similar to those described there. These effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of methylmercury management would be less than significant.

Impact AQUA-209: Effects of Invasive Aquatic Vegetation Management on Non-Covered Aquatic Species of Primary Management Concern (CM13)

NEPA Effects: Refer to Impact AQUA-11 under delta smelt a discussion of the effects of invasive aquatic vegetation management on non-covered species of primary management concern. There are minor differences and the effects are similar except for predatory species (striped bass and largemouth bass) and Sacramento tule perch. Invasive aquatic vegetation provides staging habitat for predatory fish at intermediate abundance which improves their hunting success. Sacramento tule perch also use the cover of aquatic plants in the Sacramento and San Joaquin rivers and in Suisun marsh. Consequently, reducing large amounts of invasive aquatic habitat will lower predatory species hunting success rates and provide less cover for Sacramento tule perch. However, this control will not substantially reduce places for predatory species to hunt and there will still be many other habitats in which the predatory species can successfully hunt and in which Sacramento tule perch would find shelter from predators. The effect on them will not be adverse. Control of invasive aquatic vegetation would not occur within California bay shrimp habitat and there would be no effect on them.

CEQA Conclusion: Refer to Impact AQUA-11 under delta smelt a discussion of the effects of invasive aquatic vegetation management on non-covered species of primary management concern. There are minor differences and the effects are similar except for predatory species, California bay shrimp and Sacramento tule perch. Invasive aquatic vegetation provides staging habitat for predatory fish which improves their hunting success. Control of invasive aquatic vegetation would not occur within California bay shrimp habitat and there would be no effect on them. Sacramento tule perch also use the cover of aquatic plants in the Sacramento and San Joaquin rivers and in Suisun marsh. Consequently, reducing the amount of invasive aquatic habitat will lower predatory species hunting success rates and provide less cover for Sacramento tule perch. However, this control will not substantially reduce places for predatory species to hunt and there will still be many other habitats in which Sacramento tule perch would find shelter from predators. Therefore the effect on them will not be significant and no mitigation is required.

Impact AQUA-210: Effects of Dissolved Oxygen Level Management on Non-Covered Aquatic Species of Primary Management Concern (CM14)

NEPA Effects: Refer to Impact AQUA-12 under delta smelt a discussion of the effects of dissolved oxygen level management on non-covered species of primary management concern. The potential effects would be similar to those described there. California bay shrimp do not occur in this habitat and there would be no effect on them. These effects would be beneficial.

CEQA Conclusion: As described immediately above, the impacts of oxygen level management would be beneficial.

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (CM15)

NEPA Effects: Refer to Impact AQUA-13 under delta smelt a discussion of the effects of predatory fish (striped bass and largemouth bass) and predator management on non-predatory fish. The purpose of predatory fish management is to reduce the numbers of predatory fish and to reduce their hunting success. To the extent that localized predator control efforts of *CM15 Localized Reduction of Predatory Fish* reduce the overall abundance of fish predators in the Delta, this management will have negative effects on predatory fish. However, the numbers of predatory fish are high and the extent of the habitats in which they hunt is extensive. Therefore the effects of this management will not be adverse. California bay shrimp do not occur in these habitats and there would be no effect on them.

CEQA Conclusion: Refer to Impact AQUA-13 under delta smelt a discussion of the effects of predatory fish and predator management on non-predatory fish. The purpose of predatory fish management is to reduce the numbers of predatory fish and to reduce their hunting success. To the extent that localized predator control efforts of *CM15 Localized Reduction of Predatory Fish* reduce the overall abundance of fish predators in the Delta, this management will have negative effects on predatory fish. However, the numbers of predatory fish are high and the extent of the habitats in which they hunt is extensive. Therefore the effects of this management will not be significant. No mitigation is required. California bay shrimp do not occur in these habitats and there would be no effect on them.

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (CM16)

NEPA Effects: Refer to Impact AQUA-14 under delta smelt a discussion of the effects of nonphysical fish barriers on non-covered species of primary management concern. Although there are minor differences the effects are similar except for Sacramento-San Joaquin roach, hardhead, and Sacramento perch which are unlikely to be present in their vicinity. California bay shrimp do not occur in these habitats and there would be no effect on them. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of nonphysical fish barriers would be less than significant.

Impact AQUA-213: Effects of Illegal Harvest Reduction on Non-Covered Aquatic Species of Primary Management Concern (CM17)

NEPA Effects: Refer to Impact AQUA-15 under delta smelt a discussion of the effects of illegal harvest reduction on non-covered species of primary management concern. The potential effects would be similar to those described there. California bay shrimp do not occur in these habitats and there would be no effect on them. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of illegal harvest reduction would be less than significant.

Impact AQUA-214: Effects of Conservation Hatcheries on Non-Covered Aquatic Species of Primary Management Concern (CM18)

NEPA Effects: Refer to Impact AQUA-16 under delta smelt a discussion of the effects of conservation hatcheries on non-covered species of primary management concern. There would be no effect.

CEQA Conclusion: As described immediately above, conservation hatcheries would have not impact.

Impact AQUA-215: Effects of Urban Stormwater Treatment on Non-Covered Aquatic Species of Primary Management Concern (CM19)

NEPA Effects: Refer to Impact AQUA-17 under delta smelt a discussion of the effects of urban stormwater treatment on non-covered species of primary management concern. These effects would be beneficial.

CEQA Conclusion: As described immediately above, the impacts of stormwater management would be beneficial.

Impact AQUA-216: Effects of Removal/Relocation of Nonproject Diversions on Non-Covered Aquatic Species of Primary Management Concern (CM21)

NEPA Effects: Refer to Impact AQUA-18 under delta smelt a discussion of the effects of removal/relocation of nonproject diversion on non-covered species of primary management concern. Although there are minor differences the effects are similar except for Sacramento-San Joaquin roach, hardhead, and Sacramento perch which are unlikely to be present near these diversions. California bay shrimp do not occur in these habitats and there would be no effect on them. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of removal/relocation of nonproject diversions would be less than significant.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

As previously described under the methods for the reservoir coldwater fish habitat analysis (Section 11.3.2.7), Shasta Reservoir was analyzed first and that approach was then applied, in combination with CALSIM modeling and the selected minimum coldwater habitat volumes, to evaluate the effects of the alternatives on coldwater habitat for the other major CVP and SWP reservoirs.

The evaluation of the Shasta Reservoir coldwater habitat volume can be described in three basic steps: 1) describe the reservoir geometry (volume and surface area) as a function of elevation, 2) describe the seasonal (monthly) water temperatures as a function of the elevation, storage level and outlet elevation(s), and 3) determine the portion of the reservoir volume with temperatures less than 60°F for the full range of carryover storages simulated with CALSIM. The coldwater habitat assessment compares the number of years with carryover storage less than the selected minimum volume index corresponding to the minimum acceptable coldwater habitat volume between the NAA and the BDCP alternatives, for each reservoir.

The reservoir geometry (surface area and volume) as a function of the water elevation and the elevation of the reservoir outlets are the basic features that determine the coldwater habitat in each reservoir. Table 11-1A-100 gives a summary of the Shasta Reservoir area (acres) and volume (acre-feet) for 25-feet increments of elevation. Figure 11-1A-6 shows the Shasta Reservoir volume (thousand acre-feet [taf]) as a function of elevation. The bottom of Shasta Reservoir is at 630 feet msl, but there is very little storage volume (50 taf) below an elevation of 700 ft. The maximum elevation of about 1,065 corresponds to a maximum storage of about 4,550 taf. Figure 11-1A-6 shows the Shasta Reservoir surface area (acres) as a function of elevation. The bottom sediment area (where benthic food organisms live) is about the same as the water surface area (where photosynthesis and heat exchange occurs).

The elevations of the reservoir outlets are also important for understanding the coldwater pool. The coldest water at the bottom of the reservoir (below the outlet penstocks to the hydropower turbines) remains at nearly the same temperature during the stratified period. Shasta Dam has river outlets with gate sills (bottoms) located at elevation 742 feet and 942 feet (the river gate at 842 feet is no longer operational). The gates are about 8 feet high, so water comes from a zone approximately

20 feet high centered at about 750 feet and 950 feet (when they are used). The intakes for the 15-feet diameter penstocks to the hydropower turbines are located with a centerline elevation of 815 feet, so water is drawn from elevations of approximately 800 feet to 830 feet. The spillway crest elevation is at 1,037 feet. During the 1976–1977 and the 1987–1992 drought periods, when Shasta Reservoir storage was low and water temperatures released through the hydropower plant were greater than 55°F, the low-level river outlets (at 750 feet and 850 feet) were used to blend with the hydropower releases (from 800–830 feet) to provide cooler release temperatures at Keswick Dam for winter run spawning and egg incubation. Subsequently, to protect winter-run spawning and egg incubation temperatures and also make full hydropower releases, the temperature control device (TCD) was designed and constructed. The TCD, which began operating in 1998, allows all releases to be made through the hydropower penstocks. Three levels of louver "gates" allow the penstock water to be blended from three elevation zones. Higher level releases are used early in the summer to preserve as much of the cold water as possible; the open gate levels are adjusted towards the bottom gate during the summer. By preserving the coldest water for the early fall period (September and October), the cold water habitat in the reservoir is also protected through the summer months; however, use of the low level gate allows more of the cold water from the bottom of the reservoir to be released in September and October. Table 11-1A-100 indicates that the storage volume located below the penstocks (800 feet) is about 350 taf with a benthic area within this protected cold water habitat of about 5,000 acres.

Table 11-1A-100. Shasta Reservoir Geometry

Elevation (feet)	Surface Area (acres)	Volume (acre-feet)
1,075	30,908	4,792,000
1,050	27,654	4,068,649
1,025	24,633	3,388,333
1,000	21,800	2,830,000
975	19,200	2,345,000
950	16,600	1,860,000
925	14,300	1,505,000
900	12,000	1,150,000
875	10,100	907,500
850	8,200	665,000
825	6,617	490,624
800	5,080	342,000
775	3,800	233,333
750	2,800	150,000
725	1,914	85,714
700	1,200	50,000
675	771	18,750
650	343	3,437

The seasonal (monthly) reservoir release temperature and the vertical temperature profiles within the reservoir are directly linked and depend on the elevation of the outlets and the reservoir geometry and water surface elevation. The relationships between carryover storage and release temperatures for the major CVP and SWP reservoirs are shown and described in Appendix 29C

"Climate Change and Effects of Reservoir Operations on Water Temperatures." Release temperatures are relatively cool and stable until the fall months. The release temperatures increase and the remaining coldwater habitat volume decreases as the carryover reservoir storage is reduced in dry years. Only if the carryover storage is reduced below a specific volume (taf) are the release temperatures moderately increased. For storages below this threshold, the release temperature increases as the storage is reduced and the coldwater habitat volume is substantially reduced.

The cold water habitat of a reservoir is located below the vertical temperature gradient that develops in the spring months of April-June. Figure 11-1A-7 illustrates the seasonal development of surface warming and temperature stratification in Shasta Reservoir, and the fall cooling of surface temperatures in the fall and early winter months during 1995. These data were collected just upstream of Shasta Dam at depths corresponding to elevations of 650 feet to the surface in 25-feet increments. The water temperatures were never quite fully- mixed and isothermal (same temperatures) in 1995. The temperatures at the end of January and the end of February were about 45^{0}F at the bottom and 50^{0}F at the top (water surface elevation of 1,025 feet). Surface temperatures were less than 55^{0}F at the end of March and April, but increased to 65^{0}F at the end of May and June. The warmest surface temperatures (80^{0}F) were measured at the end of July, with slightly cooler surface temperatures of 75^{0}F at the end of August and September. At the end of October the surface temperatures were less than 65^{0}F and the surface cooling had caused the water to mix (isothermal) to a depth of about 100 feet. By the end of December the surface temperatures were less than 60^{0}F and the surface mixed layer had a depth of about 150 feet.

Warming of the reservoir below the surface heated layer is caused by water releases from the outlets; warmer water from above is drawn down to replace the water released from the penstock (elevation 800 feet) or the low-level river outlet (elevation 750 feet). The warming may also depend on the reservoir inflow and outflow during these summer months. Inflowing water will usually be cooler than the surface temperature and will enter the reservoir profile at the matching temperature; this will expand the depth of this temperature layer. The effects of inflowing water can be stronger during the fall, when the cooler inflow contributes to the deepening of the surface mixed layer.

The effects of reservoir storage drawdown on the coldwater habitat volume can be tracked by evaluating the coldwater habitat volume available through the year. Figure 11-1A-7 shows the entire reservoir was coldwater habitat (<60°F) from January through April. The surface layer was warmer than 60^{0}F in the summer months, but the reservoir volume below elevation 900 feet was less than 60^{0}F at the end of September and the volume below elevation 875 feet was less than 60^{0}F at the end of October. The minimum Shasta Reservoir storage at the end of September 1995 was about 3,400 taf (1,025 feet). The coldwater habitat volume would likely be more limited in years with a lower carryover storage volume. The end-of-September storage simulated with the CALSIM reservoir operation model will be used as the annual index for assessing coldwater habitat volume. A relationship between end of September storage and coldwater habitat volume was determined from the temperature profiles simulated with the Sacramento River Water Quality Model (SRWQM) developed for Reclamation by RMA. This model was used for each of the alternatives to simulate reservoir temperatures, release temperatures and downstream river temperatures. The model predicts reservoir profiles that were used to develop carryover storage-cold water habitat relationship for Shasta Reservoir.

Figure 11-1A-8 shows an example of the simulated relationship between reservoir storage and coldwater habitat (defined as less than 58°F in this example) for the No Action Baseline for 1922 to

2003. August was used in this example because September temperatures were not available in the coldwater habitat results. The SRWQM results show a strong relationship between August storage and coldwater habitat volume. The maximum coldwater habitat volume in August was about 1,500 taf (below elevation 925 feet) for <58^{0}F. The coldwater habitat volumes were reduced when the August storage volume was less than about 3,000 taf (below elevation 1,000 feet). Figure 11-1A-9 shows the SRWQM-simulated relationship between Shasta Reservoir volume and coldwater habitat volume for the end of August. The relationship between Shasta Reservoir storage and coldwater habitat volume can be used to assess the effects of reduced end-of-year storage on coldwater habitat volume.

The evaluation of the annual carryover storage effects on coldwater habitat volumes can be made using either a specified "threshold" for coldwater habitat impact for each reservoir, or using a "scale" for coldwater habitat effects that would vary with carryover volume for each reservoir. Impacts could then be measured as the increase in the number of years with storage below the selected threshold value, or as the reduction in the average coldwater habitat effects calculated from a baseline carryover storage sequence to an alternative sequence of carryover storage values. However, because a rating scale will provide the average coldwater habitat benefits rather than emphasizing the poor conditions in the lower storage years, large impacts in a few years will be masked by the generally suitable conditions. For this reason, the threshold storage method is preferred for impact evaluation. The impact evaluation of Shasta Reservoir operations on coldwater habitat volume was based on a specified threshold storage that would protect sufficient coldwater habitat volume for the fish populations in the reservoir.

Figure 11-1A-9 can be used as the basis for a specified threshold volume or for a specified "scaling" of carryover storage coldwater benefits. Assuming 60^{0}F as the upper limit for coldwater habitat, carryover storage of about 3,500 taf (maximum end-of September Shasta storage) would provide a coldwater habitat volume of 1,500 taf. Carryover storage of 2,500 taf would provide a coldwater habitat volume of about 750 taf, which is about half of the maximum coldwater habitat volume of 1,500 taf. Carryover storage of 2,000 taf would provide a coldwater habitat volume of about 500 taf, which is about 33% of the maximum coldwater habitat volume. Carryover storage of 1,500 taf would provide a coldwater habitat volume of about 250 taf, which is about 15% of the maximum coldwater habitat volume. Carryover storage of 1,000 taf would provide a coldwater habitat volume of about 50 taf, which is less than 5% of the maximum coldwater habitat volume. Because the minimum coldwater volume needed to protect the coldwater fish population in Shasta Reservoir is not known, the assessments for three carryover storage thresholds (2,500 taf, 2,000 taf, and 1,500 taf) were compared. Table 11-1A-101 shows the summary of the Shasta Reservoir coldwater habitat for three possible threshold values. The number of years with carryover storage less than the selected threshold (indicating a substantial reduction in coldwater habitat) for each alternative was compared to the number of years below the threshold storage for the baseline. As the carryover storage threshold is reduced, the likely impacts on coldwater habitat will be greater, but the impacts will be less frequent (measured as the number of years with carryover storage below the threshold). A coldwater habitat adverse effect determination was based on the number of additional years with carryover storage below the specified threshold value. An increase of greater than 5% of the years (5 more years) was selected as a substantial change in coldwater habitat conditions because these low storage conditions are expected infrequently during multi-year dry periods.

A comparison of the baseline cases shows the expected impacts on coldwater habitat from the effects of climate change shifts in hydrology as well as operational changes related to the Fall X2 requirements (USFWS BO) compared to the previous D-1641 Delta outflow criteria. The Shasta Reservoir carryover storage for the Existing Conditions baseline with no Fall X2 requirement (Existing Conditions) was less than 2,500 taf in 19 years, was less than 2,000 taf in 13 years and was less than 1,500 taf in 9 years (out of 82 years). The Shasta Reservoir carryover storage for the No Action Alternative (NAA) was less than 2,500 taf in 44 years, was less than 2,000 taf in 22 years and was less than 1,500 taf in 15 years. The increases for all of the storage thresholds would be judged adverse because an increase of greater than 5% of the years (5) was selected as the significance criteria. About 20–25% of the baseline carryover storage values should be less than the selected storage threshold, so that the threshold represents the lowest 20–25% of the years and so that the number of years with these impacted coldwater habitat conditions could be increased if the carryover storage values were reduced substantially by an alternative. The Shasta carryover storage threshold was selected to be 2,000 taf; the storage was less than this threshold in about 27% of the years (22/82) for the NAA.

Table 11-1A-101 indicates that using the 2,000 taf carryover storage threshold with a greater than 5% (5 year) increase criteria, none of the alternatives, including Alternative 1A, would have an adverse effect on Shasta Reservoir coldwater habitat in the late-long-term (LLT) when compared to the NAA. All of the alternatives would have Shasta Reservoir carryover storages of less than 2,000 taf in about the same number of years (19–23) as the baseline (22).

Evaluation of Effects on Coldwater Habitat in Other CVP and SWP Reservoirs

It is generally assumed that the availability of cold water can affect the success or sustainability of reservoir fish populations but specific management or biological criteria for defining this relationship for the major CVP and SWP reservoirs are not available. Based on the rationale presented above for Shasta Reservoir, carryover storage thresholds for each of the CVP and SWP reservoirs have been selected for this analysis for coldwater habitat conditions.

Table 11-1A-10 shows the summary of coldwater habitat evaluations for each of the six major CVP and SWP reservoirs. A single carryover storage threshold value was selected for each reservoir. Following the Shasta Reservoir example, this was based on a combination of available temperature profiles, hydropower penstock elevations, and minimum simulated storage values for each reservoir. Threshold carryover storage values were selected for each reservoir so that about 20–25% of the baseline carryover storage values would be less than the storage threshold; and assuming that greater than 5% more years (5 years) with less than the threshold storage would be an adverse effect on coldwater habitat conditions for each reservoir as a result of substantially less coldwater habitat being available during those years.

Trinity Reservoir has a maximum storage of about 2,500 taf and maximum carryover storage of 1,975 taf. The minimum simulated storage was about 250 taf, corresponding to the hydropower penstock intake. About 20% of CALSIM-simulated Trinity Reservoir carryover storages for the NAA baseline were less than 750 taf. The Trinity River Restoration Agreement required minimum carryover storages of 600 taf, and the 2009 NMFS BO requires "consultation" with Reclamation if the Trinity Reservoir carryover storage is expected to be less than 400 taf. The Trinity Reservoir carryover storage threshold was selected to be 750 taf, with a greater than 5% increase (5 years) impact criteria. Table 11-1A-102 indicates that none of the BDCP alternatives have adverse effects on the Trinity Reservoir coldwater habitat conditions. Figure 11-1A-10 shows the Trinity Reservoir carryover storages for the BDCP Alternatives (LLT) compared to the NAA carryover storages for 1922–2003. This provides a graphical description of the similarity of the Trinity Reservoir carryover storage sequences simulated with the CALSIM model for 1922–2003.

Shasta Reservoir has a maximum storage of about 4,500 taf and maximum carryover storage - of 3,400 taf. The minimum simulated storage is about 550 taf, corresponding to the hydropower penstock intake. About 27% of CALSIM-simulated Shasta Reservoir carryover storage for the NAA was below 2,000 taf. The 2009 NMFS BO requires “consultation” with Reclamation if the Shasta Reservoir carryover storage is expected to be less than 1,900 taf. The Shasta Reservoir carryover storage threshold was selected to be 2,000 taf, with a greater than 5% increase (5 years) impact criteria. Table 11-1A-102 indicates that none of the BDCP alternatives have adverse effects on the Shasta Reservoir coldwater habitat conditions. Figure 11-1A-11 shows the Shasta Reservoir carryover storages for the Alternatives (LLT) compared to the NAA carryover storages for 1922–2003. This provides a graphical description of the similarity of the Shasta Reservoir carryover storage sequences simulated with the CALSIM model for 1922–2003.

Oroville Reservoir has a maximum storage of about 3,500 taf and maximum carryover storage of 3,350 taf. The minimum simulated storage was about 500 taf, corresponding to the hydropower penstock intake. The 28% cumulative distribution of CALSIM-simulated Oroville Reservoir carryover storage for the NAA was about 1,000 taf. The Oroville target carryover storage is 1,000 taf; SWP deliveries are adjusted to maintain this minimum operational storage. The Oroville Reservoir carryover storage threshold was selected to be 1,000 taf, with a greater than 5% increase (5 years) impact criteria. Table 11-1A-102 indicates that none of the alternatives have adverse effects on the Oroville Reservoir coldwater habitat conditions. Figure 11-1A-12 shows the Oroville Reservoir carryover storages for the Alternatives (LLT) compared to the NAA carryover storages for 1922–2003. This provides a graphical description of the similarity of the Oroville Reservoir carryover storage sequences simulated with the CALSIM model for 1922–2003. Most of the alternatives would increase the carryover storage in Oroville Reservoir compared to the NAA; benefits for coldwater fish habitat in Oroville Reservoir are therefore expected for most alternatives.

Folsom Reservoir has a maximum storage of about 1,000 taf and maximum carryover storage of 650 taf. The minimum simulated storage is about 100 taf, corresponding to the hydropower penstock intake. The 18% cumulative distribution of CALSIM-simulated Folsom Reservoir carryover storage for the NAA was about 250 taf. The 2009 NMFS BO requires “consultation” with Reclamation if the Folsom Reservoir carryover storage is expected to be less than 250 taf. The Folsom Reservoir carryover storage threshold was selected to be 250 taf, with a greater than 5% increase (5 years) impact criteria. Table 11-1A-102 indicates that some of the alternatives may have adverse effects on the Folsom Reservoir coldwater habitat conditions. Figure 11-1A-13 shows the Folsom Reservoir carryover storages for the Alternatives (LLT) compared to the NAA carryover storages for 1922–2003. This provides a graphical description of the similarity of the Folsom Reservoir carryover storage sequences simulated with the CALSIM model for 1922–2003. Because Folsom Reservoir maximum storage is only 1,000 taf and the carryover storage is relatively low most years, there is not a major coldwater fish population (trout) in Folsom Reservoir; the potential impacts on coldwater habitat in Folsom Reservoir are somewhat less than for coldwater habitat in Trinity, Shasta, and Oroville Reservoirs.

New Melones Reservoir has a maximum storage of about 2,400 taf and maximum carryover storage of 2,000 taf. The minimum simulated storage is about 100 taf, corresponding to the hydropower penstock intake. About 26% of CALSIM-simulated New Melones Reservoir carryover storage for the NAA were less than 750 taf. The New Melones Reservoir carryover storage threshold was selected to be 750 taf, with a greater than 5% increase (5 years) impact criteria. Table 11-1A-102 indicates that none of the alternatives have adverse effects on the New Melones Reservoir coldwater habitat conditions. Figure 11-1A-14 shows the New Melones Reservoir carryover storages for the Alternatives (LLT) compared to the NAA baseline carryover storages for 1922–2003. This provides a graphical description of the similarity of the New Melones Reservoir carryover storage sequences simulated with the CALSIM model for 1922–2003. Because the New Melones Reservoir (and all other San Joaquin Basin Reservoirs) operations were only changed for the climate change hydrology, there were no simulated differences in the New Melones Reservoir operations for the alternatives. There were, therefore, no impacts on New Melones Reservoir coldwater habitat conditions.

San Luis Reservoir has a maximum storage of about 2,000 taf and maximum carryover storage of 1,725 taf. The minimum simulated storage is about 100 taf, corresponding to the hydropower penstock intake. About 26% of CALSIM-simulated San Luis Reservoir carryover storage for the NAA were less than 350 taf. The San Luis Reservoir carryover storage threshold was selected to be 350 taf, with a greater than 5% increase (5 years) impact criteria. Figure 11-1A-15 shows the San Luis Reservoir carryover storages for the Alternatives (LLT) compared to the NAA carryover storages for 1922–2003. This provides a graphical description of the differences in the San Luis Reservoir carryover storage sequences simulated with the CALSIM model for 1922–2003. Table 11-1A-102 indicates that several of the alternatives will reduce the San Luis carryover storage substantially, with more than 4 additional years with carryover storage of less than 350 taf. However, because San Luis Reservoir is an off-stream storage reservoir that is filled each year with water exported from the Delta, the temperature stratification in the reservoir is usually eliminated by the pumping of relatively warm water into the reservoir through the inlet that is located near the bottom of the reservoir. The releases from San Luis Reservoir are also made through the intake/outlet structure near the bottom of the reservoir so that the coldest water is released during the spring and summer. Therefore, there is no coldwater habitat in the reservoir; San Luis Reservoir is dominated by warm-water fish (largemouth bass and striped bass). Although the San Luis Reservoir carryover storage was reduced by most of the alternatives, there is no coldwater habitat in San Luis Reservoir during most years and therefore no impacts to the coldwater habitat.

NEPA Effects: In summary, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 1A would not be substantially reduced when compared to the No Action Alternative.

CEQA Conclusion: In general, Alternative 1A would reduce the quantity of coldwater fish habitat in the CVP and SWP as shown in Table 11-1A-102. There would be a greater than 5% increase (5 years) for several of the reservoirs when compared to Existing Conditions, which could result in a significant impact.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 1A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. As a result, the CEQA conclusion regarding Alternative 1A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on coldwater habitat in upstream reservoirs. This impact is found to be less than significant and no mitigation is required.

Table 11-1A-101. Evaluation of Coldwater Habitat Impacts for Shasta Reservoir Using Three Different Carryover Storage Thresholds (Years with Carryover Storage Less than Threshold, out of 82 Years)

11.3.4.3 Alternative 1B—Dual Conveyance with East Alignment and Intakes 1–5 (15,000 cfs; Operational Scenario A)

Alternative 1B would be nearly identical to Alternative 1A except that the up to 15,000 cfs of water routed from the north Delta to the south Delta would be conveyed by gravity through a canal along the east side of the Delta instead of through pipelines/tunnels. While the five intakes would be located and constructed on the east bank of the Sacramento River identical to those under Alternative 1A, the difference in the type of conveyance facility (e.g., canal) results in different construction details to a limited extent as they relate to potential impacts on fish. Specifically, eight culvert and three tunnel siphons would be utilized to divert canal water beneath existing water courses and their construction would occur within those water courses. Alternative 1B would also have one barge landing and 19 bridge crossings compared to six barge landings and no bridge crossings for Alternative 1A. Approximately 4,500 barge trips would occur during construction. Besides the primary difference of utilizing a canal rather than a tunnel, Alternative 1B would have other structural differences such as inclusion of an intermediate pumping plant and elimination of the intermediate forebay. However, these latter differences would not affect fish resources and are not evaluated further in this chapter. Overall, construction impacts from Alternative 1B would be similar to Alternative 1A but with additional in-water work as described above. However, implementation of mitigation measures (described below) and environmental commitments (see Appendix 3B, *Environmental Commitments*) would reduce impacts as described under Alternative 1A.

Water supply and conveyance operations would follow the guidelines described as Scenario A, which is identical to those analyzed under Alternative 1A. CM2–CM22 would be implemented under this alternative, and these conservation measures would be identical to those under Alternative 1A. See Chapter 3, *Description of Alternatives*, for additional details on Alternative 1B.

Delta Smelt

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on delta smelt and their designated critical habitat would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-1 and AQUA-2), the effects described for delta smelt under Alternative 1A also appropriately characterize effects under Alternative 1B.

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

The potential effects of construction and maintenance of water conveyance facilities on delta smelt would be similar to those described under Alternative 1A, Impact AQUA-1 and AQUA-2. Unlike Alternative 1A, which would convey water from the north Delta to the south Delta through pipelines/tunnels, Alternative 1B would convey water through a surface canal. The surface canal conveyance in Alternative 1B would include an east-side canal with eight culvert siphons constructed below the following crossings: Stone Lake drain, Beaver Slough, Hog Slough, Sycamore Slough, White Slough, Disappointment Slough, BNSF Railroad, and Middle River.

Small numbers of delta smelt eggs, larvae, and adults could be present in the Delta in June and July during construction of intake facilities, barge landing, and invert culvert siphons.

As concluded in Alternative 1A, Impact AQUA-1 and AQUA-2, the effects will result in both temporary and permanent alteration of migration, spawning, and rearing habitats used by delta smelt. However, these effects are not expected to be adverse from a population standpoint, because local water quality conditions, very low electrical conductivity and typically low turbidity limit the suitability of this river reach for delta smelt (Werner et al. 2010). Moreover, any habitat losses will be offset by habitat restoration and beneficial operational effects on the Delta as a whole.

NEPA Effects: For the reasons described above, the construction and short-term maintenance activities would not be adverse for delta smelt.

CEQA Conclusion: As described in Impact AQUA-1 under Alternative 1A for delta smelt, the impact of the construction and maintenance of water conveyance facilities on delta smelt would not be significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1. Water Operations of CM1

Alternative 1B has the same diversion and conveyance operations as Alternative 1A. The primary difference between the two alternatives is that conveyance under Alternative 1B would be in a lined or unlined canal, instead of a pipeline. Because there would be no difference in conveyance capacity or operations, there would be no differences between these two alternatives in upstream of the Delta river flows or reservoir operations, Delta inflow, and hydrodynamics in the Delta. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-3 through AQUA-6), the fish effects described for Alternative 1A also appropriately characterize effects under Alternative 1B.

The following impacts are those presented under Alternative 1A that are identical for Alternative 1B.

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

NEPA Effects: With the exception of Impact AQUA-5, the other impact mechanisms listed above would not be adverse to delta smelt under Alternative 1B. This is the same conclusion as described in detail under Alternative 1A, and is based on the expected overall limited or slightly beneficial impacts. However, the overall effect of Impact AQUA-5 on delta smelt rearing habitat would remain adverse because of the potential adverse change in the fall abiotic habitat and the uncertainty regarding BDCP restoration efforts (see Alternative 1A, AQUA-5 for details on expected effects).

CEQA Conclusion: The effects of all of the above listed impact mechanisms would be less than significant, or slightly beneficial to delta smelt, and no mitigation would be required. Detailed discussions regarding these conclusions are presented in Alternative 1A.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 1B has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for Alternative 1A (Impact AQUA-7 through AQUA-9) also appropriately characterize effects under Alternative 1B.

The following impacts are those presented under Alternative 1A that are identical for Alternative 1B.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on delta smelt are the same for Alternative 1B, as those described under Alternatives 1A. The effects could be not adverse and/or generally beneficial. Specifically for AQUA-8, the effects of contaminants on delta smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on delta smelt are uncertain.

CEQA Conclusion: All three of the impact mechanisms listed above would all be beneficial or less than significant, because they are intended to increase suitable habitat and habitat functions. Therefore, no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 1B has the same Other Conservation Measures as Alternative 1A. Because no substantial differences in other conservation measure-related fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A, the fish effects of the other conservation measures described for Alternative 1A (Impact AQUA-10 through AQUA-18) also appropriately characterize effects under Alternative 1B.

The following impacts are those presented under Alternative 1A that are identical for Alternative 1B.

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (CM12)

Impact AQUA-11: Effects of Invasive Aquatic Vegetation Management on Delta Smelt (CM13)

Impact AQUA-12: Effects of Dissolved Oxygen Level Management on Delta Smelt (CM14)

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (CM15)

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (CM16)

Impact AQUA-15: Effects of Illegal Harvest Reduction on Delta Smelt (CM17)

Impact AQUA-16: Effects of Conservation Hatcheries on Delta Smelt (CM18)

Impact AQUA-17: Effects of Urban Stormwater Treatment on Delta Smelt (CM19)

Impact AQUA-18: Effects of Removal/Relocation of Nonproject Diversions on Delta Smelt (CM21)

NEPA Effects: As described in Alternative 1A, none of these impact mechanisms (Impact AQUA 10 through 18) would be adverse to delta smelt, and some would be at least slightly beneficial.

CEQA Conclusion: All nine of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Longfin Smelt

The potential effects of construction and maintenance of water conveyance facilities on longfin smelt would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-19 and AQUA-20), the effects described for longfin smelt under Alternative 1A also appropriately characterize effects for longfin smelt under Alternative 1B.

The following impacts on longfin smelt are those presented under Alternative 1A that are identical for Alternative 1B.

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

***NEPA Effects*:** These impact mechanisms would not be adverse to longfin smelt, although construction activities could result in adverse effects from impact pile driving activities. However, the implementation of the avoidance and minimization measures and Mitigation Measures AQUA-1a and AQUA-1b (described under Impact AQUA-1 in Alternative 1A for delta smelt) would minimize or eliminate adverse effects (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-19 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on longfin smelt would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to Alternative 1A (Impact AQUA-21 through AQUA-24), the effects described for longfin smelt under Alternatives 1A also appropriately characterize effects under Alternative 1B.

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

Impact AQUA-23: Effects of Water Operations on Rearing Habitat for Longfin Smelt

Discussion provided above, under Impact AQUA-22

Impact AQUA-24: Effects of Water Operations on Migration Conditions for Longfin Smelt

Discussion provided above, under Impact AQUA-22

NEPA Effects: As discussed under Impact AQUA-21 through AQUA-24 in Alternative 1A, the effect of lower Delta winter-spring outflow under Alternative 1B on longfin smelt spawning and rearing has the potential to be adverse. This effect is a result of the specific reservoir operations, exports and resulting flows associated with this alternative. However, Alternative 1B includes an adaptive management plan that could be used to adjust spring operations as determined necessary through the adaptive management process. These adaptive management procedures are described in Mitigation Measures 22a through 22c, under Alternative 1A.

CEQA Conclusion: These impact mechanisms could result in significant effects to longfin smelt given the outflow-abundance relationship described by Kimmerer et al. (2009), although there are uncertainties regarding the outcome as a result of habitat restoration, and changes in winter-spring outflow. However, implementation of Mitigation Measures AQUA-22a through 22c, habitat restoration, and reduced larval entrainment would reduce this impact to less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-22a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Longfin Smelt to Determine Feasibility of Mitigation to Reduce Impacts to Spawning and Rearing Habitat

Please refer to Mitigation Measure AQUA-22a under Impact AQUA-22 of Alternative 1A.

Mitigation Measure AQUA-22b: Conduct Additional Evaluation and Modeling of Impacts on Longfin Smelt Rearing Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-22b under Impact AQUA-22 of Alternative 1A.

Mitigation Measure AQUA-22c: Consult with USFWS and CDFW to Identify and Implement Feasible Means to Minimize Effects on Longfin Smelt Rearing Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-22c under Impact AQUA-22 of Alternative 1A.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on longfin smelt would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-25 through AQUA-36), the effects described for longfin smelt under Alternative 1A also appropriately characterize effects for longfin smelt under Alternative 1B.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (CM12)

Impact AQUA-29: Effects of Invasive Aquatic Vegetation Management on Longfin Smelt (CM13)

Impact AQUA-30: Effects of Dissolved Oxygen Level Management on Longfin Smelt (CM14)

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (CM15)

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (CM16)

Impact AQUA-33: Effects of Illegal Harvest Reduction on Longfin Smelt (CM17)

Impact AQUA-34: Effects of Conservation Hatcheries on Longfin Smelt (CM18)

Impact AQUA-35: Effects of Urban Stormwater Treatment on Longfin Smelt (CM19)

Impact AQUA-36: Effects of Removal/Relocation of Nonproject Diversions on Longfin Smelt (CM21)

NEPA Effects: The impact mechanisms listed above would range from no effect, to no adverse effect, or beneficial effects on longfin smelt for the reasons identified for Alternative 1A. Specifically for AQUA-26, the effects of contaminants on longfin smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on longfin smelt are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would range from no impact, to less than significant, or beneficial for longfin smelt for the reasons identified under Alternative 1A, and no mitigation would be required.

Winter-Run Chinook Salmon

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on winter-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-37 and AQUA-38), the effects described for winter-run Chinook salmon under Alternative 1A also appropriately characterize effects for winter-run Chinook salmon under Alternative 1B.

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: These impact mechanisms would not be adverse to winter-run Chinook salmon. While construction activities (Impact AQUA-37) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-37 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on winter-run Chinook salmon would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impacts AQUA-39 through AQUA-42), the effects described for winter-run Chinook salmon also appropriately characterize the effects under Alternative 1B.

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

NEPA Effects: Although analysis conducted as part of the EIR/EIS determined that Alternative 1B would have unavoidable adverse effects on winter-run Chinook salmon spawning, incubation, and/or rearing habitat, as well as overall migration conditions. This conclusion was based on the best available scientific information at the time and may prove to have been over- or understated. The effects are a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, these would be unavoidable adverse effects. The implementation of the mitigation measures listed below would reduce the severity of effects, although not necessarily to a not adverse level.

CEQA Conclusion: Similar to the discussion provided above, and for Alternative 1A, these impact mechanisms would have a significant effect on winter-run Chinook salmon spawning, incubation, and rearing habitat and/or migration conditions under Alternative 1B. The implementation of the mitigation measures listed below would reduce the severity of effects, although not necessarily to a less than significant level.

Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor potential effects on spawning, incubation, and rearing habitat to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 1B.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 1B operations only, and not effects of climate change or sea level rise. Development of mitigation actions for the incremental impact on winter-run Chinook salmon habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 1B. The mitigation measures identified below would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-40a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Please refer to Mitigation Measure AQUA-40a under Alternative 1A (Impact AQUA-40) for winter-run Chinook salmon.

Mitigation Measure AQUA-40b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Spawning Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-40b under Alternative 1A (Impact AQUA-40) for winter-run Chinook salmon.

Mitigation Measure AQUA-40c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Spawning Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-40c under Alternative 1A (Impact AQUA-40) for winter-run Chinook salmon.

Mitigation Measure AQUA-41a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Please refer to Mitigation Measure AQUA-41a under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-41b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Rearing Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-41b under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-41c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Rearing Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-41c under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-42a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-42a under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-42b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-42b under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-42c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-42c under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on winter-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-43 through AQUA-54), the effects described for winter-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 1B.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (CM12)

Impact AQUA-47: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Winter-Run ESU) (CM13)

Impact AQUA-48: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Winter-Run ESU) (CM14)

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (CM15)

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (CM16)

Impact AQUA-51: Effects of Illegal Harvest Reduction on Chinook Salmon (Winter-Run ESU) (CM17)

Impact AQUA-52: Effects of Conservation Hatcheries on Chinook Salmon (Winter-Run ESU) (CM18)

Impact AQUA-53: Effects of Urban Stormwater Treatment on Chinook Salmon (Winter-Run ESU) (CM19)

Impact AQUA-54: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Winter-Run ESU) (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, these impact mechanisms would not be adverse, and would typically be beneficial to winter-run Chinook salmon. Specifically for AQUA-44, the effects of contaminants on winter-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on winter-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Spring-Run Chinook Salmon

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on spring-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-55 and AQUA-56), the effects described for spring-run Chinook salmon under Alternative 1A also appropriately characterize effects for spring-run Chinook salmon under Alternative 1B.

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

NEPA Effects: While construction activities (Impact AQUA-55) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality). The periodic and short-term maintenance activities would not be adverse.

CEQA Conclusion: Similar to the discussion provided above for Alternatives 1A, Impact AQUA-55 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on spring-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-57 and AQUA-60), the effects described for spring-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 1B.

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

NEPA Effects: As discussed in detail for Alternative 1A, the effects of Alternative 1B operations on entrainment, spawning and egg incubation habitat, and through-Delta migration conditions for spring-run Chinook salmon would be adverse due to predation and habitat loss associated with the five intakes of the north Delta facilities, and flow changes in the Feather River. However, the implementation of applicable conservation measures (CM6, *Channel Margin Enhancement* and CM15, *Predator Control*), as described in Chapter 3, Section 3.6, would minimize potential effects. In addition, the implementation of the mitigation measures listed below also has the potential to reduce the severity of the impact to migration conditions, although not necessarily to a not adverse level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

CEQA Conclusion: As discussed above, and in detail for Alternative 1A, the effects of the impact mechanisms listed above (except for Impact AQUA-59) would be significant under Alternative 1B for spring-run Chinook salmon. However, differences between Alternative 1B (which is under LLT conditions that include future sea level rise and climate change) and Existing Conditions may therefore either overstate the effects of Alternative 1B, or suggest significant effects that are largely attributable to sea level rise and climate change rather than the alternative. Based on the overall assessment, Alternative 1B could result in a significant and unavoidable effect on migration conditions. While the mitigation measures listed below would reduce the severity of effects, they are likely to remain significant and unavoidable.

Mitigation Measure AQUA-58a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Please refer to Mitigation Measure AQUA-58a under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-58b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Spawning Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-58b under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-58c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Spawning Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-58c under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-60a under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-60b under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-60c under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on spring-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-61 through AQUA-72). Therefore, the effects on spring-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 1B.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (CM12)

Impact AQUA-65: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Spring-Run ESU) (CM13)

Impact AQUA-66: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Spring-Run ESU) (CM14)

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (CM15)

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (CM16)

Impact AQUA-69: Effects of Illegal Harvest Reduction on Chinook Salmon (Spring-Run ESU) (CM17)

Impact AQUA-70: Effects of Conservation Hatcheries on Chinook Salmon (Spring-Run ESU) (CM18)

Impact AQUA-71: Effects of Urban Stormwater Treatment on Chinook Salmon (Spring-Run ESU) (CM19)

Impact AQUA-72: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Spring-Run ESU) (CM21)

NEPA Effects: As discussed for Alternative 1A, the above listed impact mechanisms would not be adverse, and with the implementation of environmental commitments and conservation measures, the effects would typically be beneficial to spring-run Chinook salmon. Specifically for AQUA-62, the effects of contaminants on spring-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on spring-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Fall-/Late Fall–Run Chinook Salmon

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-73 and AQUA-74), the fish effects described for fall- and late fall-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 1B.

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would not be adverse to fall- and late fall-run Chinook salmon. While construction activities (Impact

AQUA-73) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-73 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on fall- and late fall-run Chinook salmon would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impacts AQUA-75 through AQUA-78), the effects described for fall- and late fall-run Chinook salmon also appropriately characterize the effects for Alternative 1B.

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: As indicated under Alternative 1A, the analysis results indicate that the effect of Alternative 1B is adverse because it has the potential to substantially interfere with the movement of fall-/late fall-run Chinook salmon. This would include adverse effects on fall-/late fall-run Chinook salmon through-delta migration conditions on the Sacramento River, relative to NAA, while through-Delta conditions on the San Joaquin River would be positive. The implementation of the conservation and mitigation measures listed below also has the potential to reduce the severity of the impact though not necessarily to a not adverse level.

CEQA Conclusion: The effects of Alternative 1B would be similar to those discussed above under Alternative 1A. The implementation of applicable conservation measures (CM6, *Channel Margin Enhancement* and CM15, *Predator Control*), as described in Chapter 3, Section 3.6, would minimize potential effects. In addition, the implementation of the mitigation measures listed below also has the potential to reduce the severity of the impact though not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that could be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-78a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Fall-/Late Fall–Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-78a under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78b: Conduct Additional Evaluation and Modeling of Impacts on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-78b under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-78c under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Restoration and Conservation Measures

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM12)

Impact AQUA-83: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM13)

Impact AQUA-84: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM14)

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM15)

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM16)

Impact AQUA-87: Effects of Illegal Harvest Reduction on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM17)

Impact AQUA-88: Effects of Conservation Hatcheries on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM18)

Impact AQUA-89: Effects of Urban Stormwater Treatment on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM19)

Impact AQUA-90: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, these restoration and conservation commitment impact mechanisms (Impact AQUA-79 through AQUA-90),would not be adverse, and would typically be beneficial to fall- and late fall-run Chinook salmon. Specifically for AQUA-80, the effects of contaminants on fall- and late fall-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on fall- and late fall-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Steelhead

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on steelhead would be similar to those described under Alternatives 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on steelhead would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-91 and AQUA-92), the fish effects described for steelhead under Alternative 1A also appropriately characterize effects under Alternative 1B.

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: These impact mechanisms would typically not be adverse to steelhead. While construction activities (Impact AQUA-91) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-91 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of` water conveyance facility operations on steelhead would be similar to those described above under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-93 through AQUA-96), the effects described for steelhead under Alternative 1A also appropriately characterize effects under Alternative 1B.

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

NEPA Effects: As described in detail under Alternative 1A, these impact mechanisms would result in variable effects on steelhead, but the effects would not result in biologically meaningful reductions in overall survival of steelhead. Therefore, the effects would not be adverse to steelhead under Alternative 1B.

CEQA Conclusion: Collectively, the analysis indicates that the difference between the CEQA baseline and Alternative 1B could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and interfere with steelhead migrations in some areas. Alternative 1B would also negatively affect juvenile and adult migration conditions in some areas. Despite the variability in effects of Alternative 1B, if adjusted to exclude sea level rise and climate change, the alternative would not in itself result in a significant impact on steelhead.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on steelhead would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B, compared to those described in detail for Alternative 1A (Impact AQUA-97 through AQUA-108), the effects described for steelhead under Alternative 1A also appropriately characterize the effects under Alternative 1B.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (CM12)

Impact AQUA-101: Effects of Invasive Aquatic Vegetation Management on Steelhead (CM13)

Impact AQUA-102: Effects of Dissolved Oxygen Level Management on Steelhead (CM14)

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (CM15)

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (CM16)

Impact AQUA-105: Effects of Illegal Harvest Reduction on Steelhead (CM17)

Impact AQUA-106: Effects of Conservation Hatcheries on Steelhead (CM18)

Impact AQUA-107: Effects of Urban Stormwater Treatment on Steelhead (CM19)

Impact AQUA-108: Effects of Removal/Relocation of Nonproject Diversions on Steelhead (CM21)

NEPA Effects: As discussed for Alternative 1A, these impact mechanisms would not be adverse, and would typically be beneficial to steelhead. Specifically for AQUA-98, the effects of contaminants on steelhead with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on steelhead are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Sacramento Splittail

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on Sacramento splittail would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-109 and AQUA-110). Therefore, the effects described for Sacramento splittail under Alternative 1A also appropriately characterize effects for Sacramento splittail under Alternative 1B.

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: These impact mechanisms would generally not be adverse to Sacramento splittail. While construction activities (Impact AQUA-109) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-109 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The effects of Impact AQUA-110 would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on Sacramento splittail would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B, compared to those described in detail for Alternative 1A (Impacts AQUA-111 through AQUA-114), the effects described under Alternative 1A would also appropriately characterize the effects under Alternative 1B.

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

NEPA Effects: As discussed in detail for Alternative 1A, the operations impact mechanisms would not be adverse to Sacramento splittail.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be less than significant, and no mitigation would be required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on Sacramento splittail would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impacts AQUA-115 through AQUA-126), the fish effects described also appropriately characterize the effects under Alternative 1B.

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (CM12)

Impact AQUA-119: Effects of Invasive Aquatic Vegetation Management on Sacramento Splittail (CM13)

Impact AQUA-120: Effects of Dissolved Oxygen Level Management on Sacramento Splittail (CM14)

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (CM15)

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (CM16)

Impact AQUA-123: Effects of Illegal Harvest Reduction on Sacramento Splittail (CM17)

Impact AQUA-124: Effects of Conservation Hatcheries on Sacramento Splittail (CM18)

Impact AQUA-125: Effects of Urban Stormwater Treatment on Sacramento Splittail (CM19)

Impact AQUA-126: Effects of Removal/Relocation of Nonproject Diversions on Sacramento Splittail (CM21)

NEPA Effects: As discussed for Alternative 1A, the other impact mechanisms would not be adverse, and would typically be beneficial to Sacramento splittail. Specifically for AQUA-116, the effects of contaminants on Sacramento splittail with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on Sacramento splittail are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Green Sturgeon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on green sturgeon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on green sturgeon would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-127 and AQUA-128).,Therefore, the fish effects described for green sturgeon under Alternative 1A also appropriately characterize effects for green sturgeon under Alternative 1B.

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: Construction activities (Impact AQUA-127) could result in adverse effects from impact pile driving activities. However, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality). However, maintenance activities (Impact AQUQ-128) would not be adverse to green sturgeon.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-127 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The other impact mechanism would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance operations on green sturgeon would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impacts AQUA-129 through AQUA-132). Therefore, the effects described for green sturgeon under Alternative 1A, also appropriately characterize the effects under Alternative 1B.

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

NEPA Effects: As discussed for Alternative 1A, Impact AQUA-132 is expected to negatively affect green sturgeon migration habitat conditions under Alternative 1B. These effects are a result of the specific reservoir operations and resulting flows associated with this alternative. Therefore, while there is no feasible mitigation available, the implementation of the mitigation measures listed below has the potential to reduce the severity of the impact, but not necessarily to a level considered to be not adverse.

CEQA Conclusion: Similar to the discussion provided above, and for Alternative 1A, Impact AQUA-132 could result in significant, but unavoidable effects on water temperature, juvenile and adult green sturgeon migration habitat conditions, compared to Existing Conditions. Implementation of the mitigation measures listed below has the potential to reduce the severity of the impact though not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-132a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Green Sturgeon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-132a under Alternative 1A (Impact AQUA-132) for green sturgeon.

Mitigation Measure AQUA-132b: Conduct Additional Evaluation and Modeling of Impacts on Green Sturgeon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-132b under Alternative 1A (Impact AQUA-132) for green sturgeon.

Mitigation Measure AQUA-132c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Green Sturgeon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-132c under Alternative 1A (Impact AQUA-132) for green sturgeon.

Restoration and Conservation Measures

Alternative 1B has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A, the effects of the restoration and conservation measures would be similar.

The following impacts are those presented under Alternative 1A that are identical for Alternative 1B.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (CM12)

Impact AQUA-137: Effects of Invasive Aquatic Vegetation Management on Green Sturgeon (CM13)

Impact AQUA-138: Effects of Dissolved Oxygen Level Management on Green Sturgeon (CM14)

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (CM15)

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (CM16)

Impact AQUA-141: Effects of Illegal Harvest Reduction on Green Sturgeon (CM17)

Impact AQUA-142: Effects of Conservation Hatcheries on Green Sturgeon (CM18)

Impact AQUA-143: Effects of Urban Stormwater Treatment on Green Sturgeon (CM19)

Impact AQUA-144: Effects of Removal/Relocation of Nonproject Diversions on Green Sturgeon (CM21)

NEPA Effects: These impact mechanisms would not be adverse, and with the implementation of environmental commitments and conservation measures, the effects would typically be beneficial to green sturgeon. Specifically for AQUA-134, the effects of contaminants on green sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on green sturgeon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

White Sturgeon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on white sturgeon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on white sturgeon would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-145 and AQUA-146). Therefore, the fish effects described for white sturgeon under Alternative 1A also appropriately characterize effects for white sturgeon under Alternative 1B.

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: As concluded for Alternative 1A (Impact AQUA-145 and AQUA-146), environmental commitments and mitigation measures would be available to avoid and minimize potential effects, so the effect would not be adverse for white sturgeon.

CEQA Conclusion: As described under Alternative 1A (Impact AQUA-145 and AQUA-146), the impact of the construction and maintenance of water conveyance facilities on white sturgeon would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on white sturgeon would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impacts AQUA-147 through AQUA-150), the effects described for white sturgeon also appropriately characterize the effects under Alternative 1B.

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

NEPA Effects: As discussed above under Alternative 1A, the available information indicates that overall entrainment effects on white sturgeon populations, on available spawning, rearing or migration habitat conditions are not expected to substantially change under Alternative 1B compared to NAA. However, targeted investigations will be implemented to deal with scientific uncertainty regarding the mechanisms responsible for the positive correlation between year class strength and river/Delta flow. If upstream conditions are determined to be the primary mechanisms, then Alternative 1B would not be adverse, but if the positive correlation is related to in-Delta and through-Delta flow conditions, then Alternative 1B would be deemed adverse due to the magnitude of reductions in through-Delta flow conditions in Alternative 1B as compared to NAA.

CEQA Conclusion: As described for Alternative 1A, operational activities could result in a slight decrease in entrainment of white sturgeon, although the other impact mechanism could substantially reduce the amount of suitable habitat, contrary to the NEPA conclusion set forth above. There would also be small to moderate decreases in flows during most of the spawning and egg incubation period in some areas. However, Alternative 1B does not have the potential to substantially reduce the amount of suitable rearing habitat and substantially interfere with the movement of fish. Overall, the differences between Existing Conditions and Alternative 1B would generally be due to climate change, sea level rise, and future demand, and not the alternative. Therefore, this impact is found to be less than significant and no mitigation is required.

Restoration and Conservation Measures

Alternative 1B has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A, the effects of these measures described for white sturgeon under Alternative 1A (Impact AQUA-151 through Impact AQUA-162) also appropriately characterize effects under Alternative 1B.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (CM12)

Impact AQUA-155: Effects of Invasive Aquatic Vegetation Management on White Sturgeon (CM13)

Impact AQUA-156: Effects of Dissolved Oxygen Level Management on White Sturgeon (CM14)

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (CM15)

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (CM16)

Impact AQUA-159: Effects of Illegal Harvest Reduction on White Sturgeon (CM17)

Impact AQUA-160: Effects of Conservation Hatcheries on White Sturgeon (CM18)

Impact AQUA-161: Effects of Urban Stormwater Treatment on White Sturgeon (CM19)

Impact AQUA-162: Effects of Removal/Relocation of Nonproject Diversions on White Sturgeon (CM21)

NEPA Effects: The restoration and conservation measure impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on white sturgeon for NEPA purposes, for the reasons identified for Alternative 1A (Impact AQUA-151 through 162). Specifically for AQUA-152, the effects of contaminants on white sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on white sturgeon are uncertain.

CEQA Conclusion: The restoration and conservation measure impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on white sturgeon, for the reasons identified for Alternative 1A (Impact AQUA-151 through 162), and no mitigation is required.

Pacific Lamprey

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on Pacific lamprey would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on Pacific lamprey would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-163 through AQUA-180). Therefore, the effects described for Pacific lamprey under Alternative 1A also appropriately characterize effects for Pacific lamprey under Alternative 1B.

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-163 and AQUA-164, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for Pacific lamprey.

CEQA Conclusion: As described under Alternative 1A, Impact AQUA-163 and AQUA-164, the impact of the construction and maintenance of water conveyance facilities on Pacific lamprey would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Water Operations of CM1

The potential effects of water conveyance facility operations on Pacific lamprey would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-165 and Impact AQUA-168), the effects described for Pacific lamprey under Alternative 1A also appropriately characterize effects for Pacific lamprey under Alternative 1B.

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

NEPA Effects: Similar to the results discussed in detail under Alternative 1A, effects on entrainment of Pacific lamprey would not be adverse, and could be beneficial, due to design, installation, and operation of new screens in the north Delta. However, flow reductions would be expected to increase redd dewatering risk and exposure risk to egg cohorts in some areas, such as below Thermalito Afterbay. These effects would cause substantial reductions in habitat available for spawning and egg incubation in the Feather River, and reduce overall spawning success. While the implementation of the mitigation measures listed below (Mitigation Measures AQUA-166a through AQUA-166c) would reduce the severity of effects, this would not necessarily result in a not adverse determination. However, the changes in flow would not substantially interfere with the movement of fish. While the implementation of the mitigation measures listed below (Mitigation Measures AQUA-166a through AQUA-166c) would reduce the severity of effects, this would not necessarily result in a not adverse determination.

CEQA Conclusions: As concluded under Alternative 1A, Alternative 1B water operations could substantially reduce the number of fish as a result of increased exposure to redd dewatering and elevated water temperatures, which would reduce egg survival and increase ammocoete mortality. While the implementation of the mitigation measures listed below (Mitigation Measures AQUA-166a through AQUA-166c) would reduce the severity of effects, this would not necessarily result in a less than significant determination. Alternative 1A would also substantially reduce rearing habitat. However, if adjusted to exclude the effects of sea level rise and climate change, Alternative 1B would not in itself result in a significant impact on rearing habitat for Pacific lamprey. This impact is found to be less than significant and no mitigation is required.

Mitigation Measure AQUA-166a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Pacific Lamprey to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Please refer to Mitigation Measure AQUA-166a under Impact AQUA-166 of Alternative 1A.

Mitigation Measure AQUA-166b: Conduct Additional Evaluation and Modeling of Impacts on Pacific Lamprey Spawning Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-166b under Impact AQUA-166 of Alternative 1A.

Mitigation Measure AQUA-166c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Pacific Lamprey Spawning Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-166c under Impact AQUA-166 of Alternative 1A.

Restoration and Conservation Measures

Alternative 1B has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under

Alternative 1B compared to those described in detail for Alternative 1A, the effects of these measures described for Pacific lamprey under Alternative 1A (Impact AQUA-169 through Impact AQUA-180) also appropriately characterize effects under Alternative 1B.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (CM12)

Impact AQUA-173: Effects of Invasive Aquatic Vegetation Management on Pacific Lamprey (CM13)

Impact AQUA-174: Effects of Dissolved Oxygen Level Management on Pacific Lamprey (CM14)

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (CM15)

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (CM16)

Impact AQUA-177: Effects of Illegal Harvest Reduction on Pacific Lamprey (CM17)

Impact AQUA-178: Effects of Conservation Hatcheries on Pacific Lamprey (CM18)

Impact AQUA-179: Effects of Urban Stormwater Treatment on Pacific Lamprey (CM19)

Impact AQUA-180: Effects of Removal/Relocation of Nonproject Diversions on Pacific Lamprey (CM21)

NEPA Effects: As discussed for Alternative 1A, these impact mechanisms would not be adverse, and would typically be beneficial to Pacific lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

River Lamprey

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on river lamprey would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on river lamprey would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-181 through AQUA-198), the fish effects described for river lamprey under Alternative 1A also appropriately characterize effects for river lamprey under Alternative 1B.

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-181 and AQUA-182, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for river lamprey.

CEQA Conclusion: As described under Alternative 1A, Impact AQUA-181 and AQUA-182, the impact of the construction and maintenance of water conveyance facilities on river lamprey would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Water Operations of CM1

The potential effects of water conveyance facility operations on river lamprey would be similar to those described under Alternative 1A, for Impact AQUA-183 and Impact AQUA-186, which appropriately characterizes effects under Alternative 1B.

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

NEPA Effects: As discussed in detail for Alternative 1A, the effects of Alternative 1B on river lamprey entrainment and entrainment-related predation, spawning habitat, and migration conditions would not be adverse. However, Alternative 1B operations have the potential to substantially reduce river lamprey rearing habitat, and the number of fish as a result of ammocoete mortality. These effects would be due to increased exposure to critical water temperatures in the Sacramento, Feather, American, and Stanislaus Rivers and substantial increases in exposure to flow reductions that could lead to stranding in the American River. These effects on rearing habitat would be adverse. Implementation of the mitigation measures listed below has the potential to reduce the severity of the impact, although not necessarily to a not adverse level.

CEQA Conclusion: As described above, and in detail under Alternative 1A, the CEQA analyses indicate that Alternative 1B could have significant and unavoidable effects on river lamprey rearing habitat. However, the implementation of the mitigation measures listed below also has the potential to reduce the severity of the impact though not necessarily to a not adverse or a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-185a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to River Lamprey to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Please refer to Mitigation Measure AQUA-185a under Alternative 1A (Impact AQUA-185) for river lamprey.

Mitigation Measure AQUA-185b: Conduct Additional Evaluation and Modeling of Impacts River Lamprey Rearing Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-185b under Alternative 1A (Impact AQUA-185) for river lamprey.

Mitigation Measure AQUA-185c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on River Lamprey Rearing Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-185c under Alternative 1A (Impact AQUA-185) for river lamprey.

Restoration and Conservation Measures

Alternative 1B has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A, the effects of these measures described for river lamprey under Alternative 1A (Impact AQUA-187 through Impact AQUA-198) also appropriately characterize effects under Alternative 1B.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (CM12)

Impact AQUA-191: Effects of Invasive Aquatic Vegetation Management on River Lamprey (CM13)

Impact AQUA-192: Effects of Dissolved Oxygen Level Management on River Lamprey (CM14)

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (CM15)

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (CM16)

Impact AQUA-195: Effects of Illegal Harvest Reduction on River Lamprey (CM17)

Impact AQUA-196: Effects of Conservation Hatcheries on River Lamprey (CM18)

Impact AQUA-197: Effects of Urban Stormwater Treatment on River Lamprey (CM19)

Impact AQUA-198: Effects of Removal/Relocation of Nonproject Diversions on River Lamprey (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, the restoration and conservation measure impact mechanisms (Impact AQUA-187 through AQUA-198) have been determined to range from no effect, not adverse, or beneficial to river lamprey for NEPA purposes.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Non-Covered Aquatic Species of Primary Management Concern

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on non-covered species would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on non-covered species would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-199 through AQUA-217), the fish effects described for river lamprey under Alternative 1A also appropriately characterize effects for river lamprey under Alternative 1B.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: As concluded for Alternative 1A (Impact AQUA-199 and AQUA-200), environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for non-covered aquatic species of primary management concern.

CEQA Conclusion: As described under Alternative 1A (Impact AQUA-199 and AQUA-200), the impact of the construction and maintenance of water conveyance facilities on non-covered aquatic species of primary management concern would be less than significant except potentially for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Water Operations of CM1

The potential effects of water conveyance facility operations on non-covered species would be similar to those described under Alternative 1A. As no differences in effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A (Impact AQUA-201 through Impact AQUA-204), the effects described for non-covered aquatic species of primary management concern under Alternative 1A also appropriately characterize effects for non-covered aquatic species of primary management concern under Alternative 1B.

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: These impact mechanisms would not be adverse to the non-covered species of primary management concern, and with the implementation of environmental commitments and conservation measures, the effects would typically be beneficial to non-covered fish species of primary management concern.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-203 and AQUA-204 could result in significant, but unavoidable effects on rearing habitat and migration habitat conditions for several fish species of primary management concern. These species include largemouth bass, Sacramento-San Joaquin roach, and hardhead. There are also no feasible mitigation measures available to mitigate for these impacts. The other impact mechanisms would be less than significant, or beneficial, so no additional mitigation would be required.

Restoration and Conservation Measures

Alternative 1B has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1B compared to those described in detail for Alternative 1A, the effects of these measures described for non-covered aquatic species of primary management concern under

Alternative 1A (Impact AQUA-205 through Impact AQUA-216) also appropriately characterize effects under Alternative 1B.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (CM12)

Impact AQUA-209: Effects of Invasive Aquatic Vegetation Management on Non-Covered Aquatic Species of Primary Management Concern (CM13)

Impact AQUA-210: Effects of Dissolved Oxygen Level Management on Non-Covered Aquatic Species of Primary Management Concern (CM14)

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (CM15)

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (CM16)

Impact AQUA-213: Effects of Illegal Harvest Reduction on Non-Covered Aquatic Species of Primary Management Concern (CM17)

Impact AQUA-214: Effects of Conservation Hatcheries on Non-Covered Aquatic Species of Primary Management Concern (CM18)

Impact AQUA-215: Effects of Urban Stormwater Treatment on Non-Covered Aquatic Species of Primary Management Concern (CM19)

Impact AQUA-216: Effects of Removal/Relocation of Nonproject Diversions on Non-Covered Aquatic Species of Primary Management Concern (CM21)

NEPA Effects: As discussed in detail under Alternative 1A and 6A, these impact mechanisms would not be adverse, and would typically be beneficial to non-covered fish species of primary management concern.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: Similar to the description for Alternative 1A, Impact AQUA-217 would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 1B would not be substantially reduced when compared to the No Action Alternative.

CEQA Conclusion: Similar to the description for Alternative 1A, Alternative 1B would reduce the quantity of coldwater fish habitat in the CVP and SWP. There would be a greater than 5% increase (5 years) for several of the reservoirs, which could result in a significant impact. However, if adjusted to exclude sea level rise and climate change, Alternative 1B would not in itself result in a significant impact on coldwater habitat in upstream reservoirs. Therefore, this impact mechanism is found to be less than significant and no mitigation is required.

11.3.4.4 Alternative 1C—Dual Conveyance with West Alignment and Intakes W1–W5 (15,000 cfs; Operational Scenario A)

Alternative 1C would be nearly identical to Alternative 1A except that up to 15,000 cfs of water routed from the north Delta to the south Delta would be conveyed by gravity through a canal along the west side of the Delta instead of through pipelines/tunnels. Alternative 1C water conveyance is similar except that the route is on the west side of the Delta. Under Alternative 1C the five intakes would be constructed on the west side of the Sacramento River rather than the east side as under Alternative 1A and Alternative 1B. Similar to Alternative 1B, while there would be the same types and number of intakes, the difference in the type of conveyance facility (e.g., canal) results in different construction details to a limited extent as they relate to potential impacts on fish. Specifically, nine culvert siphons would divert canal water beneath existing water courses and their construction would occur within those water courses. Alternative 1C would also have two barge landings and 16 bridge crossings compared to six barge landings and no bridge crossings for Alternative 1A and one barge landing and 19 bridge crossings for Alternative 1B. Approximately 3,000 barge trips would occur during construction. Besides the primary difference of utilizing a canal rather than a tunnel, Alternative 1C would have other structural differences such as inclusion of an intermediate pumping plant and elimination of the intermediate forebay. However, these latter differences would not affect fish resources and are not evaluated further in this chapter. Overall, construction impacts from Alternative 1C would be similar to Alternative 1A but with additional in-water work as described above. However, implementation of Mitigation Measures (described below) and Appendix 3B, *Environmental Commitments* would reduce impacts as described under Alternative 1A.

Water supply and conveyance operations would follow the guidelines described as Operational Scenario A, which is identical to those analyzed under Alternative 1A. CM2–CM22 would be implemented under this alternative, and these conservation measures would be identical to those under Alternative 1A. See Chapter 3, *Description of Alternatives*, for additional details on Alternative 1C.

Delta Smelt

Construction and Maintenance of CM1

The potential effects of construction and maintenance of the water conveyance facilities on delta smelt and their designated critical habitat would be similar to those described for Alternative 1A (Impact AQUA-1 and AQUA-2) except that Alternative 1C would include five intakes on the west side compared to five intakes on the east side under Alternative 1A. The five west side intakes would have slightly larger dimensions and slightly more impact than the east side intakes. This would convert about 13,550 lineal feet of existing shoreline habitat into intake facility structures and would require about 31.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging.

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-1 and AQUA-2, the effect would not be adverse for delta smelt.

CEQA Conclusion: As described in Impact AQUA-1 and AQUA-2 under Alternative 1A for delta smelt, the impact of the construction of water conveyance facilities on delta smelt would not be significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.Water Operations of CM1

Alternative 1C has the same diversion and conveyance operations as Alternative 1A. The primary difference between the two alternatives is that conveyance under Alternative 1C would be in a lined or unlined canal, instead of a pipeline. Because there would be no difference in conveyance capacity or operations, there would be no differences between these two alternatives in upstream of the Delta river flows or reservoir operations, Delta inflow, and hydrodynamics in the Delta. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-3 through AQUA-6), the fish effects described for Alternative 1A also appropriately characterize effects under Alternative 1C.

The following impacts are those presented under Alternative 1A that are identical for Alternative 1C.

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

NEPA Effects: With the exception of Impact AQUA-5, the other impact mechanisms listed above, would be beneficial or not adverse to delta smelt under Alternative 1C. This is the same conclusion as described in detail under Alternative 1A, and is based on the expected overall limited or slightly beneficial impacts. However, the overall effect of Impact AQUA-5 on delta smelt rearing habitat would remain adverse because there likely would still be a loss of suitable habitat even with BDCP restoration efforts (see Alternative 1A, AQUA-5 for details on expected effects).

CEQA Conclusion: The effects of three of the above listed impact mechanisms would be less than significant, or slightly beneficial to delta smelt, and no mitigation would be required. In addition, the effects of Impact AQUA-5 would also be considered less than significant, because it would not substantially reduce rearing habitat. Therefore, no mitigation would be required for any of the impact mechanisms listed above. Detailed discussions regarding these conclusions are presented in Alternative 1A.

Restoration and Conservation Measures

Alternative 1C has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A, the effects described for Alternative 1A (Impact AQUA-7 through AQUA-18) also appropriately characterize effects under Alternative 1C.

The following impacts are those presented under Alternative 1A that are identical for Alternative 1C.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (CM12)

Impact AQUA-11: Effects of Invasive Aquatic Vegetation Management on Delta Smelt (CM13)

Impact AQUA-12: Effects of Dissolved Oxygen Level Management on Delta Smelt (CM14)

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (CM15)

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (CM16)

Impact AQUA-15: Effects of Illegal Harvest Reduction on Delta Smelt (CM17)

Impact AQUA-16: Effects of Conservation Hatcheries on Delta Smelt (CM18)

Impact AQUA-17: Effects of Urban Stormwater Treatment on Delta Smelt (CM19)

Impact AQUA-18: Effects of Removal/Relocation of Nonproject Diversions on Delta Smelt (CM21)

NEPA Effects: As described in detail under Alternative 1A, none of these impact mechanisms (Impact AQUA-7 through AQUA-18) would be adverse to delta smelt, and most would be at least slightly beneficial. Specifically for AQUA-8, the effects of contaminants on delta smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on delta smelt are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Longfin Smelt

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on longfin smelt would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on longfin smelt would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-19 and AQUA-20), the effects described for longfin smelt under Alternative 1A also appropriately characterize effects for longfin smelt under Alternative 1C.

The following impacts on longfin smelt are those presented under Alternative 1A that are identical for Alternative 1C.

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

NEPA Effects: These impact mechanisms would not be adverse to longfin smelt. While construction activities (Impact AQUA-19) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternatives 1A, Impact AQUA-19 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on longfin smelt would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment for Impact AQUA-21 through AQUA-24, the effects described for longfin smelt under Alternatives 1A also appropriately characterize effects under Alternative 1C.

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

Impact AQUA-23: Effects of Water Operations on Rearing Habitat for Longfin Smelt

Impact AQUA-24: Effects of Water Operations on Migration Conditions for Longfin Smelt

NEPA Effects: The potential effects of water operations on longfin smelt under Alternative 1C would be similar to those described above under Alternative 1A. As discussed in detail under Impact AQUA-22 (Alternative 1A), the effect of lower Delta winter-spring outflow on longfin smelt spawning and rearing has the potential to be adverse. This effect is a result of the specific reservoir operations, exports and resulting flows associated with this alternative. However, Alternative 1C also includes an adaptive management plan that could be used to adjust spring operations as determined necessary through the adaptive management process. These adaptive management procedures are described in Mitigation Measures 22a through 22c, under Alternative 1A. The other impact mechanisms would not be adverse, and would typically be beneficial to longfin smelt.

CEQA Conclusion: As described above under Alternatives 1A, water operations under Alternative 1C would generally reduce the quantity and quality of longfin smelt rearing habitat relative to Existing Conditions. The difference in rearing habitat could be significant because Delta outflows would be reduced in the spring, which would have the potential to contribute to substantial reductions in longfin smelt abundances. These effects are due to the specific reservoir operations and resulting flows associated with this alternative. However, the implementation of Mitigation Measures AQUA-22a through 22c, habitat restoration and reduced larval entrainment would reduce this impact to less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-22a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Longfin Smelt to Determine Feasibility of Mitigation to Reduce Impacts to Spawning and Rearing Habitat

Please refer to Mitigation Measure AQUA-22a under Impact AQUA-22 of Alternative 1A.

Mitigation Measure AQUA-22b: Conduct Additional Evaluation and Modeling of Impacts on Longfin Smelt Rearing Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-22b under Impact AQUA-22 of Alternative 1A.

Mitigation Measure AQUA-22c: Consult with USFWS and CDFW to Identify and Implement Feasible Means to Minimize Effects on Longfin Smelt Rearing Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-22c under Impact AQUA-22 of Alternative 1A.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on longfin smelt would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-25 through AQUA-36), the fish effects described for longfin smelt under Alternative 1A also appropriately characterize effects for longfin smelt under Alternative 1C.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (CM12)

Impact AQUA-29: Effects of Invasive Aquatic Vegetation Management on Longfin Smelt (CM13)

Impact AQUA-30: Effects of Dissolved Oxygen Level Management on Longfin Smelt (CM14)

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (CM15)

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (CM16)

Impact AQUA-33: Effects of Illegal Harvest Reduction on Longfin Smelt (CM17)

Impact AQUA-34: Effects of Conservation Hatcheries on Longfin Smelt (CM18)

Impact AQUA-35: Effects of Urban Stormwater Treatment on Longfin Smelt (CM19)

Impact AQUA-36: Effects of Removal/Relocation of Nonproject Diversions on Longfin Smelt (CM21)

NEPA Effects: As described in Alternative 1A (Impact AQUA-25 through AQUA-36) these impact mechanisms have been determined to range from no effect, to not adverse, or beneficial to longfin smelt for NEPA purposes. Specifically for AQUA-26, the effects of contaminants on longfin smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on longfin smelt are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be considered to range from no impact, to less than significant or beneficial for longfin smelt, and no mitigation would be required.

Winter-Run Chinook Salmon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on winter-run Chinook salmon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on winter-run Chinook salmon would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-37 and AQUA-38), the fish effects described for winter-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 1C.

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: These impact mechanisms would not be adverse to winter-run Chinook salmon. While construction activities (Impact AQUA-37) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 6A, Impact AQUA-37 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on winter-run Chinook salmon would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impacts AQUA-39 through AQUA-42).

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

NEPA Effects: As discussed for Alternative 1A, the impact mechanisms listed above would have significant and unavoidable adverse effects on winter-run Chinook salmon spawning, incubation, and/or rearing habitat, as well as overall migration conditions under Alternative 1C. These determinations are based on the best available scientific information at the time and may prove to have been over- or understated. The mitigation measures identified below would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and

Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures. However, implementation of these measures would not necessarily result in a not adverse determination.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would result in significant and unavoidable effects on winter-run Chinook salmon spawning, rearing, and migration conditions under Alternative 1C. The mitigation measures identified below would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures. However, the result would not necessarily result in a less than significant determination.

Mitigation Measure AQUA-40a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Please refer to Mitigation Measure AQUA-40a under Alternative 1A (Impact AQUA-40) for winter-run Chinook salmon.

Mitigation Measure AQUA-40b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Spawning Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-40b under Alternative 1A (Impact AQUA-40) for winter-run Chinook salmon.

Mitigation Measure AQUA-40c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Spawning Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-40c under Alternative 1A (Impact AQUA-40) for winter-run Chinook salmon.

Mitigation Measure AQUA-41a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Please refer to Mitigation Measure AQUA-41a under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-41b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Rearing Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-41b under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-41c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Rearing Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-41c under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-42a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-42a under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-42b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-42b under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Mitigation Measure AQUA-42c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-42c under Alternative 1A (Impact AQUA-41) for winter-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on winter-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-43 through AQUA-54), the effects described for winter-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 1C.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (CM12)

Impact AQUA-47: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Winter-Run ESU) (CM13)

Impact AQUA-48: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Winter-Run ESU) (CM14)

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (CM15)

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (CM16)

Impact AQUA-51: Effects of Illegal Harvest Reduction on Chinook Salmon (Winter-Run ESU) (CM17)

Impact AQUA-52: Effects of Conservation Hatcheries on Chinook Salmon (Winter-Run ESU) (CM18)

Impact AQUA-53: Effects of Urban Stormwater Treatment on Chinook Salmon (Winter-Run ESU) (CM19)

Impact AQUA-54: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Winter-Run ESU) (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, the impact mechanisms listed above would not be adverse, and would typically be beneficial to winter-run Chinook salmon. Specifically for AQUA-44, the effects of contaminants on winter-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on winter-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be less than significant, or beneficial, so no additional mitigation would be required.

Spring-Run Chinook Salmon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on spring-run Chinook salmon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on spring-run Chinook salmon would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-55 and AQUA-56), the fish effects described for spring-run Chinook salmon under Alternative 1A also appropriately characterize effects for spring-run Chinook salmon under Alternative 1C.

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

NEPA Effects: These impact mechanisms would not be adverse to spring-run Chinook salmon. While construction activities (Impact AQUA-55) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternatives 1A, Impact AQUA-55 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on spring-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to Alternative 1A (Impact AQUA-57 through AQUA-60).

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

NEPA Effects: As discussed in detail for Alternative 1A, the impact mechanisms listed above (except for Impact AQUA-59) would be adverse under Alternative 1C for spring-run Chinook salmon. Adverse effects would occur because entrainment, spawning and egg incubation habitat, and migration conditions for juvenile spring-run Chinook salmon would be substantially reduced, and because it has the potential to substantially increase predation and remove important instream habitat as the result of the presence of five north Delta intake structures. The implementation of conservation and mitigation measures would reduce the severity of effects, although not necessarily to a not adverse level.

CEQA Conclusion: As discussed in detail for Alternative 1A, the effects of the impact mechanisms listed above (except for Impact AQUA-59) would be significant under Alternative 1C. The effects of Alternative 1C operations on would be adverse due to predation and habitat loss associated with the five intakes of the north Delta facilities, and flow changes in the Feather River.

While the effect of Alternative 1C on migration conditions is adverse, the implementation of applicable conservation measures (CM6, *Channel Margin Enhancement* and CM15, *Predator Control*), as described in Chapter 3 (Section 3.6) would minimize potential effects. In addition, the implementation of the mitigation measures listed below also has the potential to reduce the severity of the impact though not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-58a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Please refer to Mitigation Measure AQUA-58a under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-58b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Spawning Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-58b under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-58c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Spawning Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-58c under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-60a under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-60b under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-60c under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on spring-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-61 through AQUA-72). Therefore, the effects on spring-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 1C.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (CM12)

Impact AQUA-65: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Spring-Run ESU) (CM13)

Impact AQUA-66: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Spring-Run ESU) (CM14)

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (CM15)

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (CM16)

Impact AQUA-69: Effects of Illegal Harvest Reduction on Chinook Salmon (Spring-Run ESU) (CM17)

Impact AQUA-70: Effects of Conservation Hatcheries on Chinook Salmon (Spring-Run ESU) (CM18)

Impact AQUA-71: Effects of Urban Stormwater Treatment on Chinook Salmon (Spring-Run ESU) (CM19)

Impact AQUA-72: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Spring-Run ESU) (CM21)

NEPA Effects: These impact mechanisms would not be adverse, and with the implementation of environmental commitments and conservation measures, the effects would typically be beneficial to spring-run Chinook salmon. Specifically for AQUA-62, the effects of contaminants on spring-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on spring-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Fall-/Late Fall–Run Chinook Salmon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-73 and AQUA-74), the fish effects described for fall- and late fall-run Chinook salmon under Alternative 1A also appropriately characterize effects for fall- and late fall-run Chinook salmon under Alternative 1C.

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would not be adverse to fall- and late fall-run Chinook salmon. While construction activities (Impact AQUA-73) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-73 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on fall- and late fall-run Chinook salmon would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 6A (Impacts AQUA-75 through AQUA-78).

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Overall, the effects of water operations vary by location. Similar to effects described in detail under Alternative 1A, Alternative 1C would have an adverse effect on fall-/late fall-run Chinook salmon juvenile survival because it has the potential to substantially interfere with the movement of fall-/late fall-run Chinook salmon. This would include adverse effects on fall-/late fall-run Chinook salmon through-delta migration conditions on the Sacramento River, relative to NAA, while through-Delta conditions on the San Joaquin River would be positive. The implementation of the conservation and mitigation measures listed below also has the potential to reduce the severity of the impact though not necessarily to a not adverse level.

CEQA Conclusion: Although the CEQA analyses indicate some significant effects of water operations on juvenile fall-/late fall-run Chinook salmon survival through the Delta. The implementation of applicable conservation measures (CM6, *Channel Margin Enhancement* and CM15, *Predator Control*), as described in Chapter 3 (Section 3.6) would minimize potential effects. In addition, the implementation of the mitigation measures listed below also would have the potential to reduce the severity of the effects, although not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-78a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Fall-/Late Fall–Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-78a under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78b: Conduct Additional Evaluation and Modeling of Impacts on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-78b under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-78c under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Restoration and Conservation Measures

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM12)

Impact AQUA-83: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM13)

Impact AQUA-84: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM14)

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM15)

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM16)

Impact AQUA-87: Effects of Illegal Harvest Reduction on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM17)

Impact AQUA-88: Effects of Conservation Hatcheries on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM18)

Impact AQUA-89: Effects of Urban Stormwater Treatment on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM19)

Impact AQUA-90: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM21)

NEPA Effects: As discussed for Alternative 1A, the other impact mechanisms would not be adverse, and would typically be beneficial to fall- and late fall-run Chinook salmon. Specifically for AQUA-80, the effects of contaminants on fall- and late fall-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on fall- and late fall-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would generally be beneficial or less than significant, and no mitigation would be required.

Steelhead

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on steelhead would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-91 and AQUA-92), the fish effects described for steelhead under Alternative 1A also appropriately characterize effects for steelhead under Alternative 1C.

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: These impact mechanisms would typically not be adverse to steelhead. While construction activities (Impact AQUA-91) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-91 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of` water conveyance facility operations on steelhead would be similar to those described above under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-93 through AQUA-96).

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

NEPA Effects: Collectively, these results indicate that effect is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. Flows under Alternative 1A in each waterway examined would not be reduced enough or in high enough frequency relative to NAA to affect steelhead migration. As described in detail under Alternative 1A, these impact mechanisms would result in variable effects on steelhead, but the effects would not result in biologically meaningful reductions in overall survival of steelhead. Therefore, the effects would not be adverse to steelhead under Alternative 1C.

CEQA Conclusion: Collectively, the analysis indicates that the difference between the CEQA baseline and Alternative 1C could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and interfere with steelhead migrations in some areas. Despite the variability in effects of Alternative 1C, if adjusted to exclude sea level rise and climate change, the alternative would not in itself result in a significant impact on steelhead.

Restoration and Conservation Measures

The potential effects of restoration and conservation measures on steelhead would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C, compared to those described in detail for Alternative 1A (Impact AQUA-97 through AQUA-108), the effects described for steelhead also appropriately characterize the effects under Alternative 1C.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (CM12)

Impact AQUA-101: Effects of Invasive Aquatic Vegetation Management on Steelhead (CM13)

Impact AQUA-102: Effects of Dissolved Oxygen Level Management on Steelhead (CM14)

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (CM15)

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (CM16)

Impact AQUA-105: Effects of Illegal Harvest Reduction on Steelhead (CM17)

Impact AQUA-106: Effects of Conservation Hatcheries on Steelhead (CM18)

Impact AQUA-107: Effects of Urban Stormwater Treatment on Steelhead (CM19)

Impact AQUA-108: Effects of Removal/Relocation of Nonproject Diversions on Steelhead (CM21)

NEPA Effects: As discussed for Alternative 1A, the other impact mechanisms would not be adverse, and would typically be beneficial to steelhead. Specifically for AQUA-98, the effects of contaminants on steelhead with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on steelhead are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Sacramento Splittail

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on Sacramento splittail would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on Sacramento splittail would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-109 and AQUA-110), the fish effects described for Sacramento splittail under Alternative 1A also appropriately characterize effects for Sacramento splittail under Alternative 1C.

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: These impact mechanisms would generally not be adverse to Sacramento splittail. While construction activities (Impact AQUA-109) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-109 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The effects of Impact AQUA-110 would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on Sacramento splittail would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C, compared to those described in detail for Alternative 6A (Impacts AQUA-111 through AQUA-114).

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

NEPA Effects: As discussed in detail for Alternative 1A, the operations impact mechanisms would not be adverse to Sacramento splittail.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be less than significant, and no mitigation would be required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on Sacramento splittail would be similar to those described for Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impacts AQUA-115 through AQUA-126).

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (CM12)

Impact AQUA-119: Effects of Invasive Aquatic Vegetation Management on Sacramento Splittail (CM13)

Impact AQUA-120: Effects of Dissolved Oxygen Level Management on Sacramento Splittail (CM14)

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (CM15)

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (CM16)

Impact AQUA-123: Effects of Illegal Harvest Reduction on Sacramento Splittail (CM17)

Impact AQUA-124: Effects of Conservation Hatcheries on Sacramento Splittail (CM18)

Impact AQUA-125: Effects of Urban Stormwater Treatment on Sacramento Splittail (CM19)

Impact AQUA-126: Effects of Removal/Relocation of Nonproject Diversions on Sacramento Splittail (CM21)

NEPA Effects: As discussed for Alternative 1A, the other impact mechanisms would not be adverse, and would typically be beneficial to Sacramento splittail. Specifically for AQUA-116, the effects of contaminants on Sacramento splittail with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on Sacramento splittail are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Green Sturgeon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on green sturgeon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on green sturgeon would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-127 through AQUA-144).

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: While the maintenance impact mechanism (Impact AQUA-128) would not be adverse to green sturgeon, construction activities (Impact AQUA-127) could result in adverse effects from impact pile driving activities. However, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-127 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The other impact mechanism would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on green sturgeon would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impacts AQUA-129 through AQUA-132), the effects described for green sturgeon also appropriately characterize the effects under Alternative 1C.

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

NEPA Effects: As discussed for Alternative 1A, Impact AQUA-132 is expected to negatively affect green sturgeon migration conditions under Alternative 1C. These effects are a result of the specific reservoir operations and resulting flows associated with this alternative. The implementation of the mitigation measures listed below has the potential to reduce the severity of the impact, although not necessarily to a level considered not adverse.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-132, the migration habitat conditions under Alternative 1C would be negatively affected, compared to Existing Conditions. The implementation of the mitigation measures listed below has the potential to reduce the severity of the impact, although not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-132a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Green Sturgeon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-132a under Alternative 1A (Impact AQUA-132) for green sturgeon.

Mitigation Measure AQUA-132b: Conduct Additional Evaluation and Modeling of Impacts on Green Sturgeon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-132b under Alternative 1A (Impact AQUA-132) for green sturgeon.

Mitigation Measure AQUA-132c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Green Sturgeon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-132c under Alternative 1A (Impact AQUA-132) for green sturgeon.

Restoration and Conservation Measures

Alternative 1C has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A, the effects of the restoration and conservation measures described for green sturgeon under Alternative 1A (Impact AQUA-133 through Impact AQUA-144) also appropriately characterize effects under Alternative 1C.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (CM12)

Impact AQUA-137: Effects of Invasive Aquatic Vegetation Management on Green Sturgeon (CM13)

Impact AQUA-138: Effects of Dissolved Oxygen Level Management on Green Sturgeon (CM14)

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (CM15)

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (CM16)

Impact AQUA-141: Effects of Illegal Harvest Reduction on Green Sturgeon (CM17)

Impact AQUA-142: Effects of Conservation Hatcheries on Green Sturgeon (CM18)

Impact AQUA-143: Effects of Urban Stormwater Treatment on Green Sturgeon (CM19)

Impact AQUA-144: Effects of Removal/Relocation of Nonproject Diversions on Green Sturgeon (CM21)

NEPA Effects: As discussed for Alternative 1A, these impact mechanisms would not be adverse, and with the implementation of environmental commitments and conservation measures, the effects would typically be beneficial to green sturgeon. Specifically for AQUA-134, the effects of contaminants on green sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on green sturgeon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

White Sturgeon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on white sturgeon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on white sturgeon would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-145 and AQUA-146). Therefore, the effects described for white sturgeon under Alternative 1A also appropriately characterize effects for white sturgeon under Alternative 1C.

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: As concluded for Alternative 1A (Impact AQUA-145 and AQUA-146), environmental commitments and mitigation measures would be available to avoid and minimize potential effects, so the effect would not be adverse for white sturgeon.

CEQA Conclusion: As described under Alternative 1A (Impact AQUA-145 and AQUA-146), the impact of the construction and maintenance of water conveyance facilities on white sturgeon would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on white sturgeon would be similar to those described for Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impacts AQUA-147 through AQUA-150), the effects described for white sturgeon also appropriately characterize the effects under Alternative 1C.

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

NEPA Effects: As described in detail under Alternatives 1A, the effects of water operations on white sturgeon would generally not be adverse. However, uncertainty regarding the mechanisms responsible for the positive correlation between year class strength and high river/Delta flow would be addressed through targeted research and monitoring, prior to the initiation of north Delta facilities operations. If these targeted investigations determine that the primary mechanism behind the positive correlation are related to in-Delta and through-Delta flow conditions, Alternative 1C operations would be considered to be adverse.

CEQA Conclusion: While the effects of Alternative 1C would not be significant for entrainment and spawning habitat, the results of the Impact AQUA-149 and AQUA-150 analyses indicate that the difference between the CEQA baseline and Alternative 1C could be significant, but the differences would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 1C, if adjusted to exclude sea level rise and climate change would be less than significant, and no mitigation is required.

Restoration and Conservation Measures

Alternative 1C has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C, compared to those described in detail for Alternative 1A, the effects of these measures described for white sturgeon under Alternative 1A (Impact AQUA-151 through Impact AQUA-162) also appropriately characterize effects under Alternative 1C.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (CM12)

Impact AQUA-155: Effects of Invasive Aquatic Vegetation Management on White Sturgeon (CM13)

Impact AQUA-156: Effects of Dissolved Oxygen Level Management on White Sturgeon (CM14)

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (CM15)

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (CM16)

Impact AQUA-159: Effects of Illegal Harvest Reduction on White Sturgeon (CM17)

Impact AQUA-160: Effects of Conservation Hatcheries on White Sturgeon (CM18)

Impact AQUA-161: Effects of Urban Stormwater Treatment on White Sturgeon (CM19)

Impact AQUA-162: Effects of Removal/Relocation of Nonproject Diversions on White Sturgeon (CM21)

NEPA Effects: As described for Alternative 1A, these impact mechanisms would not be adverse to white sturgeon. Specifically for AQUA-152, the effects of contaminants on white sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on white sturgeon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Pacific Lamprey

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on Pacific lamprey would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-163 and AQUA-164), the effects described for Pacific lamprey under Alternative 1A also appropriately characterize effects for Pacific lamprey under Alternative 1C.

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-163 and AQUA-164, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for Pacific lamprey.

CEQA Conclusion: As described under Alternative 1A, Impact AQUA-163 and AQUA-164, the impact of the construction and maintenance of water conveyance facilities on Pacific lamprey would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Water Operations of CM1

The potential effects of water conveyance facility operations on Pacific lamprey would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-165 and Impact AQUA-168)

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

NEPA Effects: Similar to the results discussed in detail under Alternative 1A, effects on entrainment of Pacific lamprey would not be adverse, and could be beneficial, due to design, installation, and operation of new screens in the north Delta. However, flow reductions are expected to cause substantial reductions in habitat available for spawning and egg incubation in the Feather River, and reduce overall spawning success. While the implementation of the mitigation measures listed below (Mitigation Measures AQUA-166a through AQUA-166c) would reduce the severity of effects, this would not necessarily result in a not adverse determination. However, the changes in flow would not substantially interfere with the movement of fish.

CEQA Conclusions: As concluded under Alternative 1A, Alternative 1C water operations could substantially reduce the number of fish as a result of increased exposure to redd dewatering and elevated water temperatures, which would reduce egg survival and increase ammocoete mortality. While the implementation of the mitigation measures listed below (Mitigation Measures AQUA-166a through AQUA-166c) would reduce the severity of effects, this would not necessarily result in a less than significant determination.

Mitigation Measure AQUA-166a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Pacific Lamprey to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Please refer to Mitigation Measure AQUA-166a under Impact AQUA-166 of Alternative 1A.

Mitigation Measure AQUA-166b: Conduct Additional Evaluation and Modeling of Impacts on Pacific Lamprey Spawning Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-166b under Impact AQUA-166 of Alternative 1A.

Mitigation Measure AQUA-166c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Pacific Lamprey Spawning Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-166c under Impact AQUA-166 of Alternative 1A.

Restoration and Conservation Measures

Alternative 1C has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A, the effects of these measures described for Pacific lamprey under Alternative 1A (Impact AQUA-169 through Impact AQUA-180) also appropriately characterize effects under Alternative 1C.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (CM12)

Impact AQUA-173: Effects of Invasive Aquatic Vegetation Management on Pacific Lamprey (CM13)

Impact AQUA-174: Effects of Dissolved Oxygen Level Management on Pacific Lamprey (CM14)

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (CM15)

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (CM16)

Impact AQUA-177: Effects of Illegal Harvest Reduction on Pacific Lamprey (CM17)

Impact AQUA-178: Effects of Conservation Hatcheries on Pacific Lamprey (CM18)

Impact AQUA-179: Effects of Urban Stormwater Treatment on Pacific Lamprey (CM19)

Impact AQUA-180: Effects of Removal/Relocation of Nonproject Diversions on Pacific Lamprey (CM21)

NEPA Effects: As discussed for Alternative 1A, these impact mechanisms would not be adverse, and would typically be beneficial to Pacific lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

River Lamprey

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on river lamprey would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on river lamprey would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-181 and AQUA-182)., As a result, the fish effects described for river lamprey under Alternative 1A also appropriately characterize effects for river lamprey under Alternative 1C.

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-181 and AQUA-182, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for river lamprey.

CEQA Conclusion: As described under Alternative 1A, Impact AQUA-181 and AQUA-182, the impact of the construction and maintenance of water conveyance facilities on river lamprey would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Water Operations of CM1

The potential effects of water conveyance facility operations on river lamprey would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C, compared to those described in detail for Alternative 1A (Impact AQUA-183 through Impact AQUA-186). Therefore, the effects described for river lamprey under Alternative 6A also appropriately characterize effects under Alternative 1C.

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

NEPA Effects: As discussed in detail for Alternative 1A, the effects of water operations under Alternative 1C has the potential to substantially reduce river lamprey rearing habitat, and substantially reduce the number of fish as a result of ammocoete mortality. However, the implementation of the mitigation measures listed below has the potential to reduce the severity of the impact, although not necessarily to a not adverse level. Therefore, the impact is considered adverse.

CEQA Conclusion: As described in detail under Alternative 1A, the CEQA analyses indicate that water operations under Alternative 1C has the potential to significantly reduce river lamprey rearing habitat, as well as the number of fish as a result of ammocoete mortality. While the implementation of the mitigation measures listed below has the potential to reduce the severity of the impact, it would not necessarily reduce it to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-185a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to River Lamprey to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Please refer to Mitigation Measure AQUA-185a under Alternative 1A (Impact AQUA-185) for river lamprey.

Mitigation Measure AQUA-185b: Conduct Additional Evaluation and Modeling of Impacts River Lamprey Rearing Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-185b under Alternative 1A (Impact AQUA-185) for river lamprey.

Mitigation Measure AQUA-185c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on River Lamprey Rearing Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-185c under Alternative 1A (Impact AQUA-185) for river lamprey.

Restoration and Conservation Measures

Alternative 1C has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A, the effects of the measures described for river lamprey under Alternative 1A (Impact AQUA-187 through Impact AQUA-198) also appropriately characterize effects under Alternative 1C.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (CM12)

Impact AQUA-191: Effects of Invasive Aquatic Vegetation Management on River Lamprey (CM13)

Impact AQUA-192: Effects of Dissolved Oxygen Level Management on River Lamprey (CM14)

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (CM15)

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (CM16)

Impact AQUA-195: Effects of Illegal Harvest Reduction on River Lamprey (CM17)

Impact AQUA-196: Effects of Conservation Hatcheries on River Lamprey (CM18)

Impact AQUA-197: Effects of Urban Stormwater Treatment on River Lamprey (CM19)

Impact AQUA-198: Effects of Removal/Relocation of Nonproject Diversions on River Lamprey (CM21)

NEPA Effects: As discussed for Alternative 1A, the other impact mechanisms would not be adverse, and would typically be beneficial to river lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Non-Covered Aquatic Species of Primary Management Concern

The potential effects of construction and maintenance of water conveyance facilities, operations of water conservation facilities, restoration measures and other conservation measures on non-covered species would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on non-covered aquatic species of primary management concern would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-199 through AQUA-217). Therefore, the fish effects described for non-covered aquatic species of primary management concern under Alternative 1A also appropriately characterize effects for river lamprey under Alternative 1C.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: As concluded for Alternative 1A (Impact AQUA-199 and AQUA-200), environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for non-covered aquatic species of primary management concern.

CEQA Conclusion: As described under Alternative 1A (Impact AQUA-199 and AQUA-200), the impact of the construction and maintenance of water conveyance facilities on non-covered aquatic species of primary management concern would be less than significant except potentially for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Water Operations of CM1

The potential effects of water conveyance facility operations on non-covered aquatic species of primary management concern would be similar to those described under Alternative 1A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A (Impact AQUA-201 through Impact AQUA-204).

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: These impact mechanisms would not be adverse to the non-covered species of primary management concern, as well as with the implementation of environmental commitments and conservation measures, the effects would typically be beneficial.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would generally be less than significant. However, Impact AQUA-203 and AQUA-204 could result in significant, but unavoidable effects on rearing habitat and migration habitat conditions for several fish species. These species include largemouth bass, Sacramento-San Joaquin roach, and hardhead. There are also no feasible mitigation measures available to mitigate for these impacts. The other impact mechanisms would be less than significant, or beneficial, so no additional mitigation would be required.

Restoration and Conservation Measures

Alternative 1C has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 1C compared to those described in detail for Alternative 1A, the effects of these measures described for non-covered aquatic species of primary management concern under Alternative 1A (Impact AQUA-205 through Impact AQUA-216) also appropriately characterize effects under Alternative 1C.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (CM12)

Impact AQUA-209: Effects of Invasive Aquatic Vegetation Management on Non-Covered Aquatic Species of Primary Management Concern (CM13)

Impact AQUA-210: Effects of Dissolved Oxygen Level Management on Non-Covered Aquatic Species of Primary Management Concern (CM14)

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (CM15)

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (CM16)

Impact AQUA-213: Effects of Illegal Harvest Reduction on Non-Covered Aquatic Species of Primary Management Concern (CM17)

Impact AQUA-214: Effects of Conservation Hatcheries on Non-Covered Aquatic Species of Primary Management Concern (CM18)

Impact AQUA-215: Effects of Urban Stormwater Treatment on Non-Covered Aquatic Species of Primary Management Concern (CM19)

Impact AQUA-216: Effects of Removal/Relocation of Nonproject Diversions on Non-Covered Aquatic Species of Primary Management Concern (CM21)

NEPA Effects: As discussed in detail under Alternative 1A, these impact mechanisms would not adversely affect the aquatic species of primary management concern, and with the implementation of environmental commitments and conservation measures, the effects would typically be beneficial.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: As discussed in detail under Alternative 1A, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 1C would not be substantially reduced when compared to the No Action Alternative.

CEQA Conclusion: In general, as discussed under Alternative 1A, Alternative 1C would reduce the quantity of coldwater fish habitat in the CVP and SWP compared to Existing Conditions, which could result in a significant impact. However, if adjusted to exclude sea level rise and climate change, Alternative 1C would not in itself result in a significant impact on coldwater habitat in upstream reservoirs. Therefore, this impact is found to be less than significant and no mitigation is required.

11.3.4.5 Alternative 2A—Dual Conveyance with Pipeline/Tunnel and Five Intakes (15,000 cfs; Operational Scenario B)

Like Alternative 1A, Alternative 2A would consist of pipelines and tunnels generally located in the central Delta with an intermediate forebay; however, Alternative 2A could potentially entail two different intake and intake pumping plant locations. Currently, as an alternative to Intakes 1–5, intake locations 1, 2, 3, 6, and 7 are being considered. Selection of intake locations 6 and 7 would entail construction in the same general region (north Delta), although about 5 and 6 miles farther downstream from the Intake 5 location, respectively. Thus, the same types of construction effects on fish species would occur, as those discussed for Alternative 1A. In addition, some of the conveyance pipelines and the initial tunnel (Tunnel 1) between the intake pumping plants and the intermediate forebay would be adjusted depending on the intake locations. This alternative would convey water from five fish-screened intakes between Clarksburg and Walnut Grove (Intakes 6 and 7, if selected, would be downstream of Sutter and Steamboat Sloughs) to a new Byron Tract Forebay adjacent to CCF. Construction effects for all fish species would be similar to those described for Alternative 1A.

Like Alternative 1A, the Alternative 2A facilities could convey up to 15,000 cfs from the north Delta, although Alternative 2A water conveyance operational criteria (Operational Scenario B) would be modified from those described for Alternative 1A (Operational Scenario A). Unlike Operational Scenario A, Operational Scenario B includes incorporation of Fall X2 guidelines, more restrictive (less negative) south Delta OMR flows, and an operable barrier at the head of Old River (see Section 3.6.4.2, *North Delta and South Delta Water Conveyance Operational Criteria*). Operational Scenario B also includes north Delta diversion bypass flow criteria, south Delta export/inflow ratio, flow criteria over Fremont Weir into Yolo Bypass, Delta inflow and outflow criteria, DCC gate operations, Rio Vista minimum instream flow criteria, operations for Delta water quality and residence criteria, and water quality criteria for agricultural and municipal/industrial diversions.

Delta Smelt

Construction and Maintenance of CM1

Small numbers of delta smelt eggs, larvae, and/or adults could be present in the Delta in June and July during construction of intake facilities and the barge landings (see Table 11-6). The construction and maintenance sites also occur entirely within designated delta smelt critical habitat.

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

The potential effects of construction of the water conveyance facilities on delta smelt or designated critical habitat would be similar to those described for Alternative 1A (Impact AQUA-1) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-1, the effect would not be adverse for delta smelt or designated critical habitat.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-1, the impact of the construction of water conveyance facilities on delta smelt and critical habitat would be less than significant with the implementation measures described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*, except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-2). As concluded in Alternative 1A, Impact AQUA-2, with the implementation measures described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*, the effect would not be adverse for delta smelt.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-2, with the implementation measures described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*, the impact of the maintenance of water conveyance facilities on delta smelt would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Water Exports from SWP/CVP South Delta Facilities

Overall, operational activities under Alternative 2A would benefit delta smelt by reducing average proportional entrainment at the south Delta facilities. Average juvenile proportional entrainment (March–June) would be 0.14 (i.e., 14% of the juvenile population) under Alternative 2A, which would be reduced 0.008(a 5% relative decrease) compared to baseline (0.15 NAA) (Figure 11-2A-1, Table 11-2A-1). As described under Alternative 1A (Impact AQUA-3), the greatest relative reductions in larval/juvenile proportional entrainment would be in wetter years (24% to 33% relative decrease compared to NAA). Average adult proportional entrainment (December–March) for all water year types would be reduced under Alternative 2A by 0.02 (a 27% relative decrease) under Alternative 2A compared to NAA (Figure 11-2A-2, Table 11-2A-1).

Table 11-2A-1. Differences in Proportional Entrainment of Delta Smelt at SWP/CVP South Delta Facilities

Water Year Type	Proportional Entrainment[a] Difference in Proportions (Relative Change in Proportions) EXISTING CONDITIONS vs. A2A	NAA vs. A2A
Total Population		
Wet	-0.034 (-31%)	-0.059 (-44%)
Above Normal	-0.028 (-17%)	-0.056 (-29%)
Below Normal	0.016 (7%)	-0.013 (-5%)
Dry	0.017 (6%)	-0.002 (-1%)
Critical	0.010 (3%)	0.010 (3%)
All Years	-0.007 (-3%)	-0.028 (-13%)
Juvenile Delta Smelt (March–June)		
Wet	0.005 (13%)	-0.021 (-33%)
Above Normal	0.002 (3%)	-0.027 (-24%)
Below Normal	0.030 (22%)	-0.001 (-1%)
Dry	0.026 (14%)	0.005 (3%)
Critical	0.017 (7%)	0.012 (5%)
All Years	0.015 (12%)	-0.008 (-5%)
Adult Delta Smelt[b] (December–March)		
Wet	-0.039 (-56%)	-0.038 (-55%)
Above Normal	-0.030 (-37%)	-0.029 (-36%)
Below Normal	-0.014 (-17%)	-0.012 (-15%)
Dry	-0.009 (-11%)	-0.007 (-9%)
Critical	-0.007 (-9%)	-0.002 (-2%)
All Years	-0.022 (-29%)	-0.020 (-27%)

Shading indicates >5% or more increased entrainment.

Note: Negative values indicate lower entrainment loss under Alternative 2A than under EXISTING CONDITIONS.

[a] Proportional entrainment index (U.S. Fish and Wildlife Service 2008a).

[b] Adult proportional entrainment adjusted according to Kimmerer (2011).

Water Exports from SWP/CVP North Delta Intake Facilities

As described for Alternative 1A (Impact AQUA-3 for delta smelt), delta smelt would face potential entrainment and impingement at the proposed north Delta diversion facilities. The exposure to potential entrainment would be low, however, because only a very small proportion of the population occurs at this location. The intakes would be screened to exclude fish larger than 15 mm SL, which would include juvenile delta smelt. There would be potential negative effects from entrainment of smaller life stages (eggs and larvae) and potential impingement and screen contact by juveniles and adults (Appendix B, *Entrainment*, Section B.6.2.3).

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

As described for Alternative 1A, potential entrainment and impingement risks at the north Delta intakes would be limited since delta smelt rarely occur in the vicinity of the proposed intake site. Potential larval smelt entrainment as modeled by PTM would be minimal (less than 2% under Alternative 2A) and similar to NAA. The intake would be screened to exclude fish larger than 15 mm SL.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

Potential entrainment of larval delta smelt at the NBA, as estimated by particle-tracking models was low, averaging 1.3% under Alternative 2A compared to 2.0% under NAA, a 35% reduction in relative terms (Table 11-2A-2).

Table 11-2A-2. Average Percentage (and Difference) of Particles Representing Larval Delta Smelt Entrained by the North Bay Aqueduct under Alternative 2A and Baseline Scenarios

Average Percent Particles Entrained at NBA			Difference (and Relative Difference)	
EXISTING CONDITIONS	NAA	A2A_LLT	A2A_LLT vs. EXISTING CONDITIONS	A2A_LLT vs. NAA
2.1	2.0	1.3	-0.81 (-39%)	-0.71 (-35%)

Note: 60-day DSM2-PTM simulation. Negative difference indicates lower entrainment under the alternative compared to the baseline scenario.

Predation Associated with Entrainment

As described in Impact AQUA-3 for Alternative 1A, pre-screen losses of delta smelt at the SWP/CVP facilities are believed to be high and are typically attributed to predation and other unfavorable conditions near the pumps (Castillo et al. 2012). Under Alternative 2, pre-screen losses at the south Delta facilities would decrease commensurate with entrainment reductions described above. Structures associated with the proposed north Delta intakes could attract piscivorous fish, potentially increasing localized predation risk. However few delta smelt would be expected to occur in the vicinity of the north Delta intakes, thus limiting their exposure to the predation risk. Predatory fish could potentially occur along NPBs, which could potentially increase predation risk at those times of year delta smelt are in that region of the south Delta (December–June). The effect would be beneficial for delta smelt because fewer delta smelt would be lost to predation across all SWP/CVP facilities.

NEPA Effects: Under Alternative 2A, overall potential entrainment of delta smelt would be reduced at the south Delta SWP/CVP facilities. Entrainment and impingement could potentially occur at the proposed north Delta intakes, but the risk would be low due to the location, design and operation of intakes, and offset by reduced entrainment at the south Delta facilities. Furthermore, any potential effects would be reduced by monitoring and adaptive management by the Real-Time Response Team. Overall, Alternative 2A would not have an adverse effect and may be beneficial to delta smelt due to a small reduction in entrainment and associated predation losses at the south Delta facilities, and minimizing entrainment at the north Delta facilities and NBA intakes.

CEQA Conclusion: As described above, operations under Alternative 2A would reduce average adult proportional entrainment by 0.022 (a 29% relative decrease) compared to Existing Conditions.

Larval/juvenile entrainment would increase by 0.015 (12% relative increase) on average, and increase by 0.030 (22% relative increase) in below normal years compared to Existing Conditions (Table 11-2A-1). However, this would affect a small proportion of the population (1.5% on average, 3% in below normal years).

This CEQA interpretation of the biological modeling differs from the NEPA analysis, which is likely attributable to different modeling assumptions (as described fully in Section 11.3.3 and Alternative 1A Impact AQUA-3). Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. Note that the analysis for larvae and juveniles includes both OMR flows and X2 as predictors of proportional entrainment; primarily because of sea level rise assumptions, X2 would be further upstream in the ELT and LLT even with similar water operations, so that the comparison of the action alternative in the ELT and LLT to Existing Conditions is confounded.

Therefore, the impact analysis is better informed by the results from the NEPA analysis presented above, which accounts for sea level rise by considering the NAA in the LLT. When climate change is factored in, larval-juvenile delta smelt proportional entrainment is reduced 0.008 (5% relative decrease) on average compared to conditions without BDCP, and is similar in below normal years (Table 11-2A-1).

The risk of entrainment and impingement at the proposed north Delta intakes is low due to the low abundance of delta smelt in the vicinity, and would be further minimized by fish screens. Potential entrainment of larvae would be slightly decreased (~1%) at the NBA (Table 11-2A-2).

Overall, Alternative 2A would not significantly increase entrainment and associated predation losses at the south Delta facilities, and would minimize entrainment at the north Delta facilities and NBA intakes. Furthermore, any potential impacts would be reduced by monitoring and adaptive management by the Real-Time Response Team. The impact is considered to be less than significant, and no mitigation would be required.

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

NEPA Effects: The effects of operations under Alternative 2A on abiotic spawning habitat would be about the same as described for Alternative 1A (Impact AQUA-4). Flow reductions below the north Delta intakes would not reduce available spawning habitat. In-Delta water temperatures, which can affect spawning timing, would not change across Alternatives, because they would be in thermal equilibrium with atmospheric conditions and not strongly influenced by the flow changes. The effect of Alternative 2A operations on spawning would not be adverse, because there would be little change in abiotic spawning conditions for delta smelt.

CEQA Conclusion: As described above, operations under Alternative 2A would not reduce abiotic spawning habitat availability or change spawning temperatures for delta smelt. Consequently, the impact would be less than significant, and no mitigation is required.

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

As described for Alternative 1A (Impact AQUA-5 for delta smelt), rearing habitat conditions for juvenile delta smelt were evaluated using the fall abiotic habitat index (Feyrer et al. 2011) with and without the assumption that habitat benefits are realized. Unlike Alternative 1A, Alternative 2A includes the BiOp Fall X2 requirements. The abiotic habitat index under Alternative 2A without restoration would be similar to NAA (Table 11-2A-3, Figure 11-2A-3). However, Alternative 2A is expected to further benefit delta smelt by habitat restoration (*CM2 Yolo Bypass Fisheries Enhancement and CM4 Tidal Natural Communities Restoration*), particularly in the Suisun Marsh, West Delta, and Cache Slough ROAs, which are closer to delta smelt's main areas of occurrence. Habitat restoration, similar in scale to that under Alternative 1A, is expected to increase spawning and rearing habitat and is intended to supplement food production and export to rearing areas.

NEPA Effects: Assuming BDCP habitat benefits are realized, Alternative 2A could result in an increase in the abiotic habitat index of up to 30% (compared to NAA), averaged across all water years and assuming 100% habitat occupancy (Table 11-2A-3). These effects are due to the inundation of new areas of the Delta resulting from habitat restoration effects, which will open up additional habitat for delta smelt. However, since delta smelt are pelagic, they would not be expected to occupy habitats shallower than about 3-6 feet deep in significant numbers. When analyzing effects by water years, the relative increase in abiotic habitat index would be at least 25% for all years combined, and greatest in dry years (37% NAA) and below normal years (34% NAA), with restoration. If conservation measures to restore habitat do not realize expected benefits, there would be only minor changes in abiotic habitat index.

Table 11-2A-3. Differences in Delta Smelt Fall Abiotic Index (hectares) between Alternative 2A and Existing Biological Conditions Scenarios, with Habitat Restoration, Averaged by Prior Water Year Type

	Without Restoration		With Restoration	
Water Year	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
All	992 (25%)	106 (2%)	2,325 (58%)	1,439 (30%)
Wet	2,178 (46%)	-18 (0%)	4,065 (86%)	1,869 (27%)
Above Normal	1,729 (45%)	61 (1%)	3,243 (85%)	1,575 (29%)
Below Normal	60 (1%)	208 (5%)	1,192 (29%)	1,340 (34%)
Dry	195 (5%)	286 (8%)	1,186 (33%)	1,278 (37%)
Critical	28 (1%)	28 (1%)	743 (25%)	743 (25%)

Note: Negative values indicate lower habitat indices under preliminary proposal scenarios. Water year 1922 was omitted because water year classification for prior year was not available.

CEQA Conclusion: As discussed under Alternative 1A, Alternative 2A would not result in less rearing habitat area (based on the Feyrer et al. 2011 abiotic habitat index), compared to Existing Conditions. Averaged across all water year types, Alternative 2A would result in an overall increase in the abiotic habitat index by 25% without restoration and up to 58% with restoration compared Existing Conditions (which do not include Fall X2 criteria) (Table 11-2A-3). Without BDCP habitat restoration efforts, the fall abiotic habitat index would be similar to baseline in drier years (5% more), but would increase 45–46% in above normal and wet years, when Fall X2 requirements are met. As described above, habitat restoration under Alternative 2A would further increase the delta smelt fall abiotic habitat index, resulting in up to 25–33% increase in drier years and up to 85–86% increase in wetter years, optimistically assuming 100% habitat occupancy (Figure 11-2A-3).

Note that the CEQA analysis predicts a greater increase in the abiotic habitat index relative to baseline than the NEPA analysis. It is unclear whether this increase under Alternative 2A compared to Existing Conditions is a function of Project operations, or attributable to differences in modeling assumptions (Existing Conditions does not include Fall X2). The NEPA analysis is a better approach for isolating the effect of the Alternative from the effects of sea level rise, climate change, future water demands, and implementation of required actions under the BiOps such as the Fall X2 requirement. When compared to the NAA and informed by the NEPA analysis, the average delta smelt abiotic habitat index under Alternative 2A would be similar to NAA without restoration, and 30% greater with restoration (Table 11-2A-3).

Overall, there would be a minor beneficial impact on the species compared to existing conditions without Fall X2, primarily from implementation of habitat restoration. The benefits of restored habitat for this species will depend on the success of restoration in creating physical habitat for smelt and in fostering ecological conditions that favor good feeding conditions and production of food upon which smelt can feed. The magnitude of restored habitat benefits is uncertain. As such, restoration success will have to be assessed empirically during the term of the BDCP permit. BDCP water operations will be subject to adjustment via adaptive management, in order to ensure the impacts of water operations on rearing habitat for delta smelt are not significant and to support a contribution to recovery of this species. The Adaptive Management Program will evaluate the effects of water operations and habitat restoration on the delta smelt population, including adjustments as appropriate to improve water supply reliability. In conclusion, the impact of Alternative 2A would be less than significant and would likely provide a benefit to the species because of the increase in available habitat. No mitigation is required.

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

From December to March, many mature delta smelt migrate upstream from brackish rearing areas in and around Suisun Bay and the confluence of the Sacramento and San Joaquin Rivers (U.S. Fish and Wildlife Service 2008a; Sommer et al. 2011). The initiation of migration is associated with pulses of freshwater inflow, which are turbid, cool, and less saline (Grimaldo et al. 2009). Changes in flow under Alternative2A could change turbidity, but is not expected to result in changes in water temperatures or pulses of local rainwater into the Delta. As described above in Impact AQUA-4, in-Delta water temperatures would not change in response to Alternative 2A flows. The modeling results indicate no biologically meaningful changes in water temperature within the Delta under Alternative2A and no substantial changes in the number of stressful or lethal condition days for juveniles.

Turbid water is an important habitat characteristic for delta smelt (Nobriga et al. 2008; Feyrer et al. 2011), and has been correlated to long-term changes in delta smelt abundance or survival either by itself or in combination with other factors (Thomson et al. 2010; Miller et al. 2012). Therefore, it is assumed that turbidity is an attribute of critical importance to delta smelt larvae, juveniles, and adults. Operation of the north Delta intakes (*CM1 Water Facilities and Operation*) is estimated to result in around 8 to 9% less sediment entering the Plan Area from the Sacramento River, the main source of sediment for the Delta and downstream subregions. In addition, sediment could be accreted (captured) in the ROAs (*CM4 Tidal Natural Communities Restoration*). Notching the Fremont Weir (*CM2 Yolo Bypass Fisheries Enhancements)* will also direct more Sacramento River water and sediment into the Bypass. These actions could limit sediment supply to areas currently important to delta smelt, such as Suisun Bay, which would result in less seasonal deposition of sediment that could be resuspended by wind-wave action to make/keep the overlying water column turbid. Therefore, there is a potential for a slight increase in water clarity, and a corresponding reduction in habitat quality for delta smelt. However, Alternative 2A is not expected to affect suspended sediment concentration during the first flush of precipitation that cues delta smelt migration. As such, turbidity cues associated with adult delta smelt migration should not change. With regard to suspended sediment concentrations at other times of the year, any effect will be minimized through the reintroduction of sediment collected at the north Delta intakes into tidal natural communities restoration projects (CM4), consistent with the Environmental Commitment addressing Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material.

NEPA Effects: Alternative 2 may decrease sediment supply to the estuary by 8 to 9 percent, with the potential for decreased habitat suitability for delta smelt in some locations.

CEQA Conclusion: As described above, operations under Alternative 2A would not substantially alter the turbidity cues associated with winter flush events that may initiate the adult delta smelt migration. Additionally there would be no appreciable changes in water temperatures under Alternative 2A. Consequently, the impact on adult delta smelt migration conditions would be less than significant, and no mitigation is required.

Restoration and Conservation Measures

Alternative 2A has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the effects described for delta smelt under Alternative 1A (Impact AQUA-7 through AQUA-18) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (CM12)

Impact AQUA-11: Effects of Invasive Aquatic Vegetation Management on Delta Smelt (CM13)

Impact AQUA-12: Effects of Dissolved Oxygen Level Management on Delta Smelt (CM14)

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (CM15)

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (CM16)

Impact AQUA-15: Effects of Illegal Harvest Reduction on Delta Smelt (CM17)

Impact AQUA-16: Effects of Conservation Hatcheries on Delta Smelt (CM18)

Impact AQUA-17: Effects of Urban Stormwater Treatment on Delta Smelt (CM19)

Impact AQUA-18: Effects of Removal/Relocation of Nonproject Diversions on Delta Smelt (CM21)

NEPA Effects: All of these restoration and conservation measure impact mechanisms have been determined to result in no adverse effects on delta smelt for the reasons identified for Alternative 1A. Specifically for AQUA-8, the effects of contaminants on delta smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on delta smelt are uncertain.

CEQA Conclusion: All of these restoration and conservation measure impact mechanisms would be considered less than significant, for the reasons identified for Alternative 1A, and no mitigation would be required.

Longfin Smelt

Construction and Maintenance of CM1

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

Longfin smelt are not expected to be present in the project construction zones during the expected in-water construction window (June 1–October 31) (see Table 11-6). Therefore, there is a very low potential risk of effects from construction activities. In addition, longfin smelt are pelagic species and are less likely to be present in the construction zones than other fish species.

The potential effects of construction of the water conveyance facilities on longfin smelt would be similar to those described for Alternative 1A (Impact AQUA-19) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-19, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for longfin smelt.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-19, the impact of the construction of water conveyance facilities on longfin smelt would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1.

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2A would be about the same as those described for Alternative 1A (see Impact AQUA-20). As concluded in Alternative 1A, Impact AQUA-20, the effect would not be adverse for longfin smelt.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-20, the impact of the maintenance of water conveyance facilities on longfin smelt would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Water Exports from SWP/CVP South Delta Facilities

For larval longfin smelt, particle tracking model simulations indicate that overall the magnitude of entrainment risk is low under all hydrologic conditions and starting geographic distributions (wetter and drier). Average entrainment loss under Alternative 2A with the wetter starting distribution was 0.8% compared to 1.6% under NAA, a 54% relative decrease (Table 11-2A-4). Average entrainment loss with the drier starting distribution was 1.0% for Alternative 1A compared to 2.2% under NAA, a 57% decline in relative terms. The risk of entrainment would be greater during years when outflows during late winter and spring are low (generally in dry years, as modeled by drier distribution), with reduced entrainment under Alternative 2A compared to baseline conditions. Overall, larval entrainment would be reduced under Alternative 2A relative to NAA.

Table 11-2A-4. Percentage of Particles (and Difference) Representing Longfin Smelt Larvae Entrained by the South Delta Facilities under Alternative 2A and Baseline Scenarios

	Percent Particles Entrained			Difference (and Relative Difference)	
Starting Distribution	EXISTING CONDITIONS	NAA	A2A_LLT	A2A_LLT vs. EXISTING CONDITIONS	A2A_LLT vs. NAA
Wetter	1.9	1.6	0.8	-1.09 (-58%)	-0.91 (-54%)
Drier	2.5	2.2	1.0	-1.56 (-62%)	-1.29 (-57%)

Note: 60-day runs of PTM. Negative difference values indicate lower entrainment under the alternative compared to the baseline scenario.

Juvenile and adult longfin smelt entrainment at the south Delta facilities is calculated by normalizing salvage data against fall midwater trawl abundance indices. Entrainment under Alternative 2A would be reduced compared to NAA. Entrainment averaged across all water year types would be reduced for juvenile longfin smelt by 54% compared to NAA; entrainment would decrease for adults by 66% compared to NAA (Table 11-2A-5). As discussed for Alternative 1A (Impact AQUA-21 for longfin smelt), entrainment would be highest in dry and critical years. Under Alternative 2A, entrainment in dry and critical years would be reduced 21–24% for juveniles and 25% for adults, compared to NAA. This reflects substantial reductions in reverse OMR flows under Alternative 2A for December to March.

Table 11-2A-5. Longfin Smelt Entrainment Index (March–June) at the SWP and CVP Salvage Facilities and Differences (Absolute and Percentage) between Model Scenarios

		Absolute Difference (Percent Difference)	
Life Stage	Water Year Types	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Juvenile (March–June)	Wet	-52,640 (-83%)	-58,082 (-84%)
	Above Normal	-2,383 (-53%)	-2,673 (-55%)
	Below Normal	-637 (-21%)	-845 (-26%)
	Dry	-62,687 (-12%)	-120,994 (-21%)
	Critical	-191,393 (-34%)	-117,523 (-24%)
	All Years	-132,302 (-49%)	-157,314 (-54%)
Adult (December–March)	Wet	-98 (-76%)	-102 (-77%)
	Above Normal	-431 (-66%)	-471 (-68%)
	Below Normal	-917 (-47%)	-840 (-45%)
	Dry	-348 (-29%)	-282 (-25%)
	Critical	-7,724 (-32%)	-5,590 (-25%)
	All Years	-2,393 (-66%)	-2,357 (-66%)
	Shading indicates >5% increase in entrainment index.		

Water Exports from SWP/CVP North Delta Intake Facilities

The proposed new north Delta intakes would increase entrainment potential in this area, but entrainment of longfin smelt and potential exposure to predators at the diversion structures would be extremely low because this species is rarely encountered in surveys this far upstream (California Department of Fish and Game 2012a; 2012b; 2013b).

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

Larval entrainment to NBA was assessed by particle tracking modeling of particles, using starting distributions emulating longfin smelt distribution in wetter years (i.e., greater outflow, smelt spawn further west) and drier years (i.e., longfin smelt spawning occurs further east and deeper into the Delta). Particle entrainment at the NBA was low for both starting distributions (wetter and drier), averaging 0.13–0.16% under Alternative 2A, which was 0.05–0.06% less than NAA, or 55–64% lower in relative terms (Table 11-2A-6).

Table 11-2A-6. Average Percentage (and Difference) of Particles Representing Larval Longfin Smelt Entrained by the North Bay Aqueduct under Alternative 2A and Baseline Scenarios

	Percent Particles Entrained			Difference (and Relative Difference)	
Distribution	EXISTING CONDITIONS	NAA	A2A_LLT	A2A_LLT vs. EXISTING CONDITIONS	A2A_LLT vs. NAA
Wetter	0.20	0.08	0.13	-0.07 (-35.3%)	0.05 (64.0%)
Drier	0.25	0.11	0.16	-0.08 (-33.2%)	0.06 (55.1%)

Note: 60-day runs of PTM. Negative difference values indicate lower entrainment under the alternative compared to the baseline scenario.

Entrainment to the NBA under Alternative 2A would be increased slightly (<0.1% net change) relative to NAA.

In summary, under Alternative 2A potential entrainment of longfin smelt would be reduced at the SWP/CVP south Delta facilities and the NBA. Entrainment loss of longfin smelt at the proposed north Delta intakes would be rare because longfin smelt are not expected to occur in that area of the Sacramento River, and the intakes would be screened. NPBs would be designed to deter salmonids, but their potential ability to reduce entrainment for longfin smelt is uncertain.

Predation Associated with Entrainment

Pre-screen loss of longfin smelt at the south Delta facilities is typically attributed to predation (as described for Impact AQUA-3 for Alternative 1). Under Alternative 2A, pre-screen loss is expected to decrease commensurate with entrainment reductions. Predation loss at the proposed north Delta intakes and the alternate NBA intake would be limited because longfin smelt rarely occur that far upstream. ***NEPA Effects***: The effect and conclusion for the risk of predation associated with the NPB structures would be the same as described for Alternative 1A. In conclusion, the effect on entrainment and entrainment-related predation loss under Alternative 2A would be beneficial because of the substantial reduction in entrainment and predation loss at the south Delta facilities.

CEQA Conclusion: As described above, entrainment loss of longfin smelt would be reduced under Alternative 2A. Entrainment and associated predation loss at the south Delta facilities under Alternative 2A would decrease 49% for juveniles and 66% for adults compared to Existing Conditions. Based on particle tracking simulations, entrainment of larval longfin smelt to the SWP NBA, agricultural diversions, and the south delta facilities would be expected to be less than baseline under most scenarios Predation loss at the proposed north Delta intakes and the alternate NBA intake would be limited because longfin smelt rarely occur that far upstream

The impact under Alternative 2A would be beneficial to the species because of the reduction in entrainment and predation loss for both juveniles and adults.

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

Adult longfin smelt inhabit primarily brackish water and marine areas in San Pablo and San Francisco Bays and nearshore coastal marine waters. Prespawning adult longfin smelt use the Delta for staging and spawning. The planktonic larvae are transported downstream after hatching; within the Plan Area, the early juvenile life stages rear in the low-salinity areas of the West Delta and

Suisun Bay subregions. Juvenile and adult longfin smelt occupying the Plan Area during fall through spring migrate westward into San Francisco Bay during the summer.

Longfin smelt spawn in the late winter and early spring months when water temperatures in the lower rivers and Delta are seasonally cool. Longfin smelt spawn adhesive eggs that are thought to be deposited on sand and gravel and possibly other hard substrates. Spawning occurs in the lower reaches of the Sacramento River in the vicinity of Cache Slough and Rio Vista, although some spawning occurs in the lower San Joaquin River based on presence of early larval and adult longfin smelt in CDFW larval trawl samples (California Department of Fish and Game 2009b). Spawning also occurs in Suisun Marsh and the Napa River.

Immediately after hatching from the incubating eggs, longfin smelt larvae are planktonic and drift passively with water flows; older larvae use a variety of behaviors to help retain themselves in favorable habitats (Bennett et al. 2002). Larvae are typically present in the Delta during the late winter and early spring months. Juvenile longfin smelt rear in the spring (approximately March to June) in the Suisun Bay and the West Delta subregions before migrating downstream of the Plan Area into San Pablo and San Francisco Bays and nearshore coastal marine waters, where they continue to rear for a year or more. Larval and early juvenile longfin smelt could be affected by covered activities when they are present in the Plan Area during the winter and spring months.

NEPA Effects: The indices of abundance of longfin smelt based on the Fall Midwater, Bay Otter, and Bay Midwater trawl indices have been correlated to outflow (expressed as the location of X2) in the preceding winter and spring months, when longfin smelt spawning and rearing occurs (January through June) (Kimmerer 2002a; Kimmerer et al. 2009; Rosenfield and Baxter 2007; Mac Nally et al. 2010; Thomson et al. 2010). Modeling results based on Kimmerer et al. (2009) predict longfin smelt Fall Midwater and Bay Otter Trawl indices would decrease for most water year types, relative to NAA, based on changes in winter-spring flow alone (Table 11-2A-7). Alternative 2A operations would be expected to result in 5–6% lower longfin smelt abundance compared to NAA, for all years combined.

Table 11-2A-7. Estimated Differences between Scenarios for Longfin Smelt Relative Abundance in the Fall Midwater Trawl or Bay Otter Trawl

	Fall Midwater Trawl Relative Abundance		Bay Otter Trawl Relative Abundance	
Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
All	-1,665 (-32%)	-188 (-5%)	-5,336 (-37%)	-581 (-6%)
Wet	-6,317 (-35%)	48 (0.4%)	-25,962 (-40%)	186 (0.5%)
Above Normal	-3,557 (-41%)	-725 (-13%)	-12,475 (-47%)	-2,430 (-15%)
Below Normal	-1,508 (-35%)	-209 (-7%)	-4,639 (-41%)	-619 (-8%)
Dry	-616 (-29%)	-123 (-8%)	-1,658 (-34%)	-321 (-9%)
Critical	-158 (-17%)	-24 (-3%)	-369 (-20%)	-55 (-3%)
	Shading indicates greater than 10% decrease in relative abundance.			

During the period of longfin smelt rearing from January–June, Delta outflows would be similar (<10% difference) to NAA in all months except April, when flows would be reduced 11%.

Longfin smelt may also benefit from habitat restoration actions (*CM2 Yolo Bypass Fisheries Enhancement and CM4 Tidal Natural Communities Restoration*, which are intended to provide additional food production and export to longfin smelt rearing areas in Suisun Marsh, West Delta, and Cache Slough ROAs.

CEQA Conclusion: Average Delta outflow under Alternative 2 would be similar (less than 5% difference) to Existing Conditions in winter (January, February, March) and decreased in spring (13% in April, 22% in May, 17% in June). Relative longfin smelt abundance based on Kimmerer et al. 2009 decreased 32–37% on average compared to Existing Conditions (Table 11-2A-6), with greatest reductions in above normal water years (41–47% lower under Alternative 2A). Average juvenile longfin smelt relative abundance, based on Kimmerer et al. 2009, decreased 31–36% compared to Existing Conditions (Table 11-2A-6).

Contrary to the NEPA conclusion set forth above, these results indicate that the difference between Existing Conditions and Alternative 2 could be significant because the alternative could substantially reduce relative abundance based on Kimmerer et al. 2009. However, as discussed earlier (Alternative 1A, Impact AQUA-22), this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed above (Section 11.3.3), because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA) models anticipated future conditions that would occur in 2060 (LLT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the NEPA analysis, which compares results between the alternative and NAA, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA and informed by the NEPA analysis above, longfin smelt relative abundance, based on Kimmerer et al. (2009), decreased 5% to 6% on average relative to conditions without BDCP (Table 11-2A-6). These results represent the increment of change attributable to the alternative and address the limitations of the comparison the CEQA baseline (Existing Conditions). Therefore, operations under Alternative 2A would not in itself result in a significant impact on longfin smelt rearing.

This impact is found to be less than significant, and no mitigation is required. Furthermore, as described above, other measures such as habitat restoration (CM4) could improve the quality of spawning and rearing habitat for longfin smelt, although there is some uncertainty of the outcome related to habitat restoration.

Impact AQUA-23: Effects of Water Operations on Rearing Habitat for Longfin Smelt

The analysis, NEPA Effects and CEQA Conclusion for effects of water operations on rearing habitat for longfin smelt is included in *Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt.*

Impact AQUA-24: Effects of Water Operations on Migration Conditions for Longfin Smelt

The analysis, NEPA Effects and CEQA Conclusion for effects of water operations on migration conditions for longfin smelt is included in *Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt.*

Restoration and Conservation Measures

Alternative 2A has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the effects described for longfin smelt under Alternative 1A (Impact AQUA-25 through AQUA-36) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (CM12)

Impact AQUA-29: Effects of Invasive Aquatic Vegetation Management on Longfin Smelt (CM13)

Impact AQUA-30: Effects of Dissolved Oxygen Level Management on Longfin Smelt (CM14)

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (CM15)

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (CM16)

Impact AQUA-33: Effects of Illegal Harvest Reduction on Longfin Smelt (CM17)

Impact AQUA-34: Effects of Conservation Hatcheries on Longfin Smelt (CM18)

Impact AQUA-35: Effects of Urban Stormwater Treatment on Longfin Smelt (CM19)

Impact AQUA-36: Effects of Removal/Relocation of Nonproject Diversions on Longfin Smelt (CM21)

NEPA Effects: These restoration and conservation measure impact mechanisms have been determined to range from no effect, to not adverse, or beneficial effects on longfin smelt for NEPA purposes, for the reasons identified for Alternative 1A. Specifically for AQUA-26, the effects of contaminants on longfin smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on longfin smelt are uncertain.

CEQA Conclusion: These restoration and conservation measure impact mechanisms would be considered to range from no impact, be less than significant, or beneficial on longfin smelt, for the reasons identified for Alternative 1A, and no mitigation is required.

Winter-Run Chinook Salmon

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

The potential effects of construction of the water conveyance facilities on Chinook salmon would be similar to those described for Alternative 1A (Impact AQUA-37) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-37, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-37 for Chinook salmon, the impact of the construction of water conveyance facilities on Chinook salmon would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1.

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2A would be about the same as those described for Alternative 1A (see Impact AQUA-38). As concluded in Alternative 1A, Impact AQUA-38, the impact would not be adverse for Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-38 for Chinook salmon, the impact of the maintenance of water conveyance facilities on Chinook salmon would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Entrainment losses would be reduced under Alternative 2A (A2A_LLT) at the south Delta facilities. Losses for all years combined would decrease by approximately 5,000 fish (67–68%) compared to NAA (Table 11-2A-8). Entrainment would be reduced in all water year types, ranging from moderate reductions in critical water years (18% fewer fish compared to NAA) to significant reductions in wet years (90% fewer fish entrained) (Table 11-2A-8). Pre-screen losses, typically attributed to predation, would be expected to decrease commensurate with decreased entrainment at the south Delta facilities.

The proportion of the annual winter-run Chinook population (assumed to be 500,000 juveniles approaching the Delta) lost at the south Delta facilities across all years is very small, averaging 1.4% under NAA and decreasing to 0.4% under Alternative 2A

Table 11-2A-8. Juvenile Winter-Run Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 2A

	Absolute Difference (Percent Difference)[a]	
Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-10,144 (-89%)	-10,565 (-90%)
Above Normal	-5,399 (-81%)	-5,523 (-82%)
Below Normal	-3,751 (-52%)	-3,327 (-49%)
Dry	-1,175 (-31%)	-868 (-25%)
Critical	-347 (-27%)	-208 (-18%)
All Years	-4,598 (-68%)	-4,539 (-67%)
	Shading indicates10% or greater increased entrainment.	

[a] Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

The effect of Alternative 2A on entrainment and impingement at the North Delta facilities would be the same as described for Alternative 1A (Impact AQUA-39) because both alternatives would have state-of-the-art screens installed to prevent entrainment and be designed to minimize impingement.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The effect would be the same as described for Alternative 1A (Impact AQUA-39). Entrainment and impingement effects would be minimal for Alternative 2A because intakes would have state-of-the-art screens installed.

Predation Associated with Entrainment

Pre-screen loss of juvenile Chinook salmon at the south Delta facilities is typically attributed to predation, and is expected to decrease under Alternative 2A, commensurate with entrainment reductions. Predation loss at the proposed north Delta intakes and the alternate NBA intake would be limited because of the state-of-the-art, positive barrier screens installed.

NEPA Effects: Due to reduced entrainment at the south Delta facilities, the effect of Alternative 2A water operations on winter-run Chinook entrainment would be beneficial.

CEQA Conclusion: As described above, entrainment losses of juvenile Chinook salmon at the south Delta facilities would decrease under Alternative 2A (A2A_LLT) compared to Existing Conditions (Table 11-2A-8). At the north Delta facilities and the alternate NBA intake, the screened intakes as designed would exclude this species, although there is some potential for impingement or contact by smaller fish with the screen. Overall impacts of Alternative 2A water operations on entrainment of Chinook salmon (winter-run ESU) would be beneficial due to a reduction in entrainment and no mitigation would be required.

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

In general, Alternative 2A would reduce the quantity and quality of spawning and egg incubation habitat for winter-run Chinook salmon relative to NAA

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam were examined during the May through September winter-run spawning period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Lower flows can reduce the instream area available for spawning and egg incubation. Flows under A2A_LLT during May and June would generally be similar to or greater than flows under NAA. Flows under A2A_LLT during July, August, and September would generally be lower than flows under NAA by up to 20%. These results indicate that there would be intermittent negligible-to-small flow-related effects of Alternative 2A on spawning and egg incubation habitat.

Shasta Reservoir storage volume at the end of May influences flow rates below the dam during the May through September winter-run spawning and egg incubation period. May Shasta storage volume under A2A_LLT would be similar to or greater than storage under NAA for all water year types (Table 11-2A-9).

Table 11-2A-9. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-19 (0%)	15 (0%)
Above Normal	-89 (-2%)	-3 (0%)
Below Normal	-102 (-2%)	96 (2%)
Dry	-230 (-6%)	214 (6%)
Critical	-218 (-9%)	366 (20%)

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no substantial differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-12. There would be no difference in levels of concern between NAA and Alternative 2A.

Table 11-2A-10. Maximum Water Temperature Criteria for Covered Salmonids and Sturgeon Provided by NMFS and Used in the BDCP Effects Analysis

Location	Period	Maximum Water Temperature (°F)	Purpose
Upper Sacramento River			
Bend Bridge	May–Sep	56	Winter- and spring-run spawning and egg incubation
		63	Green sturgeon spawning and egg incubation
Red Bluff	Oct–Apr	56	Spring-, fall-, and late fall–run spawning and egg incubation
Hamilton City	Mar–Jun	61 (optimal), 68 (lethal)	White sturgeon spawning and egg incubation
Feather River			
Robinson Riffle (RM 61.6)	Sep–Apr	56	Spring-run and steelhead spawning and incubation
	May–Aug	63	Spring-run and steelhead rearing
Gridley Bridge	Oct–Apr	56	Fall- and late fall–run spawning and steelhead rearing
	May–Sep	64	Green sturgeon spawning, incubation, and rearing
American River			
Watt Avenue Bridge	May–Oct	65	Juvenile steelhead rearing

Table 11-2A-11. Number of Days per Month Required to Trigger Each Level of Concern for Water Temperature Exceedances in the Sacramento River for Covered Salmonids and Sturgeon Provided by NMFS and Used in the BDCP Effects Analysis

Exceedance above Water Temperature Threshold (°F)	Level of Concern			
	None	Yellow	Orange	Red
1	0-9 days	10-14 days	15-19 days	≥20 days
2	0-4 days	5-9 days	10-14 days	≥15 days
3	0 days	1-4 days	5-9 days	≥10 days

Table 11-2A-12. Differences between Baseline and Alternative 2A Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern[a]	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Red	33 (67%)	0 (0%)
Orange	-14 (-100%)	0 (NA)
Yellow	-16 (-100%)	0 (NA)
None	-3 (-100%)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] For definitions of levels of concern, see Table 11-2A-11.

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-2A-13). Total degree-days under Alternative 2A would be up to 12% lower than under NAA during May and June and up to 16% higher during July through September.

Table 11-2A-13. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
May	Wet	987 (262%)	-215 (-14%)
	Above Normal	213 (100%)	-142 (-25%)
	Below Normal	431 (197%)	-32 (-5%)
	Dry	235 (126%)	-179 (-30%)
	Critical	477 (216%)	67 (11%)
	All	2,344 (193%)	-500 (-12%)
June	Wet	391 (102%)	-320 (-29%)
	Above Normal	48 (32%)	-181 (-48%)
	Below Normal	304 (219%)	-48 (-10%)
	Dry	554 (295%)	20 (3%)
	Critical	628 (157%)	78 (8%)
	All	1,926 (153%)	-450 (-12%)
July	Wet	757 (146%)	151 (13%)

August	Wet	2,187 (314%)	224 (8%)
	Above Normal	901 (221%)	242 (23%)
	Below Normal	1,279 (483%)	244 (19%)
	Dry	2,098 (313%)	488 (21%)
	Critical	2,764 (186%)	145 (4%)
	All	9,229 (262%)	1,342 (12%)
September	Wet	833 (113%)	124 (9%)
	Above Normal	559 (78%)	159 (14%)
	Below Normal	1,572 (211%)	426 (23%)
	Dry	2,585 (202%)	-11 (0%)
	Critical	1,971 (95%)	80 (2%)
	All	7,523 (135%)	778 (6%)

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under A2A_LLT would be lower or similar to mortality under NAA except in below normal and dry water years (82% and 20%, respectively). The increase in the percent of winter-run population subject to mortality would be 1% in both below normal and dry years. Therefore, the increase in mortality of 1% from NAA to A2A_LLT, although relatively large, would be negligible at an absolute scale to the winter-run population (Table 11-2A-14). These results indicate that climate change would cause the majority of the increase in winter-run egg mortality.

Table 11-2A-14. Difference and Percent Difference in Percent Mortality of Winter-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	1 (252%)	-0.1 (-7%)
Above Normal	2 (339%)	-0.1 (-3%)
Below Normal	2 (239%)	1 (82%)
Dry	7 (477%)	1 (20%)
Critical	42 (157%)	-2 (-3%)
All	9 (189%)	0.3 (2%)

SacEFT predicts that there would be a 31% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2A_LLT relative to NAA (Table 11-2A-15). SacEFT predicts that the percentage of years with good (lower) redd scour risk under A2A_LLT would be similar to the percentage of years under NAA. SacEFT predicts that the percentage of years with good egg incubation conditions under A2A_LLT would be similar to that under NAA. SacEFT predicts that the percentage of years with good (lower) redd dewatering risk under A2A_LLT would be similar to NAA. These results indicate that there would be a small negative effect of Alternative 2A on spawning habitat.

The biological significance of a reduction in available suitable spawning habitat varies at the population level in response to a number of factors, including adult escapement. For those years when adult escapement is less than the carrying capacity of the spawning habitat, a reduction in area would have little or no population level effect. In years when escapement exceeds carrying capacity of the reduced habitat, competition among spawners for space (e.g., increased redd superimposition) would increase, resulting in reduced reproductive success. The reduction in the frequency of years in which spawning habitat availability is considered to be good by SacEFT could result in reduced reproductive success and abundance of winter-run Chinook salmon if the number of spawners is limited by spawning habitat quantity.

Table 11-2A-15. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Winter-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Spawning WUA	-36 (-62%)	-10 (-31%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-26 (-27%)	-3 (-4%)
Redd Dewatering Risk	4 (16%)	0 (0%)
Juvenile Rearing WUA	-24 (-48%)	1 (4%)
Juvenile Stranding Risk	-3 (-15%)	-14 (-45%)

WUA = Weighted Usable Area.

NEPA Effects: Considering the range of results presented here for winter-run Chinook salmon spawning and egg incubation, this effect would be adverse because it has the potential to substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. There would be small to moderate reductions in flow during a substantial portion (3 of 5 months) of the spawning and egg incubation period that would reduce spawning and egg incubation conditions for winter-run Chinook salmon. Further, SacEFT predicts that the extent of winter-run spawning habitat would be reduced by 31% under Alternative 2A (Table 11-2A-15). This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. Even so, proposed mitigation (Mitigation Measure AQUA-40a through AQUA-40c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 2A would reduce the quantity and quality of spawning and egg incubation habitat for winter-run Chinook salmon relative to the Existing Conditions.

CALSIM flows in the Sacramento River between Keswick and upstream of Red Bluff were examined during the May through September winter-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during May and June and generally lower by up to 27% during July, August, and September.

Shasta Reservoir storage volume at the end of May under A2A_LLT would be similar to Existing Conditions in wet, above normal, and below normal water years, but lower by 6% to 9% in dry and critical water years, respectively (Table 11-2A-9). This indicates that there would be a small to moderate effect of Alternative 2A on flows during the spawning and egg incubation period.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A during May and June. Mean monthly water temperature would be up to 12% higher under Alternative 2A in July through September depending on month, water year type, and location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. The number of years classified as "red" would increase by 67% under Alternative 2A relative to Existing Conditions (Table 11-2A-12).

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-2A-13). Total degree-days under Alternative 2A would be 135% to 313% higher than that under Existing Conditions depending on month throughout the period.

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under A2A_LLT would be 157–477% greater than mortality under Existing Conditions depending on water year type (Table 11-2A-14). These increases would only affect the winter-run population during dry and critical years, in which the absolute percent increase of the winter-run population would be 7 and 42%, respectively. These results indicate that Alternative 2A would cause increased winter-run Chinook salmon egg mortality in the Sacramento River.

SacEFT predicts that there would be a 62% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2A_LLT relative to Existing Conditions (Table 11-2A-15). SacEFT predicts that the percentage of years with good (lower) redd scour risk under A2A_LLT would be similar to the percentage of years under Existing Conditions. SacEFT predicts that the percentage of years with good egg incubation conditions under A2A_LLT would be 27% lower than under Existing Conditions. SacEFT predicts that the percentage of years with good (lower) redd dewatering risk under A2A_LLT would be 16% greater than the percentage of years under Existing Conditions. These results indicate that Alternative 2A would cause small to moderate reductions in spawning WUA and egg incubation conditions.

Collectively, these results indicate that the impact would be significant because it has the potential to substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. Exceedances of NMFS temperature thresholds would be substantially greater under Alternative 2A. Egg mortality in drier years, during which winter-run Chinook salmon would already be stressed due to reduced flows and increased temperatures, would be up to 42% greater due to Alternative 2A compared to the Existing Conditions (Table 11-2A-14). Further, the extent of spawning habitat would be 62% lower due to Alternative 2A compared to the Existing Conditions (Table 11-2A-15), which represents a substantial reduction in spawning habitat and, therefore, in adult spawner and redd carrying capacity. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-40a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Although analysis conducted as part of the EIR/EIS determined that Alternative 2A would have significant and unavoidable adverse effects on spawning habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on spawning habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2A.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2A operations only. Development of mitigation actions for the incremental impact on spawning habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2A.

Mitigation Measure AQUA-40b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Spawning Habitat Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to spawning habitat under Alternative 2A. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-40c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Spawning Habitat Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on winter-run Chinook salmon habitat, the BDCP proponents will consult with NMFS, USFWS and CDFW to identify and implement any feasible operational means to minimize effects on spawning habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-40a.

If feasible means are identified to reduce impacts on spawning habitat consistent with the overall operational framework of Alternative 2A without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on winter-run Chinook salmon habitat is not feasible under Alternative 2A operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on winter-run Chinook salmon would remain significant and unavoidable.

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

In general, Alternative 2A would reduce the quantity and quality of rearing habitat for fry and juvenile winter-run Chinook salmon relative to NAA.

Sacramento River flows upstream of Red Bluff were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can lead to reduced extent and quality of fry and juvenile rearing habitat. Flows under A2A_LLT would generally be lower than flows under NAA by up to 17% during August and November, and similar to or greater than flows under NAA during September, October, and December.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under A2A_LLT would not be different from the percentage of years under NAA (Table 11-2A-14). In addition, the percentage of years with good (low) juvenile stranding risk under A2A_LLT is predicted to be 45% (14% on an absolute scale) lower than under

NAA. This indicates that the quantity and quality of juvenile rearing habitat in the Sacramento River would be lower under A2A_LLT relative to NAA.

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under A2A_LLT would have a negligible difference (<5%) in habitat-related mortality with NAA.

NEPA Effects: Collectively, these results indicate that the effect is adverse because it has the potential to substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish. There would be no substantial effects of Alternative 2A on flows or water temperatures. However, effects on juvenile stranding risk are substantial (45% increase) relative to NAA. This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. Even so, proposed mitigation (Mitigation Measure AQUA-41a through AQUA-41c) has the potential to reduce the severity of impact though not necessarily to not adverse level.

CEQA Conclusion: In general, Alternative 2A would reduce the quantity and quality of fry and juvenile rearing habitat for winter-run Chinook salmon relative to the Existing Conditions.

Sacramento River flows upstream of Red Bluff were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during October and December, but up to 24% lower than Existing Conditions during August, September, and November.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be up to 14% higher under Alternative 2A in July through October depending on month, water year type, and location. There would be no differences (<5%) between Existing Conditions and Alternative 2A in mean monthly water temperature during November and December at either location.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under A2A_LLT would be 48% lower than under Existing Conditions (Table 11-2A-15). In addition, the percentage of years with good (low) juvenile stranding risk under A2A_LLT is predicted to be 15% lower than under Existing Conditions. This indicates that the quantity and quality of juvenile rearing habitat in the Sacramento River would be lower under A2A_LLT relative to Existing Conditions.

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under A2A_LLT would be 15% higher than under Existing Conditions.

These results indicate that the impact would be significant because it has the potential to substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish. Differences in flows are moderately large during the majority of months and water years types. Further, a 48% reduction in rearing habitat quantity and 15% increase in stranding risk would reduce upstream habitat conditions for winter-run fry and juveniles. Water temperatures would be higher than those under NAA in the Sacramento River during a substantial portion of the winter-run rearing period. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-41a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Although analysis conducted as part of the EIR/EIS determined that Alternative 2A would have significant and unavoidable adverse effects on rearing habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on rearing habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2A.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2A operations only. Development of mitigation actions for the incremental impact on rearing habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2A.

Mitigation Measure AQUA-41b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Rearing Habitat Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to rearing habitat under Alternative 2A. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-41c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Rearing Habitat Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on winter-run Chinook salmon habitat, the BDCP proponents will consult with NMFS, USFWS and CDFW to identify and implement any feasible operational means to minimize effects on rearing habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-41a.

If feasible means are identified to reduce impacts on rearing habitat consistent with the overall operational framework of Alternative 2A without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on winter-run Chinook salmon habitat is not feasible under Alternative 2A operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on winter-run Chinook salmon would remain significant and unavoidable.

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

In general, Alternative 2A would affect migration conditions for winter-run Chinook salmon relative to NAA.

Upstream of the Delta

Flows in the Sacramento River upstream of Red Bluff were examined for the July through November juvenile emigration period. A reduction in flow may reduce the ability of juvenile winter-run Chinook salmon to migrate effectively down the Sacramento River. Flows under A2A_LLT would generally be similar to flows under NAA, except during August and November, in which flows would be up to 17% lower under A2A_LLT. These flow reductions would not be of a high enough magnitude to have biologically meaningful effects on juvenile emigration conditions.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run Chinook salmon juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

Flows in the Sacramento River upstream of Red Bluff were examined during the adult winter-run Chinook salmon upstream migration period (December through August). A reduction in flows may reduce the olfactory cues needed by adults to return to natal spawning grounds in the upper Sacramento River. Flows under A2A_LLT would generally be similar to or greater than those under NAA except for wet water years during August, in which flows would be up to 14% lower under A2A_LLT. These reductions would not be large or frequent enough to cause biologically meaningful effects on adult migration conditions.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

Migration flows and water temperatures would not differ substantially between Alternative 2A and NAA.

Through-Delta

The effects of Alternative 2A on through-Delta migration were evaluated using the approach described in Alternative 1A, Impact AQUA-42.

Juveniles

During the juvenile winter-run Chinook salmon emigration period (November to early May), mean monthly flows downstream of the north Delta diversion facility under Alternative 2A would be reduced up to 25% depending on the month compared to NAA.

The north Delta export facilities would replace aquatic habitat and likely attract piscivorous fish around the intake structures. The predation effects of Alternative 2A would be the same as those described for Alternative 1A (see details in Impact AQUA-42), since there are five intakes for both alternatives. The five NDD intakes would remove or modify habitat along that portion of the migration corridor (22 acres aquatic habitat and 11,900 linear feet of shoreline). Potential predation losses at the north Delta intakes, as estimated by the bioenergetics model with median density of predators (119 striped bass per 1,000 feet of intake), would be less than 2% compared to the annual production estimated for the Sacramento Valley (Table 11-1A-17). A conservative assumption of 5% loss per intake would yield a cumulative loss of 18.5% of juvenile winter-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate.

Through-Delta survival to Chipps Island by emigrating juvenile winter-run Chinook salmon was modeled by the DPM. Average survival under Alternative 2A would be 33% across all years, 26% in drier years, and 45% in wetter years (Table 11-2A-16). Compared to NAA, juvenile survival would decrease 1.2% across all year (a 4% relative decrease) and decrease 1.5% (5% relative decrease) in drier years.

Table 11-2A-16. Through-Delta Survival (%) of Emigrating Juvenile Winter-Run Chinook Salmon under Alternative 2A

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Year Type	EXISTING CONDITIONS	NAA	A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wetter Years	46.3	46.1	45.2	-1.1 (-3%)	-0.9 (-2%)
Drier Years	28.0	27.1	25.7	-2.3 (-8%)	-1.5 (-5%)
All Years	34.9	34.2	33.0	-1.9 (-5%)	-1.2 (-4%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and above normal water years (6 years).
Drier = Below normal, dry and critical water years (10 years).

Adults

Attraction flow, as estimated by the percentage of Sacramento River water at Collinsville, declined under Alternative 2A by no more than 10% during the December through June migration period for winter-run adults (Table 11-2A-17). The reductions in percentage are small in comparison with the magnitude of change in dilution reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect winter-run migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. For further discussion of the topic see the analysis for Alternative 1A.

Table 11-2A-17. Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Adult Chinook Migration Period for Alternative 2A

	Percentage of Water			Difference	
Month	EXISTING CONDITIONS	NAA	A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Sacramento River					
September	60	65	78	18	13
October	60	68	67	7	-1
November	60	66	62	2	-4
December	67	66	65	-2	-1
January	76	75	73	-3	-2
February	75	72	67	-8	-5
March	78	76	67	-11	-9
April	77	75	65	-12	-10
May	69	65	59	-10	-6
San Joaquin River					
September	0.3	0.1	1.3	1.0	1.2
October	0.2	0.3	3.6	3.4	3.3
November	0.4	1.0	5.4	5.0	4.4
December	0.9	1.0	3.0	2.1	2.0
January	1.6	1.7	3.2	1.6	1.5
February	1.4	1.5	3.8	2.4	2.3
March	2.6	2.8	6.1	3.5	3.3
April	6.3	6.6	10.6	4.3	4.0
	Shading indicates a difference of 10% or greater in flow proportion.				

NEPA Effects: Overall, the results indicate that the effect of Alternative 2A is adverse due to the cumulative effects associated with five north Delta intake facilities, including mortality related to near-field effects (e.g. impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes.

Upstream of the Delta, Alternative 2A would not affect migration conditions for winter-run Chinook salmon, as migration flows and water temperatures would not differ substantially between Alternative 2A and NAA.

Adult attraction flows under Alternative 2A would be lower than those under NAA, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 2A NDD on winter-run Chinook salmon related to impingement and predation associated with five new intakes could result in substantial effects on juvenile migrating winter-run Chinook salmon, although there is high uncertainty regarding the potential effects. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to very significant effects (~ 19% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the five new intake structures will be implemented as part of the final NDD screen design effort. Alternative 2A also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for winter-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 2A predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 2A would be similar to survival rates estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon. Until these efforts are completed and their results are fully analyzed, the overall effect of Alternative 2A on winter-run Chinook salmon through-Delta survival remains uncertain.

Therefore, primarily as a result of reduced upstream migration habitat conditions for winter-run Chinook salmon due to reduced flows along with unacceptable levels of uncertainty regarding the cumulative impacts of near-field and far-field effects associated with the presence and operation of the five intakes on winter-run Chinook salmon, this effect is adverse. While implementation of the conservation and mitigation measures listed below would address these impacts, these are not anticipated to reduce the impacts to a level considered not adverse.

CEQA Conclusion: In general, Alternative 2A would reduce migration conditions for winter-run Chinook salmon relative to the Existing Conditions.

Upstream of the Delta

Flows in the Sacramento River upstream of Red Bluff were examined during the July through November juvenile emigration period. Flows under A2A_LLT for juvenile migrants would generally be similar to flows under Existing Conditions, except during August and November, in which flows would be up to 24% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. These reductions would not be large or frequent enough to cause biologically meaningful effects on juvenile emigration conditions.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be up to 14% higher under Alternative 2A in July through October depending on month, water year type, and location. There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A during November.

Flows under A2A_LLT in the Sacramento River upstream of Red Bluff during December through August would generally be similar to flows under Existing Conditions, except during May and June, in which flows under A2A_LLT would be up to 21% greater, and during August, in which flows would be up to 24% lower. These reductions in flow would not be frequent enough to cause biologically meaningful effects on adult migration conditions.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A during December through June. Mean monthly water temperature would be up to 14% higher under Alternative 2A in July and August depending on month, water year type, and location.

Through-Delta

As described above, predation losses of migrating juvenile winter-run Chinook would increase at the five north Delta intakes, hypothetically ranging from less than 1% up to 12% that reach the north Delta. Through-Delta survival of emigrating juvenile winter-run Chinook salmon averaged across all years would decrease slightly compared to Existing Conditions (1.9% lower, a 5% relative decrease for all years) (Table 11-2A-16).

For migrating adults, olfactory cues, based on the proportion of Sacramento River flows, would be similar (<10% difference) to Existing Conditions during the winter-run Chinook salmon migration period December to February (Table 11-2A-17). For further discussion of this topic see the analysis for Alternative 1A.

Summary of CEQA Conclusion

Overall, Alternative 2A would significantly affect the migration conditions for juvenile or adult winter-run Chinook salmon, relative to the Existing Conditions. Alternative 2A would cause higher water temperatures in the Sacramento River upstream of the Delta relative to the Existing Conditions during a substantial portion of winter-run Chinook salmon juvenile and adult migration periods. There would be no effect of Alternative 2A on flows during the juvenile or adult winter-run Chinook salmon migration periods. Through-Delta survival of emigrating juveniles is expected to be substantially reduced, compared to Existing Conditions. There would be no effect of Alternative 2A on adult olfactory cues in the Delta.

Implementation of CM6 and CM15 would address these impacts, but are not anticipated to reduce them to a level considered less than significant. Although implementation of *CM6 Channel Margin Enhancement* would provide habitat similar to that which would be lost, it would not necessarily be located near the intakes and therefore would not fully compensate for the lost habitat. Additionally, implementation of this measure would not fully address predation losses. *CM15 Localized Reduction of Predatory Fishes (Predator Control)* has substantial uncertainties associated with its effectiveness such that it is considered to have no demonstrable effect. Conservation measures that address habitat and predation losses, therefore, would potentially minimize impacts to some extent but not to a less than significant level. Consequently, as a result of these changes in migration conditions, this impact is significant and unavoidable.

Applicable conservation measures are briefly described below and full descriptions are found in Chapter 3, Section 3.6.2.5 Channel Margin Enhancement (CM6) and Section 3.6.3.4 Localized Reduction of Predatory Fishes (Predator Control) (CM15).

CM6 Channel Margin Enhancement. CM6 would entail restoration of 20 linear miles of channel margin by improving channel geometry and restoring riparian, marsh, and mudflat habitats on the waterside side of levees along channels that provide rearing and outmigration habitat for juvenile salmonids. Linear miles of enhancement would be measured along one side or the other of a given channel segment (e.g., if both sides of a channel are enhanced for a length of 1 mile, this would account for a total of 2 miles of channel margin enhancement). At least 10 linear miles would be enhanced by year 10 of Plan implementation; enhancement would then be phased in 5-mile increments at years 20 and 30, for a total of 20 miles at year 30. Channel margin enhancement would be performed only along channels that provide rearing and outmigration habitat for juvenile salmonids. These include channels that are protected by federal project levees—including the Sacramento River between Freeport and Walnut Grove among several others.

CM15 Localized Reduction of Predatory Fishes (Predator Control). CM15 would seek to reduce populations of predatory fishes at specific locations or modify holding habitat at selected locations of high predation risk (i.e., predation "hotspots"). This conservation measure seeks to benefit covered salmonids by reducing mortality rates of juvenile migratory life stages that are particularly vulnerable to predatory fishes. Predators are a natural part of the Delta ecosystem. Therefore, this conservation measure is not intended to entirely remove predators at any location, or substantially alter the abundance of predators at the scale of the Delta system. This conservation measure would also not remove piscivorous birds. Because of uncertainties regarding treatment methods and efficacy, implementation of CM15 would involve discrete pilot projects and research actions coupled with an adaptive management and monitoring program to evaluate effectiveness. Effects would be temporary, as new individuals would be expected to occupy vacated areas; therefore, removal activities would need to be continuous during periods of concern. CM15 also recognizes that the NDD intakes would create new predation hotspots.

This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of the impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-42a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Although analysis conducted as part of the EIR/EIS determined that Alternative 2A would have significant and unavoidable adverse effects on migration habitat, this conclusion was based on the best available scientific information at the time and may prove to have been over- or understated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on migration habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2A.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2A operations only. Development of mitigation actions for the incremental impact on migration habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2A.

Mitigation Measure AQUA-42b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to migration habitat under Alternative 2A. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-42c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Migration Conditions Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on winter-run Chinook salmon habitat, the BDCP proponents will consult with FWS and the Department of Fish and Wildlife to identify and implement any feasible operational means to minimize effects on migration habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-42a.

If feasible means are identified to reduce impacts on migration habitat consistent with the overall operational framework of Alternative 2A without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on winter-run Chinook salmon habitat is not feasible under Alternative 2A operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on winter-run Chinook salmon would remain significant and unavoidable.

Restoration and Conservation Measures

Alternative 2A has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the effects described for winter-run Chinook salmon under Alternative 1A (Impact AQUA-43 through AQUA-54) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (CM12)

Impact AQUA-47: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Winter-Run ESU) (CM13)

Impact AQUA-48: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Winter-Run ESU) (CM14)

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (CM15)

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (CM16)

Impact AQUA-51: Effects of Illegal Harvest Reduction on Chinook Salmon (Winter-Run ESU) (CM17)

Impact AQUA-52: Effects of Conservation Hatcheries on Chinook Salmon (Winter-Run ESU) (CM18)

Impact AQUA-53: Effects of Urban Stormwater Treatment on Chinook Salmon (Winter-Run ESU) (CM19)

Impact AQUA-54: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Winter-Run ESU) (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on winter-run Chinook salmon for NEPA purposes, for the reasons identified for Alternative 1A. Specifically for AQUA-44, the effects of contaminants on winter-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on winter-run Chinook salmon are uncertain.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on winter-run Chinook salmon, for the reasons identified for Alternative 1A, and no mitigation is required.

Spring-Run Chinook Salmon

Construction and Maintenance of CM1

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

The potential effects of construction of the water conveyance facilities on spring-run Chinook salmon would be similar to those described for Alternative 1A (Impact AQUA-55) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-55, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for spring-run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-55, the impact of the construction of water conveyance facilities on spring-run Chinook salmon would not be significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

The maintenance-related effects of Alternative 2A would be identical for all four Chinook salmon ESUs. Accordingly, for a discussion of the impacts listed below, please refer to the discussion of these effects for winter-run Chinook for Alternative 1A (Impact AQUA-38). Therefore, the impact would not be adverse for spring-run Chinook salmon.

Water Operations of CM1

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Losses under Alternative 2A would decrease by approximately 54% compared to NAA averaged across all years (Table 11-2A-8). Annual average loss of juvenile spring-run Chinook salmon under Alternative 2A would be approximately 18,000 fish for the combined SWP and CVP south Delta facilities. Losses would be greatest in dry (~16,000 fish) and wet years (~12,800 fish), and lowest in below normal years (~5,200 fish). Entrainment reductions under Alternative 2A would be greater in wetter years, ranging from a 5% decrease in dry years up to 86% decrease in wet years compared to Existing Conditions (Table 11-2A-18). Pre-screen losses, typically attributed to predation, would also decrease commensurate with entrainment reductions.

The proportion of the annual spring-run Chinook population (assumed to be 750,000 juveniles approaching the Delta) lost at the south Delta facilities across all years averaged 5.1–5.3% under NAA, and would decrease to 2.4% under Alternative 2A.

Table 11-2A-18. Juvenile Spring-Run Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 2A

	Absolute Difference (Percent Difference)[a]	
Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-79,450 (-86%)	-78,649 (-86%)
Above Normal	-19,700 (-66%)	-16,431 (-62%)
Below Normal	-1,919 (-27%)	-1,105 (-17%)
Dry	-1,760 (-10%)	-848 (-5%)
Critical	-916 (-9%)	-2,311 (-20%)
All Years	-21,554 (-55%)	-20,586 (-54%)

Shading indicates 10% or greater increased entrainment.

[a] Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

The impacts from the proposed SWP/CVP north Delta intakes on spring-run Chinook salmon would be the same as described for Impact AQUA-57 for spring-run Chinook Salmon under Alternative 1A. State-of-the-art fish screens operated with an adaptive management plan would be expected to eliminate entrainment risk for juvenile spring-run Chinook salmon to these intakes.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The effects would be the same as described in Impact AQUA-39 for Alternative 1A. Entrainment and impingement effects on juvenile spring-run Chinook salmon would be minimal for Alternative 2A because intakes would have state-of-the-art screens installed.

NEPA Effects: Under Alternative 2A, entrainment of juvenile spring-run Chinook salmon at the south Delta facilities was estimated to be similar to or somewhat lower than NAA across all water years (considering the all-year salvage density results). Therefore, the effect would not be adverse.

CEQA Conclusion: As described above, operational activities associated with water exports from SWP/CVP south Delta facilities would result in an overall decrease in entrainment for juvenile spring-run Chinook salmon, although there is substantial variation among water year types (Table 11-2A-8). However, with the added entrainment risks at the proposed north Delta facilities the overall entrainment rates are expected to be similar for Alternative 2A as Existing Conditions. Consequently, the impact of water operations on entrainment of juvenile Chinook salmon (spring-run ESU) is considered less than significant, and no mitigation would be required.

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

In general, the effects of Alternative 2A on spawning and egg incubation habitat for spring-run Chinook salmon relative to NAA are uncertain.

Sacramento River

Flows in the Sacramento River upstream of Red Bluff during the spring-run Chinook salmon spawning and incubation period (September through January) under A2A_LLT would be greater than, similar to, and lower than those under NAA depending on month and water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during December and January would be greater than or similar to those under NAA regardless of water year type. Flows during September would be up to 17% greater than or similar to those under NAA in wet, dry, and critical years, up to 15% lower in above normal and below normal years, but similar when all years are combined. Flows during October would not be different from those under NAA in all water years except below normal years, when flows are 6% lower. Flows in November would be similar or lower (up to -17%) depending on water year type.

Shasta Reservoir storage volume at the end of September influences flows downstream of the dam during the spring-run spawning and egg incubation period (September through January). Storage under A2A_LLT would be similar to, or greater than storage under NAA in all water year types (Table 11-2A-19).

Table 11-2A-19. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-286 (-9%)	226 (8%)
Above Normal	-346 (-11%)	269 (10%)
Below Normal	-229 (-8%)	125 (5%)
Dry	-172 (-7%)	339 (17%)
Critical	-137 (-12%)	245 (30%)

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results* *utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September at Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-12 for Bend Bridge and in Table 11-2A-20 for Red Bluff. There would be no difference in levels of concern between NAA and Alternative 2A at Bend Bridge. At Red Bluff, there would be 1 (2%) and 4 (24%) more years with a "red" and "orange" level of concern, respectively, under Alternative 2A. There would be 5 (71%) fewer years with a "yellow" level of concern.

Table 11-2A-20. Differences between Baseline and Alternative 2A Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Red Bluff, October through April

Level of Concern[a]	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Red	37 (308%)	1 (2%)
Orange	11 (183%)	4 (24%)
Yellow	-6 (-46%)	-5 (-71%)
None	-42 (-82%)	0 (0%)

[a] For definitions of levels of concern, see Table 11-2A-11.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days under Alternative 2A would be up to 12% lower than those under NAA during May and June and up to 16% higher during July through September (Table 11-2A-13). At Red Bluff, total degree-days under Alternative 2A would differ from those under NAA during October, November, and March (6%, 8%, and 9% higher, respectively), 5% lower during April, and similar during remaining months, for all years combined (Table 11-2A-21).

Table 11-2A-21. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Red Bluff, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
October	Wet	1,277 (497%)	108 (8%)
	Above Normal	526 (202%)	49 (7%)
	Below Normal	825 (395%)	119 (13%)
	Dry	1,153 (235%)	82 (5%)
	Critical	909 (152%)	-14 (-1%)
	All	4,690 (258%)	344 (6%)
November	Wet	97 (9,700%)	7 (8%)
	Above Normal	75 (NA)	14 (23%)
	Below Normal	59 (NA)	11 (23%)
	Dry	163 (2,038%)	12 (8%)
	Critical	105 (2,625%)	-5 (-4%)
	All	499 (3,838%)	39 (8%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	9 (NA)	0 (0%)
	Above Normal	5 (NA)	1 (25%)
	Below Normal	36 (400%)	15 (50%)
	Dry	63 (450%)	-1 (-1%)
	Critical	25 (2,500%)	-2 (-7%)
	All	138 (575%)	13 (9%)
April	Wet	260 (226%)	-1 (0%)
	Above Normal	208 (149%)	-21 (-6%)
	Below Normal	228 (289%)	-2 (-1%)
	Dry	261 (140%)	-59 (-12%)
	Critical	152 (1,267%)	1 (1%)
	All	1,109 (208%)	-82 (-5%)

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under A2A_LLT would be similar to mortality under NAA in dry and critical years, but greater in wet (13% greater), above normal (9% greater), and below normal (28% greater) water years (Table 11-2A-22). Absolute scale increases of 3% of the spring-run population under wet and above normal water years would be negligible to the overall population. However, the 12% increase in mortality in below normal years would be a small negative effect on the spring-run population. Combining all water years, there would be no effect of Alternative 2A on egg mortality (3% absolute change).

Table 11-2A-22. Difference and Percent Difference in Percent Mortality of Spring-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	18 (178%)	3 (13%)
Above Normal	25 (188%)	3 (9%)
Below Normal	41 (345%)	12 (28%)
Dry	56 (287%)	0 (0%)
Critical	22 (30%)	0 (0%)
All	32 (143%)	3 (7%)

SacEFT predicts that there would be a minimal (<5%) difference in the percentage of years with good spawning availability, measured as weighted useable area, between A2A_LLT and NAA (Table 11-2A-23). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under A2A_LLT relative to NAA (Table 11-2A-23). SacEFT predicts that there would be a 26% decrease (9% decrease on absolute scale) in the percentage of years with good (lower) egg incubation conditions under A2A_LLT relative to NAA. SacEFT predicts that there would be a 6% decrease (2% decrease on absolute scale) in the percentage of years with good (lower) redd dewatering risk under A2A_LLT relative to NAA.

Table 11-2A-23. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Spring-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Spawning WUA	-22 (-31%)	-1 (-2%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-61 (-71%)	-9 (-26%)
Redd Dewatering Risk	-17 (-35%)	-2 (-6%)
Juvenile Rearing WUA	1 (5%)	1 (5%)
Juvenile Stranding Risk	-8 (-42%)	-3 (-21%)
WUA = Weighted Usable Area.		

There is an apparent discrepancy in results of the SacEFT model and Reclamation egg mortality model with regard to conditions for spring-run salmon eggs. SacEFT predicts that egg incubation habitat would decrease (9% absolute scale decrease) and the Reclamation egg mortality model predicts that overall egg mortality would be unaffected by Alternative 2A, except in below normal water years. The SacEFT uses mid-August through early March as the egg incubation period, based on Vogel and Marine (1991), and the reach between ACID Dam and Battle Creek for redd locations. The Reclamation egg mortality model uses the number of days after Julian week 33 (mid-August) that it takes to accumulate 750 temperature units to hatching and another 750 temperature units to emergence. Temperatures units are calculated by subtracting 32°F from daily river temperature and are computed on a daily basis. As a result, egg incubation duration is generally mid-August through January, but is dependent on river temperature. The Reclamation model uses the reach between ACID Dam and Jelly's Ferry (approximately 5 river miles downstream of Battle Creek), which includes 95% of Sacramento River spawning locations based on 2001–2004 redd survey data (Reclamation 2008). These differences in egg incubation period and location likely account for the difference between model results. Although the SacEFT model has been peer-reviewed, the Reclamation egg mortality model has been extensively reviewed and used in prior biological assessments and BiOps. Therefore, both results are considered valid and were considered in drawing conclusions about spring-run egg mortality in the Sacramento River.

Clear Creek

Flows in Clear Creek were examined during the spring-run Chinook salmon spawning and egg incubation period (September through January). Flows under A2A_LLT would be similar to or greater than flows under NAA throughout the period for all water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest reduction in flows under A2A_LLT would be the same as that under NAA in all water year types (Table 11-2A-24).

Water temperatures were not modeled in Clear Creek.

Table 11-2A-24. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	0 (NA)	0 (NA)
Above Normal	-27 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-67 (NA)	0 (0%)
Critical	-33 (-50%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) where spring-run Chinook primarily spawn during September through January (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would not differ from

NAA because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006).

Oroville Reservoir storage volume at the end of September influence flows downstream of the dam during the spring-run spawning and egg incubation period. Storage volume at the end of September under A2A_LLT would be similar to or up to 16% greater than storage under NAA depending on water year type (Table 11-2A-25).

Table 11-2A-25. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-929 (-32%)	85 (5%)
Above Normal	-859 (-36%)	-68 (-4%)
Below Normal	-559 (-28%)	50 (4%)
Dry	-192 (-14%)	161 (16%)
Critical	-71 (-7%)	117 (15%)

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the egg incubation period compared to the flow in September when spawning is assumed to occur. Minimum flows in the low-flow channel during October through January were identical among A2A_LLT and NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of Alternative 2A on redd dewatering in the Feather River low-flow channel.

Mean monthly water temperatures were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) during September through January (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during September through January (Table 11-2A-26). The percent of months exceeding the threshold under Alternative 2A would generally be lower (up to 11% lower on an absolute scale) than the percent under NAA during September, October and November and similar during other months.

Table 11-2A-26. Differences between Baseline and Alternative 2A Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, September through January

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2A_LLT					
September	0 (0%)	0 (0%)	6 (7%)	17 (24%)	35 (85%)
October	53 (239%)	51 (683%)	48 (780%)	44 (1,800%)	31 (1,250%)
November	54 (2,200%)	47 (3,800%)	41 (3,300%)	27 (NA)	14 (NA)
December	4 (NA)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
NAA vs. A2A_LLT					
September	0 (0%)	-1 (-1%)	-1 (-1%)	-6 (-6%)	-7 (-9%)
October	-11 (-13%)	-7 (-11%)	-1 (-2%)	-2 (-5%)	-6 (-16%)
November	-10 (-15%)	-11 (-19%)	-7 (-15%)	-5 (-15%)	-11 (-45%)
December	0 (0%)	0 (0%)	-1 (-100%)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 56°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during September through January (Table 11-2A-27). Total degree-months would be similar between NAA and Alternative 2A during September and January, lower during October and November, and 20% higher during December.

Table 11-2A-27. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, September through January

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
September	Wet	29 (27%)	4 (3%)
	Above Normal	14 (33%)	4 (8%)
	Below Normal	39 (65%)	8 (9%)
	Dry	70 (101%)	-18 (-11%)
	Critical	50 (77%)	-12 (-9%)
	All	202 (59%)	-14 (-2%)
October	Wet	84 (1,680%)	-12 (-12%)
	Above Normal	31 (310%)	-4 (-9%)
	Below Normal	52 (743%)	-2 (-3%)
	Dry	83 (1,186%)	3 (3%)
	Critical	33 (413%)	-8 (-16%)
	All	282 (762%)	-24 (-7%)
November	Wet	56 (NA)	0 (0%)
	Above Normal	24 (800%)	-1 (-4%)
	Below Normal	26 (2,600%)	-8 (-23%)
	Dry	48 (NA)	-3 (-6%)
	Critical	24 (NA)	-4 (-14%)
	All	177 (4,425%)	-17 (-9%)
December	Wet	1 (NA)	0 (0%)
	Above Normal	2 (NA)	1 (100%)
	Below Normal	3 (NA)	0 (0%)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	6 (NA)	1 (20%)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

NEPA Effects: Available analytical tools show conflicting results regarding the temperature effects of relatively small changes in predicted summer and fall flows in the Sacramento River. Several models (CALSIM, SRWQM, and Reclamation Egg Mortality Model) generally show no change in upstream conditions as a result of Alternative 2A. However, one model, SacEFT, shows adverse effects under some conditions. After extensive investigation of these results, they appear to be a function of high model sensitivity to relatively small changes in estimated upstream conditions, which may or may not accurately predict adverse effects. The new NDD structures allow for spring time deliveries of water south of the Delta that are currently constrained under the NAA. For this reason, additional spring storage criteria may be necessary to ensure Shasta Reservoir operations similar to what was modeled. These discussions will occur in the Section 7 consultation with Reclamation on Shasta

Reservoir and system-wide operations, which is outside the scope of BDCP. In conclusion, Alternative 2A modeling results support a finding that effects are uncertain. Modeled results are mixed and operations that match the CALSIM modeling are not assured. Model results will be submitted to independent peer review to confirm that adverse effects are not reasonably anticipated to occur.

There would be no effects of Alternative 2A on spawning and egg incubation conditions in Clear Creek and no or beneficial effects in the Feather River.

CEQA Conclusion: In general, Alternative 2A would not affect spawning and egg incubation habitat for spring-run Chinook salmon relative to the Existing Conditions.

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were examined during the spring-run Chinook salmon spawning and incubation period (September through January). Flows during September would be up to 55% greater than or similar to those under Existing Conditions in wet, above normal, and critical years and up to 17% lower than those under Existing Conditions in below normal and dry water years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during October and January would be up to 10% greater than or similar to those under Existing Conditions depending on water year type. Flows during November would be 3% to 13% lower than those under Existing Conditions depending on water year type. Flows during December would be up to 7% greater than or similar to those under Existing Conditions in all water years except wet year, in which flows are 8% lower than under Existing Conditions.

Shasta Reservoir Storage volume at the end of September would be 7% to 12% lower under A2A_LLT relative to Existing Conditions (Table 11-2A-19).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At Keswick, temperatures under Alternative 2A during September and October would be up to 10% and 7% greater, respectively, than those under Existing Conditions, but not different in other months during the period. At Bend Bridge, temperatures under Alternative 2A during September and October would be up to 9% and 6% greater, respectively, than those under Existing Conditions, but not different in other months during the period.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September at Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern” as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-12 for Bend Bridge and in Table 11-2A-20 for Red Bluff. At Bend Bridge, there would be a 67% increase in the number of years with a “red” level of concern under Alternative 2A relative to Existing Conditions. At Red Bluff, there would be 308% and 183% increases in the number of years with “red” and “orange” levels of concern, respectively, under Alternative 2A relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days under Alternative 2A would be up to 1135% to 313% higher than those under Existing

Conditions depending on the month (Table 11-2A-13). At Red Bluff, total degree-days under Alternative 2A would be 208% to 3838% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-2A-21).

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under A2A_LLT would be 30% to 345% greater than mortality under Existing Conditions depending on water year type (Table 11-2A-22).

SacEFT predicts that there would be a 31% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2A_LLT relative to Existing Conditions (Table 11-2A-23). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under A2A_LLT relative to Existing Conditions. SacEFT predicts that there would be a 71% decrease in the percentage of years with good (lower) egg incubation conditions under A2A_LLT relative to Existing Conditions, respectively. SacEFT predicts that there would be a 35% decrease in the percentage of years with good (lower) redd dewatering risk under A2A_LLT relative to Existing Conditions. These results indicate that spawning and egg incubation conditions for spring-run Chinook salmon would be poor relative to Existing Conditions.

Clear Creek

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under A2A_LLT would generally be similar to or greater than flows under Existing Conditions except in critical years during September through November (6% to 29% reduction) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest reduction in flows under A2A_LLT would be similar to or lower magnitude than that under Existing Conditions in wet and below normal water years (Table 11-2A-24). The greatest reduction in flows under A2A_LLT would be 27% to 67% lower (more negative) than Existing Conditions in above normal, dry, and critical years.

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River low-flow channel under A2A_LLT are not different from Existing Conditions during the spring-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in October through January (800 cfs) would be equal to or greater than the spawning flows in September (773 cfs) for all model scenarios.

Oroville Reservoir storage volume at the end of September would be 7% to 36% lower under A2A_LLT relative to Existing Conditions depending on water year type (Table 11-2A-25).

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. Minimum flows in the low-flow channel during October through January were identical between A2A_LLT and Existing Conditions

(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of Alternative 2A on redd dewatering in the Feather River low-flow channel.

Mean monthly water temperatures were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) during September through January (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Temperatures under Alternative 2A would be 6% to 11% greater than those under Existing Conditions in all months during the period.

The percent of months exceeding the 56°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during September through January (Table 11-2A-26). The percent of months exceeding the threshold under Alternative 2A would be similar to or up to 54% higher (absolute scale) than under Existing Conditions during September through November. There would be little to no difference in the percent of months exceeding the threshold between Existing Conditions and Alternative 2A during December and January.

Total degree-days exceeding 56°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during September through January (Table 11-2A-27). Total degree-months exceeding the threshold under Alternative 2A would be 59% to 4425% greater than those under Existing Conditions during September through November. There would be minimal to no difference in total degree-months between Existing Conditions and Alternative 2A during December and January.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-58 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, when compared to the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above, which is directly related to the inclusion of climate change effects in Alternative 2A. There are biologically meaningful flow reductions and temperature increases in the Sacramento River under Alternative 2A, relative to Existing Conditions, that would lead to increased egg mortality and overall reduced habitat conditions in spring-run spawning and egg incubation habitat conditions. Flows in the Feather River low-flow channel do not differ between Alternative 2A and Existing Conditions. However, water temperature analyses in the Feather River low-flow channel using NMFS thresholds indicate that there would be substantial negative effects on temperature conditions during spring-run Chinook salmon spawning and egg incubation.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow and reservoir storage outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between future conditions without the BDCP (NAA) and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning and egg incubation habitat for spring-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

In general, Alternative 2A would not affect the quantity and quality of rearing habitat for fry and juvenile spring-run Chinook salmon relative to NAA.

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows between December and March under A2A_LLT would generally be similar to or greater than those under NAA. Flows during November would be up to 17% lower under A2A_LLT than under NAA.

As reported in Impact AQUA-40, May Shasta storage volume under A2A_LLT would be similar to or greater than storage under NAA for all water year types (Table 11-2A-9).

As reported in Impact AQUA-58, September Shasta storage volume would be similar to or greater than storage under NAA in all water year types (Table 11-2A-19).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

SacEFT predicts that the percentage of years with good juvenile rearing WUA conditions under A2A_LLT would be similar to that under NAA (Table 11-2A-23). However, the percentage of years with good (lower) juvenile stranding risk conditions under A2A_LLT would be 21% lower than under NAA, although this would be a 3% difference on an absolute scale.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality would be 6% lower under A2A_LLT than NAA.

Clear Creek

Flows in Clear Creek below Whiskeytown during the November through March spring-run rearing period under A2A_LLT would generally be similar to or greater than flows under NAA, except for critical years in February and below normal years in March in which flows would be 6% to 8% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during November through June were reviewed to determine flow-related effects on larval and juvenile spring-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low flow channel throughout this period under A2A_LLT would not differ from those under NAA. In the high flow channel, flows under A2A_LLT would be mostly similar to or greater than flows under NAA during November through June with few exceptions during which flows would be up to 12% lower under A2A_LLT.

May Oroville storage under A2A_LLT would be similar to storage under NAA (Table 11-2A-28).

As reported in Impact AQUA-58, September Oroville storage volume would be similar to or up to 5% lower than under NAA depending on water year type (Table 11-2A-25).

Table 11-2A-28. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-78 (-2%)	-32 (-1%)
Above Normal	-205 (-6%)	-49 (-1%)
Below Normal	-404 (-12%)	-51 (-2%)
Dry	-576 (-21%)	-56 (-3%)
Critical	-272 (-15%)	44 (3%)

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

The percent of months exceeding the 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during May through August (Table 11-2A-29). The percent of months exceeding the threshold under Alternative 2A would generally be similar to or lower (up to 23% lower on an absolute scale) than the percent under NAA.

Table 11-2A-29. Differences between Baseline and Alternative 2A Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 63°F Threshold, May through August

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2A_LLT					
May	2 (NA)	2 (NA)	0 (NA)	0 (NA)	0 (NA)
June	26 (47%)	27 (100%)	23 (475%)	7 (NA)	1 (NA)
July	0 (0%)	0 (0%)	1 (1%)	25 (34%)	48 (122%)
August	0 (0%)	12 (14%)	36 (62%)	51 (178%)	40 (400%)
NAA vs. A2A_LLT					
May	-4 (-60%)	0 (0%)	-1 (-100%)	0 (NA)	0 (NA)
June	-7 (-8%)	-23 (-30%)	-19 (-39%)	-14 (-65%)	-4 (-75%)
July	0 (0%)	0 (0%)	0 (0%)	-1 (-1%)	-6 (-7%)
August	0 (0%)	0 (0%)	-5 (-5%)	-2 (-3%)	-7 (-13%)

Total degree-days exceeding 63°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during May through August (Table 11-2A-30). Total degree-months under Alternative 2A would be similar to or lower than those under NAA depending on the month except for July when it would be 3% higher.

Table 11-2A-30. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Feather River above Thermalito Afterbay, May through August

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
May	Wet	1 (NA)	0 (0%)
	Above Normal	1 (NA)	0 (0%)
	Below Normal	0 (NA)	0 (NA)
	Dry	2 (NA)	0 (0%)
	Critical	3 (NA)	-1 (-25%)
	All	7 (NA)	-1 (-13%)
June	Wet	24 (160%)	-5 (-11%)
	Above Normal	12 (86%)	-5 (-16%)
	Below Normal	17 (131%)	-5 (-14%)
	Dry	30 (130%)	-3 (-5%)
	Critical	20 (333%)	-5 (-16%)
	All	104 (146%)	-22 (-11%)
July	Wet	44 (37%)	3 (2%)
	Above Normal	20 (45%)	0 (0%)
	Below Normal	28 (47%)	0 (0%)
	Dry	41 (58%)	5 (5%)
	Critical	38 (73%)	6 (7%)
	All	171 (49%)	14 (3%)
August	Wet	43 (48%)	10 (8%)
	Above Normal	21 (84%)	3 (7%)
	Below Normal	31 (82%)	2 (3%)
	Dry	47 (118%)	-6 (-6%)
	Critical	32 (76%)	-8 (-10%)
	All	174 (74%)	1 (0.2%)

NA = could not be calculated because the denominator was 0.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because habitat would not be substantially reduced. There would be no substantial effects of Alternative 2A on rearing habitat for spring-run Chinook salmon in the Sacramento and Feather Rivers or in Clear Creek. Biological models, including SacEFT and SALMOD, support these findings.

CEQA Conclusion: In general, under Alternative 2A water operations, the quantity and quality of rearing habitat for fry and juvenile spring-run Chinook salmon would not be affected relative to Existing Conditions (the CEQA baseline).

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows between December and March under A2A_LLT would be generally similar to or greater than those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during November would be lower under A2A_LLT than under Existing Conditions.

As reported in Impact AQUA-40, Shasta Reservoir storage volume at the end of May under A2A_LLT would be similar to Existing Conditions in wet, above normal, and below normal water years, but lower by 6% to 9% in dry and critical water years (Table 11-2A-9). As reported in Impact AQUA-58, storage volume at the end of September under A2A_LLT would be 7% to 12% lower relative to Existing Conditions (Table 11-2A-19).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, there would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in most months, except for 5% to 14% increases during July through October.

SacEFT predicts that the percentage of years with good juvenile rearing WUA conditions under A2A_LLT would be greater than that under Existing Conditions (Table 11-2A-23). The percentage of years with good (lower) juvenile stranding risk conditions under A2A_LLT would be 42% lower than under Existing Conditions.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality under A2A_LLT would be 165% higher than under Existing Conditions.

Clear Creek

Flows in Clear Creek during the November through March rearing period under A2A_LLT would generally be similar to or greater than flows under Existing Conditions, except for critical years in November and December in which flows would be 6% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Relatively constant flows in the low flow channel throughout the November through June period under A2A_LLT would not differ from those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). In the high flow channel (at Thermalito Afterbay), flows under A2A_LLT would be mostly lower (up to 45%) during November, December, and February and both higher and lower depending on water year type during March.

May Oroville storage volume under A2A_LLT would be lower than Existing Conditions by 6% to 21% depending on water year type, except in wet years, in which storage would be similar to Existing Conditions (Table 11-2A-28).

As reported in Impact AQUA-58, September Oroville storage volume would be 7% to 36% lower under A2A_LLT relative to Existing Conditions depending on water year type (Table 11-2A-25).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during the November through June juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Water temperature under Alternative 2A would be 5% to 10% greater than those under Existing Conditions during November through March, but similar (<5% difference) during April through June.

The percent of months exceeding the 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during May through August (Table 11-2A-29). The percent of months exceeding the threshold under Alternative 2A would be similar to those under Existing Conditions during May, but up to 51% greater during June through August.

Total degree-days exceeding 63°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during May through August (Table 11-2A-30). Total degree-months under Alternative 2A would be similar to those under Existing Conditions during May, but 49% to 146% higher during June through August.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-59 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat, contrary to the NEPA conclusion set forth above. Flows and temperatures in the Sacramento River would generally be unchanged under Alternative 2A relative to Existing Conditions, both SacEFT and SALMOD predict negative effects on juvenile rearing habitat. There would be no effects of Alternative 2A on flows in Clear Creek. Flows in the low-flow channel would be unchanged by Alternative 2A. However, flows in the high-flow channel would be mostly lower by up to 44% during the half of the fry and juvenile rearing period. Temperatures in both portions of the Feather River would experience increased water temperatures during substantial portions of the rearing period under Alternative 2A and NMFS temperature thresholds would be exceeded at a substantially higher frequency.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for spring-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

In general, Alternative 2A would reduce migration conditions for spring-run Chinook salmon relative to NAA.

Upstream of the Delta

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were evaluated during the December through May juvenile Chinook salmon spring-run migration period. Flows under A2A_LLT during December through May would always be similar to or greater than flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through May juvenile Chinook salmon spring-run emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were evaluated during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to or greater than flows under NAA except during July and August (up to 15% lower depending on month and water year type).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Clear Creek

Flows in Clear Creek during the November through May juvenile Chinook salmon spring-run migration period under A2A_LLT would generally be similar to or greater than flows under NAA except in critical years during February (6% lower), and in below normal years in March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek during the April through August adult spring-run Chinook salmon upstream migration period under A2A_LLT would generally be similar to or greater than flows under NAA with exceptions in critical water years during June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to or greater than flows under NAA in all months and water years except during November in above normal years (8% lower).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during April through June would be similar to or greater than flows under NAA. Flows under A2A_LLT during July and August would generally be lower than flows under NAA by up to 44%.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Through-Delta

The effects of Alternative 2A on through-Delta migration were evaluated using the approach described in Alternative 1A, Impact AQUA-42.

Juveniles

Flows under Alternative 2A would generally decrease up to 25% depending on month downstream of the north Delta facilities compared to baseline conditions (NAA). The intake structures would replace aquatic habitat and likely attract piscivorous fish around the intake structures. As described for Alternative 1A, the five NDD intakes would remove or modify habitat along that portion of the migration corridor (22 acres aquatic habitat and 11,900 linear feet of shoreline). Potential predation losses at the north Delta intakes, as estimated by the bioenergetics model with median density of predators (119 striped bass per 1,000 feet of intake), would be less than 2% compared to the annual production estimated for the Sacramento Valley (Table 11-1A-17). A conservative assumption of 5% loss per intake would yield a cumulative loss of 19.2% of juvenile spring-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate.

Through-Delta survival to Chipps Island (DPM) by emigrating juvenile spring-run Chinook salmon under Alternative 2A would average 29% across all years, 24% in drier years, and 38% in wetter years (Table 11-2A-31). Compared to NAA, juvenile survival would decrease slightly, 1.4% lower across all years (a 5% relative decrease) and 2.7% lower (7% relative decrease) in wetter years.

Table 11-2A-31. Through-Delta Survival (%) of Emigrating Juvenile Spring-Run Chinook Salmon under Alternative 2A

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Year Type	EXISTING CONDITIONS	NAA	A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wetter Years	42.1	40.4	37.8	-4.4 (-10%)	-2.7 (-7%)
Drier Years	24.8	24.3	23.7	-1.1 (-4%)	-0.6 (-3%)
All Years	31.3	30.3	29.0	-2.3 (-7%)	-1.4 (-5%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and above normal water years (6 years).
Drier = Below normal, dry and critical water years (10 years).

Adults

When climate change effects are accounted for (NAA), during the overall spring-run upstream migration from March-June the proportion of Sacramento River water would decrease 6% to 10% compared to NAA (Table 11-2A-17). Although Sacramento River attraction flows would be reduced during these months relative to Existing Conditions, the Sacramento River would still represent 59% to 67% of Delta flows. For a discussion of the topic see the analysis for Alternative 1A. Overall the impact on adult winter-run salmon upstream migration would be less than significant. No mitigation would be required.

NEPA Effects: Overall, the results indicate that the effect of Alternative 2A is adverse due to the cumulative effects associated with five north Delta intake facilities, including mortality related to near-field effects (e.g. impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes.

Upstream of the Delta migration conditions for spring-run Chinook salmon under Alternative 2A would not be adverse because flow and temperature conditions would generally be similar to those under the NEPA baseline.

Adult attraction flows under Alternative 2A would be lower than those under NAA, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 2A NDD on spring-run Chinook salmon related to impingement and predation associated with five new intakes could result in substantial effects on juvenile migrating spring-run Chinook salmon, although there is high uncertainty regarding the potential effects. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to very significant effects (~ 19% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the five new intake structures will be implemented as part of the final NDD screen design effort. Alternative 2A also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for spring-run Chinook salmon. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 2A predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 2A would be similar to survival rates estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon. Until these efforts are completed and their results are fully analyzed, the overall effect of Alternative 2A on spring-run Chinook salmon through-Delta survival remains uncertain.

Therefore, primarily as a result of reduced upstream migration habitat conditions for spring-run Chinook salmon due to unacceptable levels of uncertainty regarding the cumulative impacts of near-field and far-field effects associated with the presence and operation of the five intakes on spring-run Chinook salmon, this effect is adverse. While implementation of the conservation and mitigation measures listed below would address these impacts, these are not anticipated to reduce the impacts to a level considered not adverse.

CEQA Conclusion:

Upstream of the Delta

In general, Alternative 2A would affect migration conditions for spring-run Chinook salmon relative to the Existing Conditions.

Sacramento River

Flows in the Sacramento River upstream of Red Bluff during December through May juvenile spring-run Chinook salmon migration period under A2A_LLT would generally be similar to or greater than flows under Existing Conditions except during December in wet water years (8% decrease), during March in below normal water years (10% decrease), and during May in wet water years (15% decrease) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through May juvenile Chinook salmon spring-run emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period

Flows in the Sacramento River upstream of Red Bluff during the April through August adult spring-run Chinook salmon upstream migration period under A2A_LLT would generally be similar to or greater than Existing Conditions except during May in wet years (15% decrease), July in critical years (13% decrease), and August in wet (7% decrease), dry (11% decrease) and critical (24% decrease) water years.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A during April through June. Mean monthly water temperatures under Alternative 2A would be higher in dry and critical years during July (6% and 9% higher, respectively), and up to 12% greater relative to Existing Conditions during August.

Clear Creek

Flows in Clear Creek during the November through May juvenile Chinook salmon spring-run migration period under A2A_LLT would generally be similar to or greater than flows under Existing Conditions except in critical years during November (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek during the April through August adult spring-run Chinook salmon upstream migration period under A2A_LLT would generally be similar to or greater than flows under Existing Conditions with exceptions during August of critical water years (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows were examined for the Feather River at the confluence with the Sacramento River during the November through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during November and December under A2A_LLT would generally be lower than flows under Existing Conditions by up to 31%. Flows during January through May would generally be similar to or greater than flows under Existing Conditions, with few exceptions.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Water temperatures under Alterative 2A would be 5% to 6% greater than those under Existing Conditions in November and December, but similar during January through May.

Flows were examined for the Feather River at the confluence with the Sacramento River during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during April through June under A2A_LLT would generally be similar to or greater than flows under Existing Conditions with exceptions during which flows would be up to 24% lower. Flows during July and August under A2A_LLT would generally be lower by up to 53% than flows under Existing Conditions.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation*

Temperature Model Results utilized in the Fish Analysis). Water temperatures under Alternative 2A would be 5% to 8% higher than those under Existing Conditions during July and August, and similar during April through June.

Through-Delta

Through Delta survival by emigrating juvenile spring-run Chinook salmon would decrease 2.3% (7% relative decrease) under Alternative 2A across all years compared to Existing Conditions (Table 11-2A-31). Losses due to predation at the five north Delta intakes could hypothetically range from less than 2% up to 19.2% of juvenile spring-run Chinook that reach the north Delta, as calculated for Impact AQUA-60 for Alternative 1A.

Attraction flow, as estimated by the percentage of Sacramento River water at Collinsville, declined 10% to 12% during the April and May migration period for spring-run adults under Alternative 2A compared to Existing Conditions (Table 11-2A-17). The reductions in percentage are small in comparison with the magnitude of change in dilution reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to significantly impact adult migration. Sacramento River attraction flows would still represent 59% to 67% of Delta flows. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 in Alternative 1A.

Summary of CEQA Conclusion

Migration conditions throughout most of the Plan Area would generally decline for emigrating juvenile spring-run Chinook salmon. Through Delta survival would be reduced under Alternative 2A. Attraction flows would be slightly lower compared to Existing Conditions during the adult migration period. Potential predation losses would increase at the five intake structures, ranging hypothetically from 2% to 19.2% of juveniles that reach the Delta. This impact is significant.

Upstream of the Delta, the results indicate that the effect would be less than significant because it would not substantially reduce the suitability of migration habitat or interfere with the movement of fish. Flows in the Sacramento River and Clear Creek and water temperatures in the Sacramento and Feather Rivers would generally not be affected by Alternative 2A. Flows would be lower in 2 months of the 7-month juvenile migration period and in 2 months of the 5-month adult migration period, although there would be no other flow reductions in the Feather River.

With respect to the NDD intakes, implementation of CM6 and CM15 and Mitigation Measures AQUA-60a through AQUA-60c would address these impacts, but are not anticipated to reduce them to a level considered less than significant. Although implementation of *CM6 Channel Margin Enhancement* would provide habitat similar to that which would be lost, it would not necessarily be located near the intakes and therefore would not fully compensate for the lost habitat. Additionally, implementation of this measure would not fully address predation losses. *CM15 Localized Reduction of Predatory Fishes (Predator Control)* has substantial uncertainties associated with its effectiveness such that it is considered to have no demonstrable effect. Conservation measures that address habitat and predation losses, therefore, would potentially minimize impacts to some extent but not to a less than significant level. Consequently, as a result of these changes in migration conditions, this impact is significant and unavoidable.

Applicable conservation measures are briefly described below and full descriptions are found in Chapter 3, Section 3.6.2.5 Channel Margin Enhancement (CM6) and Section 3.6.3.4 Localized Reduction of Predatory Fishes (Predator Control) (CM15).

CM6 Channel Margin Enhancement. CM6 would entail restoration of 20 linear miles of channel margin by improving channel geometry and restoring riparian, marsh, and mudflat habitats on the waterside side of levees along channels that provide rearing and outmigration habitat for juvenile salmonids. Linear miles of enhancement would be measured along one side or the other of a given channel segment (e.g., if both sides of a channel are enhanced for a length of 1 mile, this would account for a total of 2 miles of channel margin enhancement). At least 10 linear miles would be enhanced by year 10 of Plan implementation; enhancement would then be phased in 5-mile increments at years 20 and 30, for a total of 20 miles at year 30. Channel margin enhancement would be performed only along channels that provide rearing and outmigration habitat for juvenile salmonids. These include channels that are protected by federal project levees—including the Sacramento River between Freeport and Walnut Grove among several others.

CM15 Localized Reduction of Predatory Fishes (Predator Control). CM15 would seek to reduce populations of predatory fishes at specific locations or modify holding habitat at selected locations of high predation risk (i.e., predation "hotspots"). This conservation measure seeks to benefit covered salmonids by reducing mortality rates of juvenile migratory life stages that are particularly vulnerable to predatory fishes. Predators are a natural part of the Delta ecosystem. Therefore, this conservation measure is not intended to entirely remove predators at any location, or substantially alter the abundance of predators at the scale of the Delta system. This conservation measure would also not remove piscivorous birds. Because of uncertainties regarding treatment methods and efficacy, implementation of CM15 would involve discrete pilot projects and research actions coupled with an adaptive management and monitoring program to evaluate effectiveness. Effects would be temporary, as new individuals would be expected to occupy vacated areas; therefore, removal activities would need to be continuous during periods of concern. CM15 also recognizes that the NDD intakes would create new predation hotspots.

In addition to the conservation measures, the mitigation measures identified below would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures. However, this would not necessarily result in a less than significant determination.

Mitigation Measure AQUA-60a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-60a under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-60b under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-60c under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Restoration and Conservation Measures

Alternative 2A has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the effects described for spring-run Chinook salmon under Alternative 1A (Impact AQUA-61 through AQUA-72) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (CM12)

Impact AQUA-65: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Spring-Run ESU) (CM13)

Impact AQUA-66: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Spring-Run ESU) (CM14)

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (CM15)

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (CM16)

Impact AQUA-69: Effects of Illegal Harvest Reduction on Chinook Salmon (Spring-Run ESU) (CM17)

Impact AQUA-70: Effects of Conservation Hatcheries on Chinook Salmon (Spring-Run ESU) (CM18)

Impact AQUA-71: Effects of Urban Stormwater Treatment on Chinook Salmon (Spring-Run ESU) (CM19)

Impact AQUA-72: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Spring-Run ESU) (CM21)

NEPA Effects: These impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on spring-run Chinook salmon for NEPA purposes, for the reasons identified for Alternative 1A. Specifically for AQUA-62, the effects of contaminants on spring-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on spring-run Chinook salmon are uncertain.

CEQA Conclusion: These impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on spring-run Chinook salmon, for the reasons identified for Alternative 1A, and no mitigation is required.

Fall-/Late Fall–Run Chinook Salmon

Construction and Maintenance of CM1

The construction- and maintenance-related effects of Alternative 2A would be identical for all four Chinook salmon ESUs. Accordingly, for a discussion of the impacts listed below, please refer to the discussion of these effects for winter-run Chinook (Impact AQUA-43 and Impact AQUA-44).

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

The potential effects of construction of the water conveyance facilities on fall-/late fall–run Chinook salmon would be similar to those described for Alternative 1A (Impact AQUA-73) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-73, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for fall-/late fall–run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-73, the impact of construction of the water conveyance facilities on fall-/late fall–run Chinook salmon would not be significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

The construction-related effects of Alternative 2A would be identical for all four Chinook salmon ESUs. Accordingly, for a discussion of the impacts listed below, please refer to the discussion of these effects for winter-run Chinook (Alternative 2A, Impact AQUA-38).

Water Operations of CM1

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Alternative 2A (A2A_LLT) would decrease entrainment of fall-run Chinook salmon by approximately 58% and late fall–run Chinook salmon by approximately 41% compared to NAA (Table 11-2A-32). Entrainment reductions under Alternative 2A would be greater in wetter years, ranging from a 8% decrease in dry years up to 84% decrease compared to Existing Conditions.

Table 11-2A-32. Juvenile Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 2A

	Absolute Difference (Percent Difference)[a]	
Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Fall-Run Chinook Salmon		
Wet	-107,545 (-84%)	-112,297 (-84%)
Above Normal	-22,439 (-67%)	-21,191 (-66%)
Below Normal	-5,003 (-36%)	-4,247 (-32%)
Dry	-3,371 (-16%)	-1,612 (-8%)
Critical	-7,610 (-21%)	-10,686 (-28%)
All Years	-31,474 (-57%)	-31,940 (-58%)
Late Fall–Run Chinook Salmon		
Wet	-3,829 (-65%)	-4,006 (-66%)
Above Normal	-307 (-55%)	-315 (-55%)
Below Normal	-22 (-41%)	-26 (-46%)
Dry	-26 (-22%)	-37 (-28%)
Critical	-37 (-25%)	-50 (-31%)
All Years	-692 (-37%)	-811 (-41%)
	Shading indicates 10% or greater increased entrainment.	

[a] Estimated annual number of fish lost, based on normalized data.

For juvenile late fall-run Chinook salmon, entrainment under Alternative 2A would decrease by 41% compared to NAA averaged across all years (Table 11-2A-32). Entrainment reductions would be substantially greater in wetter years, ranging from approximately 28% decrease in dry years to 66% decrease in wet years compared to Existing Conditions.

The proportion of the annual juvenile population (assumed to be 23 million fall-run juveniles and 1 million late fall–run juveniles) lost at the south Delta facilities is very low under baseline conditions (<0.25% for both runs), and would be reduced under Alternative 2A.

Water Exports from SWP/CVP North Delta Intake Facilities

Impacts from the proposed north Delta intake facilities for fall-/late fall–run Chinook salmon, such as impingement and predation exposure risks, would be expected to be similar to those described above for winter-run Chinook salmon. Impacts would also be the same as described for Alternative 1A. State-of-the-art fish screens would be expected to eliminate entrainment risk for juvenile fall-/late fall–run Chinook salmon to these intakes.

Water Exports with a Dual Conveyance for the SWP North Bay Aqueduct

The effects would be the same as described for Impact AQUA-39 under Alternative 1A. Entrainment and impingement effects on fall-/late fall–run Chinook salmon would be minimal for Alternative 2A because intakes would have state-of-the-art screens installed.

NEPA Effects: Under Alternative 2A potential entrainment of juvenile Chinook salmon of all races (winter, spring, fall and late fall–run) would be similar or reduced compared to baseline at the SWP/CVP south delta facilities and the NBA. Entrainment of Chinook salmon at the proposed SWP/CVP north Delta intakes would not be expected to occur due to the state-of-the-art fish screens; there would be a potential for impingement, but this risk would be minimized due to the design and operation of the facilities. Therefore the effect on fall-/late fall–run Chinook salmon entrainment from Alternative 2A would not be adverse.

CEQA Conclusion: As described above, entrainment of juvenile Chinook salmon of all races (winter, spring, fall and late fall–run) would be similar or reduced compared to baseline at the SWP/CVP south delta facilities, agricultural diversions, and the NBA. Entrainment of Chinook salmon at the proposed SWP/CVP north delta intakes would not be expected to occur due to the state-of-the-art fish screens; there would be a potential for impingement, but this risk would be minimized due to the design and operation of the facilities. Overall, impacts of water operations on entrainment of juvenile Chinook salmon (fall-/late fall–run ESU) would be beneficial due to a general reduction in entrainment and no mitigation would be required.

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 2A would not affect spawning and egg incubation habitat for fall-/late fall–run Chinook salmon relative to NAA.

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be greater than or similar to flows under NAA in October, December, and January. Flows under A2A_LLT would generally be greater than or similar to NAA during October, December, and January, except in below normal years during October. During November, flows under A2A_LLT would be 5% to 17% lower than under NAA depending on water year type.

Shasta Reservoir storage at the end of September would affect flows during the fall-run spawning and egg incubation period. As reported in Impact AQUA-58 for spring-run Chinook salmon, end of September Shasta Reservoir storage would be similar to or greater than storage under NAA in all water year types (Table 11-2A-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-20. There would be 1 (2%) and 4 (24%) more years with "red" and "orange" level of concern under Alternative 2A. There would be 5 (71%) fewer years with a "yellow" level of concern under Alternative 2A.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under Alternative 2A would be 6% higher than those under NAA during October, 8% higher during November, 9% higher during March, 5% lower during April, and similar during remaining months (Table 11-2A-21).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under A2A_LLT would be lower than or similar to mortality under NAA in all water year types including below normal years (up to 10% greater relative to NAA, but absolute increase of 2% of fall-run population) (Table 11-2A-33).

Table 11-2A-33. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	11 (110%)	1 (6%)
Above Normal	12 (109%)	1 (4%)
Below Normal	13 (126%)	2 (10%)
Dry	17 (120%)	1 (2%)
Critical	9 (31%)	-0.5 (-1%)
All	13 (90%)	1 (4%)

SacEFT predicts that there would be a 46% increase in the percentage of years with good spawning availability for fall-run Chinook salmon, measured as weighted usable area, under A2A_LLT relative to NAA (Table 11-2A-34). SacEFT predicts that there would be a 12% reduction in the percentage of years with good (lower) redd scour risk under A2A_LLT relative to NAA. SacEFT predicts that there would be no difference between A2A_LLT and NAA. SacEFT predicts that there would be a 19% increase in the percentage of years with good (lower) redd dewatering risk under A2A_LLT relative to NAA.

Table 11-2A-34. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Fall-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Spawning WUA	3 (6%)	16 (46%)
Redd Scour Risk	-3 (-5%)	-8 (-12%)
Egg Incubation	-25 (-27%)	0 (0%)
Redd Dewatering Risk	5 (19%)	5 (19%)
Juvenile Rearing WUA	5 (15%)	-2 (-5%)
Juvenile Stranding Risk	-9 (-29%)	2 (10%)

WUA = Weighted Usable Area.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be greater than or similar to flows under NAA throughout the period.

Shasta Reservoir storage at the end of September would affect flows during the late fall–run spawning and egg incubation period. As reported in Impact AQUA-58 for spring-run Chinook salmon, end of September Shasta Reservoir storage would be similar to or greater than storage under NAA in all water year types (Table 11-2A-19).

The Reclamation egg mortality model predicts that late fall-run Chinook salmon egg mortality in the Sacramento River under A2A_LLT would be similar to mortality under NAA in all water years, including below normal water years in which, although there would be an 11% relative increase, the absolute increase would be 1% of the late fall-run population (Table 11-2A-35).

Table 11-2A-35. Difference and Percent Difference in Percent Mortality of Late Fall–Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	4 (182%)	-1 (-9%)
Above Normal	4 (151%)	-1 (-13%)
Below Normal	5 (313%)	1 (11%)
Dry	4 (163%)	-0.5 (-6%)
Critical	3 (148%)	0.1 (1%)
All	4 (183%)	-0.3 (-5%)

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-20. There would be 1 (2%) and 4 (24%) more years with "red" and "orange" level of concern under Alternative 2A. There would be 5 (71%) fewer years with a "yellow" level of concern under Alternative 2A. The level of concern in these years would be reduced to an "none" (from "yellow") level.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under Alternative 2A would be 6% higher than those under NAA during October, 8% higher during November, 9% higher during March, 5% lower during April, and similar during remaining months (Table 11-2A-21).

SacEFT predicts that there would be a 4% decrease in the percentage of years with good spawning availability for late fall–run Chinook salmon, measured as weighted usable area, under A2A_LLT relative to NAA (Table 11-2A-36). SacEFT predicts that there would be a negligible (<5%) difference in the percentage of years with good (lower) egg incubation conditions and redd dewatering risk between A2A_LLT and NAA.

Table 11-2A-36. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Late Fall–Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Spawning WUA	-6 (-12%)	-2 (-4%)
Redd Scour Risk	-6 (-7%)	0 (0%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	-3 (-5%)	2 (4%)
Juvenile Rearing WUA	-5 (-11%)	-23 (-37%)
Juvenile Stranding Risk	-27 (-38%)	-1 (-2%)

WUA = Weighted Usable Area.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Clear Creek flows below Whiskeytown Reservoir were examined for the September through February fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to or greater than flows under NAA in all water year types.

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest monthly reduction in Clear Creek flows during September through February under A2A_LLT would be similar to or lower magnitude than the reduction under NAA for all water year types (Table 11-2A-37).

Table 11-2A-37. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through February Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	0 (NA)	0 (NA)
Above Normal	-27 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-67 (NA)	0 (0%)
Critical	-33 (-50%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Fall-Run

Flows in the Feather River in the low flow and high flow channels were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the low-flow channel under A2A_LLT would be identical to those under NAA. Flows in the high-flow channel under A2A_LLT generally be similar to or greater than those under NAA, except in above normal years during November and December and in wet an critical years during January (7% to 12% lower).

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel during November through January were identical between A2A_LLT and NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of Alternative 2A on redd dewatering in the Feather River low-flow channel.

Mean monthly water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

The percent of months exceeding the 56°F temperature threshold in the Feather River at Gridley was evaluated during October through April (Table 11-2A-38). The percent of months exceeding the threshold under Alternative 2A would similar to or up to 40% lower (absolute scale for greater than 2.0 through greater than 5.0 degrees C above the threshold) than the percent under NAA.

Table 11-2A-38. Differences between Baseline and Alternative 2A Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 56°F Threshold, October through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2A_LLT					
October	2 (3%)	14 (16%)	25 (34%)	43 (106%)	52 (280%)
November	49 (1,333%)	31 (2,500%)	21 (NA)	11 (NA)	5 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	1 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	27 (367%)	17 (467%)	6 (500%)	6 (NA)	2 (NA)
April	12 (18%)	17 (30%)	35 (112%)	33 (193%)	21 (189%)
NAA vs. A2A_LLT					
October	0 (0%)	0 (0%)	1 (1%)	-5 (-6%)	-7 (-10%)
November	-9 (-14%)	-9 (-21%)	-11 (-35%)	-7 (-40%)	-1 (-20%)
December	-1 (-100%)	-1 (-100%)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	-2 (-67%)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-10 (-22%)	-7 (-26%)	-4 (-33%)	-1 (-17%)	-1 (-33%)
April	-7 (-8%)	-6 (-8%)	-7 (-10%)	-9 (-15%)	-6 (-16%)

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 56°F were summed by month and water year type at Gridley during October through April (Table 11-2A-39). Total degree-months would be similar between NAA and Alternative 2A for all months except December, in which degree-months 50% lower under Alternative 2A and February in which degree-months would be 33% higher.

Table 11-2A-39. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River at Gridley, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
October	Wet	99 (136%)	-3 (-2%)
	Above Normal	33 (75%)	-3 (-4%)
	Below Normal	49 (89%)	0 (0%)

	Above Normal	26 (113%)	-1 (-2%)
	Below Normal	22 (55%)	-3 (-5%)
	Dry	38 (78%)	-3 (-3%)
	Critical	31 (107%)	0 (0%)
	All	153 (99%)	-9 (-3%)

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under A2A_LLT would be similar to or lower than mortality under NAA in all water years, including critical water years in which, although there would be a 10% relative increase, the absolute increase would be 3% of the late fall-run population (Table 11-2A-40).

Table 11-2A-40. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Feather River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	17 (1,253%)	-2 (-8%)
Above Normal	14 (1,210%)	1 (10%)
Below Normal	14 (768%)	1 (4%)
Dry	19 (843%)	-0.2 (-1%)
Critical	20 (418%)	-3 (-10%)
All	17 (800%)	-1 (-4%)

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to or greater than flows under NAA, except for wet and above normal water years during October (7% and 10% lower, respectively) and critical water years during November (9% lower).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-2A-41). The percent of months exceeding the threshold under Alternative 2A would similar to or up to 11% lower (absolute scale) than the percent under NAA.

Table 11-2A-41. Differences between Baseline and Alternative 2A Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 56°F Threshold, November through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2A_LLT					
November	43 (95%)	48 (177%)	52 (382%)	43 (1,750%)	32 (2,600%)
December	1 (NA)	1 (NA)	0 (NA)	0 (NA)	0 (NA)

	Below Normal	39 (108%)	-2 (-3%)
	Dry	41 (54%)	-4 (-3%)
	Critical	36 (61%)	1 (1%)
	All	207 (94%)	-6 (-1%)

NA = could not be calculated because the denominator was 0.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. The greatest monthly reduction in American

River flows during November through January under A2A_LLT be 60% to 65% greater in magnitude than under NAA in below normal, dry, and critical water years and 11% to 30% lower in magnitude than NAA in wet and above normal water years (Table 11-2A-43).

Table 11-2A-43. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in the American River at Nimbus Dam during the October through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-20 (-91%)	5 (11%)
Above Normal	2 (7%)	12 (30%)
Below Normal	-58 (-301%)	-30 (-65%)
Dry	-25 (-54%)	-27 (-61%)
Critical	-12 (-24%)	-24 (-60%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in October, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under A2A_LLT would be similar to mortality under NAA in all water years (Table 11-2A-44).

Table 11-2A-44. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the American River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	24 (159%)	0.4 (1%)
Above Normal	22 (206%)	-1 (-3%)
Below Normal	22 (175%)	-1 (-2%)
Dry	16 (99%)	0 (0%)
Critical	9 (43%)	-1 (-3%)
All	19 (128%)	-0.2 (-1%)

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to flows under NAA throughout the period.

Water temperatures throughout the Stanislaus River would be similar under NAA and Alternative 2A throughout the October through January period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, it is concluded that the effect is not adverse because spawning and egg incubation habitat conditions are not substantially reduced. There are no reductions in flows under Alternative 2A or increases in temperatures that would translate into adverse biological effects on fall-/late fall-run Chinook salmon spawning and egg incubation habitat. Further, the Reclamation egg mortality model predicts no effects of Alternative 2A on fall-/late fall-run Chinook salmon spawning and egg incubation habitat in the Sacramento, Feather, and American Rivers and SacEFT predicts generally negligible or beneficial impacts on spawning and egg incubation habitat in the Sacramento River.

CEQA Conclusion: In general, Alternative 2A would not affect spawning and egg incubation habitat for fall-/late fall–run Chinook salmon relative to the Existing Conditions.

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff under A2A_LLT would generally be greater than or similar to Existing Conditions during October, December, and January, except in wet years during December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). During November, flows under A2_LLT would be 3% to 13% lower than under Existing Conditions depending on water year type.

Storage volume at the end of September would be 7% to 12% lower under A2A_LLT relative to Existing Conditions (Table 11-2A-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A during the period, except during October, in which temperatures would be 6% higher under Alternative 2A.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-20. There would be 308% and 183% increases in the number of years with "red" and "orange" levels of concern under Alternative 2A relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under Alternative 2A would be 9% to 3838% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-2A-21).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under A2A_LLT would be 31% to 126% greater than mortality under Existing Conditions, which is a 9% to 17% increase on an absolute scale (Table 11-2A-33).

SacEFT predicts that there would be a 6% increase in the percentage of years with good spawning availability, measured as weighted usable area, under A2A_LLT relative to Existing Conditions (Table 11-2A-34). SacEFT predicts that there would be a 5% reduction in the percentage of years with good (lower) redd scour risk under A2A_LLT relative to Existing Conditions. SacEFT predicts that there would be a 27% decrease in the percentage of years with good (lower) egg incubation conditions under A2A_LLT relative to Existing Conditions. SacEFT predicts that there would be a 35% decrease in the percentage of years with good (lower) redd dewatering risk under A2A_LLT relative to Existing Conditions.

Late Fall–Run

Flows in the Sacramento River upstream of Red Bluff were examined during the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be greater than or similar to flows under Existing Conditions, except in below normal years during March (6% lower) and wet years during May (15% lower).

Storage volume at the end of September would be 7% to 12% lower under A2A_LLT relative to Existing Conditions (Table 11-2A-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-20. There would be 308% and 183% increases in the number of years with "red" and "orange" levels of concern under Alternative 2A relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under Alternative 2A would be 9% to 3838% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-2A-21).

The Reclamation egg mortality model predicts that late fall–run Chinook salmon egg mortality in the Sacramento River under A2A_LLT would be 148% to 313% greater than mortality under Existing Conditions (Table 11-2A-35). However, absolute differences in the percent of the late-fall population subject to mortality would be minimal in all but below normal years, in which there is a 5% increase.

SacEFT predicts that there would be a 12% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2A_LLT relative to Existing Conditions (Table 11-2A-36). SacEFT predicts that there would be a 7% decrease in the percentage of years with good (lower) redd scour risk under A2A_LLT relative to Existing Conditions. SacEFT predicts that there would be no difference in the percentage of years with good (lower) egg incubation conditions under A2A_LLT relative to Existing Conditions. SacEFT predicts that there would be a 5% decrease in the percentage of years with good (lower) redd dewatering risk under A2A_LLT relative to Existing Conditions.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir under A2A_LLT during the September through February fall-run spawning and egg incubation period would generally be similar to or greater than flows under Existing Conditions, except in critical water years during October and November (7% and 6% lower, respectively).

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning occurred. The greatest monthly reduction in Clear Creek flows during October through February under A2A_LLT would be similar to or lower magnitude than those under Existing Conditions in wet and below normal water years, but the reduction would be 27%, 67%, and 33% greater (absolute, not relative, differences) under A2A_LLT in above normal, dry, and critical water years, respectively (Table 11-2A-37).

Feather River

Fall-Run

Flows in the low-flow channel during October through January under A2A_LLT would be identical to those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis* Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the high-flow channel under A2A_LLT would generally be lower by up to 44% than flows under Existing Conditions.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel were identical between A2A_LLT and Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized* *in the Fish Analysis*). Therefore, there would be no effect of Alternative 2A on redd dewatering in the Feather River low-flow channel.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under A2A_LLT would be 418% to 1,253% greater than mortality under Existing Conditions (Table 11-2A-40).

Mean monthly water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be under Alternative 2A relative to Existing Conditions by 6% to 11% higher in the low-flow channel and 5% to 9% higher in the high-flow channel depending on month.

The percent of months exceeding the 56°F temperature threshold in the Feather River at Gridley was evaluated during October through April (Table 11-2A-38). The percent of months exceeding the threshold under Alternative 2A would similar to or up to 52% higher (absolute scale) than the percent under Existing Conditions during all months except December through February, during which there would be no difference in the percent of months exceeding the threshold.

Total degree-months exceeding 56°F were summed by month and water year type at Gridley during October through April (Table 11-2A-39). Total degree-months under Alternative 2A would be 99% to 3000% higher than total degree-months under Existing Conditions, except during December through February, in which there would be no difference between Existing Conditions and Alternative 2A in total degree-months exceeding the 56°F threshold.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during October, but generally lower by up to 33% than flows under NAA during November through January.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly temperatures under Alternative 2A would be 5% to 13% greater than those under Existing Conditions depending on month.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-2A-41). The percent of months exceeding the threshold under Alternative 2A would be up to 52% greater (absolute scale) than the percent under Existing Conditions during November, March, and April and similar to the percent under Existing Conditions during December through February.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-2A-42). Total degree-months under

Alternative 2A would be 94% to 322% greater than total degree-months under Existing Conditions during November, March and April and similar to total degree months under Existing Conditions during December through February.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. The greatest monthly reduction in American River flows during November through January under A2A_LLT would be up to 301% greater magnitude than those under Existing Conditions in all years except above normal (7% lower magnitude) (Table 11-2A-43).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under A2A_LLT would be 43% to 206% greater than mortality under Existing Conditions (Table 11-2A-44).

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to Existing Conditions during October, November and December and mixed in January being similar in wet and dry years, higher in above normal years (8% higher) and lower in below normal and critical years (up to 11% lower) than those under Existing Conditions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would not be different from those under Existing Conditions during October, except for wet and critical years when they would be 5% higher, and up to 7% higher during November through January.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 8% lower than Existing Conditions during October, and generally similar to or higher than Existing Conditions during November through January.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 14% lower than flows under Existing Conditions during October and November, and generally higher than Existing Conditions during December and January (up to 18% greater.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-76 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, when compared to the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above. There would be flow reductions in all waterways except Clear Creek and the San Joaquin River and increases in the exceedances of NMFS temperature thresholds in the Sacramento, Feather, and American Rivers that would substantially affect the fall-/late fall-run population. Further, the Reclamation egg mortality model predicts moderate to substantial negative impacts of Alternative 2A on fall-/late fall-run Chinook salmon in the Sacramento, Feather, and American Rivers and SacEFT predicts substantially reduced spawning and egg incubation habitat conditions in the Sacramento River.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning and egg incubation habitat for fall-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 2A would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall–run Chinook salmon relative to NAA.

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish*

Analysis). Flows under A2A_LLT would be greater than or similar to flows under NAA throughout the period.

Shasta Reservoir storage at the end of September would affect flows during the fall-run larval and juvenile rearing period. As reported in Impact AQUA-59 for spring-run Chinook salmon, end of September Shasta Reservoir storage would be similar to or greater than storage under NAA in all water year types (Table 11-2A-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

SacEFT predicts that there would be a 5% decrease in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under A2A_LLT relative to NAA (Table 11-2A-34). SacEFT predicts that there would be a 10% increase in the percentage of years with "good" (lower) juvenile stranding risk under A2A_LLT relative to NAA.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under A2A_LLT would be similar to mortality under NAA.

Late Fall-Run

Year-round Sacramento River flows upstream of Red Bluff were examined for the late fall–run Chinook salmon juvenile rearing period of March through July (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during March through June under A2A_LLT were generally similar to or greater than those under NAA (up to 105% greater). Flows during July were up to 41% lower under A2A_LLT than under NAA.

Shasta Reservoir storage at the end of September and May would affect flows during the late fall–run larval and juvenile rearing period. As reported in Impact AQUA-156, end of September Shasta Reservoir storage would be similar to or greater than storage under NAA in all water year types (Table 11-2A-19).

As reported in Impact AQUA-59, Shasta storage at the end of May under A2A_LLT would be similar to or greater than storage under NAA for all water year types (Table 11-2A-9).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

SacEFT predicts that there would be a 37% decrease in the percentage of years with good juvenile rearing availability for late fall–run Chinook salmon, measured as weighted usable area, under A2A_LLT relative to NAA (Table 11-2A-36). SacEFT predicts that there would be a 2% reduction in the percentage of years with "good" (lower) juvenile stranding risk under A2A_LLT relative to NAA.

SALMOD predicts that late fall–run smolt equivalent habitat-related mortality under A2A_LLT would be similar to mortality under NAA.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined the January through May fall-run Chinook salmon rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to or greater than flows under NAA, except in critical years during February (6% reduction) and in below normal years during March (6% reduction).

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low flow channel throughout this period under A2A_LLT would not differ from those under NAA. In the high flow channel, flows under A2A_LLT would be mostly similar to or greater than flows under NAA during December through June with few exceptions during which flows would be up to 12% lower under A2A_LLT.

As reported in Impact AQUA-59 for spring-run Chinook salmon, May Oroville storage volume under A2A_LLT would be similar to storage under NAA, indicating that the difference is primarily a result of climate change (Table 11-2A-28).

As reported in Impact AQUA-59 for spring-run Chinook salmon, September Oroville storage volume would be similar to or up to 5% lower than under NAA depending on water year type (Table 11-2A-25).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT generally be similar to or greater than flows under NAA except in dry and critical years (6% and 7% lower, respectively) during March.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the*

Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River for Alternative 2A are not different from those under NAA, for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures throughout the Stanislaus River would be similar between NAA and Alternative 2A throughout the January through May fall-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River at Vernalis for Alternative 2A are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta for Alternative 2A are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Taken together, these results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat of fish. SacEFT predicts that there would be a 37% decrease in the percentage of years with good juvenile rearing availability for late fall-run, although the number of years with good juvenile stranding risk as predicted by SacEFT would not differ between Alternative 2A and the NEPA baseline, nor would late fall–run smolt equivalent habitat-related mortality as predicted by SALMOD. Despite the reduction in late fall-run rearing availability, there are no effects of Alternative 2A on fall-run or late fall-run in other waterways that would rise to the level of adverse.

CEQA Conclusion: In general, Alternative 2A would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall–run Chinook salmon relative to the Existing Conditions.

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be greater than or similar to flows under Existing Conditions, except in below normal years during March (10% lower) and wet years during May (15% lower).

As reported in Impact AQUA-59, end of September Shasta Reservoir storage would be 7% to 12% lower under A2A_LLT relative to Existing Conditions depending on water year type (Table 11-2A-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

SacEFT predicts that there would be an 15% increase in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under A2A_LLT relative to Existing Conditions (Table 11-2A-34). SacEFT predicts that there would be a 29% reduction in the percentage of years with "good" (lower) juvenile stranding risk under A2A_LLT relative to Existing Conditions.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under A2A_LLT would be 11% lower than mortality under Existing Conditions.

Late Fall–Run

Year-round Sacramento River flows upstream of Red Bluff were examined for the late fall–run Chinook salmon juvenile March through July rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during March through June under A2A_LLT were generally similar to or greater than those under Existing Conditions. Flows during July were generally lower under A2A_LLT than under Existing Conditions.

As reported in Impact AQUA-59, end of September Shasta Reservoir storage would be 7% to 12% lower under A2A_LLT relative to Existing Conditions depending on water year type (Table 11-2A-19).

As reported in Impact AQUA-41, end of May Shasta storage under A2A_LLT would be similar to Existing Conditions in wet, above normal, and below normal water years, but lower by 6% to 9% in dry and critical water years (Table 11-2A-9).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period except for dry and critical years in July (6% and 9% higher, respectively.

SacEFT predicts that there would be an 11% reduction in the percentage of years with good juvenile rearing availability for late fall–run Chinook salmon, measured as weighted usable area, under A2A_LLT relative to Existing Conditions (Table 11-2A-36). SacEFT predicts that there would be a 38% reduction in the percentage of years with "good" (lower) juvenile stranding risk under A2A_LLT relative to Existing Conditions.

SALMOD predicts that late fall–run smolt equivalent habitat-related mortality under A2A_LLT would be 8% higher than mortality under Existing Conditions.

Clear Creek

No temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined the January through May fall-run Chinook salmon rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to or greater than flows under Existing Conditions for the entire period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low flow channel throughout the period under A2A_LLT would not differ from those under Existing Conditions. In the high flow channel, flows under A2A_LLT would be mostly lower (up to 45%) during December and February and mostly similar to or greater than flows under Existing Conditions during January and March through June with few exceptions during which flows would be up to 46% lower under A2A_LLT.

As reported under in Impact AQUA-59, May Oroville storage volume under A2A_LLT would be lower than Existing Conditions by 6% to 21% depending on water year type, except in wet years, in which storage would be similar to Existing Conditions (Table 11-2A-25).

As reported in Impact AQUA-59, September Oroville storage volume would be 7% to 36% lower under A2A_LLT relative to Existing Conditions depending on water year type (Table 11-2A-28).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under Alternative 2A would be 5% to 11% higher than those under Existing Conditions during December through March, but not different from those under Existing Conditions during April through June. In the high-flow channel, mean monthly water temperatures under Alternative 2A would be 6% to 10% higher than those under Existing Conditions during December through February, but not different from those under Existing Conditions during March through June.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions, except during January in below normal, dry and critical years (16% to 18% lower) and in critical years during February and March (14% and 10%, respectively).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 5% to 7% higher than those under Existing Conditions during January through March and May, but not different during April.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally similar to those under Existing Conditions from October through December and 11% lower during January.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 6% higher than those under Existing Conditions in all months during the period.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 8% lower than Existing Conditions in most water years during October, similar to Existing Conditions in November through January.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 14% lower than flows under Existing Conditions during October and up to 18% greater than flows under Existing Conditions during November through January.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-77 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, when compared to the CEQA baseline, the alternative could substantially reduce suitable rearing habitat, contrary to the NEPA conclusion set forth above. Late fall–run Chinook salmon in the Sacramento River experience small to moderate reductions in flow during August and November in most water year types relative to the Existing Conditions. SacEFT predicts that there would be a 29% reduction in years with low juvenile stranding risk, indicating that flows would be more variable during the rearing period. Flows in the Feather River for fall-run Chinook salmon would be up to 45% lower than the Existing Conditions in the majority of water years during December and February. Water temperatures would be similar between Alternative 2A and Existing Conditions in the Sacramento River, although temperatures would be higher in the Feather, American, and Stanislaus Rivers under Alternative 2A. Both SacEFT and SALMOD predict reduced rearing habitat conditions under Alternative 2A relative to Existing Conditions.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for fall-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

Upstream of the Delta

In general, Alternative 2A would reduce migration conditions for fall-/late fall–run Chinook salmon relative to NAA.

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff for juvenile fall-run migrants during February through May under A2A_LLT would be similar to or greater than flows under NAA throughout the February through May juvenile fall-run migration period in all water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff during the adult fall-run Chinook salmon upstream migration period (September through October) under A2A_LLT would generally be similar to or greater than those under NAA except during above normal years during September (5% lower) and below normal years during September and October (15% and 6% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the September through October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff for juvenile late fall-run migrants (January through March) under A2A_LLT would generally be similar to or greater than flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff during the adult late fall-run Chinook salmon upstream migration period (December through February) under A2A_LLT would be similar to or greater than those under NAA regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in the Clear Creek below Whiskeytown Reservoir were examined for juvenile fall-run migrants during February through May. Flows under A2A_LLT would be similar to or greater than flows under NAA, except in critical years during February and below normal years during March (6% lower for both) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek below Whiskeytown Reservoir during the adult fall-run Chinook salmon upstream migration period (September through October) under A2A_LLT would be similar to or greater than those under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Fall-Run

Flows in the Feather River at the confluence with the Sacramento River during the fall-run juvenile migration period (February through May) under A2A_LLT would generally be similar to or greater than flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River during the September through October fall-run Chinook salmon adult migration period under A2A_LLT would generally be lower by up to 33% lower than flows under NAA in September but similar to or greater than flows under NAA in October (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the September through October fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be generally similar to or greater than flows under NAA, except for dry and critical years during March (6% and 7% lower, respectively).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Flows in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A during September would be 10% to 19% lower than those under NAA in wet, above normal, and below normal years and flows during October would be 7% to 10% lower in wet and above normal years. Flows in other water years would be similar to or greater than those under NAA.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be similar to those under NAA throughout the year. Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be similar to those under NAA throughout the year.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be similar to those under NAA throughout the year.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Sacramento River

The effects of Alternative 2A on through-Delta migration were evaluated using the approach described in Alternative 1A, Impact AQUA-42.

Fall-Run

Juveniles

Juvenile salmonids migrating down the Sacramento River would generally experience lower flows below the north Delta intakes compared to Existing Conditions. The predation effects of Alternative 2A would be the same as those described for Alternative 1A, since there are five intakes for both alternatives. Estimates of potential predation losses ranged from 1.8% (bioenergetics model, Table

11-1A-17) up to 20.3% (conservative assumption of 5% loss per intake) of fall-run annual production.

Through-Delta survival by juvenile fall-run Chinook salmon under Alternative 2A averaged across years would be 24.3% from the Sacramento River and 16.4% from the Mokelumne River, which is not much different from NAA (Table 11-2A-45). In wetter years, mean survival would be 2.5% lower from the Sacramento (8% relative decrease) and 1.5% greater (9% relative increase) from the Mokelumne.

Overall, Alternative 2A would have a negative effect on fall-run Chinook salmon juvenile survival due to habitat and predation losses at the NDD intakes.

Table 11-2A-45. Through-Delta Survival (%) of Emigrating Juvenile Fall-Run Chinook Salmon under Alternative 2A

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Year Type	EXISTING CONDITIONS	NAA	A2A	EXISTING CONDITIONS vs. A2A	NAA vs. A2A
Sacramento River					
Wetter Years	34.5	31.1	28.6	-5.9 (-17%)	-2.5 (-8%)
Drier Years	20.6	20.8	21.7	1.1 (5%)	0.9 (4%)
All Years	25.8	24.7	24.3	-1.5 (-6%)	-0.3 (-1%)
Mokelumne River					
Wetter Years	17.2	15.7	17.2	0.0 (0%)	1.5 (9%)
Drier Years	15.6	15.9	15.9	0.3 (2%)	-0.1 (<-1%)
All Years	16.2	15.9	16.4	0.2 (1%)	0.5 (3%)
San Joaquin River					
Wetter Years	19.3	20.3	16.6	-2.7 (-14%)	-3.6 (-18%)
Drier Years	10.0	9.5	10.9	1.0 (10%)	1.4 (14%)
All Years	13.5	13.6	13.1	-0.4 (-3%)	-0.5 (-4%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and above normal water years (6 years).
Drier = Below normal, dry and critical water years (10 years).

Adults

Attraction flow for fall-run adults, as estimated by the percentage of Sacramento River water at Collinsville, increased 13% in September and decreased 1% to 4% October to December under Alternative 2A compared to NAA (Table 11-2A-17). The Sacramento River would still represent a substantial proportion (62% to 78%) of Delta outflows. The reductions in percentage are small in comparison with the magnitude of change in dilution (20% or more) reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect adult Chinook salmon migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 in Alternative 1A.

Late Fall–Run

Juveniles

Juvenile salmonids migrating down the Sacramento River would generally experience lower flows below the north Delta intakes compared to Existing Conditions. Through-Delta survival by emigrating juvenile late fall–run Chinook salmon under Alternative 2A (A2A_LLT) would average 23% across all years, ranging from 20% in drier years to 27% in wet years. Juvenile survival would decrease slightly in wetter (0.6% less survival, or 2% less in relative percentage) and similar in drier years (0.3% greater survival, or 1% more in relative percentage) compared to NAA (Table 11-2A-46). Overall, Alternative 2A would not have an adverse effect on late fall–run Chinook salmon juvenile survival due an increase in survival during all water year types.

Table 11-2A-46. Through-Delta Survival (%) of Emigrating Juvenile Late Fall–Run Chinook Salmon under Alternative 2A

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Year Type	EXISTING CONDITIONS	NAA	A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wetter Years	28.8	27.3	26.7	-2.1 (-7%)	-0.6 (-2%)
Drier Years	18.8	20.2	20.5	1.7 (9%)	0.3 (1%)
All Years	22.5	22.9	22.8	0.3 (1%)	-0.1 (<-1%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and above normal water years (6 years).
Drier = Below normal, dry and critical water years (10 years).

Adults

The adult late fall–run migration is from November through March, peaking in January through March. The proportion of Sacramento River water in the Delta would be similar (<10% difference) to NAA throughout the adult late fall–run migration (Table 11-2A-17). Alternative 2A would not have an adverse effect on late fall–run adult migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 in Alternative 1A.

San Joaquin River

Fall-Run

Juveniles

The only changes on San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. There are no flow changes associated with the alternatives. Through-Delta survival by emigrating juvenile fall-run Chinook salmon under Alternative 2A (A2A_LLT) would average 13% across all years (Table 11-2A-46). Juveniles from the San Joaquin River would experience 3.6% lower survival in wetter years (18% less in relative percentage) and 1.4% greater survival in drier years (14% more in relative percentage). Across all years, survival would be similar under Alternative 2A relative to the baseline (0.5% less, or 4% relative decrease). Overall, Alternative 2A would not have an adverse effect on fall-run Chinook salmon juvenile survival due to minor differences in survival.

Adults

Alternative 2A would slightly increase the proportion of San Joaquin River water in the Delta in September through December by 1.1 to 4.4% compared to NAA). The proportion of San Joaquin River water would be similar (<5% change) to NAA (Table 11-2A-47). Therefore migration conditions under Alternative 2A would be similar to those described for Alternative 1A. The effect of Alternative 2A would not be adverse on the fall-run adult migration.

Table 11-2A-47. Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Adult Chinook Migration Period for Alternative 2A

	Percentage of Water			Difference	
Month	EXISTING CONDITIONS	NAA	A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Sacramento River					
September	60	65	78	18	13
October	60	68	67	7	-1
November	60	66	62	2	-4
December	67	66	65	-2	-1
January	76	75	73	-3	-2
February	75	72	67	-8	-5
March	78	76	67	-11	-9
April	77	75	65	-12	-10

February	1.4	1.5	3.8	2.4	2.3
March	2.6	2.8	6.1	3.5	3.3
April	6.3	6.6	10.6	4.3	4.0
	Shading indicates a difference of 10% or greater in flow proportion.				

NEPA Effects:

Overall, the results indicate that the effect of Alternative 2A is adverse because it has the potential to substantially decrease fall- and late fall-run Chinook salmon migration habitat conditions upstream of the Delta. In addition, this alternative is adverse due to the cumulative effects associated with five north Delta intake facilities, including mortality related to near-field effects (e.g. impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes.

Upstream of the Delta, flows in the Feather and American rivers would be up to 33% lower during at least one of the two months of the fall-run Chinook salmon adult migration period. These reductions in flow may impact the ability of adult fall-run Chinook salmon to migrate upstream successfully. There would be no other effects of Alternative 2A on upstream flows or water temperatures during the juvenile or adult migration periods for fall- and late fall-run Chinook salmon.

Adult attraction flows under Alternative 2A would be lower than those under NAA, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 2A NDD on fall- and late fall-run Chinook salmon related to impingement and predation associated with five new intakes could result in substantial effects on juvenile migrating fall- and late fall-run Chinook salmon, although there is high uncertainty regarding the potential effects. Estimates within the effects analysis range from very low levels of effects (<2% mortality) to very significant effects (~ 20% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the five new intake structures will be implemented as part of the final NDD screen design effort. Alternative 2A also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for fall- and late fall-run Chinook salmon. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 2A predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 2A would be similar to survival rates estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon. Until these efforts are completed and their results are fully analyzed, the overall effect of Alternative 2A on fall- and late fall-run Chinook salmon through-Delta survival remains uncertain.

Therefore, due to unacceptable levels of uncertainty regarding the cumulative impacts of near-field and far-field effects associated with the presence and operation of the five intakes on fall- and late fall-run Chinook salmon, this effect is adverse.

While the implementation of the conservation and mitigation measures described below would reduce the effects on migration conditions, these reductions would not necessarily result in a not adverse determination. Therefore, the overall effect is adverse.

CEQA Conclusion:

Upstream of the Delta

In general, Alternative 2A would affect migration conditions for fall-/late fall–run Chinook salmon relative to the Existing Conditions.

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff for juvenile fall-run migrants during February through May under A2A_LLT would generally be similar to or greater than those under Existing Conditions, except in below normal water years during March (10% lower) and in wet water years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff during the adult fall-run Chinook salmon upstream migration period (September through October) under A2A_LLT would generally be similar to or greater than those under Existing Conditions except for below normal and dry years during September (13% and 16% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the September through October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 9% and 6% greater than those under Existing Conditions during September and October, respectively.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff for juvenile late fall-run migrants (January through March) under A2A_LLT would generally be similar to or greater than flows under Existing Conditions, except in below normal water years during March (10% reduction) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff during the adult late fall-run Chinook salmon upstream migration period (December through February) under A2A_LLT would generally be similar to or greater than those under Existing Conditions, except in wet years during December (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir during the juvenile fall-run Chinook salmon upstream migration period (February through May) under A2A_LLT would be similar to or greater than those under Existing Conditions throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek below Whiskeytown Reservoir during the adult fall-run Chinook salmon upstream migration period (September through October) under A2A_LLT would generally be similar to or greater than those under Existing Conditions except in critical years (29% and 7% lower during September and October, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Fall-Run

Flows in the Feather River at the confluence with the Sacramento River during the fall-run juvenile migration period (February through May) under A2A_LLT would generally be similar to or greater than flows under Existing Conditions, except in below normal years during February and March (11% and 18% lower, respectively) and in wet years during May (24% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River during the September through October fall-run Chinook salmon adult migration period under A2A_LLT would generally be greater than flows under Existing Conditions, except in below normal and dry years during September (24% and 28% lower, respectively) and in wet and below normal water years during October (8% and 12% lower, respectively).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the September through October fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature differences (>5%) would be higher in below normal, dry and critical years during September (6%, 6% and 5% higher, respectively) and in wet and dry years during October (5% higher in both years).

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during February and March would generally be similar to or greater than flows under Existing Conditions, except for critical years (14% an 10% lower in February and March, respectively). Flows under A2A_LLT during May would be mostly lower by up to 26% than flows under Existing Conditions.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 5% to 7% higher than under Existing Conditions although April would equal or exceed 5% only in wet and above normal years.

Flows in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during September would be 28% to 56% lower than flows under Existing Conditions. Flows under A2A_LLT during October would generally be similar to or greater than those under Existing Conditions in except in wet and above normal water years (16% and 6% lower, respectively).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 6% and 12% higher than those under Existing Conditions during September and October, respectively.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be 8% to 13% lower than those under Existing Conditions throughout the period.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 6% higher than those under Existing Conditions in every month of the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be 10% and 7% lower during September and October, respectively, than those under Existing Conditions

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 6% higher than those under Existing Conditions during September and 5% higher in critical years during October but there would be no difference in mean monthly water temperatures between Alternative 2A and Existing Conditions in the other water years during October.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would generally be similar to those under Existing Conditions during February, but up to 15% lower during the remainder of the period, particularly in drier water years.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be 5% and 8% lower than those under Existing Conditions during September and October, respectively.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be similar to or greater than those under Existing Conditions during February and March and 8% and 12% lower than those under Existing Conditions during April and May, respectively.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be similar to those under Existing Conditions during both months.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Through-Delta survival as modeled by DPM was similar or slightly reduced for Alternative 2A compared to Existing Conditions, and therefore the impact would be less than significant. Based on the proportion of Sacramento River flows, olfactory cues would be similar (<10% difference) to Existing Conditions for nearly all months of the year. The proportion of flows would decrease slightly in March and April by 11 to 12%. The 11% decrease in March would affect the last month of the late fall-run adult migration. An increase in the proportion of Sacramento River flows in September by 18% though would benefit the pre-peak fall-run adult upstream migration. Through the Delta, Sacramento River flows below the NDD would be reduced compared to baseline conditions during adult and juvenile migration periods. Modeled juvenile survival is expected to be similar or slightly lower in all water year types (6% relative decrease across all years). Estimated predation losses of juveniles migrating past the five intakes could hypothetically range from 2% to 20% of annual production, although the latter estimate is a conservative upper bound. The adaptive management program would provide a mechanism for making adjustments to minimize this effect to some extent. In addition, *CM15 Localized Reduction of Predatory Fishes* could be implemented to reduce potential effects. However, the benefits of these actions are uncertain. As a result of changes in predation and habitat associated with five NDD structures, this impact is substantial.

Summary of CEQA Conclusion

There would be substantial reductions in flows and increases in temperatures in multiple upstream waterways under Alternative 2A relative to Existing Conditions that would slow or inhibit migration of juveniles and adult fall-/late fall-run Chinook salmon or increase thermal stress on migrants. In addition, Alternative 2A has the potential to substantially increase predation and remove important instream habitat in the Delta as the result of the presence of five NDD structures. Through-Delta survival of emigrating juveniles is expected to be substantially reduced, compared to Existing Conditions. Implementation of CM6 and CM15 and Mitigation Measures AQUA-78a through AQUA-78c would address these impacts, but are not anticipated to reduce them to a level considered less than significant. Although implementation of *CM6 Channel Margin Enhancement* would provide habitat similar to that which would be lost, it would not necessarily be located near the intakes and therefore would not fully compensate for the lost habitat. Additionally, implementation of this measure would not fully address predation losses. *CM15 Localized Reduction of Predatory Fishes (Predator Control)* has substantial uncertainties associated with its effectiveness such that it is considered to have no demonstrable effect. Conservation measures that address habitat and predation losses, therefore, would potentially minimize impacts to some extent but not to a less than significant level. Consequently, as a result of these changes in migration conditions, this impact is significant and unavoidable.

Applicable conservation measures are briefly described below and full descriptions are found in Chapter 3, Section 3.6.2.5 Channel Margin Enhancement (CM6) and Section 3.6.3.4 Localized Reduction of Predatory Fishes (Predator Control) (CM15).

CM6 Channel Margin Enhancement. CM6 would entail restoration of 20 linear miles of channel margin by improving channel geometry and restoring riparian, marsh, and mudflat habitats on the waterside side of levees along channels that provide rearing and outmigration habitat for juvenile salmonids. Linear miles of enhancement would be measured along one side or the other of a given channel segment (e.g., if both sides of a channel are enhanced for a length of 1 mile, this would account for a total of 2 miles of channel margin enhancement). At least 10 linear miles would be enhanced by year 10 of Plan implementation; enhancement would then be phased in 5-mile increments at years 20 and 30, for a total of 20 miles at year 30. Channel margin enhancement would be performed only along channels that provide rearing and outmigration habitat for juvenile salmonids. These include channels that are protected by federal project levees—including the Sacramento River between Freeport and Walnut Grove among several others.

CM15 Localized Reduction of Predatory Fishes (Predator Control). CM15 would seek to reduce populations of predatory fishes at specific locations or modify holding habitat at selected locations of high predation risk (i.e., predation "hotspots"). This conservation measure seeks to benefit covered salmonids by reducing mortality rates of juvenile migratory life stages that are particularly vulnerable to predatory fishes. Predators are a natural part of the Delta ecosystem. Therefore, this conservation measure is not intended to entirely remove predators at any location, or substantially alter the abundance of predators at the scale of the Delta system. This conservation measure would also not remove piscivorous birds. Because of uncertainties regarding treatment methods and efficacy, implementation of CM15 would involve discrete pilot projects and research actions coupled with an adaptive management and monitoring program to evaluate effectiveness. Effects would be temporary, as new individuals would be expected to occupy vacated areas; therefore, removal activities would need to be continuous during periods of concern. CM15 also recognizes that the NDD intakes would create new predation hotspots.

As discussed in detail for Alternative 1A, the effects of Alternative 2A operations on through-Delta migration conditions for fall-/late fall-run Chinook salmon would be significant and unavoidable, due to predation and habitat loss associated with the five NDD intakes, and flow changes in the Feather and American Rivers. However, as with the conservation measures, the implementation of the mitigation measures listed below also has the potential to reduce the severity of the impact though not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-78a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Fall-/Late Fall–Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-78a under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78b: Conduct Additional Evaluation and Modeling of Impacts on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-78b under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-78c under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 2A has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for fall- and late fall–run Chinook salmon under Alternative 1A (Impact AQUA-79 through AQUA-81) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/ Late Fall–Run ESU)

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: All three of these impact mechanisms have been determined to result in no adverse effects on fall- or late fall-run Chinook salmon for NEPA purposes. Specifically for AQUA-80, the effects of contaminants on fall- and late fall-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on fall- and late fall-run Chinook salmon are uncertain.

CEQA Conclusion: All three of these impact mechanisms would be considered less than significant on fall- or late fall-run Chinook salmon, for the reasons identified for Alternative 1A, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 2A has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for fall- and late fall-run Chinook salmon under Alternative 1A (Impact AQUA-82 through AQUA-90) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM12)

Impact AQUA-83: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM13)

Impact AQUA-84: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM14)

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM15)

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM16)

Impact AQUA-87: Effects of Illegal Harvest Reduction on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM17)

Impact AQUA-88: Effects of Conservation Hatcheries on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM18)

Impact AQUA-89: Effects of Urban Stormwater Treatment on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM19)

Impact AQUA-90: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on fall- or late fall-run Chinook salmon for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on fall- or late fall-run Chinook salmon, for the reasons identified for Alternative 1A, and no mitigation is required.

Steelhead

Construction and Maintenance of CM1

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

The potential effects of construction of the water conveyance facilities on steelhead would be similar to those described for Alternative 1A (Impact AQUA-91) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-91, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for steelhead.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-91, the impact of the construction of water conveyance facilities on steelhead would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: The potential impacts of the maintenance of water conveyance facilities under Alternative 2A would be the same as those described for Alternative 1A (see Impact AQUA-92). As concluded in Impact AQUA-92, the effect would not be adverse for steelhead.

CEQA Conclusion: As described in Impact AQUA-92 under Alternative 1A, the impact of the maintenance of water conveyance facilities on steelhead would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Water Exports from SWP/CVP South Delta Facilities

Alternative 2A would reduce overall entrainment of juvenile steelhead at the south Delta export facilities by 69%, as estimated by the salvage density method (Table 11-2A-48) across all years compared to NAA. Under Alternative 2A, the greatest reductions in entrainment would be in wetter years (90% decrease). Pre-screen loss at the south Delta facilities, typically attributed to predation, would be reduced commensurate with reductions in entrainment.

Table 11-2A-48. Juvenile Steelhead Annual Entrainment at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 2A

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. A2A	NAA vs. A2A
Wet	-5,679 (-90%)	-5,761 (-90%)
Above Normal	-10,511 (-79%)	-10,279 (-78%)
Below Normal	-5,567 (-50%)	-6,301 (-53%)
Dry	-1,711 (-25%)	-2,283 (-30%)
Critical	-1,039 (-19%)	-1,625 (-27%)
All Years	-5,999 (-68%)	-6,248 (-69%)

Note: Estimated annual number of fish lost, based on non-normalized data.

Steelhead predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Average pre-screen predation loss for steelhead entrained at the Clifton Court Forebay is about 80% (Clark et al. 2009) while predation loss for fish entrained at the CVP is assumed to be 15%. By reducing entrainment at the south Delta facilities, Alternative 2A would reduce predation losses commensurate with reductions in entrainment.

Water Exports from SWP/CVP North Delta Intake Facilities

The potential effects of the proposed North Delta diversions would be similar to these described for Chinook salmon juveniles (see Impact AQUA-39). The north Delta intakes would be screened to exclude fish larger than 15 mm, which would prevent steelhead smolts (which are larger than Chinook salmon juveniles and fry).

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

Entrainment and impingement effects on juvenile steelhead would be minimal for Alternative 2A because intakes would have state-of-the-art screens installed.

NEPA Effects: The effect under Alternative 2A would not be adverse.

CEQA Conclusion: As described above, entrainment and associated pre-screen predation losses of juvenile steelhead would decrease under Alternative 2A (A2A_LLT) compared to Existing Conditions at the south Delta export facilities (Table 11-2A-48). The north Delta screened intakes, as designed, would exclude juvenile salmonids, and decommissioning agricultural diversions would reduce potential entrainment. Impacts of water operations on entrainment of steelhead would be beneficial due to an overall reduction in entrainment and no mitigation would be required.

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

In general, the effect of Alternative 2A on steelhead spawning habitat would be negligible relative to NAA.

Sacramento River

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam, where the majority of steelhead spawning occurs, were examined during the primary steelhead spawning and egg incubation period of January through April. (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds, leading to mortality. Flows under A2A_LLT throughout the period would generally be similar to those under NAA except during February during below normal water years (7% higher flow).

Mean monthly water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

SacEFT predicts that there would be a 6% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2A_LLT relative to NAA (Table 11-2A-49). SacEFT predicts that there would be negligible (<5%) differences between NAA and A2A_LLT in the percentage of years with good (lower) redd scour risk and no (0%) difference in the percentage of years with good (lower) egg incubation conditions. These results indicate that there would be a low effect of Alternative 2A on spawning habitat quantity but no difference in redd scour risk or temperature-related egg incubation conditions.

Table 11-2A-49. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Steelhead Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Spawning WUA	0 (0%)	-3 (-6%)
Redd Scour Risk	-3 (-4%)	0 (0%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	0 (0%)	3 (6%)
Juvenile Rearing WUA	-6 (-15%)	-10 (-22%)
Juvenile Stranding Risk	-16 (-47%)	-2 (-10%)

WUA = Weighted Usable Area.

Overall, these results indicate that the effects of Alternative 2A on steelhead spawning and egg incubation habitat in the Sacramento River would be negligible.

Clear Creek

Flows in Clear Creek were examined during the steelhead spawning and egg incubation period (January through April). Flows under A2A_LLT would generally be similar to flows under NAA throughout the period, except in critical years during February (6% lower), below normal years during March (6% lower), and critical years during January (7% higher) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Results of the flow analyses for the risk of redd dewatering for Clear Creek indicate that the greatest monthly flow reduction would be identical between NAA and A2A_LLT for all water year types (Table 11-2A-50).

Table 11-2A-50. Comparisons of Greatest Monthly Reduction (Percent Change) in Instream Flow under Alternative 2A Model Scenarios in Clear Creek during the January–April Steelhead Spawning and Egg Incubation Period[a]

Water Year Type	A2A_LLT vs. EXISTING CONDITIONS	A2A vs. NAA
Wet	-25 (-38%)	0 (0%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in the month when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

No water temperature modeling was conducted in Clear Creek.

Overall, these results indicate that the effects of Alternative 2A on steelhead spawning and egg incubation habitat in Clear Creek would be negligible.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) during the steelhead spawning and egg incubation period (January through April) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the low-flow channel under A2A_LLT would not differ from NAA because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006). Flows under A2A_LLT at Thermalito Afterbay would generally be similar to or greater than flows under NAA, except in wet and critical years during January (7% and 12% lower, respectively) and in below normal years during March (8% lower).

Oroville Reservoir storage volume at the end of September and end of May influences flows downstream of the dam during the steelhead spawning and egg incubation period. Storage volume at the end of September under A2A_LLT would be similar to or up to 16% greater than storage under NAA depending on water year type (Table 11-2A-25). May Oroville storage under A2A_LLT would be similar to storage under NAA (Table 11-2A-28).

Mean monthly water temperatures in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

The percent of months exceeding the 56°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during January through April (Table 11-2A-51). The percent of months exceeding the threshold under Alternative 2A would generally be similar to or lower (up to 14% lower on an absolute scale) than the percent under NAA depending on month and degrees above the threshold.

Table 11-2A-51. Differences between Baseline and Alternative 2A Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, January through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2A_LLT					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	5 (400%)	1 (NA)	1 (NA)	1 (NA)	1 (NA)
April	32 (371%)	14 (275%)	12 (NA)	4 (NA)	0 (NA)
NAA vs. A2A_LLT					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-4 (-38%)	-1 (-50%)	0 (0%)	0 (0%)	0 (0%)
April	-12 (-23%)	-14 (-42%)	-5 (-29%)	-2 (-40%)	-1 (-100%)

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 56°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during January through April (Table 11-2A-52). Total degree-months would be similar between NAA and Alternative 2A in all months.

Table 11-2A-52. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, January through April

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	2 (NA)	0 (0%)
	Dry	3 (NA)	1 (50%)
	Critical	8 (800%)	0 (0%)
	All	13 (1,300%)	1 (8%)
April	Wet	4 (NA)	1 (33%)
	Above Normal	12 (600%)	1 (8%)
	Below Normal	16 (400%)	0 (0%)
	Dry	21 (420%)	-5 (-16%)
	Critical	21 (NA)	-2 (-9%)
	All	73 (664%)	-6 (-7%)

NA = could not be calculated because the denominator was 0.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to flows under NAA during the period except in dry and critical years during March (6% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period ((Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the*

Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-2A-41). Steelhead spawn and eggs incubate in the American River between January and April. During this period, the percent of months exceeding the threshold under Alternative 2A would similar to or up to 20% lower (absolute scale) than the percent under NAA.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-2A-42). During the January through April steelhead spawning and egg incubation period, total degree-months would be similar between NAA and Alternative 2A.

Overall, these results indicate that the effects of Alternative 2A on steelhead spawning and egg incubation habitat in the American River would be negligible or beneficial.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT throughout this period would generally be identical to flows under NAA.

Water temperatures throughout the Stanislaus River would be similar under NAA and Alternative 2A throughout the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT throughout this period would generally be identical to flows under NAA.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. There would be no substantial effects of Alternative 2A on upstream flows or water temperatures that would affect steelhead spawning and egg incubation in any waterway evaluated. Further, SacEFT predicts no effects of Alternative 2A on steelhead spawning and egg incubation habitat.

CEQA Conclusion: In general, Alternative 2A would not reduce the quantity and quality of steelhead spawning habitat relative to the Existing Conditions.

Sacramento River

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam, where the majority of steelhead spawning occurs, were examined during the primary steelhead spawning and egg incubation period of January through April. (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds, leading to mortality. At Keswick, flows under A2A_LLT would generally be similar to flows under Existing Conditions in January, March and April, and higher than flows under Existing Conditions in February with some exceptions. Upstream of Red Bluff Diversion Dam, flows would generally be similar between Existing Conditions and A2A_LLT throughout the period.

Mean monthly water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period at either location.

SacEFT predicts no differences in spawning habitat, egg incubation, and redd dewatering risk between Existing Conditions and Alternative 2A, and negligible changes (<5%) in redd scour risk (Table 11-2A-15).

Overall in the Sacramento River, Alternative 2A would have negligible reductions in mean monthly flow (-6%) that would not affect steelhead spawning conditions in a biological meaningful way. SacEFT indicates that steelhead egg incubation and redd survival metrics would not be substantially affected by Alternative 2A. Impacts of Alternative 2A on water temperature would be less than significant.

Clear Creek

Flows in Clear Creek were examined during the steelhead spawning and egg incubation period (January through April). Flows under A2A_LLT would be similar to or greater than flows under Existing Conditions throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Results of the flow analyses for the risk of redd dewatering for Clear Creek indicate that the greatest monthly flow reduction would be identical between Existing Conditions and A2A_LLT for all water year types except wet, in which the greatest reduction would be 38% lower (worse) under A2A_LLT than under Existing Conditions (Table 11-2A-50).

No water temperature modeling was conducted in Clear Creek.

Overall, these results indicate that the effects of Alternative 2A on steelhead spawning and egg incubation habitat in Clear Creek would be negligible.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) during the steelhead spawning and egg incubation period (January through April) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the low-flow channel under A2A_LLT would not differ from Existing Conditions because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006). Flows under A2A_LLT at Thermalito Afterbay would generally be similar to or greater than flows under Existing Conditions, except in above and below normal water years during January (36% and 44% lower, respectively), below normal, dry and critical water yeas during February (45%, 11%, and 8% lower, respectively), and below normal and dry water years during March (46% and 5% lower, respectively).

Oroville Reservoir storage volume at the end of September and end of May influences flows downstream of the dam during the steelhead spawning and egg incubation period. Oroville Reservoir storage volume at the end of September would be 7% to 36% lower under A2A_LLT relative to Existing Conditions depending on water year type (Table 11-2A-25). May Oroville storage volume under A2A_LLT would be lower than Existing Conditions by 6% to 21% depending on water year type, except in wet years, in which storage would be similar to Existing Conditions (Table 11-2A-28).

Mean monthly water temperatures in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under Alternative 2A would be 5% to 8% greater than those under Existing Conditions during January through March and similar to temperatures under Existing Conditions during April. In the high-flow channel, mean monthly water temperatures under Alternative 2A would be 7% greater than those under Existing Conditions during January and February and similar to temperatures under Existing Conditions during March and April except for below normal and critical years during March (6% greater for both years).

The percent of months exceeding the 56°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during January through April (Table 11-2A-51). The percent of months exceeding the threshold under Alternative 2A would generally be similar to the percent under Existing Conditions during January and February and similar to or up to 32% greater (absolute scale) than the percent under Existing Conditions depending on month and degrees above the threshold during March and April.

Total degree-months exceeding 56°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during January through April (Table 11-2A-52). Total degree-months would be similar between Existing Conditions and Alternative 2A during January and February and 664% to 1300% higher under Alternative 2A compared to Existing Conditions during March and April.

Overall, these results indicate that there would be negligible effects of Alternative 2A on mean monthly flows in the low-flow channel, but that flows in the high-flow channel would be substantially lower in some water year types and months. Alternative 2A would substantially increase exposure of spawning steelhead and their eggs to critical water temperatures, a result of reduced coldwater pool availability in Oroville Reservoir.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be lower than flows under Existing Conditions during January, greater than flows under Existing Conditions during February and March, and similar to flows under Existing Conditions during April with some exceptions. Mean monthly water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature under Alternative 2A would be 5% to 7% higher than those under Existing Conditions during the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-2A-41). Steelhead spawn and eggs incubate in the American River between January and April. During January and February, the percent of month exceeding the threshold under Existing Conditions and Alternative 2A would be identical. During March and April, the percent of months exceeding the threshold under Alternative 2A would be up to 31% greater (absolute scale) than the percent under Existing Conditions.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-2A-42). During the January and February, there would be no difference in total degree-months above the threshold between Existing Conditions and Alternative 2A. During March and April, total degree-months under Alternative 2A would be 389% and 94% greater than those under Existing Conditions, respectively.

Overall, these results indicate that the effects of Alternative 2A on flows would not be negative. Flows would be mostly greater than flows under Existing Conditions and temperatures would not differ from Existing Conditions. However, Alternative 2A would substantially increase exposure of spawning steelhead and their eggs to critical water temperatures.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT throughout this period would be up to 36% lower flows under Existing Conditions in all months with few exceptions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River was evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 6% higher than those under Existing Conditions in all months.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to or up to 18% higher than flows under Existing Conditions during January through March and up to 14% lower during April.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-94 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, when compared to the CEQA baseline, the alternative could substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above.

Alternative 2A substantial reductions in mean monthly flow in the Stanislaus River and increased exposure to elevated water temperatures in the Feather, American, and Stanislaus Rivers. There would be beneficial effects due to moderate increases in mean monthly flow for specific months and water year types in Clear Creek and the American River, primarily in wetter water year types, and in the Feather River primarily during wetter water years but also in drier water year types in April. These would not offset the negative effects of the more persistent and/or substantial flow reductions. There would be no effects in the Sacramento River.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning and egg incubation habitat for steelhead salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

In general, Alternative 2A would reduce the quantity and quality of steelhead rearing habitat relative to NAA.

Sacramento River

Juvenile steelhead rear within the Sacramento River for 1 to 2 years before migrating downstream to the ocean. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry or juveniles leading to mortality. Year-round Sacramento River flows within the reach where the majority of steelhead spawning and juvenile rearing occurs (Keswick Dam to upstream of RBDD) were evaluated (Appendix 11C, *CALSIM II Model Results utilized in the Fish*

Analysis). Flows during September, October, and between December and July under A2A_LLT would generally be similar to or greater than those under NAA. Flows during August and November would generally be lower under A2A_LLT than under NAA.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

SacEFT predicts that the percentage of years with good juvenile steelhead rearing WUA conditions under A2A_LLT would be 22% lower (10% on absolute scale) than that under NAA (Table 11-2A-49). Also, the percentage of years with good (lower) juvenile stranding risk conditions under A2A_LLT would be 10% lower (2% on absolute scale)than under NAA. These results indicate that Alternative 2A would cause a small decrease in rearing habitat availability in the Sacramento River.

Overall, these results indicate that Alternative 2A would reduce juvenile rearing conditions in the Sacramento River.

Clear Creek

Flows in Clear Creek below Whiskeytown during the year-round steelhead rearing period under A2A_LLT would generally be similar to or greater than flows under NAA, except for critical years in February and June and below normal years in March in which flows would be 6% to 8% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).Water temperatures were not modeled in Clear Creek.

It was assumed that habitat for juvenile steelhead rearing would be constrained by the month having the lowest instream flows. Juvenile rearing habitat is assumed to increase as instream flows increase, and therefore the lowest monthly instream flow was used as an index of habitat constraints for juvenile rearing. Results of the analysis indicate that juvenile steelhead rearing habitat, based on minimum instream flows, is comparable for Alternative 2A relative to NAA in wet, above normal, and critical water year types (Table 11-2A-53). Minimum flows would be 86% higher in below normal years and 100% lower (reduction from 7 cfs to 0 cfs) in dry water years.

Table 11-2A-53. Difference (cfs) and Percent Difference in Minimum Monthly Mean Flow in Clear Creek during the Year-Round Juvenile Steelhead Rearing Period

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	0 (0%)	0 (0%)
Above Normal	0 (0%)	0 (0%)
Below Normal	15 (21%)	39 (86%)
Dry	-50 (-100%)	-7 (-100%)
Critical	-50 (-100%)	0 (NA)

Note: Minimum flows occurred between October and March.
NA = could not be calculated because the denominator was 0.

Denton (1986) developed flow recommendations for steelhead in Clear Creek using IFIM (Figure 11-1A-4). The current Clear Creek management regime uses flows slightly lower than those recommended by Denton. Results from a new IFIM study on Clear Creek are currently being analyzed. Depending on results of this study the flow regime could be adjusted in the future. We expect that the modeled flows will be suitable for the existing steelhead populations in Clear Creek. No change in effect on steelhead in Clear Creek is anticipated.

Overall, these results indicate that Alternative 2A would not affect juvenile rearing conditions in Clear Creek.

Feather River

Year-round flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were reviewed to determine flow-related effects on steelhead juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The low-flow channel is the primary reach of the Feather River utilized by steelhead spawning and rearing (Cavallo et al. 2003). Relatively constant flows in the low flow channel throughout the year under A2A_LLT would not differ from those under NAA. In the high flow channel, flows under A2A_LLT would be mostly lower (up to 50%) during July, August, November, December, and February and mostly similar to or greater (up to 217%) than flows under Existing Conditions in other months.

May Oroville storage under A2A_LLT would be similar to storage under NAA (Table 11-2A-28). September Oroville storage volume would be similar to or up to 5% lower than under NAA depending on water year type (Table 11-2A-25).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period at either location.

An additional analysis evaluated the percent of months exceeding a 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) (May through August) and exceeding a 56°F threshold at Gridley (October through April) for each model scenario. In the low-flow channel, the percent of months exceeding the threshold under Alternative 2A would generally be similar to or lower (up to 23% lower on an absolute scale) than the percent under NAA (Table 11-2A-29). At Gridley, the percent of months exceeding the threshold under Alternative 2A would similar to or up to 11% lower (absolute scale) than the percent under NAA (Table 11-2A-38).

Total degree-months exceeding 56°F were summed by month and water year type in the Feather River above Thermalito Afterbay (low-flow channel) and at Gridley during November through April. In the low-flow channel, total degree-months under Alternative 2A would be similar to or lower than those under NAA depending on the month (Table 11-2A-30). At Gridley, total degree-months would be similar between NAA and Alternative 2A for December through February, while for October through April degree-months would be 6% to 33% lower under Alternative 2A (Table 11-2A-39).

Overall, these results indicate that there would be effects of Alternative 2A on flows during the juvenile steelhead rearing period in the Feather River.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to flows under NAA during January through April and October through December, greater than flows under NAA during May and June, and lower than flows under NAA during July through September.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-2A-54). During May, June, and October, the percent of months exceeding the threshold under Alternative 2A would similar to or up to 23% lower (absolute scale) than the percent under NAA. During July through September, the percent of months exceeding the threshold would mostly be similar between NAA and Alternative 2A with three degree categories in which there would be decreases of up to 6% on an absolute scale in percent of months exceeding the threshold under Alternative 2A and one degree category in which there would be an increase of 6% on the absolute scale.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-2A-55). During May, June, and October, total degree-months would be similar between NAA and Alternative 2A or up to 14% lower under Alternative 2A. During July through September, there would be 2% to 7% increases in total degree-months exceeding the threshold.

Table 11-2A-54. Differences between Baseline and Alternative 2A Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 65°F Threshold, May through October

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2A_LLT					
May	33 (169%)	26 (175%)	20 (178%)	14 (220%)	6 (125%)
June	33 (52%)	33 (63%)	17 (42%)	11 (36%)	10 (47%)
July	0 (0%)	1 (1%)	31 (49%)	36 (100%)	38 (221%)
August	0 (0%)	2 (3%)	19 (23%)	51 (105%)	65 (212%)
September	15 (17%)	41 (77%)	53 (165%)	54 (338%)	47 (633%)
October	73 (1,475%)	47 (1,900%)	36 (NA)	20 (NA)	11 (NA)
NAA vs. A2A_LLT					
May	-11 (-17%)	-9 (-18%)	-9 (-22%)	-12 (-38%)	-6 (-36%)
June	-1 (-1%)	-5 (-5%)	-23 (-29%)	-23 (-36%)	-17 (-36%)
July	0 (0%)	0 (0%)	-4 (-4%)	0 (0%)	0 (0%)
August	0 (0%)	0 (0%)	0 (0%)	2 (3%)	6 (7%)
September	0 (0%)	-4 (-4%)	0 (0%)	-4 (-5%)	-6 (-10%)
October	-2 (-3%)	-16 (-25%)	-10 (-22%)	-10 (-33%)	0 (0%)

NA = could not be calculated because the denominator was 0.

Table 11-2A-55. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 65°F in the American River at the Watt Avenue Bridge, May through October

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
May	Wet	20 (333%)	-1 (-4%)
	Above Normal	21 (NA)	-6 (-22%)
	Below Normal	17 (567%)	-6 (-23%)
	Dry	22 (100%)	-12 (-21%)
	Critical	33 (174%)	1 (2%)
	All	113 (226%)	-24 (-13%)
June	Wet	45 (265%)	-23 (-27%)
	Above Normal	19 (79%)	-13 (-23%)
	Below Normal	27 (93%)	-11 (-16%)
	Dry	34 (50%)	-6 (-6%)
	Critical	46 (92%)	-4 (-4%)
	All	170 (90%)	-58 (-14%)
July	Wet	56 (72%)	7 (6%)
	Above Normal	13 (48%)	7 (21%)
	Below Normal	28 (82%)	7 (13%)
	Dry	63 (102%)	12 (11%)
	Critical	46 (57%)	0 (0%)
	All	207 (73%)	34 (7%)
August	Wet	104 (132%)	-4 (-2%)
	Above Normal	37 (90%)	4 (5%)
	Below Normal	52 (93%)	15 (16%)
	Dry	95 (140%)	14 (9%)
	Critical	69 (87%)	5 (3%)
	All	356 (110%)	33 (5%)
September	Wet	80 (333%)	6 (6%)
	Above Normal	42 (263%)	6 (12%)
	Below Normal	49 (175%)	2 (3%)
	Dry	81 (193%)	-5 (-4%)
	Critical	53 (108%)	0 (0%)
	All	305 (192%)	9 (2%)
October	Wet	49 (4,900%)	-5 (-9%)
	Above Normal	27 (NA)	1 (4%)
	Below Normal	37 (NA)	-2 (-5%)
	Dry	37 (NA)	0 (0%)
	Critical	30 (600%)	0 (0%)
	All	179 (2,983%)	-7 (-4%)

NA = could not be calculated because the denominator was 0.

Overall, these results indicate that effects of Alternative 2A on juvenile steelhead rearing habitat in the American River would be biologically meaningful during summer months.

Stanislaus River

Flows in the Stanislaus River under Alternative 2A would not differ from those under NAA throughout the year (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Mean monthly water temperatures throughout the Stanislaus River would be similar under NAA and Alternative 2A throughout the year-round period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River under Alternative 2A would not differ from those under NAA throughout the year (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River under Alternative 2A would not differ from those under NAA throughout the year (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, it is concluded that the effect of Alternative 2A is adverse relative to NAA because it has the potential to substantially reduce rearing habitat. There would be small to moderate reductions in flows during substantial portions of the juvenile steelhead rearing period in the Sacramento, Feather, and American rivers. SacEFT predicts a small reduction in rearing habitat availability in the Sacramento River. There would be no effect on water temperatures in these rivers. Further, there would be no change in flows in any other river or on water temperature in the Stanislaus River.

CEQA Conclusion: In general, Alternative 2A would reduce the quantity and quality of steelhead rearing habitat relative to Existing Conditions.

Sacramento River

Year-round Sacramento River flows within the reach where the majority of steelhead spawning and juvenile rearing occurs (Keswick Dam to upstream of RBDD) were evaluated (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during October and between December and July under A2A_LLT would generally be similar to or greater than those under Existing Conditions. Flows during August, September and November would generally be lower under A2A_LLT than under Existing Conditions.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, mean monthly water temperatures under Alternative 2A would generally be similar to those under Existing Conditions, except during July through October, in which there would be 5% to 10% higher temperatures under Alternative 2A.

SacEFT predicts that there would be a 15% decrease in the percentage of years with good rearing availability, measured as weighted usable area, under A2A_LLT relative to Existing Conditions (Table 11-2A-49). SacEFT predicts that there would be a substantial reduction (-47%) in the number of years with good (lower) juvenile stranding risk under A2A_LLT relative Existing Conditions.

Overall, these results indicate that Alternative 2A would have biologically meaningful effects on juvenile rearing success in the Sacramento River. Alternative 2A would cause small reductions in mean monthly flows during three months of the year and SacEFT predicts that juvenile habitat area would be reduced and stranding risk would be substantially increased by 47% Water temperatures would be higher during 4 of 12 months.

Clear Creek

Flows in Clear Creek during the year-round rearing period under A2A_LLT would generally be similar to or greater than flows under Existing Conditions, except for critical years in February and August through December in which flows would be 6% to 29% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Juvenile rearing habitat is assumed to increase in Clear Creek as instream flows increase, and therefore the use of the lowest monthly instream flow as an index of habitat constraints for juvenile rearing was selected for use in this analysis. Results of the analysis of minimum monthly instream flows affecting juvenile rearing habitat are shown in Table 11-2A-53. Results indicate that Alternative 2A would have no effect on juvenile rearing habitat, based on minimum instream flows, compared to Existing Conditions in wet and above normal water years. Minimum flows would be 21% greater in below normal years and 100% lower in dry and critical years (reduction from 50 cfs to 0 cfs.

Denton (1986) developed flow recommendations for steelhead in Clear Creek using IFIM (Figure 11-1A-4). The current Clear Creek management regime uses flows slightly lower than those recommended by Denton. Results from a new IFIM study on Clear Creek are currently being analyzed. Depending on results of this study the flow regime could be adjusted in the future. We expect that the modeled flows will be suitable for the existing steelhead populations in Clear Creek. No change in effect on steelhead in Clear Creek is anticipated.

Overall in Clear Creek, Alternative 2A would result in no biologically meaningful changes in mean monthly flow that would affect juvenile rearing habitats.

Feather River

The low-flow channel is the primary reach of the Feather River utilized by steelhead spawning and rearing (Cavallo et al. 2003). There would be no change in flows for Alternative 2A relative to Existing Conditions in the low-flow channel during the year-round steelhead juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). In the high flow channel (at Thermalito Afterbay), flows under A2A_LLT would be mostly lower (up to 50%) during February July, August, November, and December, and mostly similar to or greater (up to 217%) than flows under Existing Conditions in other months.

May Oroville storage volume under A2A_LLT would be lower than Existing Conditions by 6% to 21% depending on water year type, except in wet years, in which storage would be similar to Existing Conditions (Table 11-2A-28).

As reported in Impact AQUA-58 for spring-run Chinook salmon, September Oroville storage volume would be 7% to 36% lower under A2A_LLT relative to Existing Conditions depending on water year type (Table 11-2A-25).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under Alternative 2A would be similar to those under Existing Conditions between April and August, but would be 5% to 10% higher between October and March. In the high-flow channel, mean monthly water temperatures under Alternative 2A would be similar to those under Existing Conditions between April through June and September, but would be 5% to 9% higher in the remaining eight months.

An additional analysis evaluated the percent of months exceeding a 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) (May through August) and exceeding a 56°F threshold at Gridley (October through April) for each model scenario. In the low-flow channel, the percent of months exceeding the threshold under Alternative 2A would generally be similar to the percent under Existing Conditions during May, and similar or up to 51% (absolute scale) higher than the percent under Existing Conditions during June through August (Table 11-2A-29). At Gridley, the percent of months exceeding the threshold under Alternative 2A would similar to the percent under Existing Conditions during December through February, but similar to or up to 47% greater (absolute scale) than the percent under Existing Conditions in the remaining 4 months (Table 11-2A-38).

Total degree-months exceeding 56°F were summed by month and water year type in the Feather River above Thermalito Afterbay (low-flow channel) (May through August) at Gridley during October through April. In the low-flow channel, total degree-months under Alternative 2A would be similar to those under Existing Conditions during May and 51% to 159% higher during June through August (Table 11-2A-30). At Gridley, total degree-months under Alternative 2A would be similar to those under Existing Conditions during December through and February and 18% to 2500% greater than those under Existing Conditions in the remaining months of the period (Table 11-2A-39).

Overall, these results indicate that Alternative 2A would affect juvenile steelhead rearing conditions in the Feather River. Fish rearing in the high-low channel would experience lower flows during multiple months and fish rearing in both the low- and high-flow channels would experience increased exceedances of water temperature thresholds.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 27% greater than to flows under Existing Conditions during February March, and June, similar to flows under Existing Conditions during April and October, and up to 56% lower than flows under Existing Conditions during the remaining seven months of the year.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results* *utilized in the Fish Analysis*). There would be temperature increases (>5%) of 5% to 13% in most water year types in most months although only in one water year in June and in two water years in July between Existing Conditions and Alternative 2A.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-2A-54). In comparison to Existing Conditions the temperatures would be exceeded under Alternative 2A in all degree categories in all months (by 2% to 73% on the absolute scale) except for the > 1°F category during July and August.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-2A-55). During all months, total degree-months would be higher under Alternative 2A compared to Existing Conditions by 48% to 4900%.

Overall, these results indicate that there would be substantial effects of Alternative 2A on juvenile steelhead rearing habitat in the American River during many months of the year.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be flow reductions (up to 36%) under Alternative 2A relative to Existing Conditions in all months.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the year-round juvenile steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 5% to 6% higher in all months except June, July, and October.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be 5% to 33% lower than flows under Existing Conditions during March through October, similar to flows under Existing Conditions during November through February. Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be similar to flows under Existing Conditions during March, up to 14% greater than flows under Existing Conditions during December through February, and up to 46% lower than flows under Existing Conditions during April through November.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results indicate that the effect is significant because the alternative could substantially reduce juvenile rearing habitat. Alternative 2A would cause reduced juvenile steelhead rearing habitat conditions based primarily on flow reductions in the Sacramento, Feather, American, Stanislaus, San Joaquin, and Mokelumne rivers and degraded temperature conditions in the Sacramento, Feather, American, and Stanislaus Rivers. These flow reductions and temperature increases would affect the quantity and quality of juvenile rearing habitat and would contribute to reduced survival and increased stress.

Alternative 2A would cause reduced juvenile steelhead rearing habitat conditions in each of the rivers analyzed, based on flow reductions, particularly in drier water year types, in much of the year and increased exposure to water temperatures above critical thresholds in the Feather River. These flow reductions and temperature increases would affect the quantity and quality of juvenile rearing habitat and would contribute to reduced survival and increased stress, particularly in drier water years. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-95a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Steelhead to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat.

Although analysis conducted as part of the EIR/EIS determined that Alternative 2A would have significant and unavoidable adverse effects on rearing habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on rearing habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2A.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2A operations only. Development of mitigation actions for the incremental impact on rearing habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2A.

Mitigation Measure AQUA-95b: Conduct Additional valuation and Modeling of Impacts on Steelhead Rearing Habitat Following Initial Operations of CM1.

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to rearing habitat under Alternative 2A. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-95c: Consult with NMFS, USFWS and CDFW to Identify Potentially Feasible Means to Minimize Effects on Steelhead Habitat Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on steelhead habitat, the BDCP proponents will consult with NMFS, USFWS and CDFW to identify any feasible operational means to minimize effects on rearing habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-95a.

If feasible means are identified to reduce impacts on rearing habitat consistent with the overall operational framework of Alternative 2A without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on steelhead habitat is not feasible under Alternative 2A operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on steelhead would remain significant and unavoidable.

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

In general, Alternative 2A would reduce steelhead migration conditions relative to NAA.

Upstream of the Delta

Sacramento River

Juveniles

Flows in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period. Flows under A2A_LLT would be 5% to 17% lower than flows under NAA during October depending on water year type and would be up to 13% higher during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT in the remaining six months of the migration period would be similar to flows under NAA.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Adults

Flows in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be 5% to 17% lower than flows under NAA during October depending on water year type and similar to flows under NAA in the remaining six months of the period.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period

Kelts

Flows in the Sacramento River upstream of Red Bluff were evaluated during the March and April steelhead kelt (post-spawning adult) downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during these two months would not differ between NAA and A2A_LLT.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period

Overall, these results indicate that juvenile, adult, or kelt steelhead migration conditions in the Sacramento River would not be affected by Alternative 2A.

Clear Creek

Water temperatures were not modeled in Clear Creek.

Juveniles

Flows in Clear Creek during the October through May juvenile steelhead migration period under A2A_LLT would generally be similar to or greater than flows under NAA except in critical years during February (6% lower), and in below normal years in March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows in Clear Creek during the September through March adult steelhead migration period under A2A_LLT would generally be similar to flows under NAA except in critical years during February (6% lower), and in below normal years in March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Kelt

Flows in Clear Creek during the March through April steelhead kelt downstream migration period under A2A_LLT would generally be similar to flows under NAA except in below normal years in March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall, these results indicate that juvenile, adult, or kelt steelhead migration conditions in Clear Creek would not be affected by Alternative 2A.

Feather River

Juveniles

Flows in the Feather River at the confluence with the Sacramento River were examined during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to or greater than flows under NAA in all months and water years except during November in above normal years (8% lower).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Adults

Flows in the Feather River at the confluence with the Sacramento River were examined during the September through March adult steelhead upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 33% lower than flows under NAA during September, up to 32% higher than flows under NAA during October, and generally similar to flows under NAA in the remaining five months of the period.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period

Kelt

Flows in the Feather River at the confluence with the Sacramento River were examined during the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be similar to those under NAA in March and up to 20% greater than flows under NAA in April.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Overall, these results indicate that there would be negligible effects of Alternative 2A on steelhead juvenile, adult, and kelt migration conditions. There would be some flow-based beneficial effects in some months.

American River

Juveniles

Flows in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period. Flows under A2A_LLT would generally be similar to flows under NAA except in wet and above normal water years during October (10% and 7% lower, respectively), critical water years during November (9% lower), and dry and critical water years during March (6% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Adults

Flows in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 19% lower depending on water year type than flows under NAA during September and generally similar to flows under NAA in the remaining six months of the period.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Kelt

Flows in the American River at the confluence with the Sacramento River were evaluated for the March and April kelt migration period. Flows under A2A_LLT would generally be similar to flows under NAA except in dry and critical years during March (6% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Overall in the American River, these results indicate that Alternative 2A would not affect juvenile, adult, or kelt steelhead migration in a biologically meaningful way.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River for Alternative 2A are not different from flows under NAA for any month. Therefore, there would be no effect of Alternative 2A on juvenile, adult, or kelt migration in the Stanislaus River.

Further, mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River for Alternative 2A are not different from flows under NAA for any month. Therefore, there would be no effect of Alternative 2A on juvenile, adult, or kelt migration in the Stanislaus River.

San Joaquin River

Flows in the San Joaquin River at Vernalis for Alternative 2A are not different from flows under NAA for any month. Therefore, there would be no effect of Alternative 2A on juvenile, adult, or kelt migration in the San Joaquin River.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta for Alternative 2A are not different from flows under NAA for any month. Therefore, there would be no effect of Alternative 2A on juvenile, adult, or kelt migration in the Mokelumne River.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

The approach for steelhead impact assessment is similar to that for Chinook salmon (see Impact AQUA-42 above for description of the approach). Although steelhead have a similar life history to salmon, there are a few marked differences: juvenile steelhead spend from 1 to 3 years rearing in upstream habitats and migrate downstream as larger juveniles (usually >200 mm) compared to Chinook salmon, and adults do not necessarily die after spawning but can return to the ocean to grow and reproduce again. Adults can return one to three times before dying. The post-spawned adult life stage is termed a kelt and is unique to steelhead.

Overall, juvenile steelhead can be found in the Delta during most months of the year, but the outmigration spans from October through May with a peak outmigration period in February and March. Adult steelhead can also be found in the Delta almost year round with the adult upstream migration from September through March with a peak December through February. The kelt outmigration follows on the upstream migration and spawning and therefore is January through April. Olfactory cues for upstream migrating adults were assessed using fingerprinting analysis to estimate the percentage of source water from the Sacramento and San Joaquin Rivers

Sacramento River

Juveniles

Flows in the Sacramento River below the north Delta intakes during the juvenile steelhead migration period (October through May) under Alternative 2A would be similar to NAA. Juvenile steelhead and juvenile winter-run Chinook salmon migrate downstream during the same months and would be exposed to similar conditions. As discussed above in Impact AQUA-42, the five north Delta intakes structures of Alternative 1A would increase potential predation loss of migrating juvenile salmonids and would displace 22 acres of aquatic habitat. However, juvenile steelhead would be less vulnerable than winter-run Chinook salmon to predation associated with the intake facilities because of their greater size and strong swimming ability.

Adults

For Sacramento River steelhead, straying rates of adult hatchery-origin Chinook salmon that were released upstream of the Delta are low (Marston et al. 2012). Although straying rates for hatchery-origin steelhead apparently have not been examined in detail, for this analysis of effects, it was assumed with high certainty (based on Chinook salmon rates), that Plan Area flows in relation to straying have low importance under Existing Conditions for adult Sacramento River region steelhead.

As assessed by DSM2 fingerprinting analysis, the average percentage of Sacramento River–origin water at Collinsville was always slightly lower under Alternative 2A than for NAA during the September-March steelhead upstream migration period. Attraction flow, as estimated by the percentage of Sacramento River water at Collinsville, under Alternative 2A increased 13% in September and declined 1% to 9% during the October to March migration period for steelhead adults (Table 11-2A-56). The reductions in percentage are small in comparison with the magnitude of change in dilution reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect winter-run migration. While the proportion of Sacramento River flows would be reduced under Alternative 2A, the Sacramento River would still represent a substantial 62% to 78% of Delta flows and olfactory cues would still be strong for upstream migrating adults. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. For further discussion of the topic see the analysis for Alternative 1A.

Table 11-2A-56. Summary of Finger Printing Analysis of the Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Steelhead Migration Period for Alternative 2A

	Percentage of Water			Difference	
Month	EXISTING CONDITIONS	NAA	A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Sacramento River					
September	60	65	78	18	13
October	60	68	67	7	-1
November	60	66	62	2	-4
December	67	66	65	-2	-1
January	76	75	73	-3	-2
February	75	72	67	-8	-5
March	78	76	67	-11	-9
San Joaquin River					
September	0.3	0.1	1.3	1.0	1.2
October	0.2	0.3	3.6	3.4	3.3
November	0.4	1.0	5.4	5.0	4.4
December	0.9	1.0	3.0	2.1	2.0
January	1.6	1.7	3.2	1.6	1.5
February	1.4	1.5	3.8	2.4	2.3
March	2.6	2.8	6.1	3.5	3.3
	Shading indicates 10% or greater difference in flow proportion.				

San Joaquin River

Juveniles

The only changes on San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. There no flow changes associated with the Alternatives. Alternative 2A would have no effect on steelhead migration success through the Delta.

Adults

Little information currently exists as to the importance of Plan Area flows on the straying of adult San Joaquin River region steelhead, in contrast to San Joaquin River fall-run Chinook salmon (Marston et al. 2012). Although information specific to steelhead is not available, for this analysis of effects, it was assumed with moderate certainty that the attribute of Plan Area flows (including olfactory cues associated with such flows) is of high importance to adult San Joaquin River region steelhead adults as well.

The percentage of water at Collinsville that originated from the San Joaquin River during the fall-run migration period (September to December) is small, typically 0.1% to less than 3% under NAA. Alternative 2A operations conditions would incrementally increase olfactory cues associated with the San Joaquin River, which would benefit adult steelhead migrating to the San Joaquin River.

Based on DPM results for Chinook salmon, the survival of juvenile steelhead through the Delta is not expected to decrease more than 1% (Impact AQUA-42 for Alternative 2A). Therefore, Alternative 2A would not negatively affect juvenile steelhead migration though the Delta. Based on expected Sacramento and San Joaquin River flows, adult steelhead olfactory cues and flows would be about the same for Alternatives 1A and 2A, resulting in similar impacts to adult steelhead upstream migration and kelt downstream migration. Therefore, Alternative 2A would not have a negative effect on adult, juvenile, or kelt steelhead migration through the Delta.

NEPA Effects: Overall, the results indicate that the effect of Alternative 2A is adverse due to the cumulative effects associated with five north Delta intake facilities, including mortality related to near-field effects (e.g. impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes.

Upstream of the Delta, flow and water temperature conditions during juvenile, adult, and kelt steelhead migration periods under Alternative 2A would generally be similar to those under Existing Conditions in all rivers examined.

Adult attraction flows in the Delta under Alternative 2A would be lower than those under NAA, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 2A NDD on steelhead from the Sacramento River and tributaries related to impingement and predation associated with five new intakes could result in substantial effects on juvenile migrating steelhead, although there is high uncertainty regarding the potential effects. Estimates within the effects analysis range from very low levels of effects (<2% mortality) to very significant effects (~ 19% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the five new intake structures will be implemented as part of the final NDD screen design effort. Alternative 2A also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for steelhead. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 2A predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 2A would be similar to survival rates estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon. Until these efforts are completed and their results are fully analyzed, the overall effect of Alternative 2A on steelhead through-Delta survival remains uncertain.

Therefore, primarily as a result of unacceptable levels of uncertainty regarding the cumulative impacts of near-field and far-field effects associated with the presence and operation of the five intakes on steelhead, this effect is adverse.

While the implementation of the conservation and mitigation measures described below would address these impacts, these measures are not anticipated to reduce the impact to a level considered not adverse.

CEQA Conclusion: In general, under Alternative 2A water operations, the quantity and quality of steelhead migration habitat would not be affected relative to the CEQA baseline.

Upstream of the Delta

Sacramento River

Juveniles

Flows in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period. Flows under A2A_LLT would be up to 13% lower than flows under Existing Conditions during November but would generally not differ between model scenarios for the remaining seven months of the migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento*

River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in all months but October, in which temperatures under Alternative 2A would be 6% greater than those under Existing Conditions.

Adults

Flows in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 13% lower than flows under Existing Conditions during November but would generally not differ between model scenarios for the remaining six months of the migration period.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in all months except September and October, in which temperatures under Alternative 2A would be 5% to 12% greater than those under Existing Conditions.

Kelts

Flows in the Sacramento River upstream of Red Bluff were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be similar to those under Existing Conditions except in below normal water years during March (7% lower).Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

Overall in the Sacramento River, these results indicate that there would be no biologically meaningful impacts of Alternative 2A on juvenile, adult, and kelt migration.

Clear Creek

Water temperatures were not modeled in Clear Creek.

Juveniles

Flows in Clear Creek during the October through May juvenile steelhead migration period under A2A_LLT would generally be similar to or greater than flows under Existing Conditions except in critical years during October (7% lower) and November (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows in Clear Creek during the September through March adult steelhead migration period under A2A_LLT would generally be similar to flows under Existing Conditions except in critical years during September (29% lower), October (7% lower), and November (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Kelt

Flows in Clear Creek during the March through April steelhead kelt downstream migration period under A2A_LLT would generally be similar to or greater than flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall, these results indicate that Alternative 2A would not affect juvenile, adult, or kelt migration conditions in Clear Creek.

Feather River

Juveniles

Flows in the Feather River at the confluence with the Sacramento River were examined during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 32% greater than flows under Existing Conditions during October, up to 20% lower than flows under Existing Conditions during November, and similar to flows under Existing Conditions in the remaining six months of the period.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in all months except November and December and two water years in October, in which temperatures under Alternative 2A would be 6% greater than temperatures under Existing Conditions.

Adults

Flows in the Feather River at the confluence with the Sacramento River were examined during the September through March adult steelhead upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be up to 113% greater than flows under Existing Conditions during September and October, up to 20% lower than flows under Existing Conditions during November, and similar to flows under Existing Conditions in the remaining four months of the period.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A during January through March. During November and December, temperatures under Alternative 2A would be 5% greater than temperatures under Existing Conditions. Temperatures in three water years during September and two water years during October would be 5% greater than temperatures under Existing Conditions.

Kelt

Flows in the Feather River at the confluence with the Sacramento River were examined during the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model*

Results utilized in the Fish Analysis). Flows under A2A_LLT would be similar to or up to 19% greater than flows under Existing Conditions except in below normal water years during March (18% lower).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

Overall, these results indicate that migration conditions for steelhead in the Feather River would not be affected by Alternative 2A. Flows and temperatures would be mostly similar between Existing Conditions and Alternative 2A.

American River

Juveniles

Flows in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be up to 27% greater than flows under Existing Conditions during February and March. Flows under A2A_LLT would generally be up to 33% lower than flows under Existing Conditions during November through January and May. Flows would be similar to those under Existing Conditions during October and April.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 5% to 12% higher than those under Existing Conditions in all months during the period except April when only one water year would reach the 5% value.

Adults

Flows in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would generally be up to 27% greater than flows under Existing Conditions during February and March. Flows under A2A_LLT would generally be up to 33% lower than flows under Existing Conditions during September and November through January. Flows would be similar to those under Existing Conditions during October.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 5% to 12% higher than those under Existing Conditions in all months during the period.

Kelt

Flows in the American River at the confluence with the Sacramento River were evaluated for the March and April kelt migration period. Flows under A2A_LLT would generally be up to 14% greater than flows under Existing Conditions during March and generally similar to flows under Existing Conditions during April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March and April kelt migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 5% higher than those under Existing Conditions in March but temperatures would be similar between Existing Conditions and Alternative 2A during April.

Overall, these results indicate that Alternative 2A would reduce juvenile and adult migration conditions during a portion of their respective migration periods, but not kelt migration.

Stanislaus River

Juveniles

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under Alternative 2A would be 6% to 16% lower than flows under Existing Conditions depending on month except during January, in which there would be no difference.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the October through May steelhead juvenile downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 6% higher than those under Existing Conditions in all months during the period except October, in which temperature would be similar between Existing Conditions and Alternative 2A.

Adults

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under Alternative 2A would be 6% to 16% lower than flows under Existing Conditions depending on month, except during January, in which there would be no differences.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 6% higher than those under Existing Conditions in all months during the period except October, in which temperature would be similar between Existing Conditions and Alternative 2A.

Kelt

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under Alternative 2A would be 8% to 11% lower than flows under Existing Conditions during March and April, respectively.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under Alternative 2A would be 6% higher than those under Existing Conditions during March and April.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Juveniles

Flows in the San Joaquin River at Vernalis were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under Alternative 2A would 5% greater than flows under Existing Conditions during January, 5% lower during October and in drier years during March, April, and May, and similar in the remaining 3 months of the period.

Adults

Flows in the San Joaquin River at Vernalis were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under Alternative 2A would 5% greater than flows under Existing Conditions during January, 8% lower during September and in drier years during March, and similar in the remaining 4 months of the period.

Kelt

Flows in the San Joaquin River at Vernalis were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under Alternative 2A would be similar to flows under Existing Conditions during wet and above normal water years and up to 16% lower during below normal, dry, and critical years in both March and April.

Mokelumne River

Water temperature modeling was not conducted in the Mokelumne River.

Juveniles

Flows in the Mokelumne River at Delta were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under Alternative 2A would be similar to flows under Existing Conditions during March, 5% to 12% lower than flows under Existing Conditions during October, November, April, and May, and 12% to 14% higher than flows under Existing Conditions during December through February.

Adults

Flows in the Mokelumne River at Delta were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under Alternative 2A would be similar to flows under Existing Conditions during March, 5% to 27% lower than flows under Existing Conditions during September, October, and November, and 12% to 14% higher than flows under Existing Conditions during December through February.

Kelt

Flows in the Mokelumne River at Delta were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under Alternative 2A would be similar to flows under Existing Conditions during March and 8% lower during April.

Through-Delta

Sacramento River

Juveniles

Juvenile steelhead migrating down the Sacramento River (October through May) would generally experience lower flows below the north Delta intakes compared to Existing Conditions. Through migrating juvenile Chinook salmon indicate that at these magnitudes of flow reductions predicted for Alternative 1A and 2A, juvenile survival would decrease less than 0.5%, well under the criteria of a 5% change in Delta migration survival. The five intake structures would attract predators and would displace about 22 acres of aquatic habitat.

Adults

Based on the proportion of Sacramento River flows, olfactory cues would be similar (<10% difference) to Existing Conditions for nearly all months of the year. The proportion of flows would decrease slightly in March by 11% during the post-peak period, but increase in September by 18% during the pre-peak.

San Joaquin River

Juveniles

The only changes on San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. There no flow changes associated with the Alternatives. Alternative 2A would have no effect on steelhead migration success through the Delta.

Adults

Little information apparently currently exists as to the importance of Plan Area flows on the straying of adult San Joaquin River region steelhead, in contrast to San Joaquin River fall-run Chinook salmon

(Marston et al. 2012). Although information specific to steelhead is not available, for this analysis of effects, it was assumed with moderate certainty that the attribute of Plan Area flows (including olfactory cues associated with such flows) is of high importance to adult San Joaquin River region steelhead adults as well.

The percentage of water at Collinsville that originated from the San Joaquin River during the fall-run migration period (September to December) is small, typically 0.1% to less than 3% under Existing Conditions. Alternative 2A operations conditions would incrementally increase olfactory cues associated with the San Joaquin River, which would benefit adult steelhead migrating to the San Joaquin River.

Summary of CEQA Conclusion

Collectively, these results indicate that there would be significant impacts of Alternative 2A on steelhead migration conditions because the alternative could substantially interfere with the movement of fish. Alternative 2A would have significant impacts on migration in the American, Feather, Stanislaus, San Joaquin, and Mokelumne Rivers due to flow reductions and elevated water temperatures. These effects on flows and temperatures would reduce the ability for steelhead juveniles, adult, and kelts to migrate successfully. Through-Delta juvenile steelhead survival would be reduced under Alternative 2A. Potential predation losses would increase at the five intake structures, ranging hypothetically from <2% to 19% of juveniles that reach the Delta. Approximately 22 acres of habitat would be removed for new intake structures.

With respect to the NDD intakes, implementation of CM6 and CM15 and Mitigation Measures AQUA-60a through AQUA-60c would address these impacts, but are not anticipated to reduce them to a level considered less than significant. Although implementation of *CM6 Channel Margin Enhancement* would provide habitat similar to that which would be lost, it would not necessarily be located near the intakes and therefore would not fully compensate for the lost habitat. Additionally, implementation of this measure would not fully address predation losses. *CM15 Localized Reduction of Predatory Fishes (Predator Control)* has substantial uncertainties associated with its effectiveness such that it is considered to have no demonstrable effect. Conservation measures that address habitat and predation losses, therefore, would potentially minimize impacts to some extent but not to a less than significant level. Consequently, as a result of these changes in migration conditions, this impact is significant and unavoidable.

Applicable conservation measures are briefly described below and full descriptions are found in Chapter 3, Section 3.6.2.5 Channel Margin Enhancement (CM6) and Section 3.6.3.4 Localized Reduction of Predatory Fishes (Predator Control) (CM15).

CM6 Channel Margin Enhancement. CM6 would entail restoration of 20 linear miles of channel margin by improving channel geometry and restoring riparian, marsh, and mudflat habitats on the waterside side of levees along channels that provide rearing and outmigration habitat for juvenile salmonids. Linear miles of enhancement would be measured along one side or the other of a given channel segment (e.g., if both sides of a channel are enhanced for a length of 1 mile, this would account for a total of 2 miles of channel margin enhancement). At least 10 linear miles would be enhanced by year 10 of Plan implementation; enhancement would then be phased in 5-mile increments at years 20 and 30, for a total of 20 miles at year 30. Channel margin enhancement would be performed only along channels that provide rearing and outmigration habitat for juvenile salmonids. These include channels that are protected by federal project levees—including the Sacramento River between Freeport and Walnut Grove among several others.

CM15 Localized Reduction of Predatory Fishes (Predator Control). CM15 would seek to reduce populations of predatory fishes at specific locations or modify holding habitat at selected locations of high predation risk (i.e., predation "hotspots"). This conservation measure seeks to benefit covered salmonids by reducing mortality rates of juvenile migratory life stages that are particularly vulnerable to predatory fishes. Predators are a natural part of the Delta ecosystem. Therefore, this conservation measure is not intended to entirely remove predators at any location, or substantially alter the abundance of predators at the scale of the Delta system. This conservation measure would also not remove piscivorous birds. Because of uncertainties regarding treatment methods and efficacy, implementation of CM15 would involve discrete pilot projects and research actions coupled with an adaptive management and monitoring program to evaluate effectiveness. Effects would be temporary, as new individuals would be expected to occupy vacated areas; therefore, removal activities would need to be continuous during periods of concern. CM15 also recognizes that the NDD intakes would create new predation hotspots.

In addition to the conservation measures, the mitigation measures identified below would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures. However, this would not necessarily result in a less than significant determination.

Mitigation Measure AQUA-96a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Steelhead to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Although analysis conducted as part of the EIR/EIS determined that Alternative 2A would have significant and unavoidable adverse effects on migration habitat, this conclusion was based on the best available scientific information at the time and may prove to have been over- or understated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on migration habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2A.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2A operations only. Development of mitigation actions for the incremental impact on migration habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2A.

Mitigation Measure AQUA-96b: Conduct Additional Evaluation and Modeling of Impacts on Steelhead Migration Conditions Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to migration habitat under Alternative 2A. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-96c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Steelhead Migration Conditions Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on steelhead habitat, the BDCP proponents will consult with FWS and the Department of Fish and Wildlife to identify and implement any feasible operational means to minimize effects on migration habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-96a.

If feasible means are identified to reduce impacts on migration habitat consistent with the overall operational framework of Alternative 2A without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on steelhead habitat is not feasible under Alternative 2A operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on steelhead would remain significant and unavoidable.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 2A has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for steelhead under Alternative 1A (Impact AQUA-97 through AQUA-99) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

NEPA Effects: All three of these impact mechanisms have been determined to result in no adverse effects on steelhead for NEPA purposes. Specifically for AQUA-98, the effects of contaminants on steelhead with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on steelhead are uncertain.

CEQA Conclusion: All three of these impact mechanisms would be considered less than significant on steelhead, for the reasons identified for Alternative 1A, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 2A has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for steelhead under Alternative 1A (Impact AQUA-100 through AQUA-108) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (CM12)

Impact AQUA-101: Effects of Invasive Aquatic Vegetation Management on Steelhead (CM13)

Impact AQUA-102: Effects of Dissolved Oxygen Level Management on Steelhead (CM14)

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (CM15)

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (CM16)

Impact AQUA-105: Effects of Illegal Harvest Reduction on Steelhead (CM17)

Impact AQUA-106: Effects of Conservation Hatcheries on Steelhead (CM18)

Impact AQUA-107: Effects of Urban Stormwater Treatment on Steelhead (CM19)

Impact AQUA-108: Effects of Removal/Relocation of Nonproject Diversions on Steelhead (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on steelhead for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on steelhead, for the reasons identified for Alternative 1A, and no mitigation is required.

Sacramento Splittail

Construction and Maintenance of CM1

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

The potential effects of construction of the water conveyance facilities on Sacramento splittail would be similar to those described for Alternative 1A (Impact AQUA-109) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. As concluded for Alternative 1A, Impact AQUA-109, the effect would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-109, the impact of the construction of water conveyance facilities on Sacramento splittail would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

The potential effects of the maintenance of water conveyance facilities under Alternative 2A would be the same as those described for Alternative 1A (see Impact AQUA-110). As concluded in Alternative 1A, Impact AQUA-110, the effect would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-110, the impact of the maintenance of water conveyance facilities on Sacramento splittail would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Water Exports from SWP/CVP South Delta Facilities

Under Alternative 2A, total entrainment of juvenile splittail at the south Delta facilities (estimated from Yolo Bypass inundation) averaged across all years would be expected to be 211% greater than NAA, and 1,315% greater in above normal years (Table 11-2A-57). However, this increase is entirely due to the substantial increase in juvenile splittail abundance resulting from additional floodplain habitat in wetter water year types. The per capita rate of splittail entrainment averaged across all years would be reduced 47% for juveniles (Table 11-2A-58) and reduced 68% for adults (Table 11-2A-59). Per capita entrainment would be most reduced in wet water years (61% reduction for juveniles, 91% reduction for adults) and least reduced in below normal water years (26% reduction) for juveniles and critical water years (20%) for adults. The decrease in per capita entrainment of splittail is due to reductions in south Delta water exports during the main May–June entrainment period.

Table 11-2A-57. Juvenile Sacramento Splittail Entrainment Index[a] (Yolo Bypass Days of Inundation Method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 2A

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	2,606,381 (272%)	2,419,722 (211%)
Above Normal	479,962 (1,049%)	488,567 (1,315%)
Below Normal	12,772 (374%)	13,204 (442%)
Dry	1,312 (46%)	1,657 (65%)
Critical	-267 (-18%)	184 (17%)
All Years	899,081 (288%)	841,372 (227%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on normalized data, estimated from Yolo Bypass Inundation Method.

Table 11-2A-58. Juvenile Sacramento Splittail Entrainment Index[a] (per Capita Method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 2A

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-1,353,127 (-68%)	-1,028,808 (-61%)
Above Normal	-72,034 (-54%)	-54,202 (-47%)
Below Normal	-2,786 (-28%)	-2,468 (-26%)
Dry	-989 (-49%)	-499 (-33%)
Critical	-566 (-42%)	-308 (-29%)
All Years	-309,989 (-57%)	-208,441 (-47%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on normalized data, estimated from delta inflow.

Table 11-2A-59. Adult Sacramento Splittail Entrainment Index[a] (Salvage Density Method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 2A

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-3,600 (-91%)	-3,736 (-91%)

Below Normal	-1,770 (-52%)	-1,505 (-48%)
Dry	-818 (-33%)	-653 (-29%)
Critical	-861 (-26%)	-639 (-20%)
All Years	-2,390 (-69%)	-2,312 (-68%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on normalized data. Average (December–March).

Water Exports from SWP/CVP North Delta Intake Facilities

The impact from entrainment of splittail to the proposed SWP/CVP north Delta intakes is the same as Impact AQUA-111 under Alternative 1A. Splittail larvae would be vulnerable to entrainment to these intakes, although little is known about their densities around this vicinity. Entrainment and impingement monitoring would be implemented to determine the extent to which splittail larvae are present.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The effect of implementing dual conveyance for the NBA with an alternative Sacramento River intake would be the same as described under Alternative 1A (Impact AQUA-111). Reduced pumping from Barker Slough could reduce entrainment losses of larval splittail produced in the Yolo Bypass. There would be potential for increased predation and impingement risk associated with the alternative intake, which would be screened to exclude splittail greater than 10 mm.

Predation Associated with Entrainment

As described for Alternative 1A (Impact AQUA-111), Sacramento splittail predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Per capita splittail entrainment at the south Delta would be reduced under Alternative 2A by 47% compared to NAA; predation losses would be expected to decrease at a similar proportion.

The impact from potential predation associated with the north Delta intake structures (5 intakes) would be the same as described for Alternative 1A (Impact AQUA-111). Potential predation at the north Delta would be partially offset by reduced predation loss at the SWP/CVP south Delta intakes and the increased production of juvenile splittail resulting from CM2 actions (Yolo Bypass Fisheries Enhancement). Further, the fishery agencies concluded that predation was not a factor currently limiting splittail abundance.

NEPA Effects: The effect of Alternative 2A on entrainment and predation loss would not be adverse, because while predation loss of splittail would be increased, it would be offset by the substantial reductions in per capita entrainment risk at the south Delta facilities and the increased production of juvenile splittail under CM2 (Yolo Bypass Fisheries Enhancement).

CEQA Conclusion: Operational activities associated with decreased water exports from SWP/CVP south Delta facilities would result in an overall decrease in the proportion of the splittail population entrained. However, operational activities associated with reduced south Delta water exports would result in an overall decrease in the proportion of splittail population entrained for all water year types. Estimated per capita juvenile entrainment to the south Delta facilities would be reduced 57% while adult per capita entrainment would be reduced 69% relative to Existing Conditions. At the proposed north Delta facilities, Sacramento splittail would be subject to larval entrainment and impingement, and predation losses at the same levels described for Alternative 1A (Impact AQUA-111).

In conclusion, the impact from entrainment and predation loss would be less than significant, because increase in predation losses at the north Delta under Alternative 2A would be offset by the substantial reduction in south Delta entrainment losses and the increased production of juvenile splittail from CM2 actions. No mitigation would be required.

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

In general, Alternative 2A would have beneficial effects on splittail spawning habitat relative to NAA by increasing the quantity and quality of spawning habitat in the Yolo Bypass. There would be negligible effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River, and negligible effects on water temperatures in the Feather River, relative to NAA. There would be beneficial effects on spawning conditions in channel margin and side-channel habitats from increases in mean monthly flow during the spawning period in both the Sacramento River and the Feather River. There would also be a beneficial effect from reductions in the occurrence of critical high water temperatures in the Feather River in wetter water year types.

Sacramento splittail spawn in floodplains and channel margins and in side-channel habitat upstream of the Delta, primarily in the Sacramento River and Feather River. Floodplain spawning overwhelmingly dominates production in wet years. During low-flow years when floodplains are not inundated, spawning in side channels and channel margins would be much more critical.

Floodplain Habitat

Effects of Alternative 2A on floodplain spawning habitat were evaluated for Yolo Bypass. Increased flows into Yolo Bypass may reduce flooding and flooded spawning habitat to some extent in the Sutter Bypass (the upstream counterpart to Yolo Bypass) but this effect was not quantified. Effects in Yolo Bypass were evaluated using a habitat suitability approach based on water depth (2 m threshold) and inundation duration (minimum of 30 days). Effects of flow velocity were ignored because flow velocity was generally very low throughout the modeled area for most conditions, with generally 80 to 90% of the total available area having flow velocities of 0.5 foot per second or less (a reasonable critical velocity for early life stages of splittail; Young and Cech 1996).

The proposed changes to the Fremont Weir would increase the frequency and duration of Yolo Bypass inundation events compared to NAA, especially for dry and critical year types; the changes are attributable to the influence of the Fremont Weir notch at lower flows. Only the inundation events lasting more than 30 days are considered biologically beneficial to splittail, so are the focus of the analyses provided here. A2A_LLT compared to NAA for the drier type years (below normal, dry, and critical), results in no change or an increase in frequency for events greater than 30 days compared to NAA over the 82-year simulation period (Figure 11-2A-4, Table 11-2A-60). For below normal years, Alternative 2A would result in occurrence of 2 inundation events ≥70 days, compared to 0 such events for NAA. For dry and critical years, project-related increases are for 30–49 day duration events as there are no events of longer duration. These results indicate that overall project-related effects on occurrence of various duration inundation events would be beneficial for splittail spawning by creating better spawning habitat conditions.

Table 11-2A-60. Differences in Frequencies of Inundation Events (for 82-Year Simulations) of Different Durations on the Yolo Bypass under Different Scenarios and Water Year Types, February through June, from 15 2-D and Daily CALSIM II Modeling Runs

Number of Days of Continuous Inundation	Change in Number of Inundation Events for Each Scenario	
	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
30–49 Days		
Wet	-5	-3
Above Normal	0	0
Below Normal	4	4
Dry	1	1
Critical	1	1
50–69 Days		
Wet	-5	-5
Above Normal	1	1
Below Normal	0	0
Dry	0	0
Critical	0	0
≥70 Days		
Wet	8	7
Above Normal	1	1
Below Normal	2	2
Dry	0	0
Critical	0	0

There would be increases in area of suitable splittail habitat in Yolo Bypass under A2A_LLT ranging from 5 to 949 acres relative to NAA. Areas under A2A_LLT would be 56%, 60%, and 196% greater than areas under NAA in wet, above normal, and below normal water years, respectively (Table 11-2A-61). There would also be increases in area under A2A_LLT in dry and critical years relative to NAA, but they would be minimal (14 and 5 acres, respectively). These results indicate that increases in inundated acreage in each water year type would result in increased habitat and have a beneficial effect on splittail spawning.

Table 11-2A-61. Increase in Splittail Weighted Habitat Area (Acres and Percent) in Yolo Bypass from Existing Biological Conditions to Alternative 2A by Water Year Type from 15 2-D and Daily CALSIM II Modeling Runs

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	1,088 (70%)	949 (56%)
Above Normal	698 (61%)	690 (60%)
Below Normal	245 (187%)	249 (196%)
Dry	14 (NA)	14 (NA)
Critical	5 (NA)	5 (NA)

NA = percent differences could not be computed because no splittail weighted habitat occurred in the bypass for NAA and EXISTING CONDITIONS in those years (dividing by 0).

A potential adverse effect of Alternative 2A that is not included in the modeling is reduced inundation of the Sutter Bypass as a result of increased flow diversion at the Fremont Weir. The Fremont Weir notch with gates opened would increase the amount Sacramento River flow diverted from the river into the bypass when the river's flow is greater than about 14,600 cfs (Munévar pers. comm.). As much as about 6,000 cfs more flow would be diverted from the river with the opened notch than without the notch, resulting in a 6,000 cfs decrease in Sacramento River flow at the weir. A decrease of 6,000 cfs in the river, according to rating curves developed for the river at the Fremont Weir, could result in as much as 3 feet of reduction in river stage (Munévar pers. comm.), although understanding of how notch flows would affect river stage is incomplete (Kirkland pers. comm.). In any case, a lower river stage at the Fremont Weir would be expected to result in a lower level of inundation in the lower Sutter Bypass. Because of the uncertainties regarding how drawdown of the river will propagate, the relationship between notch flow and the magnitude of lower Sutter Bypass inundation is poorly known. Despite this uncertainty, it is evident that *CM2 Yolo Bypass Fisheries Enhancement* has the potential to reduce some of the habitat benefits of Yolo Bypass inundation on splittail production due to effects on Sutter Bypass inundation. Splittail use the Sutter Bypass for spawning and rearing as they do the Yolo Bypass.

Channel Margin and Side-Channel Habitat

Splittail spawning and larval and juvenile rearing also occur in channel margin and side-channel habitat upstream of the Delta. These habitats are likely to be especially important during dry years, when flows are too low to inundate the floodplains (Sommer et al. 2007). Side-channel habitats are affected by changes in flow because greater flows cause more flooding, thereby increasing availability of such habitat, and because rapid reductions in flow dewater the habitats, potentially stranding splittail eggs and rearing larvae. Effects of the BDCP on flows in years with low-flows are expected to be most important to the splittail population because in years of high-flows, when most production comes from floodplain habitats, the upstream side-channel habitats contribute relatively little production.

Effects on channel margin and side-channel habitat were evaluated by comparing flow conditions for the Sacramento River at Wilkins Slough and the Feather River at the confluence with the Sacramento River for the time-frame February through June. These are the most important months for splittail spawning and larval rearing (Sommer pers. comm.), and juveniles likely emigrate from the side-channel habitats during May and June if conditions become unfavorable.

Differences between model scenarios for monthly average flows during February through June by water-year type were determined for the Sacramento River at Wilkins Slough and for the Feather River at the confluence (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For the Sacramento River at Wilkins Slough, flows during February through April under A2A_LLT would be similar to flows under NAA. During May and June, flows under A2A_LLT would be up to 26% greater than flows under NAA, resulting in a beneficial effect on rearing conditions. Water temperature in the Sacramento River under Alternative 2A would not differ from results for Alternative 1A, which indicate that these results indicate that there would be some increases in flow (up to 26%) would have beneficial effects on splittail rearing conditions in the Sacramento River.

For the Feather River at the confluence, flows during February and March under A2A_LLT would be similar to flows under NAA. During April through June, flows under A2A_LLT would be up to 73% greater than flows under NAA, resulting in a beneficial effect on spawning conditions.

Simulated daily and monthly water temperatures in Sacramento River at Hamilton City and Feather River at the confluence with the Sacramento River, respectively were used to investigate the potential effects of Alternative 2A on the suitability of water temperatures for splittail spawning and egg incubation. A range of 45°F to 75°F was selected for evaluating the suitable range for splittail spawning and egg incubation.

There would be no biologically meaningful difference (>5% absolute scale) between NAA and Alternative 2A in the frequency of water temperatures in the Sacramento and Feather Rivers being within the suitable 45°F to 75°F regardless of water year type.

Overall, Alternative 2A would have negligible or beneficial effects on upstream spawning and rearing conditions in the upper Sacramento and Feather rivers.

Table 11-2A-62. Difference (Percent Difference) in Percent of Days or Months[a] during February to June in Which Temperature Would Be below 45°F or above 75°F in the Sacramento River at Hamilton City and Feather River at the Confluence with the Sacramento River[b]

Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)
Temperatures above 75°F		
Wet	3 (NA)	-2 (-43%)
Above Normal	0 (NA)	-9 (-100%)
Below Normal	6 (NA)	-6 (-50%)
Dry	13 (300%)	0 (0%)
Critical	13 (800%)	0 (0%)
All	7 (560%)	-3 (-27%)

NA = could not be calculated because the denominator was 0.

[a] Days were used in the Sacramento River and months were used in the Feather River.

[b] Based on the modeling period of 1922 to 2003.

Stranding Potential

As indicated above, rapid reductions in flow can dewater channel margin and side-channel habitats, potentially stranding splittail eggs and rearing larvae. Due to a lack of quantitative tools and historical data to evaluate possible stranding effects, the following provides a narrative summary of potential effects. The Yolo Bypass is exceptionally well-drained because of grading for agriculture, which likely helps limit stranding mortality of splittail. Moreover, water stage decreases on the bypass are relatively gradual (Sommer et al. 2001). Stranding of Sacramento splittail in perennial ponds on the Yolo Bypass does not appear to be a problem under Existing Conditions (Feyrer et al. 2004). Yolo Bypass improvements would be designed, in part, to further reduce the risk of stranding by allowing water to inundate certain areas of the bypass to maximize biological benefits, while keeping water away from other areas to reduce stranding in isolated ponds. Actions under Alternative 2A to increase the frequency of Yolo Bypass inundation would increase the frequency of potential stranding events. For splittail, an increase in inundation frequency would also increase the production of Sacramento splittail in the bypass. While total stranding losses may be greater under Alternative 2A than under NAA, the total number of splittail would be expected to be greater under Alternative 2A.

In the Yolo Bypass, Sommer et al. (2005) found these potential losses are offset by the improvement in rearing conditions. Henning et al. (2006) also noted the potential for stranding risk as wetlands desiccate and oxygen concentrations decline, but the seasonal timing of use by juveniles may decrease these risks. Sommer et al. (2005) addressed the question of stranding and concluded the potential improvements in habitat capacity outweighed the potential stranding problems that may exist in some years. Overall, these effects are not adverse.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. The effects of Alternative 2A on splittail spawning habitat are primarily beneficial. There would be benefits due to increased inundation in the Yolo Bypass that would increase the quantity and quality of spawning habitat there, and benefits to channel margin and side-channel habitat in the Sacramento River and Feather River from increases in mean monthly flow and decreases in high water temperatures during the spawning period.

CEQA Conclusion: In general, Alternative 2A would have beneficial effects on splittail spawning habitat relative to the Existing Conditions by increasing the quantity of spawning habitat in the Yolo Bypass through increased acreage subjected to periodic inundation. There would be negligible effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River, with some beneficial effect due to increases in mean monthly flow for some months and water year types during the spawning period. There would be negative effects on water temperatures in the Feather River relative to the Existing Conditions, but the benefits due to increased inundation in the Yolo Bypass would outweigh the detrimental effects of increased water temperatures in the Feather River because the Yolo Bypass is a more important spawning habitat to splittail than channel margin habitat in the Feather River, as evidenced by the large amount of spawning activity when inundated.

Floodplain Habitat

Comparisons of splittail weighted habitat area for Alternative 2A and Existing Conditions show relatively little difference between the two scenarios in longer-duration inundation events, with no change or relatively small increases or decreases for Alternative 2A compared to Existing Conditions (Table 11-2A-60 and Figure 11-2A-4). However, Alternative 2A would result in increased acreage of suitable spawning habitat compared to Existing Conditions (Table 11-2A-61), with increases of between 5 and 1,088 acres of suitable spawning habitat depending on water year type. Increased areas for wet, above normal, and below normal water years are predicted to be 70%, 61%, and 187%, respectively, for Alternative 2A. Comparisons for dry and critical water years indicate project-related increases of 14 and 5 acres of suitable spawning habitat, respectively, compared to 0 acres for Existing Conditions. These results indicate that Alternative 2A would have beneficial effects on splittail habitat through increasing spawning habitats.

Channel Margin and Side-Channel Habitat

Modeled flows were evaluated in the Sacramento River at Wilkins Slough for the February through June splittail spawning and early life stage rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Results indicate that Alternative 2A would have negligible effects (<5%) on channel margin and side-channel habitats during February through April with the exception of one small decrease in flow (-6%) during March in below normal years. Flows under A2A_LLT would generally be up to 42% greater than flows under Existing Conditions during May and June. These results indicate that effects of Alternative 2A on flows would generally have beneficial effects on splittail spawning and rearing conditions in the upper Sacramento River.

Flows in the Feather River at the confluence with the Sacramento River were evaluated during February through June. Flows during this period would generally be similar between Existing Conditions and A2A_LLT with some exceptions. Based on the relatively small magnitude and infrequent nature of the flow differences, the effects of Alternative 2A on flow would not have biologically meaningful effects on splittail rearing conditions in the Feather River.

There would generally be no biologically meaningful difference (>5% absolute scale) between Existing Conditions and Alternative 2A in the frequency of water temperatures in the Sacramento and Feather Rivers being within the suitable 45°F to 75°F, except in dry and critical water years (13% greater) for the 75°F threshold in the Feather River.

There would be no difference between Existing Conditions and A2A_LLT in the number of years in which temperatures would be below 45°F (Table 11-2A-62) because there are never any months with temperatures below 45°F under any scenario. Exceedances above 75°F under A2A_LLT would occur more often than under Existing Conditions in all water years except above normal. These results indicate that Alternative 2A would have negative temperature effects on splittail spawning in the Feather River and would provide benefits in wetter water year types.

Stranding Potential

Because there would be little difference in flow conditions between Alternative 2A and Existing Conditions, the project would not have biologically meaningful effects on stranding potential.

Summary of CEQA Conclusion

Overall, these results indicate that the impact is less than significant because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. No mitigation is necessary.

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

NEPA Effects: In general, Alternative 2A would have beneficial effects on splittail rearing habitat relative to NAA based on an increase in the quantity and quality of rearing habitat in the Yolo Bypass, beneficial effects on rearing conditions in channel margin and side-channel habitats in the Sacramento River and the Feather River, and reductions in the occurrence of critical high water temperatures in the Feather River in wetter water year types.

Sacramento splittail rear in floodplain and main-channel environments; the analyses of splittail weighted habitat area in Yolo Bypass and effects of flow conditions on channel margin and side-channel habitats provided in the previous impact, Impact AQUA-112, apply to rearing as well as spawning habitat for splittail. As concluded above, the effect is not adverse because it would not substantially reduce suitable rearing habitat or substantially reduce the number of fish as a result of juvenile mortality. Effects of Alternative 2A on flow would have beneficial effects on the availability of channel margin and main-channel habitat through increases in mean monthly flow for some months and water year types during the rearing period. Increased flows into Yolo Bypass may reduce flooding and flooded rearing habitat to some extent in the Sutter Bypass but would create habitat in the Yolo Bypass that would have a beneficial effect on rearing conditions.

CEQA Conclusion: In general, Alternative 2A would have beneficial effects on splittail rearing habitat relative to the Existing Conditions by increasing the quantity of rearing habitat in the Yolo Bypass, and increases in mean monthly flow for some months and water year types in the Sacramento River and the Feather River.

Project effects on splittail rearing habitat are the same as described for spawning habitat in the previous impact discussion, Impact AQUA-112. As concluded above, the impact is not significant because it would not substantially reduce suitable rearing habitat or substantially reduce the number of fish as a result of juvenile mortality and no mitigation is necessary. Effects of Alternative 2A on flow would not have negative effects on the availability of channel margin and main-channel habitat, and would have a beneficial effect through increases in mean monthly flow for some months and water year types during the rearing period. Increased flows into Yolo Bypass may reduce flooding and flooded rearing habitat to some extent in the Sutter Bypass but would create habitat in the Yolo Bypass that would have a beneficial effect on rearing conditions. Benefits to rearing habitat availability in the Yolo Bypass would outweigh negative effects of increased exposures to water temperatures above the upper threshold of 75°F in the Feather River in drier water year types.

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

Upstream of the Delta

In general, effects of Alternative 2A would not affect splittail migration conditions in the Sacramento River or the Feather River relative to NAA based on negligible or beneficial effects on mean monthly flow during the migration period and negligible or beneficial effects on water temperatures in the Feather River.

The effects of Alternative 2A on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. There would be benefits to channel margin and side-channel habitat in both locations from increases in mean monthly flow and decreases in high water temperatures compared to baseline conditions.

Through-Delta

Alternative 2A is expected to reduce OMR reverse flows during the period of juvenile splittail migration through the Delta. OMR flows are greatly improved in June and July compared to baseline conditions across all water years. While flows are decreased slightly in all water year types except wet in May, OMR flows averaged across all water years are still positive and flowing towards the San Francisco estuary.

NEPA Effects: The effect of Alternative 2A is not adverse because it would not substantially reduce or degrade migration habitat or substantially reduce the number of fish as a result of mortality. Similarly, because OMR flows are overall improved, the effect of Alternative 2A on through-Delta migration conditions for Sacramento splittail would be beneficial.

CEQA Conclusion:

Upstream of the Delta

In general, effects of Alternative 2A would not affect splittail migration conditions in the Sacramento River relative to the Existing Conditions, but would reduce the suitability of channel conditions for migration in the Feather River due to increased exposure to critical water temperatures. However, splittail spawning in the Feather River is not as important as in Yolo Bypass, and therefore, net effects from Alternative 2A on migration conditions in the Feather River would be negligible.

Effects of Alternative 2A on splittail migration conditions are the same as described for channel margin and side-channel habitats in Impact AQUA-112. As concluded above, the impact is not significant because it would not substantially reduce suitable migration habitat or substantially reduce the number of fish as a result of mortality and no mitigation is necessary. Effects of Alternative 2A on flow would not have negative effects on the availability of channel margin and main-channel habitat, and would have a beneficial effect through increases in mean monthly flow for some months and water year types during the migration period. Benefits to habitat availability in the Yolo Bypass would outweigh negative effects of increased exposures to water temperatures above the upper threshold of 75°F in the Feather River in drier water year types.

Through-Delta

As described above, average OMR flows under Alternative 2A are expected to improve during the juvenile splittail migration through the Delta, especially during the summer months. In dry and below-normal water years in May, the reverse OMR flows would be increased under Alternative 2A compared to Existing Conditions, however monthly average OMR flows would be still be slightly improved in May compared to Existing Conditions. In addition, the periods of increased reverse flows in May would remain within the NMFS and USFWS BiOp requirements, thus the changes are expected to have a less-than-significant impact. Therefore, the impact on splittail migration survival would be beneficial because of the overall improvement in OMR flows.

Summary of CEQA Conclusion

Overall, Alternative 2A would not affect splittail migration conditions in the Sacramento River relative to the Existing Conditions, the impact is not significant because it would not substantially reduce suitable migration habitat or substantially reduce the number of fish as a result of mortality and no mitigation is necessary. Similarly, Alternative 2A is expected to reduce OMR reverse flows during the period of juvenile splittail migration through the Delta, resulting in greatly improved conditions in June and July compared to baseline conditions across all water years. Therefore the impact on splittail migration survival is less than significant. No mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 2A has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for Sacramento splittail under Alternative 1A (Impact AQUA-115 through AQUA-117) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

NEPA Effects: All three of these impact mechanisms have been determined to result in no adverse effects on Sacramento splittail for NEPA purposes. Specifically for AQUA-116, the effects of contaminants on Sacramento splittail with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on Sacramento splittail are uncertain.

CEQA Conclusion: All three of these impact mechanisms would be considered less than significant on Sacramento splittail, for the reasons identified for Alternative 1A, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 2A has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for Sacramento splittail under Alternative 1A (Impact AQUA-118 through AQUA-126) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (CM12)

Impact AQUA-119: Effects of Invasive Aquatic Vegetation Management on Sacramento Splittail (CM13)

Impact AQUA-120: Effects of Dissolved Oxygen Level Management on Sacramento Splittail (CM14)

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (CM15)

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (CM16)

Impact AQUA-123: Effects of Illegal Harvest Reduction on Sacramento Splittail (CM17)

Impact AQUA-124: Effects of Conservation Hatcheries on Sacramento Splittail (CM18)

Impact AQUA-125: Effects of Urban Stormwater Treatment on Sacramento Splittail (CM19)

Impact AQUA-126: Effects of Removal/Relocation of Nonproject Diversions on Sacramento Splittail (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on Sacramento splittail for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on Sacramento splittail, for the reasons identified for Alternative 1A, and no mitigation is required.

Green Sturgeon

Construction and Maintenance of CM1

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

The potential effects of construction of the water conveyance facilities on green sturgeon would be similar to those described for Alternative 1A (Impact AQUA-127) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-127, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for green sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-127, the impact of the construction of water conveyance facilities on green sturgeon would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2A would be the same as those described for Alternative 1A (see Impact AQUA-128). As concluded in Alternative 1A, Impact AQUA-128, the effect would not be adverse for green sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-128, the impact of the maintenance of water conveyance facilities on green sturgeon would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

Water Exports from SWP/CVP South Delta Facilities

Alternative 2A is expected to substantially reduce overall entrainment of juvenile green sturgeon at the south Delta export facilities. Average annual loss of juvenile green sturgeon, as estimated by the salvage density method, would be approximately 58 fish for the combined SWP and CVP south Delta facilities (Table 11-2A-63; A2A_LLT). Losses would be slightly greater in wetter water year types (32 fish) than in drier years (26 fish). Losses would decrease 60–64% for Alternative 2A as compared to NAA. Entrainment reductions would be greater in wetter years (69–71% decrease) compared to Existing Conditions.

Water Exports from SWP/CVP North Delta Intake Facilities

The overall potential entrainment effects of operating the new north Delta intakes under Alternative 2A would be the same as described for Impact AQUA-129 under Alternative 1A. The intakes would have screens to avoid or reduce entrainment; there would be no adverse effect.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The overall potential entrainment effects of operating the dual conveyance of the North Bay Aqueduct under Alternative 2A would be the same as described for Impact AQUA-129 under Alternative 1A. The intakes would have screens to avoid or reduce entrainment; there would be no adverse effect.

Predation Associated with Entrainment

Juvenile green sturgeon predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Sturgeon develop bony scutes at a young age which reduces their predation vulnerability. The total reduction of juvenile green sturgeon entrainment, and hence predation loss, would change minimally between Alternative 2A and NAA (88 fish). Based on their early development of scutes and rapid growth rates, the number of juvenile green sturgeon lost to predation at the south Delta facilities would change negligibly between Alternative 2A and NAA. The impact and conclusion for predation risk associated with NPB structures and the north Delta intakes would be the same as described for Alternative 1A (Impact AQUA-3 for green sturgeon).

NEPA Effects: The effect on entrainment and predation losses under Alternative 2A would not be adverse, because green sturgeon grow rapidly and develop bony scutes early in their development which reduces their predation risk.

CEQA Conclusion: As described above, annual entrainment losses of juvenile green sturgeon across all years would decrease 65% under Alternative 2A (A2A_LLT) (58 fish) relative to Existing Conditions (166 fish) (Table 11-2A-63). impacts of water operations on green sturgeon would be beneficial due to an overall reduction in entrainment and no mitigation would be required.

Table 11-2A-63. Juvenile Green Sturgeon Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities for Alternative 2A

	Entrainment Index			Absolute Difference (Percent Difference)	
Water Year[b]	EXISTING CONDITIONS	NAA	A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet and Above Normal	116	104	32	-84 (-72%)	-72 (-69%)
Below Normal, Dry, and Critical	50	42	26	-24 (-48%)	-16 (-38%)
All Years	166	146	58	-108 (-65%)	-88 (-60%)

[a] Estimated annual number of fish lost.
[b] Sacramento Valley water year-types.

The impact of predation associated with entrainment would be the same as described immediately above because the rapid growth and development of bony scutes reduces the predation risk for juvenile green sturgeon. Since few juvenile green sturgeon are entrained at the south Delta, reductions in entrainment (65% reduction compared to Existing Conditions, representing 108 fish) under Alternative 2A would have little effect on entrainment-related predation loss. Overall, the impact would be less than significant, because there would be little change in predation loss under Alternative 2A.

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

In general, Alternative 2A would not affect spawning and egg incubation habitat for green sturgeon relative to NAA.

Sacramento River

Mean monthly flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon. Lower flows can reduce the instream area available for spawning and egg incubation. Flows under A2A_LLT would always be similar to or greater than flows under NAA during March through July (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). During July flows would be lower than under NAA up to 6%. Also flows can be lower or higher in individual months of individual years

These results indicate that there would be very few reductions in flows in the Sacramento River under Alternative 2A.

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The number of days on which temperature exceeded 63°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above the 63°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-64. There would be no difference in levels of concern between NAA and Alternative 2A.

Table 11-2A-64. Differences between Baseline and Alternative 2A Scenarios in the Number of Years in Which Water Temperature Exceedances above 63°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Red	11 (275%)	2 (13%)
Orange	1 (100%)	1 (50%)
Yellow	2 (100%)	-1 (-25%)
None	-14 (-19%)	-2 (-3%)

Total degree-days exceeding 63°F at Bend Bridge were summed by month and water year type during May through September (Table 11-2A-65). Total degree-days under Alternative 2A would be 22% and 11% lower than under NAA during May and June, respectively, and 8% to 17% higher during July through September.

Table 11-2A-65. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
May	Wet	38 (292%)	-17 (-25%)
	Above Normal	0 (NA)	-5 (-100%)
	Below Normal	4 (NA)	2 (100%)
	Dry	0 (NA)	0 (NA)
	Critical	4 (NA)	3 (300%)
	All	46 (354%)	-17 (-22%)
June	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	1 (NA)	1 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	6 (NA)	-12 (-67%)
	All	7 (NA)	-11 (-61%)
July	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	1 (NA)	1 (NA)
	Dry	6 (NA)	6 (NA)
	Critical	734 (9,175%)	104 (16.3%)
	All	741 (9,263%)	111 (17%)
August	Wet	3 (NA)	0 (0%)
	Above Normal	1 (NA)	1 (NA)
	Below Normal	2 (NA)	2 (NA)
	Dry	125 (NA)	59 (89%)
	Critical	1,652 (822%)	91 (5%)
	All	1,783 (887%)	153 (8%)
September	Wet	0 (NA)	0 (NA)
	Above Normal	16 (NA)	14 (700%)
	Below Normal	80 (NA)	67 (515%)
	Dry	556 (1,794%)	73 (14%)
	Critical	1,295 (485%)	33 (2%)
	All	1,947 (653%)	187 (9%)

NA = could not be calculated because the denominator was 0.

Feather River

In the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during February through June, flows under A2A_LLT would be similar to or greater than flows under NAA during March through June except for March of below normal water years (8%) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These results indicate that there would be very few reductions in flows in the Feather River under Alternative 2A.

Mean monthly water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The percent of months exceeding the 64°F temperature threshold in the Feather River at Gridley was evaluated during May through September (Table 11-2A-66). For this impact, only the months of May and June were examined because spawning and egg incubation does not generally extend beyond June in the Feather River. Subsequent months are examined under Impact AQUA-131. In both May and June, the percent of months exceeding the threshold under Alternative 2A would be similar to or lower (up to 32% lower on an absolute scale) than the percent under NAA.

Table 11-2A-66. Differences between Baseline and Alternative 2A Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 64°F Threshold, May through September

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2A_LLT					
May	27 (85%)	17 (93%)	12 (125%)	11 (300%)	7 (300%)
June	0 (0%)	-4 (-4%)	0 (0%)	0 (0%)	7 (15%)
July	0 (0%)	0 (0%)	0 (0%)	10 (11%)	26 (38%)
August	0 (0%)	0 (0%)	7 (8%)	17 (22%)	35 (56%)
September	10 (14%)	10 (18%)	23 (83%)	32 (433%)	25 (1,000%)
NAA vs. A2A_LLT					
May	-12 (-17%)	-21 (-37%)	-10 (-31%)	-4 (-20%)	-2 (-20%)
June	-6 (-6%)	-12 (-13%)	-16 (-17%)	-28 (-31%)	-32 (-37%)
July	0 (0%)	0 (0%)	0 (0%)	0 (0%)	-2 (-3%)
August	0 (0%)	0 (0%)	-1 (-1%)	-2 (-2%)	0 (0%)
September	11 (16%)	5 (8%)	2 (5%)	-4 (-9%)	-1 (-4%)

Total degree-days exceeding 64°F were summed by month and water year type at Gridley during May through September (Table 11-2A-67). Only May and June were examined for spawning and egg incubation habitat here. Subsequent months are examined under Impact AQUA-131. Total degree-months exceeding the threshold under Alternative 2A would be 11% to 23% lower than those under NAA during May and June.

Table 11-2A-67. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 64°F in the Feather River at Gridley, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
May	Wet	18 (300%)	-6 (-20%)
	Above Normal	9 (82%)	-5 (-20%)
	Below Normal	17 (213%)	-7 (-22%)
	Dry	27 (193%)	-2 (-5%)
	Critical	20 (118%)	0 (0%)
	All	92 (164%)	-19 (-11%)
June	Wet	21 (28%)	-46 (-32%)
	Above Normal	-9 (-18%)	-38 (-48%)
	Below Normal	0 (0%)	-32 (-33%)
	Dry	42 (45%)	-11 (-7%)
	Critical	35 (63%)	-4 (-4%)
	All	89 (26%)	-131 (-23%)
July	Wet	46 (27%)	30 (16%)
	Above Normal	21 (40%)	4 (6%)
	Below Normal	44 (65%)	12 (12%)
	Dry	91 (106%)	47 (36%)
	Critical	75 (95%)	21 (16%)
	All	277 (61%)	114 (18%)
August	Wet	52 (29%)	35 (18%)
	Above Normal	39 (87%)	17 (25%)
	Below Normal	51 (73%)	19 (19%)
	Dry	100 (147%)	22 (15%)
	Critical	49 (58%)	-1 (-1%)
	All	291 (65%)	92 (14%)
September	Wet	-8 (-21%)	19 (158%)
	Above Normal	8 (50%)	17 (243%)
	Below Normal	36 (129%)	-4 (-6%)
	Dry	51 (182%)	-1 (-1%)
	Critical	53 (265%)	-1 (-1%)
	All	139 (106%)	29 (12%)

San Joaquin River

Flows in the San Joaquin River at Vernalis under Alternative 2A during March through June would not be different from flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

No water temperatures modeling was conducted in the San Joaquin River.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable spawning and egg incubation habitat or substantially reduce the number of individuals as a result of egg mortality. Flows in the Sacramento, Feather and San Joaquin River and water temperatures in the Sacramento and Feather Rivers under Alternative 2A would not be lower than those under NAA and therefore, would not to degrade spawning and egg incubation habitat conditions. Alternative 2A would reduce the frequency of exceedances above NMFS temperature thresholds in the Sacramento and Feather Rivers.

CEQA Conclusion: In general, Alternative 2A would not affect spawning and egg incubation habitat for green sturgeon relative to the Existing Conditions.

Sacramento River

In the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon, mean monthly flows under A2A_LLT would nearly always be similar to or greater than those under Existing Conditions, except in March during wet years (6% to 10% reduction depending on location), in May during wet years (14% to 15% reduction depending on location), and in July during critical years (12% reduction) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Also flows can be lower or higher in individual months of individual years. These results indicate that there would be very few reductions in flows in the Sacramento River under Alternative 2A relative to the Existing Conditions.

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

The number of days on which temperature exceeded 63°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-2A-64). The combination of number of days and degrees above the 63°F threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-64. The number of "red" years would be 275% higher under Alternative 2A relative to Existing Conditions.

Total degree-days exceeding 63°F at Bend Bridge were summed by month and water year type during May through September (Table 11-2A-65). Water temperatures under Alternative 2A would exceed the threshold 46 degree-days (354%) and 7 degree-days (no relative change calculation possible due to division by 0) more than those under Existing Conditions during May and June, respectively.

Feather River

In the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during February through June, flows under A2A_LLT would nearly always be similar to or greater than those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The only exceptions would be in below normal, dry and critical years in February (8% to 45% lower, in below normal and dry years during March (5% to 46% lower depending on location and water year type), in wet years during May (24% to 31% lower depending on location), and at the confluence during June of wet (8% reduction) and critical years (11% reduction). These results indicate that there would be few reductions in flows in the Feather River under Alternative 2A relative to the Existing Conditions.

Mean monthly water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would generally be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period, except during February and during below normal and critical years in March, in which mean monthly temperatures under Alternative 2A would be 6% higher than those under Existing Conditions.

The percent of months exceeding the 64°F temperature threshold in the Feather River at Gridley was evaluated during May through September (Table 11-2A-66). For this impact, only the months of May and June were examined because spawning and egg incubation does not generally extend beyond June in the Feather River. Subsequent months are examined under Impact AQUA-131. During the period, the percent of months exceeding the threshold under Alternative 2A would be similar to or higher (up to 27% higher on an absolute scale) than the percent under Existing Conditions.

Total degree-days exceeding 64°F were summed by month and water year type at Gridley during May through September (Table 11-2A-67). Only May and June were examined for spawning and egg incubation habitat here. Subsequent months are examined under Impact AQUA-131. Total degree-months exceeding the threshold under Alternative 2A would be 164% to 26% higher than those under Existing Conditions during May and June.

San Joaquin River

Flows in the San Joaquin River at Vernalis under Alternative 2A during March through June would not be different from flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-130 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable spawning and egg incubation habitat, contrary to the NEPA conclusion set forth above. Flows in the Sacramento, Feather, and San Joaquin River would generally be similar between Alternative 2A and the CEQA baseline, but the exceedance above NMFS temperature thresholds would be greater in the Sacramento and Feather Rivers under Alternative 2A.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on green sturgeon spawning and egg incubation habitat. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

In general, Alternative 2A would not affect the quantity and quality of green sturgeon larval and juvenile rearing habitat relative to NAA.

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Feather River

Mean monthly water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The percent of months exceeding the 64°F temperature threshold in the Feather River at Gridley was evaluated during May through September (Table 11-2A-66). The percent of months exceeding the threshold under Alternative 2A would be similar to or lower (up to 32% lower on an absolute scale) than the percent under NAA in all months except September, in which the percent of months under Alternative 2A would be 2% to 11% (absolute scale) higher than the percent under NAA.

Total degree-days exceeding 64°F were summed by month and water year type at Gridley during May through September (Table 11-2A-67). Total degree-months exceeding the threshold under Alternative 2A would be 11% to 23% lower than those under NAA during May and June and 12% to 18% greater than those under NAA during July through September.

San Joaquin River

Flows in the San Joaquin River at Vernalis under Alternative 2A during the March through June spawning and egg incubation periods would similar to those under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted in the San Joaquin River.

NEPA Effects: Collectively, the results indicate that the effect would not be adverse because does not have the potential to substantially reduce suitable rearing habitat. Flows and water temperatures would not differ substantially between Existing Conditions and Alternative 2A in any river evaluated during the green sturgeon spawning and egg incubation period.

CEQA Conclusion: In general, Alternative 2A would not affect the quantity and quality of green sturgeon larval and juvenile rearing habitat relative to the Existing Conditions.

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature under Alternative 2A would be similar to those under Existing Conditions during May and June, but 5% to 12% higher than those under Existing Conditions during July through October.

Feather River

Mean monthly water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month except August and in dry and critical years in July, in which temperatures under Alternative 2A would be 5% to 9% greater than those under Existing Conditions.

The percent of months exceeding the 64°F temperature threshold in the Feather River at Gridley was evaluated during May through September (Table 11-2A-66). The percent of months exceeding the threshold under Alternative 2A would be similar to or greater (up to 32% higher on an absolute scale) than the percent under Existing Conditions in all months during the period.

Total degree-days exceeding 64°F were summed by month and water year type at Gridley during May through September (Table 11-2A-67). Total degree-months exceeding the threshold under Alternative 2A would be 26% to 164% greater than those under Existing Conditions depending on month.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Collectively, the results of the Impact AQUA-131 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable rearing habitat, contrary to the NEPA conclusion set forth above. Alternative 2A would cause higher temperatures for rearing larval and juvenile green sturgeon in the Sacramento and Feather River that could increase stress, mortality, and susceptibility to disease.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on green sturgeon rearing habitat. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

In general, Alternative 2A would reduce green sturgeon migration conditions relative to NAA.

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick and Wilkins Slough and in the Feather River between Thermalito and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through June adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River flows under A2A_LLT would generally be similar to or greater than flows under NAA in all months except July, August, and November, during which flows would be up to 28% lower depending on location, month, and water year type.

Larval transport flows were also examined by utilizing the positive correlation between white sturgeon year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved green sturgeon larval transport that results in improved year class strength. Results for white sturgeon presented in Impact AQUA-150 below suggest that, using the positive correlation between Delta outflow and year class strength, green sturgeon year class strength would be lower under Alternative 2A.

Feather River flows under A2A_LLT would generally be lower by up to 52% than those under NAA during July through August. Flows during other months under A2A_LLT would generally be similar to or greater than flows under NAA with some exceptions.

NEPA Effects: Collectively, these results indicate that the effect is adverse because it has the potential to substantially interfere with the movement of green sturgeon. Reductions in flows in the Feather River during July through September would affect larval and juvenile migratory abilities by slowing or inhibiting downstream migration, but would not affect adult migration. Reductions in flows in the Sacramento River during July, August, and November would affect the migration of all three life stages.

This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. Even so, proposed mitigation (Mitigation Measure AQUA-132a through AQUA-132c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 2A would reduce green sturgeon migration conditions relative to the Existing Conditions.

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick and Wilkins Slough and in the Feather River between Thermalito and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through July adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions in all months except August, September, and November. Flows during other months would generally be similar to or greater than flows under Existing Conditions.

Flows in the Feather River under A2A_LLT would generally be up to 53% lower than flows under Existing Conditions in July, August, November, and December. Flows during other months under A2A_LLT would generally be similar to or greater than flows under Existing Conditions.

For Delta outflow, the percent of months exceeding flow thresholds under A2A_LLT would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (8% to 75% lower on a relative scale) (Table 11-2A-73).

Summary of CEQA Conclusion

Collectively, these results indicate that the impact would be significant because it has the potential to substantially interfere with the movement of fish. The reduction in flows in the Sacramento River during August, September, and December and in the Feather River during July, August, November, and December would affect larval, juvenile, and adult migration period, which could slow or inhibit their migration in both rivers. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-132a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Green Sturgeon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Although analysis conducted as part of the EIR/EIS determined that Alternative 2A would have significant and unavoidable adverse effects on spawning habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on migration habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2A.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2A operations only. Development of mitigation actions for the incremental impact on migration habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2A.

Mitigation Measure AQUA-132b: Conduct Additional Evaluation and Modeling of Impacts on Green Sturgeon Migration Conditions Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to migration habitat under Alternative 2A. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-132c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Green Sturgeon Migration Conditions Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on green sturgeon habitat, the BDCP proponents will consult with NMFS, USFWS and CDFW to identify and implement any feasible operational means to minimize effects on migration habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-132a.

If feasible means are identified to reduce impacts on migration habitat consistent with the overall operational framework of Alternative 2A without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on green sturgeon habitat is not feasible under Alternative 2A operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on green sturgeon would remain significant and unavoidable.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 2A has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for green sturgeon under Alternative 1A (Impact AQUA-133 through AQUA-135) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

NEPA Effects: All three of these impact mechanisms have been determined to result in no adverse effects on green sturgeon for NEPA purposes. Specifically for AQUA-134, the effects of contaminants on green sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on green sturgeon are uncertain.

CEQA Conclusion: All three of these impact mechanisms would be considered less than significant on green sturgeon, for the reasons identified for Alternative 1A, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 2A has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for green sturgeon under Alternative 1A (Impact AQUA-136 through AQUA-144) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (CM12)

Impact AQUA-137: Effects of Invasive Aquatic Vegetation Management on Green Sturgeon (CM13)

Impact AQUA-138: Effects of Dissolved Oxygen Level Management on Green Sturgeon (CM14)

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (CM15)

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (CM16)

Impact AQUA-141: Effects of Illegal Harvest Reduction on Green Sturgeon (CM17)

Impact AQUA-142: Effects of Conservation Hatcheries on Green Sturgeon (CM18)

Impact AQUA-143: Effects of Urban Stormwater Treatment on Green Sturgeon (CM19)

Impact AQUA-144: Effects of Removal/Relocation of Nonproject Diversions on Green Sturgeon (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on green sturgeon for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on green sturgeon, for the reasons identified for Alternative 1A, and no mitigation is required.

White Sturgeon

Construction and Maintenance of CM1

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

The potential effects of construction of the water conveyance facilities on white sturgeon would be similar to those described for Alternative 1A (Impact AQUA-145) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-145, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for white sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-145, the impact of the construction of water conveyance facilities on white sturgeon would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2A would be the same as those described for Alternative 1A (see Impact AQUA-146). As concluded in Alternative 1A, Impact AQUA-146, the effect would not be adverse for white sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-146 for white sturgeon, the impact of the maintenance of water conveyance facilities on white sturgeon would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Water Exports from SWP/CVP South Delta Facilities

Alternative 2A is expected to substantially reduce overall entrainment of juvenile white sturgeon at the south Delta export facilities, estimated as salvage density, by about 66–69% across all years as compared to NAA (Table 11-2A-68). As discussed for Alternative 1A (Impact AQUA-3), entrainment is highest in wet and above normal water years. Under Alternative 2A, entrainment in wet and above normal water years would be reduced 68–71% for juveniles, compared to baseline conditions. Therefore, Alternative 2A would not have adverse effects on juvenile white sturgeon.

Water Exports from SWP/CVP North Delta Intake Facilities

The potential entrainment effects of operating the new north Delta intakes under Alternative 2A would be the same as described for Impact AQUA-129 under Alternative 1A. The intakes would have screens to avoid or reduce entrainment; there would be no adverse effect.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The potential entrainment effects of operating dual conveyance of the North Bay Aqueduct under Alternative 2A would be the same as described for Impact AQUA-129 under Alternative 1A. The intakes would have screens to avoid or reduce entrainment; there would be no adverse effect.

Predation Associated with Entrainment

Juvenile white sturgeon predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Sturgeon develop bony scutes at a young age which reduces their predation vulnerability. The total reduction of juvenile white sturgeon entrainment, and hence predation loss, would change minimally between Alternative 2A and NAA (182 fish). Based on their early development of scutes and rapid growth rates, the number of juvenile white sturgeon lost to predation at the south Delta facilities would change negligibly between Alternative 2A and NAA. The impact and conclusion for predation risk associated with NPB structures and the north Delta intakes would be the same as described for Alternative 1A.

NEPA Effects: As concluded for Alternative 1A, the effect on entrainment and predation under Alternative 2A would not be adverse, because sturgeon grow rapidly and develop bony scutes early in their development which reduces they predation risk.

CEQA Conclusion: As described above, operational activities associated with water exports from SWP/CVP south Delta facilities would result in an overall decrease in entrainment of white sturgeon under Alternative 2A compared to Existing Conditions (Table 11-2A-68; Existing Conditions vs. 2A_LLT). Impacts of Alternative 2A water operations on entrainment of white sturgeon would be beneficial due to an overall reduction in entrainment and no mitigation would be required.

Table 11-2A-68. Juvenile White Sturgeon Entrainment Index[a] at the SWP and CVP Salvage Facilities for Sacramento Valley Water Year-Types and Differences (Absolute and Percentage) between Model Scenarios

	Absolute Difference (Percent Difference)	
Water Year[b]	NAA vs. A2A_LLT	EXISTING CONDITIONS vs. A2A_LLT
Wet and Above Normal	-164 (-68%)	-211 (-73%)
Below Normal, Dry, and Critical	-18 (-54%)	-25 (-61%)
All Years	-211 (-66%)	-182 (-72%)

[a] Estimated annual number of fish lost.
[b] Sacramento Valley water year-types.

The impact of predation associated with entrainment would be the same as described immediately above because the rapid growth and development of bony scutes reduces the predation risk for juvenile white sturgeon. Since few juvenile white sturgeon are entrained at the south Delta, reductions in entrainment (69% reduction compared to Existing Conditions, representing 236 fish) under Alternative 2A would have little effect in affecting entrainment related predation loss. Overall, the impact would be less than significant, because there would be little change in predation loss under Alternative 2A.

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

In general, Alternative 2A would not affect spawning and egg incubation habitat for white sturgeon relative to NAA.

Sacramento River

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon. Flows at Keswick under A2A_LLT would always be similar to or greater than flows under NAA during February to May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT would be greater than those under NAA in 1 to 2 water years (up to 8% lower) during February through April, but would be similar to NAA during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These results indicate that there would be reductions in flows in the Sacramento River during this period under Alternative 2A.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above each threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-69. For the 61°F threshold, there would be 13 fewer (30% fewer) "red" years under Alternative 2A than under NAA. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between NAA and Alternative 2A.

Table 11-2A-69. Differences between Baselines and Alternative 2A in the Number of Years in Which Water Temperature Exceedances above the 61°F and 68°F Thresholds Are within Each Level of Concern, Sacramento River at Hamilton City, March through June

Level of Concern	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
61°F threshold		
Red	36 (450%)	-13 (-30%)
Orange	-1 (-7%)	2 (14%)
Yellow	-15 (-48%)	6 (38%)
None	-20 (-71%)	5 (63%)
68°F threshold		
Red	0 (NA)	0 (NA)
Orange	0 (NA)	0 (NA)
Yellow	1 (NA)	-2 (-200%)
None	-1 (-1%)	2 (2%)

NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-2A-70, Table 11-2A-71). Total degree-days exceeding the 61°F threshold under Alternative 2A would be 19% higher than those under NAA during March, although this is an increase of only 3 degree-days, which would not cause biologically meaningful effect to white sturgeon. During April through June, total degree days exceeding the threshold would be 15% to 18% lower than those under NAA. Total degree-days exceeding the 68°F threshold would not differ between NAA and Alternative 2A during March and April, but would be 45% to 55% lower under Alternative 2A than under NAA during May and June.

Table 11-2A-70. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 61°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	7 (NA)	3 (75%)
	Dry	11 (NA)	0 (0%)
	Critical	1 (NA)	0 (0%)
	All	19 (NA)	3 (19%)
April	Wet	65 (542%)	-1 (-1%)
	Above Normal	60 (600%)	-8 (-10%)
	Below Normal	62 (1,033%)	0 (0%)
	Dry	114 (224%)	-30 (-15%)
	Critical	15 (1,500%)	1 (7%)
	All	316 (395%)	-38 (-9%)
May	Wet	927 (278%)	-188 (-13%)
	Above Normal	207 (95%)	-144 (-25%)
	Below Normal	382 (208%)	-67 (-11%)
	Dry	237 (117%)	-196 (-31%)
	Critical	381 (189%)	31 (6%)
	All	2,134 (187%)	-564 (-15%)
June	Wet	514 (89%)	-444 (-29%)
	Above Normal	91 (30%)	-275 (-41%)
	Below Normal	387 (183%)	-115 (-16%)
	Dry	634 (189%)	-68 (-7%)
	Critical	589 (157%)	43 (5%)
	All	2,215 (123%)	-859 (-18%)

NA = could not be calculated because the denominator was 0.

Table 11-2A-71. Differences between Baseline and Alternative 2A Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 68°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
April	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
May	Wet	26 (371%)	-10 (-23%)
	Above Normal	0 (NA)	-20 (-100%)
	Below Normal	1 (NA)	1 (NA)
	Dry	0 (NA)	-2 (-100%)
	Critical	2 (NA)	1 (100%)
	All	29 (414%)	-30 (-45%)
June	Wet	4 (NA)	-4 (-50%)
	Above Normal	1 (100%)	-3 (-60%)
	Below Normal	2 (NA)	0 (0%)
	Dry	0 (NA)	0 (NA)
	Critical	11 (NA)	-16 (-59%)
	All	18 (1,800%)	-23 (-55%)

NA = could not be calculated because the denominator was 0.

Feather River

In the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during February to May, flows under A2A_LLT would be similar to or greater than flows under NAA, except for March of below normal water years (8%) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These results indicate that there would be very few reductions in flows in the Feather River under Alternative 2A.

Mean monthly water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period. Mean monthly water temperatures would not differ between NAA and Alternative 2A at either location throughout the period.

San Joaquin River

Flows in the San Joaquin River at Vernalis under Alternative 2A during February through May would not be different from flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Water temperature modeling was not conducted for the San Joaquin River.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. Flows under Alternative 2A are generally greater than or similar to flows under NAA. In addition, there would be no effect on water temperatures in the Sacramento and Feather Rivers or on exceedances above NMFS water temperature thresholds for spawning adults and egg incubation in the Sacramento River.

CEQA Conclusion: In general, under Alternative 2A water operations, the quantity and quality of spawning and egg incubation habitat for white sturgeon would not be affected relative to the CEQA baseline.

Sacramento River

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon. Flows at Keswick under A2A_LLT would generally be similar to or greater than flows under Existing Conditions with few exceptions (up to 14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows at Verona under A2A_LLT would generally be similar to those under Existing Conditions except in February in which flows would be up to 8% lower. These results indicate that there would not be reductions in flows in the Sacramento River during this period under Alternative 2A.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2A in any month or water year type throughout the period.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-2A-10). The combination of number of days and degrees above each threshold were further assigned a "level of concern" as defined in Table 11-2A-11. Differences between baselines and Alternative 2A in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2A-69. For the 61°F threshold, there would be 36 more (450% increase) "red" years under Alternative 2A than under Existing Conditions. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between Existing Conditions and Alternative 2A.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-2A-70, Table 11-2A-71). Total degree-days exceeding the 61°F threshold under Alternative 2A would be 19 degree-days (percent change unable to be calculated due to division by 0) to 2215 degree-days (123%) higher depending on month. Total degree-days exceeding the 68°F threshold would not differ between Existing Conditions and Alternative 2A during March and April. During May and June, total degree-days would be 29 (414%)

and 18 (1800%) degree-days higher under Alternative 2A, although these small absolute differences would not cause a biologically meaningful effect on white sturgeon.

Feather River

In the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during February to May, flows under A2A_LLT would generally be similar to or greater than those under Existing Conditions, except during February at Thermalito Afterbay, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These results indicate that there would be very few reductions in flows in the Feather River under Alternative 2A.

Mean monthly water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would not differ between Existing Conditions and Alternative 2A at either location throughout the period, except below Thermalito Afterbay during February, in which temperatures under Alternative 2A would be 6% higher than temperatures under Existing Conditions.

San Joaquin River

Flows in the San Joaquin River at Vernalis under Alternative 2A during the February through May period would be similar to or lower than flows under Existing Conditions in some water years during February and up to 16% lower during March through May.

Water temperature modeling was not conducted for the San Joaquin River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-148 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat, contrary to the NEPA conclusion set forth above. Flows in the San Joaquin River would be lower during a substantial portion of the spawning and egg incubation period. Lower flows could reduce white sturgeon spawning habitat availability or reduce water quality in spawning and egg incubation areas. Also, water temperatures under Alternative 2A in the Feather River would exceed NMFS thresholds at a substantially higher frequency than that under Existing Conditions. Elevated water temperatures can lead to reduced white sturgeon spawning success and higher egg mortality.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for white sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

In general, Alternative 2A would not affect the quantity and quality of white sturgeon larval and juvenile rearing habitat relative to NAA.

Water temperature was used to determine the potential effects of Alternative 2A on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 2A in any month or water year type throughout the period

Water temperatures were not modeled in the San Joaquin River.

NEPA Effects: These results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable rearing habitat. There would be no differences in water temperatures between the NEPA baseline and Alternative 2A in either the Sacramento or Feather Rivers throughout the white sturgeon rearing period.

CEQA Conclusion: In general, Alternative 2A would not affect the quantity and quality of white sturgeon larval and juvenile rearing habitat relative to the Existing Conditions.

Water temperature was used to determine the potential effects of Alternative 2A on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions and Alternative 2A during November through June, but up to 11% higher under Alternative 2A relative to Existing Conditions during August through October and in dry and critical years during July.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions during April through June and in most years during July and September, but 5% to 9% higher under Alternative 2A relative to Existing Conditions during August and October through February.

Water temperatures were not modeled in the San Joaquin River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-149 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, when compared to the CEQA baseline, the alternative could substantially reduce suitable rearing, contrary to the NEPA conclusion set forth above. There would be small, but persistent, increases in water temperatures during substantial portions of the larval and juvenile white sturgeon rearing period in both the Sacramento and Feather Rivers.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for white sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

In general, the effects of Alternative 2A on white sturgeon migration conditions relative to NAA are uncertain.

Analyses for white sturgeon focused on the Sacramento River (North Delta to RM 143—i.e., Wilkins Slough and Verona CALSIM nodes). Larval transport flows were represented by the average number of months per year that exceeded thresholds of 17,700 cfs (Wilkins Slough) and 31,000 cfs (Verona) (Table 11-2A-72). Exceedances of the 17,700 cfs threshold for Wilkins Slough under A2A_LLT were similar to those under NAA. The number of months per year above 31,000 cfs at Verona would range from a reduction of 1.5 months (67% lower in wet years) to an increase of 0.8 months (350% higher in dry years) relative to NAA depending on water year type. Overall, there is no consistent difference between Alternative 2A and the baselines.

Table 11-2A-72. Difference and Percent Difference in Number of Months between February and May in Which Flow Rates Exceed 17,700 and 5,300 cfs in the Sacramento River at Wilkins Slough and 31,000 cfs at Verona

	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wilkins Slough, 17,700 cfs[a]		
Wet	-0.04 (-2%)	0 (0%)
Above Normal	0.3 (18%)	0.1 (5%)
Below Normal	-0.1 (-25%)	0 (0%)
Dry	0 (0%)	0 (0%)
Critical	0 (0%)	0 (0%)
Wilkins Slough, 5,300 cfs[b]		
Wet	-0.2 (-2%)	0.04 (1%)
Above Normal	-0.3 (-4%)	0.1 (1%)
Below Normal	0.3 (5%)	0.6 (12%)
Dry	0.5 (10%)	0.2 (4%)
Critical	0.3 (10%)	0.3 (7%)
Verona, 31,000 cfs[a]		
Wet	-1.8 (-72%)	-1.5 (-67%)
Above Normal	-0.5 (-30%)	-0.3 (-22%)
Below Normal	0.4 (71%)	0.4 (100%)
Dry	0.7 (260%)	0.8 (350%)
Critical	0 (0%)	0 (0%)

[a] Months analyzed: February through May.
[b] Months analyzed: November through May.

Larval transport flows were also examined by utilizing the positive correlation between year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved larval transport that results in improved year class strength. The percent of months exceeding flow thresholds under A2A_LLT generally be lower than those under NAA (up to 67%) with few exceptions (Table 11-2A-73). These results suggest that, using the positive correlation between Delta outflow and year class strength, year class strength would be lower under Alternative 2A.

Table 11-2A-73. Difference and Percent Difference in Percentage of Months in Which Average Delta Outflow is Predicted to Exceed 15,000, 20,000, and 25,000 Cubic Feet per Second in April and May of Wet and Above-Normal Water Years

Flow	Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
April			
15,000 cfs	Wet	-8 (-8%)	-8 (-8%)
	Above Normal	-17 (-18%)	-17 (-18%)
20,000 cfs	Wet	-8 (-9%)	-8 (-9%)
	Above Normal	-25 (-33%)	-17 (-25%)
25,000 cfs	Wet	-19 (-24%)	-15 (-20%)
	Above Normal	-25 (-43%)	-17 (-33%)
May			
15,000 cfs	Wet	-12 (-13%)	-4 (-5%)
	Above Normal	-25 (-30%)	0 (0%)
20,000 cfs	Wet	-38 (-45%)	-15 (-25%)
	Above Normal	-8 (-20%)	0 (0%)
25,000 cfs	Wet	-31 (-44%)	-19 (-33%)
	Above Normal	-25 (-75%)	-17 (-67%)
April/May Average			
15,000 cfs	Wet	-12 (-12%)	-4 (-4%)
	Above Normal	-25 (-25%)	-17 (-18%)
20,000 cfs	Wet	-23 (-26%)	-19 (-23%)
	Above Normal	-17 (-25%)	0 (0%)
25,000 cfs	Wet	-19 (-24%)	-8 (-11%)
	Above Normal	-25 (-50%)	-25 (-50%)

For juveniles, year-round migration flows at Verona were more than 5% lower under A2A_LLT relative to NAA throughout much of the year under each water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For adults, the average number of months per year during the November through May adult migration period in which flows in the Sacramento River at Wilkins Slough exceed 5,300 cfs was determined (Table 11-2A-72). The average number of months exceeding 5,300 cfs under A2A_LLT would generally be similar to the number of months under NAA, except in below normal (12% higher), dry (9% higher), and critical (10% higher) water year types. These increase in exceedances are considered small (<15%) and would not affect white sturgeon adult migration.

These results suggest that, using the positive correlation between Delta outflow and year class strength, year class strength would be lower under Alternative 2A. However, there is high uncertainty that year class strength is due to Delta outflow or if both year class strength and Delta outflows are caused by another unknown factor. There is no difference in the ability of Alternative 2A to meet flow targets in the Sacramento River relative to NAA (Table 11-2A-72).

NEPA Effects: Upstream flows (above north Delta intakes) are similar between Alternative 2A and NAA (Table 11-2A-72). However, due to the removal of water at the North Delta intakes, there are substantial differences in through-Delta flows between Alternative 2A and NAA (Table 11-2A-73). Analysis of white sturgeon year-class strength (USFWS 1995) found a positive correlation between year class strength and Delta outflow during April and May. However, this conclusion was reached in the absence of north Delta intakes and the exact mechanism that causes this correlation is not known at this time. One hypothesis suggests that the correlation is caused by high flows in the upper river resulting in improved migration, spawning, and rearing conditions in the upper river. Another hypothesis suggests that the positive correlation is a result of higher flows through the Delta triggering more adult sturgeon to move up into the river to spawn. It is also possible that some combination of these factors are working together to produce the positive correlation between high flows and sturgeon year-class strength.

The scientific uncertainty regarding which mechanisms are responsible for the positive correlation between year class strength and river/Delta flow will be addressed through targeted research and monitoring to be conducted in the years leading up to the initiation of north Delta facilities operations. If these targeted investigations determine that the primary mechanisms behind the positive correlation between high flows and sturgeon year-class strength are related to upstream conditions, then Alternative 2A would be deemed Not Adverse due to the similarities in upstream flow conditions between Alternative 2A and NAA. However, if the targeted investigations lead to a conclusion that the primary mechanisms behind the positive correlation are related to in-Delta and through-Delta flow conditions, then Alternative 2A would be deemed Adverse due to the magnitude of reductions in through-Delta flow conditions in Alternative 2A as compared to NAA.

CEQA Conclusion: In general, under Alternative 2A water operation, migration conditions for white sturgeon would not change relative to the CEQA baseline.

The number of months per year with exceedances above the 17,700 cfs threshold for Wilkins Slough under A2A_LLT would be similar to those under Existing Conditions in wet, dry, and critical years (Table 11-2A-72). The number of months per year above 17,000 cfs at Wilkins Slough under A2A_LLT would be 18% greater than under Existing Conditions in above normal years and 25% lower than under Existing Conditions in below normal water years. The number of months per year above 31,000 cfs at Verona would range from a reduction of 1.8 months (72% reduction in wet years) to an increase of 0.7 months (260% higher in dry years) relative to Existing Conditions depending on water year type.

For Delta outflow, the percent of months exceeding flow thresholds under A2A_LLT would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (8% to 75% lower on a relative scale) (Table 11-2A-73).

For juveniles, year-round migration flows would be more than 5% lower under A2A_LLT relative to Existing Conditions throughout much of the year under each water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For adult migration, the average number of months exceeding 5,300 cfs under A2_LLT would generally be similar to the number of months under Existing Conditions, except in below normal (5% higher) and in dry and critical water years (10% higher in both) (Table 11-2A-72).

Summary of CEQA Conclusion

The results of the AQUA-150 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat, contrary to the NEPA conclusion set forth above.

As discussed above, the Delta outflow-white sturgeon year class strength correlation has high uncertainty such that it is not possible to determine whether reduced outflow would result in a significant impact. However, the inability of Alternative 2A to meet flow targets in the Sacramento River relative to the Existing Conditions would have biologically meaningful effects on white sturgeon (Table 11-2A-72).

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion of not adverse, and therefore would not in itself result in a significant impact on migration conditions for white sturgeon. Additionally, as described above in the NEPA Effects statement, further investigation is needed to better understand the association of Delta outflow to sturgeon recruitment, and if needed, adaptive management would be used to make adjustments to meet the biological goals and objectives. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 2A has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for white sturgeon under Alternative 1A (Impact AQUA-151 through AQUA-153) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

NEPA Effects: All three of these impact mechanisms have been determined to result in no adverse effects on white sturgeon for NEPA purposes. Specifically for AQUA-152, the effects of contaminants on white sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on white sturgeon are uncertain.

CEQA Conclusion: All three of these impact mechanisms would be considered less than significant on white sturgeon, for the reasons identified for Alternative 1A, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 2A has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for white sturgeon under Alternative 1A (Impact AQUA-154 through AQUA-162) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (CM12)

Impact AQUA-155: Effects of Invasive Aquatic Vegetation Management on White Sturgeon (CM13)

Impact AQUA-156: Effects of Dissolved Oxygen Level Management on White Sturgeon (CM14)

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (CM15)

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (CM16)

Impact AQUA-159: Effects of Illegal Harvest Reduction on White Sturgeon (CM17)

Impact AQUA-160: Effects of Conservation Hatcheries on White Sturgeon (CM18)

Impact AQUA-161: Effects of Urban Stormwater Treatment on White Sturgeon (CM19)

Impact AQUA-162: Effects of Removal/Relocation of Nonproject Diversions on White Sturgeon (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on white sturgeon for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on white sturgeon, for the reasons identified for Alternative 1A, and no mitigation is required.

Pacific Lamprey

Construction and Maintenance of CM1

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

The potential effects of construction of the water conveyance facilities on Pacific lamprey would be similar to those described for Alternative 1A (Impact AQUA-163) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-163, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for Pacific lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-163, the impact of the construction of water conveyance facilities on Pacific lamprey would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2A would be the same as those described for Alternative 1A (see Impact AQUA-164). As concluded in Alternative 1A, Impact AQUA-164, the effect would not be adverse for Pacific lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-164, the impact of the maintenance of water conveyance facilities on Pacific lamprey would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

Water Exports

Alternative 2A is expected to substantially reduce average annual entrainment of Pacific lamprey, estimated by salvage density, by about 59–60% (Table 11-2A-74) averaged across all years compared to NAA.

The potential entrainment impacts of Alternative 2A on Pacific lamprey would be the same as described above for Alternative 1A (Impact AQUA-165). These actions would avoid or reduce potential entrainment and the effect is not adverse.

The analysis of Pacific lamprey and river lamprey entrainment at the SWP/CVP south Delta facilities is combined because the salvage facilities do not distinguish between the two lamprey species. Similar to Alternative 1A (Impact AQUA-165), Alternative 2A is not expected to have an adverse effect on lamprey.

Predation Associated with Entrainment

Lamprey predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Average pre-screen predation loss for fish entrained at the south Delta is 75% at Clifton Court Forebay and 15% at the CVP. Lamprey entrainment to the south Delta would be reduced by 59–60% compared to NAA and predation losses would be expected to be reduced at a similar proportion. The impact and conclusion for predation risk associated with NPB structures would be the same as described for Alternative 1A.

NEPA Effects: Predation at the north Delta would be increased due to the construction of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta is unknown because of the lack of knowledge about their distribution and population abundances in the Delta. As described for Alternative 1A, the overall effect on entrainment and predation of lamprey is considered not adverse.

CEQA Conclusion: As described above, annual entrainment losses of lamprey would be decreased under Alternative 2A by approximately 60% compared to Existing Conditions (Table 11-2A-74). At the north Delta facilities and the alternate NBA intake, the screened intakes as designed would exclude this species. Decommissioning agricultural diversions would slightly reduce potential entrainment. Impacts of Alternative 2A water operations on entrainment on Pacific lamprey are anticipated to be less than significant and may be beneficial, due to reductions in entrainment at the Delta export facilities. No mitigation would be required.

Table 11-2A-74. Lamprey Annual Entrainment Index at the SWP and CVP Salvage Facilities for Alternative 2A[a]

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
All Years	-2,044 (-60%)	-1,939 (-59%)

[a] Number of fish lost, based on non-normalized data, for all months.

The impact of predation associated with entrainment would be the same as described immediately above because the additional predation losses associated with the proposed north Delta intakes would be offset by the reduction in predation loss at the south Delta. The relative impact of predation loss on the lamprey population is unknown since there is little available knowledge on their distribution and abundance in the Delta. The impact is considered to be less than significant. No mitigation is required.

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

In general, effects of Alternative 2A would not affect the quantity and quality of Pacific lamprey spawning habitat relative to NAA.

Flow-related impacts on Pacific lamprey spawning habitat were evaluated by estimating effects of flow alterations on egg exposure, called redd dewatering risk, and effects on water temperature. A redd is a gravel-covered nest of eggs; Pacific lamprey eggs take between 18 and 49 days to incubate and must remain covered by sufficient water for that time. Rapid reductions in flow can dewater redds leading to mortality. Locations for each river used in the dewatering risk analysis were based on available literature, personal conversations with agency experts, and spatial limitations of the CALSIM II model, and include the Sacramento River at Keswick, Sacramento River at Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and American River at Nimbus Dam and at the confluence with the Sacramento River. Pacific lamprey spawn in these rivers between January and August so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage). Water temperature results from the SRWQM and the Reclamation Temperature Model were used to assess the exceedances of water temperatures under all model scenarios in the upper Sacramento, Trinity, Feather, American, and Stanislaus rivers.

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, substrate) of Pacific lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, the change in month-over-month flows is used as a surrogate for a more formal analysis, and a month-over-month flow reduction of 50% was chosen as a best professional estimate of flow conditions in which redd dewatering is expected to occur, but does not estimate empirically derived redd dewatering events. As such, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, January to August.

Flows in all rivers evaluated indicate an increase in redd cohorts exposed to month-over-month flow reductions between January and August for Alternative 2A compared to NAA would only occur in the Feather River, which would consist of a small increase in dewatering risk (9 cohorts or 8%) (Table 11-2A-75). These results indicate no effect of Alternative 2A on the number of Pacific lamprey redd cohorts predicted to experience a month-over-month change in flow of greater than 50% in the Sacramento, Trinity, and American Rivers. Alternative 2A would result in a small increase (8%) in the number of cohorts predicted to experience a month-over-month change of flow greater than 50% in the Feather River which would not constitute have biologically meaningful effects.

Table 11-2A-75. Differences between Model Scenarios in Dewatering Risk of Pacific Lamprey Redd Cohorts[a]

Location	Comparison[b]	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Sacramento River at Keswick	Difference	9	-13
	Percent Difference	16%	-17%
Sacramento River at Red Bluff	Difference	8	-10
	Percent Difference	15%	-14%
Trinity River down-stream of Lewiston	Difference	0	0
	Percent Difference	0%	0%
Feather River at Thermalito Afterbay	Difference	-33	9
	Percent Difference	-22%	8%
American River at Nimbus Dam	Difference	36	-1
	Percent Difference	42%	-1%
American River at Sacramento River confluence	Difference	40	0
	Percent Difference	42%	0%

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%.

[b] Positive values indicate a higher value in Alternative 2A than in the baseline.

Significant reduction in survival of eggs and embryos of Pacific lamprey were observed at 22°C (71.6°F; Meeuwig et al. 2005). Therefore, in the Sacramento River, this analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) using daily data from SRWQM. For other rivers, the analysis predicted the number of consecutive 2 month periods during which at least one month exceeds 22°C (71.6°F) using monthly averaged data from the Reclamation temperature model. Each individual day or month starts a new "egg cohort" such that there are 19,928 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from January 1 through August 31, and 648 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Exact spawning locations of Pacific lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

In most locations, egg cohort exposure would not differ between NAA and Alternative 2A (Table 11-2A-76). However, the number of cohorts exposed to 22°C (71.6°F) under Alternative 2A would be 11% higher in the Sacramento River at Hamilton City and 61% higher in the Feather River at Thermalito Afterbay. The increase in the Sacramento River is negligible considering that it represents a difference of <0.1% of the total number of egg cohorts evaluated (19,928 cohorts).

Table 11-2A-76. Differences (Percent Differences) between Model Scenarios in Pacific Lamprey Egg Cohort Temperature Exposure[a]

Location	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Sacramento River at Keswick	51 (NA)	0 (0%)
Sacramento River at Hamilton City	1,188 (NA)	120 (11%)
Trinity River at Lewiston	6 (NA)	1 (20%)
Trinity River at North Fork	15 (NA)	-3 (-17%)
Feather River at Fish Barrier Dam	0 (NA)	-1 (-100%)
Feather River below Thermalito Afterbay	124 (517%)	56 (61%)
American River at Nimbus	71 (645%)	-3 (-4%)
American River at Sacramento River Confluence	161 (288%)	1 (0%)
Stanislaus River at Knights Ferry	2 (NA)	0 (0%)
Stanislaus River at Riverbank	87 (4,350%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey egg cohorts experiencing water temperatures above 71.6°F during January to August on at least one day during a 49-Day incubation period in the Sacramento River or for at least one month during a 2-month incubation period for each model scenario in other rivers. Positive values indicate a higher value in the proposed project than in EXISTING CONDITIONS or NAA.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because Alternative 2A does not have the potential to substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. Flows reductions that increase redd dewatering risk would be of similar or lower frequency under Alternative 2A relative to the NEPA baseline in all locations except the in Feather River at Thermalito Afterbay, in which there is a small (9%) increase. There would be increased exposure risk of eggs to elevated temperatures in the Feather River, but this isolated result is not expected to cause a biologically meaningful effect to the Pacific lamprey population.

CEQA Conclusion: In general, Alternative 2A would not affect the quantity and quality of Pacific lamprey spawning habitat relative to the Existing Conditions.

Rapid reductions in flow can dewater redds leading to mortality. In the Sacramento American Rivers, Alternative 2A would increase in the number of redd cohorts predicted to experience a month-over-month change in flow of greater than 50% relative to Existing Conditions (Table 11-2A-75). The small values (9 and 8 cohorts) in the Sacramento River would not translate into biologically meaningful effects considering the total number of redd cohorts evaluated (656 cohorts). Changes would be most substantial for the American River (increased risk of dewatering exposure to 36 cohorts or 43% at Nimbus Dam, and 40 cohorts or 42% at the confluence). For the Feather River, there are 25 fewer redd cohorts (-33 cohorts or -17%) predicted to experience a month-over-month change in flow of greater than 50% for Alternative 2A relative to Existing Conditions. No effects are predicted for the Trinity River (0%).These results indicate that Alternative 2A would not have biologically meaningful effects on Pacific lamprey redd dewatering risk in the Sacramento, Feather, and Trinity Rivers; but would affect dewatering risk in the Sacramento River and the American River (maximum increases of 36 cohorts or 43% at Nimbus Dam and 40 cohorts or 42% at the confluence).

The number of egg cohorts exposed to 22°C (71.6°F) under Alternative 2A would be greater than that under Existing Conditions in all rivers (Table 11-1A-76).

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-166 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above. Redd dewatering risk under Alternative 2A would be higher relative to Existing Conditions in the American River, which would increase the risk of desiccation of eggs in this river. There would be increases in egg cohorts exposed to water temperatures above 71.6°F under Alternative 2A relative to Existing Conditions in at least one location in all rivers evaluated. Increased exposure to elevated temperatures would reduce egg survival in these rivers.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for Pacific lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

In general, Alternative 2A would have negligible effects on Pacific lamprey rearing habitat conditions relative to NAA.

Flow-related impacts to Pacific lamprey rearing habitat were evaluated by estimating effects of flow alterations on ammocoete exposure, called ammocoete stranding risk. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Comparisons of effects were made for ammocoete cohorts in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River. An ammocoete is the filter-feeding larval stage of the lamprey that remains relatively immobile in the sediment in the same location for 5 to 7 years, after which it migrates downstream. During the upstream rearing period there is potential for ammocoete stranding from rapid reductions in flow.

The analysis of ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (January through August) and spend 7 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than the flow reduction at any time during the period.

Effects of Alternative 2A on Pacific lamprey ammocoete stranding were analyzed by calculating month-over-month flow reductions for the Sacramento River at Keswick for January through August (Table 11-2A-77). Results indicate either no effect (0%), negligible effects (<5%), or decreases (-12%) in the occurrence of flow reductions attributable solely to the project.

Table 11-2A-77. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

	Percent Difference[a]

NA = all values were 0.
[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 2A.

Results of comparisons for the Sacramento River at Red Bluff provide similar conclusions, with slightly more variability in results (Table 11-2A-78). Results for Alternative 2A compared to NAA indicate no change (0%), negligible increases (<5%), and small to moderate decreases (-7 to -12%) attributable to the project that would not have biologically meaningful effects on stranding risk.

Table 11-2A-78. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Red Bluff

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 2A.

Table 11-2A-82. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, American River at the Confluence with the Sacramento River

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
-50%	0	0
-55%	0	0
-60%	1	0
-65%	1	0
-70%	7	-1
-75%	35	-1
-80%	236	14
-85%	221	-8
-90%	168	-36

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 2A.

These results indicate that Alternative 2A would primarily have no effect (0%), negligible effects (<5%), or decreases in stranding risk that would be beneficial to on rearing success. Isolated occurrences of small increases in dewatering for some flow reduction categories would not have biologically meaningful effects. There would also be small, beneficial effects in the Sacramento River (decreased occurrence of month-over-month flow reductions to -12%) and more substantial beneficial effects in the American River (decreased occurrence of flow reductions to -60%) due to project-related effects of Alternative 2A.

To evaluate water temperature-related effects of Alternative 2A on Pacific lamprey ammocoetes, we examined the predicted number of ammocoete "cohorts" that experience water temperatures greater than 71.6°F for at least one day in the Sacramento River (because daily water temperature data are available) or for at least one month in the Feather, American, Stanislaus, and Trinity rivers over a 7 year period, the maximum likely duration of the ammocoete life stage (Moyle 2002). Each individual day or month starts a new "cohort" such that there are 18,244 cohorts for the Sacramento River, corresponding to 82 years of ammocoetes being "born" every day each year from January 1 through August 31, and 593 cohorts for the other rivers using monthly data over the same period.

In general, there would be no differences in the number of ammocoete cohorts exposed to temperatures greater than 71.6°F in each river (Table 11-2A-83).There would be 23 more cohorts (20% increase) exposed under Alternative 2A in the Trinity River at Lewiston, but there would be 22 fewer cohorts (7% decrease) exposed at North Fork. In addition, there would be 72 more cohorts (14% increase) exposed under Alternative 2A in the Feather River below Thermalito Afterbay, but there would be 56 fewer cohorts (100% decrease) fewer exposed at Fish Barrier Dam. Overall, the small to moderate increases and decreases will balance out within rivers such that there would be no overall effect on Pacific lamprey ammocoetes.

Table 11-2A-83. Differences (Percent Differences) between Model Scenarios in Pacific Lamprey Ammocoete Cohorts Exposed to Temperatures in the Feather River Greater than 71.6°F in at Least One Day or Month

Location	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Sacramento River at Keswick[b]	1,705 (NA)	0 (0%)
Sacramento River at Hamilton City[b]	12,464 (NA)	1,209 (11%)
Trinity River at Lewiston	136 (NA)	23 (20%)
Trinity River at North Fork	283 (NA)	-22 (-7%)
Feather River at Fish Barrier Dam	0 (NA)	-56 (-100%)
Feather River below Thermalito Afterbay	211 (55%)	72 (14%)
American River at Nimbus	359 (185%)	-8 (-1%)
American River at Sacramento River Confluence	159 (37%)	0 (0%)
Stanislaus River at Knights Ferry	56 (NA)	0 (0%)
Stanislaus River at Riverbank	530 (946%)	0 (0%)

NA = could not be calculated because the denominator was 0.
[a] Positive values indicate a higher value in Alternative 2A than in EXISTING CONDITIONS or NAA.
[b] Based on daily data; all other locations use monthly data; 1922–2003.

NEPA Effects: These results indicate that the effect would not be adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. There would be negligible effects on ammocoete cohort survival under Alternative 2A relative to the NEPA baseline for all locations. There would be increase and decreases in exposure risk of ammocoetes to elevated temperatures within each river evaluated that would balance out such that there would be no net effect on Pacific lamprey ammocoetes.

CEQA Conclusion: In general, under Alternative 2A water operations, the quantity and quality of Pacific lamprey rearing habitat would not be affected relative to the CEQA baseline

Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Comparisons of Alternative 2A to Existing Conditions for the Sacramento River at Keswick indicate negligible changes (<5%) in occurrence of flow reductions for all flow reduction categories (Table 11-2A-77). Comparisons for the Sacramento River at Red Bluff indicate no effect (0%) or negligible effects (±5%) for all flow reduction categories except for 60%, 70% and 85% flow reductions (increases of 7%, 9% and 100% [from 56 to 112], respectively) (Table 11-2A-78). Increases of 18-41% are predicted for flow reduction categories from 75% to 90% for the Trinity River (Table 11-2A-79) based on increases from approximately 400 to 500 ammocoete cohorts exposed to stranding risk.

The number of Pacific lamprey ammocoete cohorts exposed to 71.6°F temperatures under Alternative 2A would be substantially higher than those under Existing Conditions in at least one location in all rivers evaluated (Table 11-1A-83).

Summary of CEQA Conclusion

The results of the Impact AQUA-167 CEQA analysis indicate that that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of ammocoete mortality, contrary to the NEPA conclusion set forth above. Increased water temperatures would increase stress and reduce survival of lamprey ammocoetes. In the Sacramento River, Trinity River, and the American River at Nimbus Dam and at the confluence with the Sacramento River, there would be substantial increases in the number of cohorts exposed to stranding risk due to flow reductions in each of the higher flow reduction categories. Increased stranding risk in these rivers would increase the risk of desiccation and reduce survival of ammocoete cohorts. There would be no effect on ammocoete stranding risk under Alternative 2A relative to Existing Conditions in the Feather River, and small increases in stranding risk for the Sacramento River at Red Bluff that would not have biologically meaningful effects. Exposure of ammocoetes to elevated temperatures under Alternative 2A would be substantially higher than those under Existing Conditions in at least one location in all rivers evaluated.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for Pacific lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

In general, effects of Alternative 2A would be negligible relative to NAA based on a prevalence of negligible effects or beneficial increases in mean monthly flow for most of the locations analyzed, which would have a beneficial effect on migration conditions.

After 5–7 years, Pacific lamprey ammocoetes migrate downstream and become macropthalmia (juveniles) once they reach the Delta. Migration generally is associated with large flow pulses in winter months (December through March) (USFWS unpubl. data) meaning alterations in flow have the potential to affect downstream migration conditions. The effects of Alternative 2A on seasonal migration flows for Pacific lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the migration pathways of Pacific lamprey during the likely migration period (December through May) were examined for the Sacramento River at Rio Vista and Red Bluff, the Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

CALSIM flow data form the basis for the summary of changes in adult lamprey migration flows.

Sacramento River

Macropthalmia The difference in mean monthly flow rate for the Sacramento River at Rio Vista for December to May for Alternative 2A compared to NAA indicates reductions in flow for most months/water year types in the migration period with persistent flow reductions ranging from -5% to -31% depending on the specific month and water year (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. There would be project-related decreases in flow during January to April in dry and critical years (to -18%) when reductions in flow would have the greatest effect on migration conditions. The project-related decreases in flow in the Sacramento River at Rio Vista could adversely affect outmigrating macropthalmia during these months.

For the Sacramento River at Red Bluff, the difference in mean monthly flow rate for Alternative 2A compared to NAA indicate negligible effects (<5%) on flow attributable to the project for December through April and increases in flow attributable to the project during May ranging from 6% to 13% (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. The project-related increases in flow in the Sacramento River at Red Bluff would have a beneficial effect on migration conditions.

These results indicate that project-related effects of Alternative 2A on flow consist of negligible effects (<5%), or small increases in flow that would have a beneficial effect on migration in the Sacramento River at Red Bluff, but that effects for Sacramento River at Rio Vista would consist primarily of reductions in flow, including during drier water years, for much of the macropthalmia migration period that would adversely affect outmigrating macropthalmia.

Adults

For the Sacramento River at Red Bluff for the time-frame January to June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), effects of Alternative 2A on mean monthly flow indicate effects would be negligible (<5%) with small increases in flow (to 14%) during May and June for some water years. Increases in flow would have a beneficial effect on migration conditions.

Feather River

Macropthalmia Comparisons for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate negligible (<5%) project-related effects or small increases in flow (to 9%) for December through March, and more substantial increases during April and May in some water year types (to 29%). Increases in mean monthly flow would be beneficial for migration conditions. Based on negligible effects and/or increases in flow that would be beneficial for migration, the project would not have adverse effects on macropthalmia in the Feather River at the confluence.

Adults

For the Feather River at the confluence with the Sacramento River, January to June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), mean monthly flows under Alternative 2A are variable, with primarily negligible changes (<5%) for most months and water year types, with the exception of fairly substantial increases for most water year types for April (10–20%), May (9–29%), and June (17–73%) that would have beneficial effects on migration conditions.

American River

Macropthalmia Comparisons for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate negligible effects (<5%) or small to moderate increases in flows in all months, with more substantial increases during May (to 28%), with the exception of small decreases during March in dry (-6%) and critical (-7%) years that would not have biologically meaningful effects on migration conditions. The increases in flow would be beneficial for migration conditions.

Overall flow-related effects of Alternative 2A on outmigrating macropthalmia are negligible (<5%) in the Sacramento River at Red Bluff, Feather River at the confluence with the Sacramento River, and American River at the confluence with the Sacramento River. Effects of Alternative 2A on flow in the Sacramento River at Rio Vista would consist of flow reductions, particularly in drier water year types, which would affect outmigrating macropthalmia.

Adults

Comparisons of mean monthly flow for the American River at the confluence with the Sacramento River for January to June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate predominantly negligible effects (<5%) attributable to the project with the exception of increased flows in May (11–28%) and June (23–31%) which would enhance migration especially during drier water year types, and small decreases in flow (to -7%) during March in dry and critical years that would not have biologically meaningful effects on migration conditions.

Project-related effects of Alternative 2A on mean monthly flows during the Pacific lamprey adult migration period would consist of negligible effects (<5%) or increases in flow (up to 73% depending on the location, month, and water year type) that would not negatively affect adult migration in the rivers analyzed in a biological meaningful way. Project-related increases in flows would enhance migration, particularly in drier water year types such as for the American River.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish. Flows in the Sacramento River at Rio Vista under Alternative 2A would be reduced relative to NAA, with persistent flow reductions to -31% throughout the migration period that would affect conditions for outmigrating macropthalmia at that location. The degree to which this reduction would affect lamprey is unknown, but given the predominance of negligible effects in other locations, it is not likely that reduced flows at this location would affect the Pacific lamprey population. Effects of Alternative 2A in the other locations analyzed would consist primarily of negligible effects (<5%), infrequent, small decreases in flow (to -7%) that would not have biologically meaningful effects, and small to substantial (to 73%) increases in flow that would have beneficial effects on migration conditions.

CEQA Conclusion: In general, the effect of Alternative 2A on Pacific lamprey migration conditions would be negligible relative to the Existing Conditions.

Sacramento River

Macropthalmia Comparisons of mean monthly flow rates in the Sacramento River at Rio Vista (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May for Alternative 2A relative to Existing Conditions indicate reductions in flow ranging from -5% to -48% in most water years for each of these months. These results indicate that effects of Alternative 2A on flow would have negative effects on outmigrating macropthalmia in the Sacramento River. Comparisons for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate negligible (<5%) effects or small increases or decreases in flow (to 11%) that would not have biologically meaningful effects on migration conditions. Exceptions include a decrease in flow of -15% during May in wet years when flow reductions would not be as critical for migration conditions, and an increase of 16% during May in dry years that would have beneficial effects on migration. Therefore, Alternative 2A would not have biologically meaningful negative effects on outmigrating macropthalmia at this location.

Adults

Comparisons of mean monthly flow for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) during the Pacific lamprey adult migration period from January through June indicate that for most months and water year types, flows under Alternative 2A would be similar to (<5% difference) flows under Existing Conditions, with infrequent occurrences of small-scale (to 13%) increases or decreases in flow that would not have biologically meaningful effects on migration conditions. Exceptions include a slightly greater reduction in flow during May in wet years (-15%) when effects of flow reductions would be less critical for migration, and slightly greater increases in flow during May in dry years (16%) and during June in above normal years (21%) that would have beneficial effects on migration. Therefore, effects of Alternative 2A consist of negligible effects or increases in flow that would have beneficial effects, and small reductions in flow that would not have biologically meaningful effects.

Feather River

Macropthalmia Comparisons for the Feather River at the confluence (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate variable effects by month and water year type, with increases in flow during December in above normal and below normal years (to 11%) and decreases in wet and critical years (to -31%), generally increases in flow during January through March in wetter years (to 20%) and decreases during some drier water year types (to -18%), and negligible effects or increases in flow (to 24%) during April and May except for a decrease (-24%) during May in wet years. Increases in flow would have beneficial effects on migration conditions, and decreases in wetter water years would not have significant effects on migration. Based on this limited occurrence of flow decreases at times that would be most critical for migration, and the prevalence of negligible effects or flow increases for most of the migration period, effects of Alternative 2A on flows would not have biologically meaningful effects on macropthalmia migration in the Feather River.

Adults

Comparisons of mean monthly flow for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January to June indicate variable effects of Alternative 2A depending on the month and water year type, with primarily negligible effects (<5%) and small increases or decreases in flow (to about 13%) that would not have biologically meaningful effects on migration conditions, with the exception of more substantial increases in flow during February in wet years (20%), March in above normal years (14%), April in dry years (19%), May in below normal years (24%), and June in above normal (51%) and below normal (58%) years. These flow increases would have a beneficial effect on migration conditions. There would be more substantial decreases in flow during March in below normal years (-18%) and during May in wet years (-24%) when effects of flow reduction on migration would be less critical. These flow reductions are isolated occurrences of relatively small magnitude and would therefore not have biologically meaningful effects on migration conditions. Therefore, effects of Alternative 2A on flow would not affect migration conditions in the Feather River.

American River

Macropthalmia Comparisons for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate negligible effects (<5%) or decreases in flow during December and April, increases in flow during January through March for some wetter water year types (to 27%) and decreases for some drier water year types (to -18%), and decreases to -26% during May in all water year types except dry (increase of 16%). Decreases in drier water years for December through March and May encompass much of the migration period and would affect macropthalmia migration conditions for that time-frame (particularly critical years).

Overall conclusions are that impacts of Alternative 2A on mean monthly flows during the Pacific lamprey macropthalmia migration period, December to May, would not affect migration conditions in the Sacramento River at Red Bluff and the Feather River, but would affect conditions in the Sacramento River at Rio Vista and in the American River during drier water years.

Adults

Comparisons of mean monthly flow for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January to June indicate variable effects of Alternative 2A depending on the month and water year type, with meaningful changes in flow (±>5%) consisting of increases up to 27% (February, above normal years) that would have beneficial effects on migration conditions, and decreases to -18% in drier years. There would be primarily negligible effects (<5%) or small decreases (to -9%) during April. There would be decreases (to -26%) in all but critical years (increase of 16%) during May, and decreases during June in wet (-27%) and critical (-36%) years with increases (to 24%) in the remaining water years. Conclusions are that effects of Alternative 2A consist of variable effects on flow and predicted flow reductions would not have biologically meaningful effects on river lamprey macropthalmia migration based on the magnitude of the decreases and infrequent or isolated occurrences.

Summary of CEQA Conclusion

Collectively, these results indicate that the impact is not significant because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish, and no mitigation is necessary. Effects of Alternative 2A compared to Existing Conditions during the January to June adult Pacific lamprey migration period consist predominantly of negligible effects (<5%), increases in flow, or small, isolated occurrences of decreases in flow for some water year types that would not have biologically meaningful effects on migration conditions. Flows at Rio Vista would decrease for much of the period. However, the degree to which this reduction would affect lamprey is unknown, but given the predominance of negligible effects in other locations, it is not likely that reduced flows at this location would affect the Pacific lamprey population.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 2A has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for Pacific lamprey under Alternative 1A (Impact AQUA-169 through AQUA-171) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

NEPA Effects: All three of these impact mechanisms have been determined to result in no adverse effects on Pacific lamprey for NEPA purposes.

CEQA Conclusion**:** All three of these impact mechanisms would be considered less than significant on Pacific lamprey, for the reasons identified for Alternative 1A, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 2A has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for Pacific lamprey under Alternative 1A (Impact AQUA-172 through AQUA-180) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (CM12)

Impact AQUA-173: Effects of Invasive Aquatic Vegetation Management on Pacific Lamprey (CM13)

Impact AQUA-174: Effects of Dissolved Oxygen Level Management on Pacific Lamprey (CM14)

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (CM15)

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (CM16)

Impact AQUA-177: Effects of Illegal Harvest Reduction on Pacific Lamprey (CM17)

Impact AQUA-178: Effects of Conservation Hatcheries on Pacific Lamprey (CM18)

Impact AQUA-179: Effects of Urban Stormwater Treatment on Pacific Lamprey (CM19)

Impact AQUA-180: Effects of Removal/Relocation of Nonproject Diversions on Pacific Lamprey (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on Pacific lamprey for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion**:** The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on Pacific lamprey, for the reasons identified for Alternative 1A, and no mitigation is required.

River Lamprey

Construction and Maintenance of CM1

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

The potential effects of construction of the water conveyance facilities on river lamprey would be similar to those described for Alternative 1A (Impact AQUA-181) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-181, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for river lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-181, the impact of the construction of water conveyance facilities on river lamprey would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2A would be the same as those described for Alternative 1A (see Impact AQUA-182). As concluded in Alternative 1A, Impact AQUA-182, the effect would not be adverse for river lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-182 for lamprey, the impact of the maintenance of water conveyance facilities on river lamprey would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

The potential entrainment impacts of Alternative 2A on river lamprey would be the same as described above for Alternative 1A (Impact AQUA-183).

NEPA Effects: The analysis of river lamprey entrainment at the SWP/CVP south Delta facilities is combined with the analysis of Pacific lamprey because the salvage facilities do not distinguish between the two lamprey species. Like Alternative 1A (Impact AQUA-3), Alternative 2A is expected to substantially reduce average annual entrainment of lamprey, estimated by salvage density, by about 59–60% (Table 11-2A-84) averaged across all years compared to NAA. Overall, Alternative 2A would not have adverse effects on lamprey.

CEQA Conclusion: As described above, annual entrainment losses of juvenile green sturgeon would be decreased under Alternative 2A by approximately 60% compared to Existing Conditions (Table 11-2A-84). At the north Delta facilities and the alternate NBA intake, the screened intakes as designed would exclude this species. Decommissioning agricultural diversions would slightly reduce potential entrainment. Impacts of water operations on entrainment of river lamprey are considered less than significant and may be beneficial; no mitigation is required.

Table 11-2A-84. Lamprey Annual Entrainment Index at the SWP and CVP Salvage Facilities for Alternative 2A[a]

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
All Years	-2,044 (-60%)	-1,939 (-59%)

[a] Number of fish lost, based on non-normalized data, for all months.

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

In general, Alternative 2A would not affect the quantity and quality of river lamprey spawning habitat relative to NAA.

Flow-related impacts to river lamprey spawning habitat were evaluated by estimating effects of flow alterations on redd dewatering risk as described for Pacific lamprey with appropriate time-frames for river lamprey incorporated into the analysis. Lower flows can reduce the instream area available for spawning and rapid reductions in flow can dewater redds leading to mortality. The same locations were analyzed as for Pacific lamprey: the Sacramento River at Keswick and Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and American River at Nimbus Dam and at the confluence with the Sacramento River. River lamprey spawn in these rivers between February and June so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage).

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, substrate) of river lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, as described for Pacific lamprey, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, February to June.

Flows in all rivers evaluated indicated increases in redd cohorts exposed would only occur in the Feather River (9% increase) (Table 11-2A-85). All other locations would experience no change (0%) or negligible change (±5%) attributable to the project. The increased risk for the Feather River is small (9%) and would not cause a biologically meaningful effect on spawning success.

Table 11-2A-85. Differences between Model Scenarios in Dewatering Risk of River Lamprey Redd Cohorts[a]

Location	Comparison[b]	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Sacramento River at Keswick	Difference	4	1
	Percent Difference	13%	3%
Sacramento River at Red Bluff	Difference	2	0
	Percent Difference	5%	0%
Trinity River downstream of Lewiston	Difference	-4	-2
	Percent Difference	-6%	-3%
Feather River Below Thermalito Afterbay	Difference	-5	5
	Percent Difference	-7%	9%
American River at Nimbus	Difference	10	1
	Percent Difference	18%	2%
American River at Sacramento River confluence	Difference	16	-1
	Percent Difference	27%	-1%

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%.

[b] Positive values indicate a higher value in Alternative 2A than in EXISTING CONDITIONS or NAA).

River lamprey generally spawn between February and June (Beamish 1980, Moyle 2002). Using Pacific lamprey as a surrogate, eggs are assumed to hatch in 18-49 days depending on water temperature (Brumo 2006) and are, therefore, assumed to be present during roughly the same period and locations as spawners. Moyle et al. (1995) indicate that river lamprey "adults need… temperatures [that] do not exceed 25°C," although there is no mention of thermal requirements for eggs in this or any existing literature. Meeuwig et al. (2005) reported that, for Pacific lamprey eggs, significant reductions in survival were observed at 22°C (71.6°F). Therefore, for this analysis, both temperatures, 22°C (71.6°F) and 25°C (77°F), were used as upper thresholds of river lamprey eggs. The analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) or 25°C (77°F) using daily data from USRWQM. For other rivers, the analysis predicted the number of consecutive two-month periods during which at least one month exceeds 22°C (71.6°F) or 25°C (77°F) using monthly averaged data from the Bureau's temperature model. Each individual day or month starts a new "egg cohort" such that there are 12,320 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from February 1 through June 30, and 405 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Spawning locations of river lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

For both thresholds, there would be few differences in egg cohort exposure between NAA and Alternative 2A among all sites (Table 11-2A-86). Differences of 20 cohorts in the Sacramento River at Hamilton City are negligible to the population considering the total number of cohorts is 12,320. In the Feather River below Thermalito Afterbay, there would be 10 more cohorts (26% increase) exposed to the 71.6°F threshold under Alternative 2A relative to NAA, although differences at the 77°F threshold would be negligible. In addition, there would be no differences between NAA and Alternative 2A in egg exposure at the Fish Barrier Dam in the Feather River. Overall, except at one location in the Feather River for the more conservative threshold temperature (71.6°F), these results indicate that there would be no differences in egg exposure to elevated temperatures under Alternative 2A.

Table 11-2A-86. Differences (Percent Differences) between Model Scenarios in River Lamprey Egg Cohort Temperature Exposure

Location	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
71.6°F Threshold		
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	315 (NA)	-8 (-2%)
Trinity River at Lewiston	0 (NA)	-1 (-100%)
Trinity River at North Fork	4 (NA)	-1 (-20%)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	39 (433%)	10 (26%)
American River at Nimbus	21 (420%)	-4 (-13%)
American River at Sacramento River Confluence	43 (154%)	-11 (-13%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	-1 (-100%)	-35 (-100%)
77°F Threshold		
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	56 (NA)	20 (56%)
Trinity River at Lewiston	0 (NA)	0 (NA)
Trinity River at North Fork	0 (NA)	0 (NA)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	4 (NA)	2 (100%)
American River at Nimbus	5 (NA)	1 (25%)
American River at Sacramento River Confluence	7 (NA)	1 (17%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey egg cohorts experiencing water temperatures above 71.6°F and 77°F during February to June on at least one day during a 49-Day incubation period in the Sacramento River or for at least one month during a 2-month incubation period for each model scenario in other rivers. Positive values indicate a higher value in the proposed project than in EXISTING CONDITIONS or NAA.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because it does not have the potential to substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. Alternative 2A would cause minor effects to river lamprey redd dewatering and exposure to elevated water temperatures that would not be substantial.

CEQA Conclusion: In general, Alternative 2A would not affect the quantity and quality of river lamprey spawning habitat relative to the Existing Conditions due to increases in exposure to critical water temperatures in the Feather River and moderate increases in dewatering risk from flow reductions in the Sacramento River and the American River.

Lower flows can reduce the instream area available for spawning and rapid reductions in flow can dewater redds leading to mortality. Effects of Alternative 2A on flow reductions during the river lamprey spawning period from February to June in the Sacramento River and American River consist of increases in river lamprey redd cohort dewatering risk relative to Existing Conditions (Table 11-2A-85). Changes would be most substantial for the American River (increased risk of dewatering exposure to 10 cohorts or 18% at Nimbus Dam, and 16 cohorts or 27% at the confluence). For the Trinity River there are 4 fewer redd cohorts (-6%), and for the Feather River there are five fewer redd cohorts (-7%), predicted to experience a month-over-month change in flow of greater than 50% for Alternative 2A relative to Existing Conditions.

In most locations, the number of ammocoete cohorts exposed to each threshold under Alternative 2A would be similar to or lower than those under NAA (Table 11-2A-86). Biologically meaningful exceptions includes the Trinity River at Lewiston, Feather River below Thermalito Afterbay and the Sacramento River at Hamilton City for the 71.6°F threshold, and the Feather River below Thermalito Afterbay for the 77°F threshold. In all cases, there would be another location within the river that would have similar or lower exceedances under Alternative 2A.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-184 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above. Alternative 2A would reduce river lamprey survival due to increases in water temperature in the Feather River below Thermalito Afterbay relative to the Existing Conditions. Increased water temperatures would increase stress and reduce survival of lamprey ammocoetes. Alternative 2A would cause minor impacts on river lamprey redd dewatering that would be less than significant.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for river lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

In general, Alternative 2A would not affect the quantity and quality of river lamprey rearing habitat relative to NAA due to increased exposure to critical water temperatures in the Feather River below Thermalito Afterbay. There would be a beneficial effect from substantial decreases in exposure to flow reductions in the American River, but negligible effects on stranding risk in the other locations analyzed.

Flow-related effects on river lamprey rearing habitat were evaluated by estimating effects of flow alterations on ammocoete exposure, or stranding risk, as described for Pacific lamprey. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Effects of Alternative 2A on flow were evaluated in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River. As for Pacific lamprey, the analysis of river lamprey ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (February through June) and spend 5 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than the flow reduction at any time during the period. Comparisons of flow reductions for Alternative 2A relative to NAA for the Sacramento River at Keswick (Table 11-2A-87) predicted either no effect (0%), negligible effects (±5%), or small decreases (-13%) in the occurrence of flow reductions attributable solely to the project, which would have beneficial effects on rearing success.

Table 11-2A-87. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

-85%	44	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 2A.

Results of comparisons for the Sacramento River at Red Bluff (Table 11-2A-88) provided similar conclusions, with slightly more variability in results. Alternative 2A compared to NAA indicated no change (0%), negligible increases (<5%), and small decreases (-3 to -12%) attributable to the project for different flow reduction categories. There is a single flow reduction category, 60%, that would experience a small increase in occurrence attributable to the project, 6%. Based on the general decrease in frequency of most of the flow reduction categories, the small increase (6%) predicted for 60% flow reduction event would not have biologically meaningful effects on rearing success.

Flow reduction comparisons for the American River at Nimbus Dam (Table 11-2A-91) and at the confluence with the Sacramento River (Table 11-2A-92) indicated no effect (0%), negligible increases (<5%), or substantial decreases (to -55%) attributable to the project, with an increase of 15% for only one flow reduction category, 80% flow reduction, for the confluence. Based on the general decrease in frequency of most of the flow reduction categories, the small increase (15%) predicted for a single flow reduction category (80%) would not have biologically meaningful effects.

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 2A.

River lamprey generally spawn between February and June (Beamish 1980, Moyle 2002). Using Pacific lamprey as a surrogate, eggs are assumed to hatch in 18-49 days depending on water temperature (Brumo 2006) and are, therefore, assumed to be present during roughly the same period and locations as spawners. Moyle et al. (1995) indicate that river lamprey "adults need… temperatures [that] do not exceed 25°C," although there is no mention of thermal requirements for eggs in this or any existing literature. Meeuwig et al. (2005) reported that, for Pacific lamprey eggs, significant reductions in survival were observed at 22°C (71.6°F). Therefore, for this analysis, both temperatures, 22°C (71.6°F) and 25°C (77°F), were used as upper thresholds of river lamprey eggs. The analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) or 25°C (77°F) using daily data from USRWQM. For other rivers, the analysis predicted the number of consecutive two-month periods during which at least one month exceeds 22°C (71.6°F) or 25°C (77°F) using monthly averaged data from the Bureau's temperature model. Each individual day or month starts a new "egg cohort" such that there are 12.320 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from February 1 through June 30, and 405 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Spawning locations of river lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

In the Sacramento River at Hamilton City, there would be 685 more cohorts (could not calculate relative difference due to division by 0) exposed to the 71.6°F threshold under Alternative 2A relative to Existing Conditions, although this represents a small proportion (6%) of the total number of cohorts evaluated (12,320 cohorts) (Table 11-2A-93). Therefore, would not be biologically meaningful. There would be 15 more (30% increase) and 60 more (19% increase) cohorts exposed to elevated temperatures in the Trinity River at Lewiston and in the Feather River below Thermalito Afterbay, respectively. These would also be small proportions of total cohorts and, therefore, would not be biologically meaningful. There are no other increases in any rivers at the 71.6°F temperature threshold and no biologically meaningful increases at the 77°F temperature threshold.

Table 11-2A-93. Differences (Percent Differences) between Model Scenarios in River Lamprey Ammocoete Cohorts Exposed to Temperatures in the Feather River Greater than 71.6°F and 77°F in at Least One Month

Location	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
71.6°F Threshold		
Sacramento River at Keswick[b]	1,218 (NA)	0 (0%)
Sacramento River at Hamilton City[b]	10,180 (NA)	685 (7%)
Trinity River at Lewiston	65 (NA)	15 (30%)

Stanislaus River at Knights Ferry	25 (NA)	0 (0%)
Stanislaus River at Riverbank	335 (1,340%)	0 (0%)
77°F Threshold		
Sacramento River at Keswick[b]	0 (NA)	0 (NA)
Sacramento River at Hamilton City[b]	0 (NA)	0 (NA)
Trinity River at Lewiston	0 (NA)	0 (NA)
Trinity River at North Fork	0 (NA)	0 (NA)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	90 (NA)	50 (125%)
American River at Nimbus	175 (NA)	-45 (-20%)
American River at Sacramento River Confluence	235 (470%)	5 (2%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Positive values indicate a higher value in the preliminary proposal than in EXISTING CONDITIONS or NAA.

[b] Based on daily data; all other locations use monthly data; 1922–2003.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because it does not have the potential to substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. Alternative 2A would not affect river lamprey ammocoete stranding relative to the NEPA baseline. Further, increases in exposure to water temperatures under Alternative 2A would not be biologically meaningful.

CEQA Conclusion: In general, Alternative 2A would not affect the quantity and quality of river lamprey rearing habitat relative to the Existing Conditions

Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Comparisons of Alternative 2A to Existing Conditions for the Sacramento River at Keswick indicate decreases (to -8%) or negligible increases (<5%) in the occurrence of flow reductions for all flow reduction categories (Table 11-2A-87) with the exception of a small increase (6%) in month-over-month flow reductions of 60% and a 44% increase in reductions of 85%. Comparisons for the Sacramento River at Red Bluff indicate slightly more variable results with no effect (0%) or negligible effects (<5%) for all flow reduction categories except for small increases (6% to 13%) in the 55%, 70% through 80% flow reductions, and a more substantial increase (100%, or from 0 to 50 cohorts) in the 85% flow reduction category (Table 11-2A-88).

Comparisons for the Trinity River indicated no effect (0%) for flow reduction categories from 50% to 70%, and increases ranging from 26% to 59% for the higher flow reduction categories (Table 11-2A-89).

Comparisons for the Feather River indicated no effect or reductions in frequency of occurrence for all flow reduction categories (Table 11-2A-90).

Comparisons for the American River at Nimbus Dam (Table 11-2A-91) and at the confluence with the Sacramento River (Table 11-2A-92) indicated increased chance of occurrence of flow reductions between 70 and 90% for Alternative 2A compared to Existing Conditions; meaningful (>5%) predicted increases are from 48 to 388% (increase in cohorts exposed from 25 to 122) for Nimbus Dam and from 20 to 290% (increase in cohorts exposed from 50 to 195) for the confluence.

The number of ammocoete cohorts exposed to 71.6°F under Alternative 2A would be substantially higher than those under Existing Conditions in most locations examined (Table 11-A1-93). The number of ammocoete cohorts exposed to 77°F under Alternative 2A would be similar at all locations except the Feather River below Thermalito Afterbay and at both locations in the American River, at which exposure would increase by 90 to 235 cohorts.

Summary of CEQA Conclusion

The results of the Impact AQUA-185 CEQA analysis indicate that that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of ammocoete mortality, contrary to the NEPA conclusion set forth above. There would be substantial increases in stranding risk in the Trinity and American Rivers under Alternative 2A relative to the Existing Conditions. Increased stranding risk in these rivers would increase the risk of desiccation and reduce survival of ammocoete cohorts. Additionally, the risk of exposure to elevated water temperatures would substantially increase under Alternative 2A relative to the Existing Conditions. Increased water temperatures would increase stress and reduce survival of lamprey ammocoetes.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in

the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for river lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

In general, Alternative 2A would have negligible effects on river lamprey migration conditions relative to NAA due to negligible effects on mean monthly flows. There would be beneficial effects due to moderate increases in mean monthly flow for some months and water year types but these generally would be offset by flow reductions in other months.

Macropthalmia

After 3 to 5 years river lamprey ammocoetes migrate downstream and become macropthalmia once they reach the Delta. River lamprey migration generally occurs September through November (USFWS unpubl. data). The effects of water operations on seasonal migration flows for river lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the likely migration pathways of river lamprey during the likely migration period (September through November) were examined to predict how Alternative 2A may affect migration flows for outmigrating macropthalmia.

Analyses were conducted for the Sacramento River at Red Bluff, Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

Sacramento River

Comparisons for the Sacramento River at Red Bluff for September through November indicate variable effects of Alternative 2A depending on the month and the water year type. Alternative 2A indicates variable effects, with project-related increases (9% to 17% in dry and critical years) that would have beneficial effects on migration conditions and decreases (-5% and -15% in above normal and below normal years) in September, primarily negligible effects (<5%) in October, and decreases in flows for all but critical years (with <5% difference) in November (-11 to -17%). Decreases in wetter years in September would less detrimental because flows are higher; the increases in drier water years would be beneficial for outmigration. Decreases (to 17%) for all but critical years in November would affect migration conditions during that month, which is the last month in the relatively short migration period.

Feather River

Comparisons for the Feather River at the confluence with the Sacramento River for September through November indicate decreases in flow during wetter years in September (-10, -19, and -33% for wet, above normal, below normal, respectively) and increases in flow during drier years (6 and 19% for dry and critical years, respectively. The increases in flow during dry and critical years for

September would have a positive effect on migration when flow conditions are most critical. There would also be project-related increases in flow during October in all water years, ranging from 9 to 32% depending on water year type. Project-related effects during November would be negligible (<5%) in all water year types with the exception of a small decrease in mean monthly flow (-8%) during above normal years that would not have biologically meaningful effects. These results indicate Alternative 2A would not affect migration in the Feather River.

American River

Comparisons for the American River at the confluence with the Sacramento River for September through November indicate decreased flows during September in wetter water years (to -19%) and negligible effects (<5%) in drier water years when flow effects would be more detrimental for migration, increases in mean monthly flows during October in drier water year types (10 and 15% for below normal and dry years), and negligible project-related changes during November except for small changes in dry (+6%) and critical (-9%) water years. These results indicate Alternative 2A would not affect migration conditions in the American River.

Overall conclusions are that, with some variation in results by location, month, and water year type, Alternative 2A would generally not have biologically meaningful effects on macropthalmia migration based on negligible effects (<5%), decreases in flow during wetter water year types that would not have biologically meaningful effects, and increases in flow during drier water years that would have a beneficial effect on migration.

Adults

Effects of Alternative 2A on flow during the adult migration period, September through November, would be the same as described for the macropthalmia migration period, September through November, above.

NEPA Effects: Collectively, these results indicate that is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. Flows under Alternative 2A would not be reduced from NAA in any waterway analyzed that would affect river lamprey macropthalmia or adults in a biologically meaningful way. There would be small to moderate increases in mean monthly flow for some months and water year types that would have beneficial effects on migration conditions.

CEQA Conclusion: In general, under Alternative 2A water operations, the quantity and quality of suitable migration habitat for river lamprey would not be affected relative to the CEQA baseline.

Macropthalmia

Sacramento River

Comparisons for the Sacramento River at Red Bluff for September through November indicate variable effects of Alternative 2A during September, with increases in mean monthly flow for wetter water year types (38 to 55%) that would have beneficial effects on migration conditions, and decreases for drier water year types (-13 and -17% for below normal and dry years, respectively). Alternative 2A would have negligible effects (±<5%) for October with the exception of increased flows (10%) during dry years. Alternative 2A would result in small decreases in mean monthly flows compared to Existing Conditions for all water year types in November (-6 to -13%). Persistent small to moderate reductions in flow in drier water years for two of the three months in the migration period would affect migration conditions in the Sacramento River.

Feather River

Comparisons for the Feather River at the confluence with the Sacramento River for September through November indicate variable results by month and water year type, with increases for wetter years and decreases in drier years in September, variable results with primarily increases in drier years (13 and 15% for dry and critical years, respectively) in October that would have a small beneficial effect on migration, and primarily decreases for most water year types in November (-6 to -20%). Decreased mean monthly flows in September and November during drier water years would affect migration conditions; increases in these water year types in September would have a beneficial effect.

American River

Comparisons for the American River at the confluence with the Sacramento River for September through November indicate reductions in flow for most months and most water year types, ranging from -6 to -56%, with the exception of a 20% increase in mean monthly flow during October for below normal water years. There would also be negligible decreases (<5%) for October flows during dry years. The predominance of decreased flows for Alternative 2A compared to Existing Conditions would affect migration conditions, with substantial decreases for dry and critical years in September (-42 and -56%, respectively) and November (-33 and -28%, respectively).

Overall, these results indicate that Alternative 2A would cause decreases in mean monthly flow during all or portions of the river lamprey macropthalmia migration period in the Sacramento River (to -17% in dry years), Feather River (to -20%), and American River (to -56%).

Adults

Effects of Alternative 2A on flow during the adult migration period, September through November, would be the same as described for the macropthalmia migration period, September through November, above.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-186 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2A could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Reductions in flows during the macropthalmia and adult migration periods would reduce migration ability of both life stages. For macropthalmia, reduced migration ability would increase straying risk and delay initiation of the oceanic life stage. For adults, reduced flows would reduce the ability to sense olfactory cues if adults use such cues to return to natal spawning grounds.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 2A indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 2A. This indicates that the differences between Existing Conditions and Alternative 2A found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration conditions for river lamprey. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 2A has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for river lamprey under Alternative 1A (Impact AQUA-187 through AQUA-189) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

NEPA Effects: All three of these impact mechanisms have been determined to result in no adverse effects on river lamprey for NEPA purposes.

CEQA Conclusion: All three of these impact mechanisms would be considered less than significant on river lamprey, for the reasons identified for Alternative 1A, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 2A has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 2A compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for river lamprey under Alternative 1A (Impact AQUA-190 through AQUA-198) also appropriately characterize effects under Alternative 2A.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2A.

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (CM12)

Impact AQUA-191: Effects of Invasive Aquatic Vegetation Management on River Lamprey (CM13)

Impact AQUA-192: Effects of Dissolved Oxygen Level Management on River Lamprey (CM14)

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (CM15)

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (CM16)

Impact AQUA-195: Effects of Illegal Harvest Reduction on River Lamprey (CM17)

Impact AQUA-196: Effects of Conservation Hatcheries on River Lamprey (CM18)

Impact AQUA-197: Effects of Urban Stormwater Treatment on River Lamprey (CM19)

Impact AQUA-198: Effects of Removal/Relocation of Nonproject Diversions on River Lamprey (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on river lamprey for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on river lamprey, for the reasons identified for Alternative 1A, and no mitigation is required.

Non-Covered Aquatic Species of Primary Management Concern

Construction and Maintenance of CM1

The effects of construction and maintenance of CM1 under Alternative 2A would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

Refer to Impact AQUA-1 under delta smelt for a discussion of the effects of construction of water conveyance facilities on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of water conveyance facilities under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-1) except that Alternative 2A could potentially include two different intakes than under Alternative 1A. This would convert about 11,350 lineal feet of existing shoreline habitat into intake facility structures and would require about 26 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects. Additionally, California bay shrimp would not be affected because they do not occur in the vicinity and Sacramento-San Joaquin roach and hardhead are unlikely to be affected because their primary distributions are upstream.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-199, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for non-covered species of management concern.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-199, the impact of the construction of the water conveyance facilities on non-covered aquatic species of primary management concern would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

Refer to Impact AQUA-2 under delta smelt for a discussion of the effects of maintenance of water conveyance facilities on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of water conveyance facilities under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-2). California bay shrimp would not be affected because they do not occur in the vicinity and Sacramento-San Joaquin roach and hardhead are unlikely to be affected because their primary distributions are upstream. Consequently, the effects would not be adverse.

Water Operations of CM1

The effects of water operations of CM1 under Alternative 2A include a detailed analysis of the following species:

- Striped Bass
- American Shad
- Threadfin Shad
- Largemouth Bass

- Sacramento tule perch
- Sacramento-San Joaquin roach – California species of special concern
- Hardhead – California species of special concern
- California bay shrimp

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-201 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

Striped bass spawn mostly upstream of the Delta in the Sacramento River, between Colusa and the Feather River confluence; however spawning can take place as far downstream as Isleton (Moyle 2002). Limited spawning occurs in the south Delta and lower San Joaquin River. Striped bass eggs could be transported downstream from spawning grounds towards the proposed north Delta intakes. Although these intakes would be screened to exclude fish smaller than 15 mm, striped bass eggs or larvae that drift downstream would have the potential to be entrained. Similarly, the screens of the alternate NBA intake would be screened to exclude larger fish, but eggs and larvae would be exposed to entrainment.

At the south Delta facilities, entrainment peaks during the summer months, based on historical salvage. Entrainment losses under Alternative 2A would be expected to decrease compared to baseline conditions since exports are substantially reduced in the summer. This result is based on the assumption that striped bass entrainment is proportional to south Delta exports.

Striped bass may be vulnerable to entrainment at the new alternate NBA intake on the Sacramento River. Similar to the north Delta diversion intakes, the NBA alternate intake on the Sacramento River would be equipped with state-of-the-art fish screens that would exclude larger juveniles and adult striped bass, but would not exclude eggs and larvae.

Agricultural diversions are potential sources of entrainment for small fish such as larval and juvenile striped bass (Nobriga et al. 2004). These diversions are typically small and located on-shore, which may reduce the vulnerability of striped bass to entrainment to these diversions due to their pelagic nature. Reduction or consolidation of diversions from the ROA's (approximately 4–12% of diversions) would not increase entrainment and may provide a minor benefit. In addition, restoration activities as part of the conservation measures should increase the amount of habitat for young striped bass (e.g. inshore rearing habitat), and increase their food supply. The expectation is that these habitat changes would result in at least a minor improvement in production of juvenile striped bass.

NEPA Effects: In summation, potential entrainment would increase for Sacramento River eggs and larvae that drift downstream past the north Delta intakes and the NBA alternative intake on the Sacramento River compared to baseline (no intake facilities), while entrainment of bass at the south Delta facilities would potentially decrease. Although egg and larval survival is correlated with striped bass young of year (YOY) production, the variability in egg and larval survival is dampened by a population bottleneck between YOY abundance and striped bass recruitment at three years of age (Kimmerer et al. 2000). Hence variations in striped bass survival rates during the first few months of life are moderated by this bottleneck (Kimmerer et al. 2000). Therefore it would be expected that reductions in entrainment of juveniles and adults at the south Delta intakes would have a greater population impact than increases in entrainment at the proposed SWP/CVP north Delta intakes and the NBA intake. Furthermore, reductions in agricultural diversions may also reduce entrainment of striped bass. Overall, the effect on striped bass entrainment is not adverse.

CEQA Conclusion: The impact of water operations on entrainment of striped bass would be the same as described immediately above. The changes in entrainment under Alternative 2A would not substantially reduce the striped bass population when other conservation measures are taken into consideration. The impact would be less than significant and no mitigation would be required.

American Shad

The majority of American shad spawning occurs upstream of the Delta but some spawning is believed to occur in the Delta along the Sacramento River (Stevens 1966). American shad eggs stay suspended in the water column and may gradually drift downstream towards the proposed north delta intakes. The north Delta is also used as nursery habitat for American shad. The intakes of the north Delta diversion and the NBA intake would be screened, but small life stages (eggs and larvae) would have the potential to be entrained. Some larval American shad would be in the north Delta, but only a small fraction of the total larval population would encounter the proposed North Delta intakes when they are still vulnerable to entrainment.

At the SWP/CVP south Delta facilities, historical salvage of American shad was highest in the summer months but continued to be elevated through the fall months. American shad entrainment losses under Alternative 2A would decrease compared to baseline conditions due to reduced south delta exports for all months. Reduced south delta entrainment would also be expected to reduce predation loss associated with these facilities, especially within Clifton Court Forebay. Reduction or consolidation of agricultural diversions in ROA's would not increase entrainment.

NEPA Effects: Overall, the effect on American shad is not adverse, and would likely be slightly beneficial.

CEQA Conclusion: The impact of water operations on entrainment of American shad would be the same as described immediately above. The changes in entrainment under Alternative 2A would not substantially reduce the American shad population. The impact would be less than significant and no mitigation would be required.

Threadfin Shad

Threadfin shad are widely distributed throughout the Delta, however they are most abundant in the southeastern region of the Delta where areas of dense SAV in shallow water serve as important spawning and rearing habitat (Feyrer et al. 2009). The proposed SWP/CVP north delta intakes and alternate NBA intake would be located well upstream of this region, which would limit potential entrainment of shad eggs and larvae, and the intakes would be screened to avoid entrainment of juveniles and adults.

At the SWP/CVP south Delta facilities, historical salvage of threadfin shad peaks sharply in the summer months, with smaller peaks occurring in late fall and early winter. Threadfin shad entrainment losses would decrease due to reduced south Delta exports under Alternative 2A Additionally, reduced south delta entrainment is expected to reduce the amount of elevated predation loss associated with these facilities, especially within Clifton Court Forebay.

Agricultural diversions may be sources of entrainment for threadfin shad. Reduction or consolidation of these agricultural diversions under the Plan would decrease or have no impact on threadfin shad entrainment.

NEPA Effects: Overall, entrainment would be reduced, which would benefit threadfin shad. The effect on threadfin shad is not adverse.

CEQA Conclusion: The impact of water operations on entrainment of threadfin shad would be the same as described immediately above. The changes in entrainment under Alternative 2A would not substantially reduce and may benefit the threadfin shad population. The impact would be less than significant and no mitigation would be required.

Largemouth Bass

Historically, entrainment of largemouth bass to the south delta export facilities peaks during the summer months. At the SWP/CVP south Delta facilities, entrainment losses under Alternative 2A are expected to decrease compared to baseline conditions, assuming largemouth bass entrainment is proportional to south Delta exports. Water exports from the south delta would decrease in all months under Alternative 2A compared to baseline conditions.

Largemouth bass are predominantly distributed in the central and south sections of the Delta in areas of dense SAV, and thus would have minimal overlap with propose north Delta intake facilities and alternate NBA intake on the Sacramento River. The proposed intakes would be screened to exclude fish larger than 15 mm. Largemouth bass lay demersal eggs in a nest guarded by the male, and newly hatched largemouth bass hold around their nests until they begin feeding. Parental male bass protect newly hatched young bass for several weeks. These behaviors further minimize the potential for larval largemouth bass to encounter and be entrained into the proposed north Delta intakes and NBA intake.

Agricultural diversions may be sources of entrainment for largemouth bass. Agricultural diversions are typically located nearshore, which is the habitat mainly used by juvenile and adult largemouth bass. Reduction or consolidation of these agricultural diversions under the Plan is not expected to increase entrainment of largemouth bass and would likely reduce overall entrainment attributable to these diversions.

NEPA Effects: Overall, entrainment of largemouth bass would decrease compared to baseline conditions. The effect from Alternative 2A is not adverse and would likely provide minor benefits.

CEQA Conclusion: The impact of water operation on largemouth bass would be as described immediately above. The changes in entrainment under Alternative 2A could benefit the largemouth bass population. The impact would be less than significant and no mitigation would be required.

Sacramento Tule Perch

At the SWP/CVP south Delta facilities, entrainment losses under Alternative 2A would be expected to decrease compared to baseline conditions, because Sacramento tule perch entrainment is assumed to be proportional to south delta exports. Because water would be exported from the proposed north delta facilities under Alternative 2A, less water will be exported from the south delta, leading to presumed reductions in largemouth bass south delta entrainment. Additionally, reduced south delta entrainment is expected to reduce the amount of the elevated predation loss associated with these facilities, especially within Clifton Court Forebay.

The proposed SWP/CVP north delta intakes would be screened with state-of-the-art fish screens so only larval fish should be vulnerable to entrainment. Because Sacramento tule perch are viviparous, newly emerged Sacramento tule perch will already too large to be entrained at the north delta facilities.

Agricultural diversions may be sources of entrainment for Sacramento tule perch. Agricultural diversions are typically located nearshore, which is the habitat mainly used by juvenile and adult Sacramento tule perch. Reduction or consolidation of these agricultural diversions under the Plan would decrease entrainment of Sacramento tule perch into these agricultural intakes.

NEPA Effects: In summation, entrainment of Sacramento tule perch is expected to decrease compared to Existing Conditions. Overall, the effect on entrainment from Alternative 2A is not adverse.

CEQA Conclusion: The impact of water operations on entrainment of Sacramento tule perch would be the same as described immediately above. The changes in entrainment under Alternative 2A would not substantially reduce the Sacramento tule perch population. The impact would be less than significant and no mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: The effect of water operations on entrainment of Sacramento-San Joaquin roach under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-201). For a detailed discussion, please see Alternative 1A, Impact AQUA-201. The effects would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of Sacramento-San Joaquin roach would be the same as described immediately above and would be less than significant.

Hardhead

NEPA Effects: The effect of water operations on entrainment of hardhead under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-3). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. For a discussion, please see Alternative 1A, Impact AQUA-3. The effects would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of hardhead would be the same as described immediately above and would be less than significant.

California Bay Shrimp

California bay shrimp do not occur in the vicinity of the intakes so there would be no entrainment effect on them.

CEQA Conclusion: California bay shrimp do not occur in the vicinity of the intakes so there would no entrainment impact on them.

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-202 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

In general, Alternative 2A would slightly improve the quality and quantity of upstream habitat conditions for striped bass relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under NAA during April through June except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be substantially greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be greater than flows under NAA regardless of water year type.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year types (Table 11-2A-94).

Table 11-2A-94. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 59°F to 68°F Water Temperature Range for Striped Bass Spawning, Embryo Incubation, and Initial Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-3 (-6%)	-8 (-19%)
Above Normal	-27 (-60%)	-24 (-133%)
Below Normal	-12 (-28%)	-14 (-46%)
Dry	-4 (-8%)	0 (0%)
Critical	8 (21%)	-6 (-12%)
All	-6 (-14%)	-9 (-24%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 2A would not cause a substantial reduction in striped bass spawning, incubation, or initial rearing habitat. Flows in all rivers examined during the April through June spawning, incubation, and initial rearing period under Alternative 2A would generally be similar to or greater than flows under NAA. The percentage of months outside the 59°F to 68°F water temperature range would generally be lower under Alternative 2A than under NAA.

CEQA Conclusion: In general, Alternative 2A would slightly improve the quality and quantity of upstream habitat conditions for striped bass relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would always be similar to or greater than flows under Existing Conditions during April through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (31% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal years during April (7% lower) and wet and critical years during June (25% and 31% lower, respectively), but generally lower, by up to 24%, during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June would be lower than the percentage under Existing Conditions in all water years except critical years (21% higher) (Table 11-2A-94).

Collectively, these results indicate that the impact would not be significant because Alternative 2A would not cause a substantial reduction in spawning, incubation, and initial rearing habitat of striped bass. Therefore, no mitigation is necessary. Flows in all rivers except the San Joaquin and Stanislaus rivers during the April through June spawning, incubation, or initial rearing period under Alternative 2A would generally be similar to or greater than flows under the Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 2A, although this effect would not be biologically meaningful to striped bass. The percentage of months outside the 59°F to 68°F water temperature range would generally be lower under Alternative 2A than under Existing Conditions.

American Shad

In general, Alternative 2A would slightly improve the quality and quantity of upstream habitat conditions for American shad relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under NAA during April through June except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be substantially greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be greater than flows under NAA regardless of water year type.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside the 60°F to 70°F water temperature range would generally be lower than the percentage under NAA depending on water year type (Table 11-2A-95).

Table 11-2A-95. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 60°F to 70°F Water Temperature Range for American Shad Adult Migration and Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-6 (-14%)	-1 (-3%)
Above Normal	-6 (-17%)	-15 (-50%)
Below Normal	0 (0%)	-7 (-23%)
Dry	-2 (-5%)	-7 (-20%)
Critical	3 (8%)	-3 (-7%)
All	-3 (-7%)	-6 (-16%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 2A would not cause a substantial reduction in American shad spawning or adult migration. Flows in all rivers examined during the April through June adult migration and spawning period under Alternative 2A would generally be similar to or greater than flows under NAA. The percentage of months outside the 60°F to 70°F water temperature range would generally be lower under Alternative 2A than under NAA.

CEQA Conclusion: In general, Alternative 2A would slightly improve the quality and quantity of upstream habitat conditions for American shad relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would always be similar to or greater than flows under Existing Conditions during April through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (31% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal years during April (7% lower) and wet and critical years during June (25% and 31% lower, respectively), but generally lower, by up to 24%, during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside of the 60°F to 70°F water temperature range would be similar to or lower than the percentage under Existing Conditions in all water years except critical years (8% higher) (Table 11-2A-95).

Collectively, these results indicate that the impact would not be significant because Alternative 2A would not cause a substantial reduction in American shad adult migration and spawning habitat, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus rivers during the April through June adult migration and spawning period under Alternative 2A would generally be similar to or greater than flows under the Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 2A, although this effect would be biologically meaningful to American shad. The percentage of months outside the 60°F to 70°F water temperature range would generally be similar to or lower under Alternative 2A than under the Existing Conditions.

Threadfin Shad

In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during April through August threadfin shad spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT during April through July would generally be similar to or greater than flows under NAA throughout the period with some exceptions (up to 15% lower). During August, flows under A2A_LLT would generally be lower than flows under NAA, by up to 15%, depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA, except in critical years during August (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would nearly always be similar to or greater than flows under NAA throughout the period, except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be lower than those under NAA during July and August (up to 44% lower) and greater during April through June (up to 166% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*),

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar between NAA during April.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT below 68°F would be greater than those under NAA in wet above normal, and below normal water years (10% to 21% higher depending on water year type), 11% lower than those under NAA in dry years, and not different from those under NAA in critical water years (Table 11-2A-96).

Table 11-2A-96. Difference and Percent Difference in the Percentage of Months during April–August in Which Water Temperatures in the Feather River below Thermalito Afterbay Fall below the 68°F Water Temperature Threshold for Threadfin Shad Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-8 (-12%)	5 (10%)
Above Normal	-16 (-21%)	13 (21%)
Below Normal	-19 (-27%)	6 (11%)
Dry	-34 (-46%)	-4 (-11%)
Critical	-28 (-44%)	0 (0%)
All	-20 (-29%)	3 (7%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 2A would not cause a substantial reduction in spawning habitat. Flows in all rivers examined during the April through August spawning period under Alternative 2A would generally be similar to or greater than flows under NAA, except during summer months in the Sacramento, Feather, and American rivers. Lower flows during these months in these rivers are not of sufficient magnitude or frequency to have a biologically meaningful effect on threadfin shad. The percentage of months below the spawning temperature threshold would be moderately higher under Alternative 2A relative to NAA, but this increase is not expected to have a biologically meaningful effect on the threadfin shad population because there are no temperature-related effects in any other rivers.

CEQA Conclusion: In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during April through August spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT during April through July would generally be similar to or greater than flows under Existing Conditions, except in wet years during May and critical years during July (15% and 13% lower, respectively). Flows under A2A_LLT during August would generally be lower than flows under Existing Conditions, by up to 24% (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the period, except in critical years during May and August (6% and 33% lower, respectively) and wet years during July (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would nearly always be similar to or greater than flows under Existing Conditions throughout the period, except in critical years during August (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater (up to 153% greater) than flows under Existing Conditions during April through June and lower (up to 50% lower) during July and August (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to flows under Existing Conditions during April, lower during May, July, and August (up to 49% lower), and greater during June (up to 24% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, the percentage of months below the 68°F water temperature threshold for threadfin shad spawning under A2A_LLT would be 12% to 46% lower than the percentage under Existing Conditions, depending on water year type (Table 11-2A-96).

Collectively, these results indicate that the impact would not be significant because Alternative 2A would not cause a substantial reduction in habitat, and no mitigation is necessary. Flows in all rivers examined during the April through August spawning period under Alternative 2A would generally be similar to or greater than flows under the Existing Conditions, except during summer months in the Sacramento, Feather, and American rivers. Lower flows during these months in these rivers would not be of sufficient magnitude or frequency to cause a biologically meaningful effect on threadfin shad. The percentage of months outside all temperature thresholds are generally lower under Alternative 2A than under the Existing Conditions, indicating that there would be a net temperature-related benefit of Alternative 2A to threadfin shad.

Largemouth Bass

In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for largemouth bass relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under NAA during March through June, except in below normal years in March (6% lower) and critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would be substantially greater (up to 166% greater) than flows under NAA during March through June, except in below normal years during March (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to or greater than flows under NAA during March, April, and June, with some exceptions (up to 24% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during May under A2A_LLT would generally be greater by up to 24%.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside the 59°F to 75°F water temperature range would be similar to or lower than the percentage under NAA in all water years except dry years (5% higher) (Table 11-2A-97).

Table 11-2A-97. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 59°F to 75°F Water Temperature Range for Largemouth Bass Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-9 (-16%)	0 (0%)
Above Normal	-16 (-32%)	-2 (-7%)
Below Normal	-11 (-24%)	0 (0%)
Dry	-17 (-35%)	1 (5%)
Critical	-19 (-43%)	-8 (-33%)
All	-13 (-27%)	-1 (-3%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

CEQA Conclusion: In general, Alternative 2A would reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (10% lower) and wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March and critical years during May (6% lower in both) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would always be similar to or greater than flows under Existing Conditions during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be substantially greater (up to 153% greater) than flows under Existing Conditions during March through June, except in below normal and dry years during March (46% and 5%, respectively) and in wet years during May (31% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during March, April, and June, except in critical years during March and June (8% and 31% lower, respectively), above normal years during April (7% lower) and wet years during June (25% lower). Flows under A2A_LLT in May would generally be lower, up to 24%, than those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside of the 59°F to 75°F water temperature range for largemouth bass spawning would be lower than the percentage under Existing Conditions in all water years (Table 11-2A-97).

Collectively, these results indicate that the impact would be less than significant because Alternative 2A would not cause a substantial reduction in largemouth bass habitat. No mitigation is necessary.

Sacramento Tule Perch

The effects of water operations on spawning habitat for Sacramento tule perch under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-202). For a detailed discussion, please see Alternative 1A, Impact AQUA-202.

Sacramento-San Joaquin Roach

In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under NAA during March through June, except in below normal years in March (6% lower) and critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would be substantially greater (up to 166% greater) than flows under NAA during March through June, except in below normal years during March (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to or greater than flows under NAA during March, April, and June, with some exceptions (up to 24% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during May under A2A_LLT would generally greater by up to 24% relative to NAA.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

In the Feather River below Thermalito Afterbay, the percentage of months in which temperatures would be below the 60.8°F water temperature threshold for roach spawning initiation under A2A_LLT would be similar to or lower than the percentage under NAA in all water year types except below normal years (7% higher) (Table 11-2A-98).

Table 11-2A-98. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Fall below the 60.8°F Water Temperature Threshold Range for the Initiation of Sacramento-San Joaquin Roach Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-13 (-19%)	0 (0%)
Above Normal	-7 (-13%)	0 (0%)
Below Normal	-2 (-4%)	4 (7%)
Dry	-11 (-21%)	0 (0%)
Critical	-19 (-33%)	-4 (-11%)
All	-10 (-18%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

CEQA Conclusion: In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (10% lower) and wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March and critical years during May (6% lower in both) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would always be similar to or greater than flows under Existing Conditions during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be substantially greater (up to 153% greater) than flows under Existing Conditions during March through June, except in below normal and dry years during March (46% and 5%, respectively) and in wet years during May (31% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during March, April, and June, except in critical years during March and June (8% and 31% lower, respectively), above normal years during April (7% lower) and wet years during June (25% lower). Flows under A2A_LLT in May would generally be lower, up to 24%, than those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

In the Feather River below Thermalito Afterbay, the percentage of months in which temperatures would be below the 60.8°F water temperature threshold for roach spawning initiation under A2A_LLT would be lower than the percentage under Existing Conditions in all water years (Table 11-2A-98).

Hardhead

In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for hardhead relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would always to be similar to flows under NAA throughout the period regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be substantially greater (up to 166% greater) than flows under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would be similar to flows under NAA in April. During May, flows under A2A_LLT would generally be greater than flows under NAA (up to 24% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside the range would generally be lower than the percentage under NAA in all water year types except below normal, in which there would be no difference (Table 11-2A-99).

Table 11-2A-99. Difference and Percent Difference in the Percentage of Months during April–May in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 59°F to 64°F Water Temperature Range for Hardhead Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-4 (-6%)	-6 (-10%)
Above Normal	-18 (-29%)	-9 (-20%)
Below Normal	21 (50%)	0 (0%)
Dry	-8 (-15%)	-3 (-6%)
Critical	-4 (-8%)	-4 (-8%)
All	-2 (-4%)	-4 (-8%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

CEQA Conclusion: In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the period, except in wet years during May (15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the period, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would always be similar to or greater than flows under Existing Conditions throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the period, except in wet years during May (30% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would be similar to or greater than flows under Existing Conditions during April except in above normal years (7% lower) and generally lower than flows under Existing Conditions, by up to 24%, during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside of the 59°F to 64°F water temperature range for hardhead spawning would be lower than the percentage under Existing Conditions in all water years except below normal years (50% higher) (Table 11-2A-99).

California Bay Shrimp

The effect of water operations on spawning habitat of California bay shrimp under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-4). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species.

NEPA Effects: For a discussion, please see Alternative 1A, Impact AQUA-4. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The effects would not be adverse.

CEQA Conclusion: The impact of water operations on spawning habitat of California bay shrimp would be the same as described immediately above. The impacts would be less than significant.

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-203 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

NEPA Effects: The discussion under Alternative 2A, Impact AQUA-202 for striped bass also addresses the egg incubation and initial rearing period. That analysis indicates that there is no adverse effect on striped bass rearing during that period. Other effects of water operations on rearing habitat for striped bass under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-202). For a detailed discussion, please see Alternative 2A, Impact AQUA-202. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on striped bass rearing habitat would be less than significant.

American Shad

NEPA Effects: The effects of water operations on rearing habitat for American shad under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact

AQUA-203). For a detailed discussion, please see Alternative 1A, Impact AQUA-203. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on American shad rearing habitat would be less than significant.

Threadfin Shad

NEPA Effects: The effects of water operations on rearing habitat for threadfin shad under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203). For a detailed discussion, please see Alternative 1A, Impact AQUA-203. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on threadfin shad rearing habitat would be less than significant.

Largemouth Bass

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during all months but August and November with some exceptions (up to 15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower, by up to 25%, than NAA depending on month, water year type, and time period.

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA during the April through November period with some exceptions (up to 58% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be lower (up to 52%) than flows under NAA during July through September, greater during April through June and October (up to 105% greater), and similar during November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to NAA during April, October and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 88°F under NAA or A2A_LLT (Table 11-2A-100). As a result, there would be no difference in the percentage of months in which the 88°F water temperature threshold is exceeded between Alternative 2A and NAA.

Table 11-2A-100. Difference and Percent Difference in the Percentage of Months during April–November in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 88°F Water Temperature Threshold for Juvenile Largemouth Bass Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round adult largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during all months but August and November with some exceptions (up to 15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower than flows under NAA (up to 25% and 17% lower depending on month, water year type, and time period).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA with some exceptions (up to 12% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during February and June (6% and 8% lower, respectively) and below normal years during March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater than those under NAA during February through June and October (up to 105% greater), similar during January, November, and December, and lower during July through September (up to 52% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be greater than flows under NAA during May and June (up to 24% greater), lower during July through September (up to 27% lower), and similar during the remaining months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the year-round period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F under NAA or A2A_LLT (Table 11-2A-101). As a result, there would be no difference in the percentage of years in which the 86°F water temperature threshold is exceeded between Alternative 2A and NAA.

Table 11-2A-101. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Adult Largemouth Bass Survival[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 2A would not cause a substantial reduction in juvenile and adult rearing habitat. Flows in all rivers examined during the year under Alternative 2A are generally similar to or greater than flows under NAA in most months. Flows in July through September are generally lower in the Feather River high flow channel and in the American River below Nimbus Dam, although these reductions would not be biologically meaningful to the largemouth bass population. The percentage of months outside all temperature thresholds examined in the Feather River under Alternative 2A are generally similar to or lower than under NAA. There would be no temperature-related effects in any other rivers examined.

CEQA Conclusion: In general, Alternative 2A would reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to the Existing Conditions.

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions in all months but August and November with some exceptions (up to 17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during August and November under A2A_LLT would be up to 24% lower than flows under Existing Conditions.

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT during April through September would generally be similar to or greater than flows under Existing Conditions throughout the year with some exceptions (up to 58% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during October and November would be up to 25% lower than flows under Existing Conditions.

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the April through November period, except in critical years during August through November (6% to 29% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater (up to 217% greater) than flows under Existing Conditions during April through June and September through October and lower (up to 50% lower) during July, August, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during April and October with some exceptions (up to 31% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during May, July through September, and November would be lower by up to 50% and flows during October would be similar between Existing Conditions and A2A_LLT.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 88°F water temperature threshold for April through November juvenile largemouth bass occurrence under Existing Conditions or A2A_LLT (Table 11-2A-100). As a result, there would be no difference in the percentage of months in which the 88°F water temperature threshold is exceeded between Alternative 2A and the Existing Conditions.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round adult largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during all months but August and November with some exceptions (up to 17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower than flows under Existing Conditions (up to 24% lower and 13% lower, respectively).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year with some exceptions (up to 58% lower), except during October and November when it would generally be lower (up to 25% lower during both months) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August through November (6% to 29% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater than those under Existing Conditions during March through June and September through October (up to 217% greater), lower during February, July through August, and November through December (up to 50% lower), and similar during January (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally greater than flows under Existing Conditions during February, March, and June (up to 27% greater), lower during January, May, July through September, and November through December (up to 49% lower), and similar during April and October (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 86°F water temperature range for year-round adult largemouth bass occurrence under Existing Conditions or A2A_LLT (Table 11-2A-101). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between Alternative 2A and the Existing Conditions.

Collectively, these results indicate that the impact would be significant because Alternative 2A would cause a substantial reduction in largemouth bass habitat. Flows would be substantially lower during the majority of the year-round adult rearing period in the American River and in nearly half of the period (5 months) in the Feather River. Reduced flows in other rivers including the San Joaquin and Stanislaus rivers would not have biologically meaningful effects on largemouth bass. The percentages of months outside all temperature thresholds are generally lower under Alternative 2A than under the Existing Conditions. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available.

The NEPA and CEQA conclusions differ for this impact statement because they were determined using two unique baselines. The NEPA conclusion was based on the comparison of A2A_LLT with NAA and the CEQA conclusion was based on the comparison of A2A_LLT with Existing Conditions. These baselines differ in two ways. First, the NAA includes the Fall X2 standard in wet above normal water years whereas the CEQA Existing Conditions do not. Second, the NAA is assumed to occur during the late long-term implementation period whereas the CEQA conclusion assumes existing climate conditions. Therefore, differences in model outputs between Existing Conditions and Alternative 2A are due primarily to both the alternative and future climate change.

Sacramento Tule Perch

In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round Sacramento tule perch presence. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during all months but August and November with some exceptions (up to 15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower than flows under NAA (up to 25% and 17% lower depending on month, water year type, and time period).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA with some exceptions (up to 12% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally similar to or greater than NAA throughout the year, except in critical years during February and June (6% and 8% lower, respectively) and below normal years during March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally greater than those under NAA during February through June and October (up to 105% greater), similar during January, November, and December, and lower during July through September (up to 52% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be greater than flows under NAA during May and June (up to 24% greater), lower during July through September (up to 27% lower), and similar during the remaining months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months exceeding water temperature thresholds of 72°F and 75°F for the year-round occurrence of all life stages of Sacramento tule perch was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quantity and quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, the percentage of years under A2A_LLT exceeding the 72°F threshold would be higher than the percentage under NAA by 13% to 73% depending on water year type (Table 11-2A-102). Although relative differences in above normal, below normal, and critical years are large due to small values, the absolute differenced in percent exceedance are only 2% to 4%, respectively, and do not represent biologically meaningful effects to Sacramento tule perch.

The percentage of months under A2A_LLT exceeding the 75°F threshold would be similar to or lower than the percentage under NAA in all water year except wet and dry years (100% and 50% higher, respectively) (Table 11-2A-102). Although the relative differences in wet and dry years are large due to small values, the absolute differenced in percent exceedance are only 0.3% and 1%, respectively, and do not represent biologically meaningful effects to Sacramento tule perch.

Table 11-2A-102. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed 72°F and 75°F Water Temperature Thresholds for Sacramento Tule Perch Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
72°F Threshold		
Wet	5 (214%)	5 (73%)
Above Normal	2 (NA)	2 (67%)
Below Normal	7 (NA)	4 (58%)
Dry	12 (NA)	6 (56%)
Critical	13 (300%)	2 (13%)
All	8 (562%)	4 (49%)
75°F Threshold		
Wet	0.3 (NA)	0.3 (100%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	2 (NA)	1 (50%)
Critical	6 (900%)	0 (0%)
All	1 (1,400%)	0.3 (20%)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 2A would not cause a substantial reduction in Sacramento tule perch rearing habitat. Flows under Alternative 2A in all rivers examined throughout the year are generally similar to or greater than flows under NAA, except during summer months in the Feather and American rivers. These reductions in flows, however, would not result in an overall biologically meaningful effect on

Sacramento tule perch. The percentages of months outside temperature thresholds under Alternative 2A are generally similar to the percentages under NAA.

CEQA Conclusion: In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round Sacramento tule perch presence. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during all months but August and November with some exceptions (up to 17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower than flows under Existing Conditions (up to 24% lower and 13% lower, respectively).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year with some exceptions (up to 58% lower), except during October and November when it would generally be lower (up to 25% for during both months) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August through November (6% to 29% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater than those under Existing Conditions during March through June and September through October (up to 217% greater), lower during February, July through August, and November through December (up to 50% lower), and similar during January (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally greater than flows under Existing Conditions during February, March, and June (up to 27% greater), lower during January, May, July through September, and November through December (up to 49% lower), and similar during April and October (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months exceeding water temperatures of 72°F and 75°F for the year-round occurrence of all life stages of Sacramento tule perch was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in Clear Creek or the San Joaquin River.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the year.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT exceeding 72°F relative to the percentage under Existing Conditions would be similar to or higher, by up to 300% (Table 11-2A-102).

The percentage of months under A2A_LLT exceeding 75°F would be similar to the percentage under Existing Conditions in all water years except critical years (900% higher) (Table 11-2A-102).

Collectively, these results indicate that the impact would be significant because Alternative 2A would cause a substantial reduction in Sacramento tule perch habitat. Flows would be substantially lower during the majority of the year-round period in the American River and in half of the period in the Feather River. Flows in other rivers would not have biologically meaningful effects. The percentages of months above both temperature thresholds are generally lower under Alternative 2A than under the Existing Conditions. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available.

The NEPA and CEQA conclusions differ for this impact statement because they were determined using two unique baselines. The NEPA conclusion was based on the comparison of A2A_LLT with NAA and the CEQA conclusion was based on the comparison of A2A_LLT with Existing Conditions. These baselines differ in two ways. First, the NAA includes the Fall X2 standard in wet above normal water years whereas the CEQA Existing Conditions do not. Second, the NAA baseline is assumed to occur during the late long-term implementation period whereas the CEQA conclusion assumes existing climate conditions. Therefore, differences in model outputs between Existing Conditions and Alternative 2A are due primarily to both the alternative and future climate change.

Sacramento-San Joaquin Roach

In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach rearing period. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during all months but August and November with some exceptions (up to 15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower than flows under NAA (up to 25% and 17% lower depending on month, water year type, and time period).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA with some exceptions (up to 12% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during February and June (6% and 8% lower, respectively) and below normal years during March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater than those under NAA during February through June and October (up to 105% greater), similar during January, November, and December, and lower during July through September (up to 52% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would be greater than flows under NAA during May and June (up to 24% greater), lower during July through September (up to 27% lower), and similar during the remaining months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F under NAA or A2A_LLT (Table 11-2A-103). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between Alternative 2A and NAA.

Table 11-2A-103. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Range for Sacramento-San Joaquin Roach Survival[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] A negative value indicates a benefit (reduction in months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 2A would not cause a substantial reduction in spawning and juvenile and adult Sacramento-San Joaquin roach rearing habitat. Flows under Alternative 2A in all rivers examined throughout the year are generally similar to or greater than flows under NAA, except during summer months in the Feather and American rivers, although these reductions would not be biologically meaningful to the roach population. The percentage of months outside temperature thresholds are generally similar to or lower under Alternative 2A than under NAA.

CEQA Conclusion: In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach rearing period. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during all months but August and November with some exceptions (up to 17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower than flows under Existing Conditions (up to 24% lower and 13% lower, respectively).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year with some exceptions (up to 58% lower), except during October and November when it would generally be lower (up to 25% lower during both months) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August through November (6% to 29% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater than those under Existing Conditions during March through June and September through October (up to 217% greater), lower during February, July through August, and November through December (up to 50% lower), and similar during January (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally greater than flows under Existing Conditions during February, March, and June (up to 27% greater), lower during January, May, July through September, and November through December (up to 49% lower), and similar during April and October (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F water temperature threshold for Sacramento-San Joaquin roach occurrence under Existing Conditions or A2A_LLT (Table 11-2A-103). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between Alternative 2A and the Existing Conditions.

Collectively, these results indicate that the impact would be significant because Alternative 2A would cause a substantial reduction in Sacramento-San Joaquin roach habitat. Flows would be substantially lower during the majority of the year-round juvenile and adult rearing period in the American River and in half of the period in the Feather River. Flows in other rivers would not have biologically meaningful effects. The percentages of months outside both temperature thresholds are generally lower under Alternative 2A than under the Existing Conditions. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available.

The NEPA and CEQA conclusions differ for this impact statement because they were determined using two unique baselines. The NEPA conclusion was based on the comparison of A2A_LLT with NAA and the CEQA conclusion was based on the comparison of A2A_LLT with Existing Conditions.

These baselines differ in two ways. First, the NAA includes the Fall X2 standard in wet above normal water years whereas the CEQA Existing Conditions do not. Second, the NAA is assumed to occur during the late long-term implementation period whereas the CEQA conclusion assumes existing climate conditions. Therefore, differences in model outputs between the Existing Conditions and Alternative 2A are due primarily to both the alternative and future climate change.

Hardhead

In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for hardhead relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under NAA during all months but August and November with some exceptions (up to 15% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower than flows under NAA (up to 25% and 17% lower depending on month, water year type, and time period).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under NAA with some exceptions (up to 12% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than NAA throughout the year, except in critical years during February and June (6% and 8% lower, respectively) and below normal years during March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater than those under NAA during February through June and October (up to 105% greater), similar during January, November, and December, and lower during July through September (up to 52% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally be greater than flows under NAA during May and June (up to 24% greater), lower during July through September (up to 27% lower), and similar during the remaining months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead rearing was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside the range would be similar to or lower than the percentage under NAA in all water year except below normal (9% higher) (Table 11-2A-104).

Table 11-2A-104. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 65°F to 82.4°F Water Temperature Range for Juvenile and Adult Hardhead Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. A2A_LLT	NAA vs. A2A_LLT
Wet	-1 (-1%)	2 (3%)
Above Normal	-8 (-11%)	-4 (-6%)
Below Normal	-5 (-7%)	6 (9%)
Dry	-8 (-11%)	0 (-1%)
Critical	-6 (-8%)	1 (2%)
All	-5 (-7%)	1 (2%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 2A would not cause a substantial reduction in spawning and juvenile and adult hardhead rearing. Flows under Alternative 2A in all rivers examined throughout the year are generally similar to or greater than flows under NAA, except during summer months in the Feather and American rivers. These reductions in flows, however, would not cause an overall biologically meaningful effect on hardhead. The percentages of months outside all temperature thresholds are generally lower under Alternative 2A than under NAA.

CEQA Conclusion: In general, Alternative 2A would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions during all months but August and November with some exceptions (up to 17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A2A_LLT during August and November would be lower than flows under Existing Conditions (up to 24% lower and 13% lower, respectively).

In the Trinity River below Lewiston Reservoir, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year with some exceptions (up to 58% lower), except during October and November when it would generally be lower (up to 25% lower during both months) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A2A_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August through November (6% to 29% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A2A_LLT would generally be greater than those under Existing Conditions during March through June and September through October (up to 217% greater), lower during February, July through August, and November through December (up to 50% lower), and similar during January (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A2A_LLT would generally greater than flows under Existing Conditions during February, March, and June (up to 27% greater), lower during January, May, July through September, and November through December (up to 49% lower), and similar during April and October (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months in which year-round in-stream temperatures would be outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead rearing was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under Alternative 2A would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, the percentage of months under A2A_LLT outside of the 65°F to 82.4°F water temperature range for juvenile and adult hardhead occurrence would be similar to or lower than the percentage under Existing Conditions in all water years (Table 11-2A-104).

Collectively, these results indicate that the impact would be significant because Alternative 2A would cause a substantial reduction in hardhead habitat. Flows would be substantially lower during the majority of the year-round juvenile and adult rearing period in the American River and in half of the period in the Feather River. Flows in other rivers would not have biologically meaningful effects on hardhead. The percentages of months outside both temperature thresholds are generally lower under Alternative 2A than under the Existing Conditions. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available.

The NEPA and CEQA conclusions differ for this impact statement because they were determined using two unique baselines. The NEPA conclusion was based on the comparison of A2A_LLT with NAA and the CEQA conclusion was based on the comparison of A2A_LLT with Existing Conditions. These baselines differ in two ways. First, the NAA includes the Fall X2 standard in wet above normal water years whereas the CEQA Existing Conditions do not. Second, the NAA is assumed to occur during the late long-term implementation period whereas the CEQA conclusion assumes existing climate conditions. Therefore, differences in model outputs between the Existing Conditions and Alternative 2A are due primarily to both the alternative and future climate change.

California Bay Shrimp

NEPA Effects: The effect of water operations on rearing habitat of California bay shrimp under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-3). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. These effects would not be adverse.

CEQA Conclusion: As described above the impacts on California bay shrimp rearing habitat would be less than significant.

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-204 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

Adult striped bass migrate up the Delta via the Sacramento River to reach suitable spawning habitat upstream. It is assumed that this migration period occurs around the same timing as spawning, from April through June.

NEPA Effects: Flows in the Sacramento River below the north Delta diversion facilities would be lower than NAA during the April through June period. Monthly flows on average would be 14–23% lower than NAA. Sacramento River flows are highly variable interannually, and striped bass are still able to migrate upstream the Sacramento River during lower flow years. The effect of reduced Sacramento flows under Alternative 2A would not be adverse.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because the changes in flow (22–30% lower compared to Existing Conditions) would not interfere substantially with movement of spawning striped bass through the Delta. No mitigation would be required.

American Shad

Adult American shad migrate up the Delta to reach suitable spawning habitat upstream around March-May. American shad migrate up the Sacramento River while some shad spawn in the San Joaquin River basin. Flows in the Sacramento River below the north Delta diversion facilities would be lower than NAA during March–May. Monthly flows on average would be 18–25% less than NAA. Flows from the San Joaquin River at Vernalis would be unchanged. Sacramento River flows are highly variable interannually, and American shad are still able to migrate upstream the Sacramento River during lower flow years.

NEPA Effects: Overall, the impact to American shad migration habitat conditions would not be adverse under Alternative 2A.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because the changes in flow (22–30% lower compared to Existing Conditions) would not interfere substantially with movement of American shad from the Delta to upstream spawning habitat. No mitigation would be required.

Threadfin Shad

NEPA Effects: Threadfin shad are semi-anadromous, moving between freshwater and brackish water habitats. Threadfin shad found in the Delta to not actively migrate upstream to spawn. Therefore, there is no effect on migration habitat conditions.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because flow changes in the Delta under Alternative 2A would not alter movement patterns for threadfin shad. No mitigation would be required.

Largemouth Bass

NEPA Effects: Largemouth bass are non-migratory fish within the Delta. Therefore they do not use the Delta as migration habitat corridor. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes under Alternative 2A would not affect largemouth movements within the Delta. No mitigation would be required.

Sacramento Tule Perch

NEPA Effects: Similar with largemouth bass, Sacramento tule perch are a non-migratory species and do not use the Delta as a migration corridor as they are a resident Delta species. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes would not affect Sacramento tule perch movements within the Delta. No migration would be required.

Sacramento-San Joaquin Roach

NEPA Effects: For Sacramento-San Joaquin roach the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 2A, Impact AQUA-202 for spawning. As described there, the flows would slightly improve the upstream conditions relative to NAA. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for Sacramento-San Joaquin roach would not be significant and no mitigation is required.

Hardhead

NEPA Effects: For hardhead the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 2A, Impact AQUA-202 for spawning. As described under Impact AQUA-202, the flows would slightly improve the upstream conditions relative to NAA. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for hardhead would not be significant and no mitigation is required.

California Bay Shrimp

NEPA Effects: The effect of water operations on migration conditions of California bay shrimp under Alternative 2A would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-4). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. As described under Alternative 1A, Impact AQUA-4 the effect would not be adverse.

CEQA Conclusion: As described above the impacts on California bay shrimp rearing habitat would be less than significant.

Restoration Measures (CM2, CM4–CM7, and CM10)

The effects of restoration measures under Alternative 2A would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-7 under delta smelt for a discussion of the effects of construction of restoration measures on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of restoration measures under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-7). The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of the construction of restoration measures would be less than significant.

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-8 under delta smelt a discussion of the effects of contaminants associated with restoration measures on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of contaminants associated with restoration measures under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-8). The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of the contaminants associated with restoration measures would be less than significant.

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

Refer to Impact AQUA-9 under delta smelt a general discussion of the effects of restored habitat conditions on non-covered species of primary management concern. Although there are minor differences the effects are similar. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of restored habitat conditions under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-8). In addition, see Alternative 1A, Impact AQUA-207 for a discussion of the different effects on non-covered species of primary management concern.

NEPA Effects: Overall, the effects range from slightly beneficial to beneficial.

CEQA Conclusion: As described immediately above, the impacts of restored habitat conditions would range from slightly beneficial to beneficial.

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (CM12)

NEPA Effects: Refer to Impact AQUA-10 under delta smelt for a discussion of the effects of methylmercury management on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of methylmercury management under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-10). As described in detail under Alternative 1A, Impact AQUA-10. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of methylmercury management would be less than significant.

Impact AQUA-209: Effects of Invasive Aquatic Vegetation Management on Non-Covered Aquatic Species of Primary Management Concern (CM13)

Refer to Impact AQUA-11 under delta smelt a discussion of the effects of invasive aquatic vegetation management on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of invasive aquatic vegetation management under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-11) except for predatory species (striped bass and largemouth bass) and Sacramento tule perch. Invasive aquatic vegetation provides hiding habitat for predatory fish which improves their hunting success. Sacramento tule perch also use the cover of aquatic plants in the Sacramento and San Joaquin rivers and in Suisun marsh. Consequently, reducing the amount of invasive aquatic habitat will negatively affect these predatory species and Sacramento tule perch. However, this control will not substantially reduce the ability of the predatory species to hunt and there will still be many other habitats in which the predatory species can successfully hunt and in which Sacramento tule perch will thrive.

NEPA Effects: The overall effect will not be adverse. Control of invasive aquatic vegetation would not occur within California bay shrimp habitat and there would be no effect on them.

CEQA Conclusion: Refer to Impact AQUA-11 under delta smelt a discussion of the effects of invasive aquatic vegetation management on non-covered species of primary management concern. There are minor differences and the effects are similar except for predatory species (striped bass and largemouth bass) and Sacramento tule perch. Invasive aquatic vegetation provides hiding habitat for predatory fish which improves their hunting success. Control of invasive aquatic vegetation would not occur within California bay shrimp habitat and there would be no effect on them. Sacramento tule perch use the cover of aquatic plants in the Sacramento and San Joaquin rivers and in Suisun marsh. Consequently, reducing the amount of invasive aquatic habitat will negatively affect the predatory species and Sacramento tule perch. However, this control will not substantially reduce the ability of the predatory species to hunt and there will still be many other habitats in which the predatory species can successfully hunt and in which Sacramento tule perch will thrive. Therefore the effect on them will not be significant and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

The effects of other conservation measures under Alternative 2A would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-210: Effects of Dissolved Oxygen Level Management on Non-Covered Aquatic Species of Primary Management Concern (CM14)

NEPA Effects: Refer to Impact AQUA-12 under delta smelt for a discussion of the effects of dissolved oxygen management on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of dissolved oxygen management under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-12). For a detailed discussion, please see Alternative 1A, Impact AQUA-12. California bay shrimp do not occur in this habitat and there would be no effect on them. These effects would be beneficial.

CEQA Conclusion: As described immediately above, the impacts of oxygen level management would be beneficial.

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (CM15)

NEPA Effects: Refer to Alternative 1A, Impact AQUA-13 under delta smelt a discussion of the effects of predatory fish (striped bass and largemouth bass) and predator management on non-predatory fish. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The purpose of predatory fish management is to reduce the numbers of predatory fish and to reduce their hunting success. This management will have negative effects on predatory fish. However, the numbers of predatory fish are high and the extent of the habitats in which they hunt is extensive. Therefore the effects of this management will not be adverse. California bay shrimp do not occur in these habitats and there would be no effect on them.

CEQA Conclusion: Refer to Alternative 1A, Impact AQUA-13 under delta smelt a discussion of the effects of predatory fish and predator management on non-predatory fish. The purpose of predatory fish management is to reduce the numbers of predatory fish and to reduce their hunting success. This management will have negative effects on predatory fish. However, the numbers of predatory fish are high and the extent of the habitats in which they hunt is extensive. Therefore the effects of this management will not be significant. No mitigation is required. California bay shrimp do not occur in these habitats and there would be no effect on them.

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (CM16)

Refer to Impact AQUA-14 under delta smelt for a discussion of the effects of nonphysical fish barriers on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of nonphysical fish barriers under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-14). For a detailed discussion, please see Alternative 1A, Impact AQUA-14. The effects would be similar except for Sacramento-San Joaquin roach, hardhead and Sacramento perch which are unlikely to be present in their vicinity.

NEPA Effects: California bay shrimp do not occur in these habitats and there would be no effect on them. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of nonphysical fish barriers would be less than significant.

Impact AQUA-213: Effects of Illegal Harvest Reduction on Non-Covered Aquatic Species of Primary Management Concern (CM17)

Refer to Impact AQUA-15 under delta smelt for a discussion of the effects of illegal harvest reduction on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of illegal harvest reduction under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-15). For a detailed discussion, please see Alternative 1A, Impact AQUA-15.

NEPA Effects: California bay shrimp do not occur in these habitats and there would be no effect on them. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of illegal harvest reduction would be less than significant.

Impact AQUA-214: Effects of Conservation Hatcheries on Non-Covered Aquatic Species of Primary Management Concern (CM18)

NEPA Effects: Refer to Impact AQUA-16 under delta smelt for a discussion of the effects of conservation hatcheries on non-covered species of primary management concern. The potential effects of conservation hatcheries under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-16). For a detailed discussion, please see Alternative 1A, Impact AQUA-16. There would be no effect,

CEQA Conclusion: As described immediately above, conservation hatcheries would have not impact.

Impact AQUA-215: Effects of Urban Stormwater Treatment on Non-Covered Aquatic Species of Primary Management Concern (CM19)

NEPA Effects: Refer to Impact AQUA-17 under delta smelt for a discussion of the effects of stormwater treatment on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of stormwater treatment under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-17). The effects would be beneficial.

CEQA Conclusion: As described immediately above, the impacts of stormwater management would be beneficial.

Impact AQUA-216: Effects of Removal/Relocation of Nonproject Diversions on Non-Covered Aquatic Species of Primary Management Concern (CM21)

Refer to Impact AQUA-18 under delta smelt for a discussion of the effects of removal/relocation of nonproject diversions on non-covered species of primary management concern. The potential effects of removal/relocation of nonproject diversions under Alternative 2A would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-18). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species.

NEPA Effects: The effects would be similar except for Sacramento-San Joaquin roach, hardhead and Sacramento perch which are unlikely to be present near these diversions. California bay shrimp do not occur in these habitats and there would be no effect on them. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of removal/relocation of nonproject diversions would be less than significant.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: Similar to the description for Alternative 1A, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 2A would not be substantially reduced when compared to NAA.

CEQA Conclusion: Similar to the description for Alternative 1A, Alternative 2A would reduce the quantity of coldwater fish habitat in the CVP and SWP as shown in Table 11-1A-102. There would be a greater than 5% increase (5 years) for the reservoirs, which could result in a significant impact. These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 2A does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. As a result, the CEQA conclusion regarding Alternative 2A, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on coldwater habitat in upstream reservoirs. This impact is found to be less than significant and no mitigation is required.

11.3.4.6 Alternative 2B—Dual Conveyance with East Alignment and Five Intakes (15,000 cfs; Operational Scenario B)

Alternative 2B would include the same physical/structural water conveyance components, including a surface canal and eastern alignment, culvert and tunnel siphons, and bridges as Alternative 1B. Like Alternatives 1A and 1B, Alternative 2B would include five intake facilities on the Sacramento River. Intakes one through three would be in the same locations as Alternatives 1A and 1B, but the locations of the fourth and fifth intakes may be located 5 to 6 miles downstream of the intakes described in Alternative 1A. Also, the number of barge landings has not been determined. Overall, construction impacts associated with Alternative 2B would be the same as those described for Alternative 1B.

Currently, as an alternative to Intakes 1–5, intake locations 1, 2, 3, 6, and 7 are being considered. Selection of intake locations 6 and 7 would entail construction in the same region (north Delta) and would result in the same construction effects on fish species as discussed for Alternative 1A. This alternative would convey water from five fish-screened intakes between Clarksburg and Walnut Grove (Intakes 6 and 7, if selected, would be downstream of Sutter and Steamboat Sloughs) to a new Byron Tract Forebay adjacent to CCF. Construction effects for all fish species would be similar to those analyzed for Alternative 1A. Implementation of mitigation measures (described below) and environmental commitments (see Appendix 3B, *Environmental Commitments*) would reduce impacts as described under Alternative 1A.

Alternative 2B water conveyance operational criteria (Operational Scenario B) would be modified from those described for Alternative 1A, but the same as Alternative 2A. Like Alternatives 1A and 2A, the Alternative 2B facilities could convey up to 15,000 cfs from the north Delta. Operational Scenario B includes incorporation of Fall X2 guidelines, more restrictive south Delta OMR flows, and an operable barrier at the head of Old River (see Chapter 3, *Description of Alternatives*, Section 3.6.4.2, *North Delta and South Delta Water Conveyance Operational Criteria*). Operational Scenario B also includes north Delta diversion bypass flow criteria, south Delta export/inflow ratio, flow criteria over Fremont Weir into Yolo Bypass, Delta inflow and outflow criteria, DCC gate operations, Rio Vista minimum instream flow criteria, operations for Delta water quality and residence criteria, and water quality criteria for agricultural and municipal/industrial diversions.

CM2–CM22 would be implemented under this alternative, and these conservation measures would be identical to those under Alternative 1A. See Chapter 3, *Description of Alternatives*, for additional details on Alternative 2B.

Delta Smelt

Construction and Maintenance of CM1

Construction of Alternative 2B infrastructure would occur in the same area as described for Alternative 2A, as well as Alternative 1A, except for Intakes 6 and 7. Small numbers of delta smelt eggs, larvae, and adults could be present in the in-water construction areas in June and July (see Table 11-4). These construction and maintenance sites also occur entirely within designated delta smelt critical habitat.

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of construction of water conveyance facilities on delta smelt or designated critical habitat would be similar to those described under Alternative 1A, Impact AQUA-1. As concluded in Alternative 1A, Impact AQUA-1, the effect would not be adverse for delta smelt.

CEQA Conclusion: As described in Impact AQUA-1 under Alternative 1A for delta smelt, the impact of the construction of water conveyance facilities on delta smelt or critical habitat would not be significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2B would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-2). As concluded under Alternative 1A, Impact AQUA-2, the impact would not be adverse for delta smelt.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-2 for delta smelt, the impact of the maintenance of water conveyance facilities on delta smelt would be less than significant and no mitigation is required.

Water Operations of CM1

While Operational Scenario B under Alternative 2B (and Alternative 2A) has slight differences from Operational Scenario A (see Alternative 2B introduction above), Alternative 2B has the same diversion and conveyance operations as Alternative 2A. As a result, there would be little or no differences between these alternatives in upstream of the Delta river flows or reservoir operations, Delta inflow, and hydrodynamics in the Delta. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A (Impact AQUA-3 through AQUA-6), the fish effects described for these other alternatives also appropriately characterize effects under Alternative 2B.

The following impacts are those presented under Alternative 2A that are identical for Alternative 2B.

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

NEPA Effects: With the exception of Impact AQUA-5, the other impact mechanisms listed above, would not be adverse to delta smelt under Alternative 2B. This is the same conclusion as described in detail under Alternative 2A, and is based on the expected overall limited or slightly beneficial impacts. However, the overall effect of Impact AQUA-5 on delta smelt rearing habitat would remain adverse because there likely would still be a loss of suitable habitat even with BDCP restoration efforts (see Alternative 2A, AQUA-5 for details on expected effects).

CEQA Conclusion: The effects of three of the above listed impact mechanisms would be less than significant, or slightly beneficial to delta smelt, and no mitigation would be required. In addition, the effects of Impact AQUA-5 would also be considered less than significant, because it would not substantially reduce rearing habitat. Therefore, no mitigation would be required for any of the impact mechanisms listed above. Detailed discussions regarding these conclusions are presented in Alternative 1A.

Restoration and Conservation Measures

Alternative 2B has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A, the effects of these restoration and conservation measures described for Alternative 1A (Impact AQUA-7 through AQUA-18) also appropriately characterize effects under Alternative 2B.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2B.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (CM12)

Impact AQUA-11: Effects of Invasive Aquatic Vegetation Management on Delta Smelt (CM13)

Impact AQUA-12: Effects of Dissolved Oxygen Level Management on Delta Smelt (CM14)

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (CM15)

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (CM16)

Impact AQUA-15: Effects of Illegal Harvest Reduction on Delta Smelt (CM17)

Impact AQUA-16: Effects of Conservation Hatcheries on Delta Smelt (CM18)

Impact AQUA-17: Effects of Urban Stormwater Treatment on Delta Smelt (CM19)

Impact AQUA-18: Effects of Removal/Relocation of Nonproject Diversions on Delta Smelt (CM21)

NEPA Effects: As described in Alternative 1A, none of these impact mechanisms (Impact AQUA-7 through AQUA-18) would be adverse to delta smelt, and most would be at least slightly beneficial. Specifically for AQUA-8, the effects of contaminants on delta smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on delta smelt are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less-than-significant effects, and no mitigation is required.

Longfin Smelt

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on longfin smelt would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-19 and AQUA-20), the fish effects described for longfin smelt under Alternative 1A also appropriately characterize effects for longfin smelt under Alternative 2B.

The following impacts on longfin smelt are those presented under Alternatives 1A and 2A that are identical or very similar for Alternative 2B.

Construction and Maintenance of CM1

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

NEPA Effects: While maintenance activities would not be adverse to longfin smelt, construction activities could result in adverse effects from impact pile driving activities. The implementation of the avoidance and minimization measures included in Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternatives 1A and 2A, most of these impact mechanisms listed above would be beneficial or less than significant, and no mitigation would be required. However, several mechanisms could result in significant effects. While Impact AQUA-19 could result in significant underwater noise effects from impact pile driving, implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of conveyance facility operations on longfin smelt would be similar to those described under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A (Impact AQUA-21 and AQUA-22), the fish effects described for longfin smelt under Alternative 2A also appropriately characterize effects for longfin smelt under Alternative 2B.

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

Impact AQUA-23: Effects of Water Operations on Rearing Habitat for Longfin Smelt

Impact AQUA-24: Effects of Water Operations on Migration Conditions for Longfin Smelt

NEPA Effects: As presented under Alternative 2A, the effects of Alternative 2A operations would be expected to result in 5–6% lower longfin smelt abundance compared to NAA, for all years combined. Longfin smelt may benefit from habitat restoration actions (*CM2 Yolo Bypass Fisheries Enhancement and CM4 Tidal Natural Communities Restoration*, which are intended to provide additional food production and export to longfin smelt rearing areas in Suisun Marsh, West Delta, and Cache Slough ROAs.

CEQA Conclusion: As presented under Alternative 2A, the effects of Alternative 2B operations would be less than significant for spawning and rearing conditions. The effects on longfin smelt from reduced entrainment and predation would be beneficial. No mitigation would be required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on longfin smelt would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-25 through AQUA-36), the fish effects described for longfin smelt under Alternative 1A also appropriately characterize effects for longfin smelt under Alternative 2B.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (CM12)

Impact AQUA-29: Effects of Invasive Aquatic Vegetation Management on Longfin Smelt (CM13)

Impact AQUA-30: Effects of Dissolved Oxygen Level Management on Longfin Smelt (CM14)

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (CM15)

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (CM16)

Impact AQUA-33: Effects of Illegal Harvest Reduction on Longfin Smelt (CM17)

Impact AQUA-34: Effects of Conservation Hatcheries on Longfin Smelt (CM18)

Impact AQUA-35: Effects of Urban Stormwater Treatment on Longfin Smelt (CM19)

Impact AQUA-36: Effects of Removal/Relocation of Nonproject Diversions on Longfin Smelt (CM21)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, the impact mechanisms listed above would not be adverse to longfin smelt, and would typically be beneficial. Specifically for AQUA-26, the effects of contaminants on longfin smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on longfin smelt are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, the impact mechanisms listed above would be beneficial or less than significant, and no mitigation would be required.

Winter-Run Chinook Salmon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on winter-run Chinook salmon would be similar to those described under Alternatives 1A and 2A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on winter-run Chinook salmon would be similar to those described under Alternatives 1A and 2A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for these alternatives (Impact AQUA-37 and AQUA-38), the fish effects described for winter-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 2B.

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: These impact mechanisms would not be adverse to winter-run Chinook salmon. While construction activities (Impact AQUA-37) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, Impact AQUA-37 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on winter-run Chinook salmon would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A (Impacts AQUA-39 through AQUA-42), the effects described for winter-run Chinook salmon also appropriately characterize the effects under Alternative 2B.

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

NEPA Effects: As discussed for Alternative 2A, the impact mechanisms listed above could be adverse to winter-run Chinook salmon under Alternative 2B. The effects could be adverse because of the potential to substantially reduce suitable spawning and rearing habitat, the number of fish as a result of egg mortality, and reduced migration conditions. These effects are the result of specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, these would be an unavoidable adverse effects because there is no feasible mitigation available. However, implementing Mitigation Measure AQUA-40a through AQUA-40c and AQUA-41a through AQUA-41c has the potential to reduce the severity of impact though not necessarily to a not adverse level.

CEQA Conclusion: As discussed in detail under Alternative 2A, the effects under Alternative 2B would be significant because it has the potential to substantially reduce suitable spawning habitat and, therefore, in adult spawner and redd carrying capacity, as well as substantially reducing the number of fish as a result of egg mortality and reducing rearing habitat. These impacts are a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-40a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Please refer to Mitigation Measure AQUA-40a under Impact AQUA-40 of Alternative 2A.

Mitigation Measure AQUA-40b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Spawning Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-40b under Impact AQUA-40 of Alternative 2A.

Mitigation Measure AQUA-40c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Spawning Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-40c under Impact AQUA-40 of Alternative 2A.

Mitigation Measure AQUA-41a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Please refer to Mitigation Measure AQUA-41a under Impact AQUA-41 of Alternative 2A.

Mitigation Measure AQUA-41b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Rearing Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-41b under Impact AQUA-41 of Alternative 2A.

Mitigation Measure AQUA-41c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Rearing Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-41c under Impact AQUA-41 of Alternative 2A.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on winter-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-43 through AQUA-54), the effects described for winter-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 2B.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (CM12)

Impact AQUA-47: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Winter-Run ESU) (CM13)

Impact AQUA-48: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Winter-Run ESU) (CM14)

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (CM15)

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (CM16)

Impact AQUA-51: Effects of Illegal Harvest Reduction on Chinook Salmon (Winter-Run ESU) (CM17)

Impact AQUA-52: Effects of Conservation Hatcheries on Chinook Salmon (Winter-Run ESU) (CM18)

Impact AQUA-53: Effects of Urban Stormwater Treatment on Chinook Salmon (Winter-Run ESU) (CM19)

Impact AQUA-54: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Winter-Run ESU) (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, the impact mechanisms listed above would not be adverse, and would typically be beneficial to winter-run Chinook salmon. Specifically for AQUA-44, the effects of contaminants on winter-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on winter-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be less than significant, or beneficial, so no additional mitigation would be required.

Spring-Run Chinook Salmon

The potential effects of construction and maintenance, operations of water conveyance facilities, restoration measures and other conservation measures on spring-run Chinook salmon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on spring-run Chinook salmon would be similar to those described under Alternatives 1A and 2A, because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-55 through AQUA-56), the fish effects described for spring-run Chinook salmon under Alternative 1A also appropriately characterize effects for spring-run Chinook salmon under Alternative 2B

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

NEPA Effects: These impact mechanisms would not be adverse to spring-run Chinook salmon. While construction activities (Impact AQUA-55) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternatives 1A and 2A, Impact AQUA-55 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on spring-run Chinook salmon would be similar to those described under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to Alternative 2A (Impact AQUA-57 through AQUA-60), the fish effects described for spring-run Chinook salmon under Alternatives 2A also appropriately characterize effects under Alternative 2B.

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

NEPA Effects: As discussed in detail for Alternative 2A, except for Impact AQUA-60, the impact mechanisms listed above would not be adverse to spring-run Chinook salmon under Alternative 2B. However, adverse effects would occur from Impact AQUA-60 because habitat and migration conditions for juvenile spring-run Chinook salmon would be substantially reduced, and because it has the potential to substantially increase predation and remove important instream habitat as the result of the presence of five north Delta intake structures. The implementation of conservation and mitigation measures would reduce the severity of effects, although not necessarily to a not adverse level.

CEQA Conclusion: Similar to the discussion provided above for Alternative 2A, three of the impact mechanisms listed above would be less than significant under Alternative 2B, so no additional mitigation would be required. However, Impact AQUA-60 would result in significant reductions in migration habitat conditions. In addition to the benefits provided by the implementation of CM6 and CM15, the mitigation measures identified below would provide an adaptive management process, for assessing impacts and developing appropriate minimization measures. This process may be implemented as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6). However, the overall effect of Impact AQUA-60 would still be considered significant and unavoidable.

Mitigation Measure AQUA-60a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-60a under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-60b under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-60c under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on spring-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-61 through AQUA-72). Therefore, the effects on spring-run Chinook salmon under Alternative 1A also appropriately characterize effects for spring-run Chinook salmon under Alternative 2B.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (CM12)

Impact AQUA-65: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Spring-Run ESU) (CM13)

Impact AQUA-66: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Spring-Run ESU) (CM14)

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (CM15)

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (CM16)

Impact AQUA-69: Effects of Illegal Harvest Reduction on Chinook Salmon (Spring-Run ESU) (CM17)

Impact AQUA-70: Effects of Conservation Hatcheries on Chinook Salmon (Spring-Run ESU) (CM18)

Impact AQUA-71: Effects of Urban Stormwater Treatment on Chinook Salmon (Spring-Run ESU) (CM19)

Impact AQUA-72: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Spring-Run ESU) (CM21)

NEPA Effects: As discussed for Alternative 1A and 2A, with the implementation of environmental commitments and conservation measures (Impact AQUA-61 through AQUA-72), the effects would typically be beneficial to spring-run Chinook salmon. Specifically for AQUA-62, the effects of contaminants on spring-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on spring-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, the impact mechanisms listed above would be beneficial or less than significant, and no mitigation would be required.

Fall-/Late Fall–Run Chinook Salmon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance of water conveyance facilities on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-73 through AQUA-74), the fish effects described for fall- and late fall-run Chinook salmon under Alternative 1A also appropriately characterize effects for fall- and late fall-run Chinook salmon under Alternative 2B.

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would not be adverse to fall- and late fall-run Chinook salmon. While construction activities (Impact AQUA-73) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-73 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on fall- and late fall-run Chinook salmon would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A (Impacts AQUA-75 through AQUA-78), the fish effects described for fall- and late fall-run Chinook salmon also appropriately characterize the effects for Alternative 2B.

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Overall, the effects of water operations vary by location. Similar to effects described in detail under Alternative 2A, Alternative 2B would have an adverse effect on fall-/late fall-run Chinook salmon juvenile survival due to habitat and predation losses at the NDD intakes. Through-delta conditions on the Sacramento River would substantially affect migration conditions relative to NAA while through-Delta conditions on the San Joaquin River would be positive. However, upstream of the Delta, Alternative 2B conditions relative to NAA would not substantially affect migration conditions. The implementation of the conservation and mitigation measures listed below, would reduce the overall effects, but they would still likely remain adverse.

CEQA Conclusion: As described for Alternative 2A, the differences between the CEQA baseline and Alternative 2B vary, depending on location. Through-Delta conditions on the Sacramento River would substantially impact migration conditions relative to Existing Conditions while through-Delta conditions on the San Joaquin River would be positive relative to Existing Conditions. Upstream of the Delta conditions relative to Existing Conditions would be reduced although the impacts are related to climate change. Alternative 2B also has the potential to substantially increase predation and remove important instream habitat as the result of the presence of five NDD structures.

Implementation of *CM6 Channel Margin Enhancement* and *CM15 Localized Reduction of Predatory Fishes (Predator Control)* would address habitat and predation losses, therefore, would potentially minimize impacts to some extent but not to a less than significant level.

CM6 Channel Margin Enhancement. CM6 would entail restoration of 20 linear miles of channel margin by improving channel geometry and restoring riparian, marsh, and mudflat habitats on the waterside side of levees along channels that provide rearing and outmigration habitat for juvenile salmonids.

CM15 Localized Reduction of Predatory Fishes (Predator Control). CM15 would seek to reduce populations of predatory fishes at specific locations or modify holding habitat at selected locations of high predation risk (i.e., predation "hotspots"), including the NDD intakes. This conservation measure seeks to reduce mortality rates of juvenile migratory salmonids that are particularly vulnerable to predatory fishes. Because of uncertainties regarding treatment methods and efficacy, implementation of CM15 would involve discrete pilot projects and research actions coupled with an adaptive management and monitoring program to evaluate effectiveness.

As with the conservation measures, the implementation of the mitigation measures listed below also has the potential to reduce the severity of the impact though not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-78a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Fall-/Late Fall–Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-78a under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78b: Conduct Additional Evaluation and Modeling of Impacts on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-78b under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-78c under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-79 through AQUA-90), the fish effects under Alternative 1A also appropriately characterize effects for fall- and late fall-run Chinook salmon under Alternative 2B.

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM12)

Impact AQUA-83: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM13)

Impact AQUA-84: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM14)

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM15)

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM16)

Impact AQUA-87: Effects of Illegal Harvest Reduction on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM17)

Impact AQUA-88: Effects of Conservation Hatcheries on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM18)

Impact AQUA-89: Effects of Urban Stormwater Treatment on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM19)

Impact AQUA-90: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, these restoration and conservation commitment impact mechanisms (Impact AQUA-79 through AQUA-90),would not be adverse, and would typically be beneficial to fall- and late fall-run Chinook salmon. Specifically for AQUA-80, the effects of contaminants on fall- and late fall-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on fall- and late fall-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Steelhead

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on steelhead would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on steelhead would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-91 through AQUA-108), the fish effects described for steelhead under Alternative 1A also appropriately characterize effects for steelhead under Alternative 2B.

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: These impact mechanisms would typically not be adverse to steelhead. While construction activities (Impact AQUA-91) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-91 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of` water conveyance facility operations on steelhead would be similar to those described above under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A (Impact AQUA-93 through AQUA-96), the fish effects described for steelhead under Alternative 2A also appropriately characterize effects under Alternative 2B.

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

NEPA Effects: As discussed in detail for Alternative 2A, the above listed impact mechanisms (Impact AQUA-93 through AQUA-96) flow reductions and temperature increases would affect the quantity and quality of juvenile rearing habitat and would contribute to reduced survival and increased stress, particularly in drier water years. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. However, implementing Mitigation Measures AQUA-95a through AQUA-95c has the potential to reduce the severity of impact though not necessarily to a not adverse level.

CEQA Conclusion: Similar to the detailed discussion provided above for Alternative 2A, flow reductions and temperature increases would have a significant and unavoidable impact on the quantity and quality of juvenile rearing habitat and would contribute to reduced survival and increased stress, particularly in drier water years. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-95a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Steelhead to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat.

Please refer to Mitigation Measure AQUA-95a under Alternative 2A for winter-run Chinook salmon.

Mitigation Measure AQUA-95b: Conduct Additional Evaluation and Modeling of Impacts on Steelhead Rearing Habitat Following Initial Operations of CM1.

Please refer to Mitigation Measure AQUA-95b under Alternative 2A for winter-run Chinook salmon.

Mitigation Measure AQUA-95c: Consult with NMFS, USFWS and CDFW to Identify Potentially Feasible Means to Minimize Effects on Steelhead Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-95c under Alternative 2A for winter-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on steelhead would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B, compared to those described in detail for Alternative 1A (Impact AQUA-97 through AQUA-108), the fish effects described for steelhead also appropriately characterize the effects under Alternative 2B.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (CM12)

Impact AQUA-101: Effects of Invasive Aquatic Vegetation Management on Steelhead (CM13)

Impact AQUA-102: Effects of Dissolved Oxygen Level Management on Steelhead (CM14)

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (CM15)

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (CM16)

Impact AQUA-105: Effects of Illegal Harvest Reduction on Steelhead (CM17)

Impact AQUA-106: Effects of Conservation Hatcheries on Steelhead (CM18)

Impact AQUA-107: Effects of Urban Stormwater Treatment on Steelhead (CM19)

Impact AQUA-108: Effects of Removal/Relocation of Nonproject Diversions on Steelhead (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, these impact mechanisms would not be adverse, and would typically be beneficial to steelhead. Specifically for AQUA-98, the effects of contaminants on steelhead with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on steelhead are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Sacramento Splittail

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on Sacramento splittail would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on Sacramento splittail would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-109 and AQUA-110), the fish effects described for Sacramento splittail under Alternative 1A also appropriately characterize effects for Sacramento splittail under Alternative 2B.

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: These impact mechanisms would generally not be adverse to Sacramento splittail. While construction activities (Impact AQUA-109) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-109 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The effects of Impact AQUA-110 would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on Sacramento splittail would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B, compared to those described in detail for Alternative 2A (Impacts AQUA-111 through AQUA-114), the fish effects described would also appropriately characterize the effects under Alternative 2B.

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

NEPA Effects: As discussed in detail for Alternative 2A, the operations impact mechanisms would not be adverse to Sacramento splittail.

CEQA Conclusion: Similar to the discussion provided above for Alternative 2A, these impact mechanisms would be less than significant, and no mitigation would be required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on Sacramento splittail would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A (Impacts AQUA-115 through AQUA-126), the fish effects described also appropriately characterize the effects under Alternative 2B.

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (CM12)

Impact AQUA-119: Effects of Invasive Aquatic Vegetation Management on Sacramento Splittail (CM13)

Impact AQUA-120: Effects of Dissolved Oxygen Level Management on Sacramento Splittail (CM14)

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (CM15)

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (CM16)

Impact AQUA-123: Effects of Illegal Harvest Reduction on Sacramento Splittail (CM17)

Impact AQUA-124: Effects of Conservation Hatcheries on Sacramento Splittail (CM18)

Impact AQUA-125: Effects of Urban Stormwater Treatment on Sacramento Splittail (CM19)

Impact AQUA-126: Effects of Removal/Relocation of Nonproject Diversions on Sacramento Splittail (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, the restoration and conservation measure impact mechanisms would not be adverse, and would typically be beneficial to Sacramento splittail. Specifically for AQUA-116, the effects of contaminants on Sacramento splittail with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on Sacramento splittail are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Green Sturgeon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on green sturgeon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on Sacramento splittail would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-127 and AQUA-128), the fish effects described for green sturgeon under Alternative 1A also appropriately characterize effects for green sturgeon under Alternative 2B.

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: While the maintenance impact mechanism (Impact AQUA-128) would not be adverse to green sturgeon, construction activities (Impact AQUA-127) could result in adverse effects from impact pile driving activities. However, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-127 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The other impact mechanism would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on green sturgeon would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A (Impacts AQUA-129 through AQUA-132), the fish effects described for green sturgeon also appropriately characterize the effects under Alternative 2B.

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

NEPA Effects: As discussed for Alternative 2A, the expected effects of Impact AQUA-130 and Impact AQUA-132 on green sturgeon spawning and migration habitat under Alternative 2B would be limited, although adverse effects would still be expected from Impact AQUA-132, because it has the potential to substantially interfere with the movement of green sturgeon. This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. Therefore, this would be an unavoidable adverse effect because there is no feasible mitigation available, although the implementation of Mitigation Measures AQUA-132a through AQUA-132c, is expected to reduce the overall effects.

As discussed for Alternative 2A, the expected effects of Alternative 2B on green sturgeon entrainment and rearing habitat (Impact AQUA-129 and Impact AQUA-131) would not be adverse.

CEQA Conclusion: As discussed in detail for Alternative 2A, Impact AQUA-130 through AQUA-132 could result in significant, but unavoidable, effects on water temperature, and green sturgeon rearing and migration habitat conditions under Alternative 2B. These impacts are a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, these impacts are significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation (Mitigation Measure 132a through 132c) that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-132a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Green Sturgeon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-132a under Alternative 2A.

Mitigation Measure AQUA-132b: Conduct Additional Evaluation and Modeling of Impacts on Green Sturgeon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-132b under Alternative 2A.

Mitigation Measure AQUA-132c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Green Sturgeon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-132c under Alternative 2A.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on green sturgeon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-133 through AQUA-144), the fish effects under Alternative 1A would appropriately characterize effects under Alternative 2B.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (CM12)

Impact AQUA-137: Effects of Invasive Aquatic Vegetation Management on Green Sturgeon (CM13)

Impact AQUA-138: Effects of Dissolved Oxygen Level Management on Green Sturgeon (CM14)

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (CM15)

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (CM16)

Impact AQUA-141: Effects of Illegal Harvest Reduction on Green Sturgeon (CM17)

Impact AQUA-142: Effects of Conservation Hatcheries on Green Sturgeon (CM18)

Impact AQUA-143: Effects of Urban Stormwater Treatment on Green Sturgeon (CM19)

Impact AQUA-144: Effects of Removal/Relocation of Nonproject Diversions on Green Sturgeon (CM21)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, the restoration and conservation measure impact mechanisms listed above would not be adverse, and would typically be beneficial to green sturgeon. Specifically for AQUA-134, the effects of contaminants on green sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on green sturgeon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, the impact mechanisms related to restoration and conservation measures would be beneficial or less than significant, and no mitigation would be required.

White Sturgeon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on white sturgeon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on white sturgeon would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-145 and AQUA-146), the fish effects described for white sturgeon under Alternative 1A also appropriately characterize effects under Alternative 2B.

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: These impact mechanisms would generally not be adverse to white sturgeon. However, construction activities (Impact AQUA-145) could result in adverse effects from impact pile driving activities, although the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-145 could result in significant underwater noise effects from impact pile driving, implementation of

Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance operations on white sturgeon would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A, the effects described under Alternative 2A (Impacts AQUA-147 through AQUA-150) also appropriately characterize the effects for white sturgeon under Alternative 2B.

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

NEPA Effects: As discussed above under Alternative 2A, the impact mechanisms listed above would not be generally adverse for white sturgeon. However, there is a positive correlation between white sturgeon year class strength and river/Delta flow, such that changes in water operations could result in an adverse effect on white sturgeon migration conditions (Impact AQUA-150). While there is uncertainty regarding the particular responsible mechanisms, this uncertainty will be addressed through targeted research and monitoring conducted in the years leading up to the initiation of north Delta facilities operations. The results of these efforts would be used to determine if changes in flow under Alternative 2B are likely to result in adverse effects, as well as to guide an adaptive management process to minimize or avoid such effects.

CEQA Conclusion: With a few exceptions, these impact mechanisms listed above would be less than significant, and no mitigation would be required. As discussed for Impact AQUA-149 under Alternative 2A, if the expected operational effects are adjusted to exclude sea level rise and climate change, it would not in itself result in a significant impact on rearing habitat for white sturgeon. Therefore, this impact is less than significant and no mitigation is required. However, due to the uncertainty regarding effects of flow changes on migration conditions for white sturgeon (Impact AQUA-150), research and monitoring efforts and an associated adaptive management process is proposed. These efforts are expected to identify any significant effects and develop appropriate mitigation to reduce the effect to be less than significant.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on white sturgeon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-151 through AQUA-162), the fish effects described under Alternative 1A appropriately characterize effects for white sturgeon under Alternative 2B.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (CM12)

Impact AQUA-155: Effects of Invasive Aquatic Vegetation Management on White Sturgeon (CM13)

Impact AQUA-156: Effects of Dissolved Oxygen Level Management on White Sturgeon (CM14)

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (CM15)

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (CM16)

Impact AQUA-159: Effects of Illegal Harvest Reduction on White Sturgeon (CM17)

Impact AQUA-160: Effects of Conservation Hatcheries on White Sturgeon (CM18)

Impact AQUA-161: Effects of Urban Stormwater Treatment on White Sturgeon (CM19)

Impact AQUA-162: Effects of Removal/Relocation of Nonproject Diversions on White Sturgeon (CM21)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would not be adverse to white sturgeon and would typically be beneficial. Specifically for AQUA-152, the effects of contaminants on white sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on white sturgeon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Pacific Lamprey

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on Pacific lamprey would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on Pacific lamprey would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-163 and AQUA-164), the fish effects described for Pacific lamprey under Alternative 1A also appropriately characterize effects for Pacific lamprey under Alternative 2B.

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: While maintenance activities would generally not be adverse to Pacific lamprey, construction activities (Impact AQUA-163) could result in adverse effects from impact pile driving activities. However, the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, Impact AQUA-163 could result in significant underwater noise effects from impact pile driving. However, implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance operations on Pacific lamprey would be similar to those described under Alternative 2A (Impact AQUA-165 and AQUA-168). Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A, the fish effects described for Pacific lamprey under Alternative 2A also appropriately characterize effects for Pacific lamprey under Alternative 2B.

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

NEPA Effects: As discussed for Alternative 2A, these impact mechanisms would not be adverse.

CEQA Conclusion: Similar to the discussion provided above for 2A, these impact mechanisms would be less than significant, and no mitigation would be required. While analyses of Impact AQUA-166 and AQUA-167 indicate that the differences between Existing Conditions and Alternative 2A could be significant because of substantial reductions in suitable spawning and rearing habitat and increased egg mortality. However, these differences are generally due to climate change, sea level rise, and future demand, and not the alternative. The impacts of Alternative 2B would be similar, are would therefore be less than significant and no mitigation is required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on Pacific lamprey would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-169 and through AQUA-180), the fish effects described for Pacific lamprey under Alternative 1A also appropriately characterize effects for Pacific lamprey under Alternative 2B.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (CM12)

Impact AQUA-173: Effects of Invasive Aquatic Vegetation Management on Pacific Lamprey (CM13)

Impact AQUA-174: Effects of Dissolved Oxygen Level Management on Pacific Lamprey (CM14)

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (CM15)

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (CM16)

Impact AQUA-177: Effects of Illegal Harvest Reduction on Pacific Lamprey (CM17)

Impact AQUA-178: Effects of Conservation Hatcheries on Pacific Lamprey (CM18)

Impact AQUA-179: Effects of Urban Stormwater Treatment on Pacific Lamprey (CM19)

Impact AQUA-180: Effects of Removal/Relocation of Nonproject Diversions on Pacific Lamprey (CM21)

NEPA Effects: Similar to the discussion provided above for Alternative 1A these impact mechanisms would generally not be adverse, and would typically be beneficial to Pacific lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

River Lamprey

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on river lamprey would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on river lamprey would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-181 and AQUA-182), the fish effects described for river lamprey under Alternative 1A also appropriately characterize effects for river lamprey under Alternative 2B.

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

NEPA Effects: While construction activities (Impact AQUA-181) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality). Therefore, as discussed for Alternative 1A, these impact mechanisms would not be adverse to river lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-181 could result in significant underwater noise effects from impact pile driving, implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. Therefore, the overall effects of these impact mechanisms would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on river lamprey would be similar to those described under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 2A (Impact AQUA-183 through AQUA-186), the fish effects described for river lamprey under Alternative 2A also appropriately characterize effects for river lamprey under Alternative 2B.

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

NEPA Effects: As discussed for Alternative 2A, these impact mechanisms would not be adverse to river lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 2A for river lamprey, analyses of Impact AQUA-184, AQUA-185, and AQUA-186 indicate that the differences between Existing Conditions and Alternative 2A could be significant because of substantial reductions in suitable spawning, incubation, rearing, and migration conditions. However, these differences are generally due to climate change, sea level rise, and future water demands, and not the alternative. Thus, the effects of these impact mechanisms under Alternative 2B would be similar to those discussed under Alternative 2A, and therefore would be less than significant and no mitigation is required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on river lamprey would be similar to those described under Alternative 1A, as no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B (Impact AQUA-187 through AQUA-198), the fish effects described for river lamprey under Alternative 1A also appropriately characterize effects for river lamprey under Alternative 2B.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (CM12)

Impact AQUA-191: Effects of Invasive Aquatic Vegetation Management on River Lamprey (CM13)

Impact AQUA-192: Effects of Dissolved Oxygen Level Management on River Lamprey (CM14)

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (CM15)

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (CM16)

Impact AQUA-195: Effects of Illegal Harvest Reduction on River Lamprey (CM17)

Impact AQUA-196: Effects of Conservation Hatcheries on River Lamprey (CM18)

Impact AQUA-197: Effects of Urban Stormwater Treatment on River Lamprey (CM19)

Impact AQUA-198: Effects of Removal/Relocation of Nonproject Diversions on River Lamprey (CM21)

NEPA Effects: As discussed for Alternative 1A, these restoration and conservation measure impact mechanisms would not be adverse, and would typically be beneficial to river lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Non-Covered Aquatic Species of Primary Management Concern

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on non-covered species would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on non-covered species would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-199 and AQUA-200), the fish effects described for non-covered aquatic species of primary management concern under Alternative 1A also appropriately characterize effects for non-covered aquatic species of primary management concern under Alternative 2B.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: While construction activities (Impact AQUA-199) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, while Impact AQUA-199 could result in significant underwater noise effects from impact pile driving, implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The other impact mechanism would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on non-covered species would be similar to those described under Alternative 1A, as no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B (Impact AQUA-201 through AQUA-204). Therefore, effects discussed in detail under Alternative 1A also appropriately characterize effects for non-covered aquatic species of primary management concern under Alternative 2B.

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: As discussed for Alternative 2A, the expected effects of Impact AQUA-203 on rearing habitat for several non-covered fish species of primary management concern under Alternative 2B, would be reduced, but would not be adverse. These species are Sacramento tule perch, largemouth bass, hardhead and Sacramento-San Joaquin roach. The other impact mechanisms would not be adverse.

CEQA Conclusion: Similar to the discussion provided above for Alternative 2A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required. However, Impact AQUA-203 could result in significant, but unavoidable effects on rearing habitat conditions for several fish species of primary management concern. There are also no feasible mitigation measures available to mitigate for these impacts. The other impact mechanisms would be less than significant, so no additional mitigation would be required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on non-covered species would be similar to those described under Alternative 1A, as no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B (Impact AQUA-205 through AQUA-217). Therefore, the fish effects described for non-covered aquatic species of primary management concern under Alternative 1A also appropriately characterize effects for non-covered aquatic species of primary management concern under Alternative 2B.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (CM12)

Impact AQUA-209: Effects of Invasive Aquatic Vegetation Management on Non-Covered Aquatic Species of Primary Management Concern (CM13)

Impact AQUA-210: Effects of Dissolved Oxygen Level Management on Non-Covered Aquatic Species of Primary Management Concern (CM14)

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (CM15)

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (CM16)

Impact AQUA-213: Effects of Illegal Harvest Reduction on Non-Covered Aquatic Species of Primary Management Concern (CM17)

Impact AQUA-214: Effects of Conservation Hatcheries on Non-Covered Aquatic Species of Primary Management Concern (CM18)

Impact AQUA-215: Effects of Urban Stormwater Treatment on Non-Covered Aquatic Species of Primary Management Concern (CM19)

Impact AQUA-216: Effects of Removal/Relocation of Nonproject Diversions on Non-Covered Aquatic Species of Primary Management Concern (CM21)

NEPA Effects: As discussed for Alternative 1A, these impact mechanisms would not be adverse to the non-covered species of primary management concern.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: Similar to the description for Alternative 2A, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 2B would not be substantially reduced when compared to NAA.

CEQA Conclusion: Similar to the description for Alternative 2A, Alternative 2B would reduce the quantity of coldwater fish habitat in the CVP and SWP. However, if adjusted to exclude sea level rise and climate change, similar to the NEPA conclusion, the effect would not in itself result in a significant impact on coldwater habitat in upstream reservoirs. Therefore, this impact is found to be less than significant and no mitigation is required.

11.3.4.7 Alternative 2C—Dual Conveyance with West Alignment and Intakes W1–W5 (15,000 cfs; Operational Scenario B)

Alternative 2C would have the same physical/structural water conveyance components and west alignment as Alternative 1C. Overall construction impacts from Alternative 2C would be similar to Alternative 1A but with additional in-water work such as culvert siphons and bridge crossings that are described under Alternative 1C. However, implementation of mitigation measures (described below) and environmental commitments (Appendix 3B, *Environmental Commitments)* would reduce impacts as described under Alternative 1A. Water supply and conveyance operations would follow the guidelines described for Alternative 2A (Operational Scenario B); consequently, the analysis under Alternative 2A is applicable to Alternative 2C.

CM2–CM22 would be implemented under this alternative, and these conservation measures would be identical to those under Alternative 1A. See Chapter 3, *Description of Alternatives*, for additional details on Alternative 2C.

Delta Smelt

Construction and Maintenance of CM1

Construction of Alternative 2C infrastructure would occur in the same general area as described for Alternative 1A, which includes designated delta smelt critical habitat. Small numbers of delta smelt eggs, larvae, and adults could be present in the in-water construction areas in June and July (see Table 11-4).

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of construction of water conveyance facilities on delta smelt or critical habitat would be similar to those described under Alternative 1A, Impact AQUA-1. As concluded in Alternative 1A, Impact AQUA-1, the effect would not be adverse for delta smelt.

CEQA Conclusion: As described in Impact AQUA-1 under Alternative 1A for delta smelt, the impact of the construction of water conveyance facilities on delta smelt or critical habitat would not be significant except for construction noise associated with pile driving. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2C would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-2). As concluded under Alternative 1A, Impact AQUA-2, the impact would not be adverse for delta smelt or critical habitat.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-2 for delta smelt, the impact of the maintenance of water conveyance facilities on delta smelt or critical habitat would be less than significant and no mitigation is required.

Water Operations of CM1

Operational Scenario B, under Alternative 2C, would be the same as for Alternative 2A. As a result, there would be no substantial differences between these two alternatives in upstream of the Delta river flows or reservoir operations, Delta inflow, and hydrodynamics in the Delta. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impact AQUA-3 through AQUA-6), the fish effects described for Alternative 2A also appropriately characterize effects under Alternative 2C.

The following impacts are those presented under Alternative 2A, which are identical for Alternative 2C.

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

NEPA Effects: With the exception of Impact AQUA-5, the other impact mechanisms listed above, would not be adverse to delta smelt under Alternative 2C. This is the same conclusion as described in detail under Alternatives 1A and 2A, and is based on the expected overall limited or slightly beneficial impacts. However, the overall effect of Impact AQUA-5 on delta smelt rearing habitat would remain adverse because there likely would still be a loss of suitable habitat even with BDCP restoration efforts (see Alternative 1A, AQUA-5 for details on expected effects), although the implementation of restoration and conservation measures may reduce these effects to some extent.

CEQA Conclusion: The effects of three of the above listed impact mechanisms would be less than significant, or slightly beneficial to delta smelt, and no mitigation would be required. The effects of Impact AQUA-5 would also be considered less than significant, because it would not substantially reduce rearing habitat. Therefore, no mitigation would be required for any of the impact mechanisms listed above. Detailed discussions regarding these conclusions are presented in Alternatives 1A and 2A.

Restoration and Conservation Measures

Alternative 2C has the same restoration and conservation measures as Alternative 1A. Because no substantial differences in fish effects are anticipated anywhere in the affected environment under

Alternative 2C compared to those described in detail for Alternative 1A, the effects described for Alternative 1A (Impact AQUA-7 through AQUA-18) also appropriately characterize effects under Alternative 2C.

The following impacts are those presented under Alternative 1A that are identical for Alternative 2C.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (CM12)

Impact AQUA-11: Effects of Invasive Aquatic Vegetation Management on Delta Smelt (CM13)

Impact AQUA-12: Effects of Dissolved Oxygen Level Management on Delta Smelt (CM14)

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (CM15)

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (CM16)

Impact AQUA-15: Effects of Illegal Harvest Reduction on Delta Smelt (CM17)

Impact AQUA-16: Effects of Conservation Hatcheries on Delta Smelt (CM18)

Impact AQUA-17: Effects of Urban Stormwater Treatment on Delta Smelt (CM19)

Impact AQUA-18: Effects of Removal/Relocation of Nonproject Diversions on Delta Smelt (CM21)

NEPA Effects: As described in Alternative 1A, none of these impact mechanisms (Impact AQUA-7 through AQUA-18) would be adverse to delta smelt, and most would be at least slightly beneficial. Specifically for AQUA-8, the effects of contaminants on delta smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on delta smelt are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Longfin Smelt

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on longfin smelt would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on longfin smelt would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-19 and AQUA-20), the effects described for longfin smelt under Alternative 1A also appropriately characterize effects for longfin smelt under Alternative 2C.

The following impacts on longfin smelt are those presented under Alternative 1A that are identical for Alternative 2C.

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

NEPA Effects: As discussed under Alternative 1A, the effects of construction activities (Impact AQUA-19) could result in adverse effects from impact pile driving activities, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, Impact AQUA-19 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on longfin smelt would be similar to those described under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impact AQUA-21 through AQUA-24), the effects described for longfin smelt under Alternative 1A also appropriately characterize effects under Alternative 2C.

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

Impact AQUA-23: Effects of Water Operations on Rearing Habitat for Longfin Smelt

Impact AQUA-24: Effects of Water Operations on Migration Conditions for Longfin Smelt

NEPA Effects: As presented under Alternative 2A, the effects of Alternative 2A operations would be expected to result in 5–6% lower longfin smelt abundance compared to NAA, for all years combined. Longfin smelt may benefit from habitat restoration actions (*CM2 Yolo Bypass Fisheries Enhancement* *and CM4 Tidal Natural Communities Restoration*, which are intended to provide additional food production and export to longfin smelt rearing areas in Suisun Marsh, West Delta, and Cache Slough ROAs.

CEQA Conclusion: As presented under Alternative 2A, the effects of Alternative 2C operations would be less than significant for spawning and rearing conditions. The effects on longfin smelt from reduced entrainment and predation would be beneficial. No mitigation would be required.

Restoration and Conservation Measures

The potential effects of restoration and other conservation measures on longfin smelt would be similar to those described under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impact AQUA-25 and through AQUA-36), the effects described for longfin smelt under Alternative 2A also appropriately characterize effects under Alternative 2C.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (CM12)

Impact AQUA-29: Effects of Invasive Aquatic Vegetation Management on Longfin Smelt (CM13)

Impact AQUA-30: Effects of Dissolved Oxygen Level Management on Longfin Smelt (CM14)

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (CM15)

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (CM16)

Impact AQUA-33: Effects of Illegal Harvest Reduction on Longfin Smelt (CM17)

Impact AQUA-34: Effects of Conservation Hatcheries on Longfin Smelt (CM18)

Impact AQUA-35: Effects of Urban Stormwater Treatment on Longfin Smelt (CM19)

Impact AQUA-36: Effects of Removal/Relocation of Nonproject Diversions on Longfin Smelt (CM21)

NEPA Effects: As discussed under Alternative 1A and 2A, the effects of these impact mechanisms would not be adverse to longfin smelt, and would typically be beneficial. Specifically for AQUA-26, the effects of contaminants on longfin smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on longfin smelt are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Winter-Run Chinook Salmon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on winter-run Chinook salmon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on winter-run Chinook salmon because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-37 and AQUA-38), the effects described for winter-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 2C.

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: These impact mechanisms would not be adverse to winter-run Chinook salmon. While construction activities (Impact AQUA-37) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-37 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on winter-run Chinook salmon would be similar to those described under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impact AQUA-39 and through AQUA-42), the effects on winter-run Chinook salmon described for Alternative 2A, also appropriately characterize effects under Alternative 2C.

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

NEPA Effects: As discussed for Alternative 2A, the impact mechanisms listed above could be adverse to winter-run Chinook salmon under Alternative 2C. The effects could be adverse because of the potential to substantially reduce suitable spawning and rearing habitat, the number of fish as a result of egg mortality, as well as overall migration conditions. These effects are a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. However, implementing Mitigation Measure AQUA-40a through AQUA-40c and AQUA-41a through AQUA-41c has the potential to reduce the severity of impact though not necessarily to a not adverse level.

CEQA Conclusion: As discussed in detail under Alternative 2A, the effects under Alternative 2C would be significant because it has the potential to substantially reduce suitable spawning and rearing habitat, reduce the number of fish as a result of egg mortality, and reducing the overall migration habitat conditions. These effects are a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-40a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Please refer to Mitigation Measure AQUA-40a under Impact AQUA-40 of Alternative 2A.

Mitigation Measure AQUA-40b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Spawning Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-40b under Impact AQUA-40 of Alternative 2A.

Mitigation Measure AQUA-40c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Spawning Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-40c under Impact AQUA-40 of Alternative 2A.

Mitigation Measure AQUA-41a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Please refer to Mitigation Measure AQUA-41a under Impact AQUA-41 of Alternative 2A.

Mitigation Measure AQUA-41b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Rearing Habitat Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-41b under Impact AQUA-41 of Alternative 2A.

Mitigation Measure AQUA-41c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Rearing Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-41c under Impact AQUA-41 of Alternative 2A.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on winter-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2B compared to those described in detail for Alternative 1A (Impact AQUA-43 through AQUA-54), the effects described for winter-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 2C.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (CM12)

Impact AQUA-47: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Winter-Run ESU) (CM13)

Impact AQUA-48: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Winter-Run ESU) (CM14)

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (CM15)

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (CM16)

Impact AQUA-51: Effects of Illegal Harvest Reduction on Chinook Salmon (Winter-Run ESU) (CM17)

Impact AQUA-52: Effects of Conservation Hatcheries on Chinook Salmon (Winter-Run ESU) (CM18)

Impact AQUA-53: Effects of Urban Stormwater Treatment on Chinook Salmon (Winter-Run ESU) (CM19)

Impact AQUA-54: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Winter-Run ESU) (CM21)

NEPA Effects: As discussed for Alternative 1A and 2A, the restoration and conservation measure impact mechanisms would not be adverse, and would typically be beneficial to winter-run Chinook salmon. Specifically for AQUA-44, the effects of contaminants on winter-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on winter-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, these restoration and conservation measure impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Spring-Run Chinook Salmon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on spring-run Chinook salmon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on spring-run Chinook salmon would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-55 and AQUA-56), the effects described for spring-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 2C.

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

NEPA Effects: These impact mechanisms would not be adverse to spring-run Chinook salmon. While construction activities (Impact AQUA-55) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternatives 1A and 2A, Impact AQUA-55 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on spring-run Chinook salmon would be similar to those described under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to Alternative 2A (Impact AQUA-57 through AQUA-60), the fish effects described for spring-run Chinook salmon under Alternatives 2A also appropriately characterize effects under Alternative 2C.

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

NEPA Effects: As discussed in detail for Alternative 2A, except for Impact AQUA-60, the impact mechanisms listed above would not be adverse to spring-run Chinook salmon under Alternative 2C. However, adverse effects would occur from Impact AQUA-60 because habitat and migration conditions for juvenile spring-run Chinook salmon would be substantially reduced, and because it has the potential to substantially increase predation and remove important instream habitat as the result of the presence of five north Delta intake structures. The implementation of conservation and mitigation measures would reduce the severity of effects, although not necessarily to a not adverse level.

CEQA Conclusion: Similar to the discussion provided above for Alternative 2A, three of the impact mechanisms listed above would be less than significant under Alternative 2C, so no additional mitigation would be required. However, Impact AQUA-60 would result in significant reductions in migration habitat conditions. In addition to the benefits provided by the implementation of CM6 and CM15, the mitigation measures identified below would provide an adaptive management process, for assessing impacts and developing appropriate minimization measures. This process may be implemented as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6). However, the overall effect of Impact AQUA-60 would still be considered significant and unavoidable.

Mitigation Measure AQUA-60a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-60a under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-60b under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60c: Consult with USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-60c under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on spring-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C, compared to those described in detail for Alternative 1A (Impact AQUA-61 through AQUA-72). Therefore, the effects on spring-run Chinook salmon under Alternative 1A also appropriately characterize effects for spring-run Chinook salmon under Alternative 2C.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (CM12)

Impact AQUA-65: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Spring-Run ESU) (CM13)

Impact AQUA-66: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Spring-Run ESU) (CM14)

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (CM15)

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (CM16)

Impact AQUA-69: Effects of Illegal Harvest Reduction on Chinook Salmon (Spring-Run ESU) (CM17)

Impact AQUA-70: Effects of Conservation Hatcheries on Chinook Salmon (Spring-Run ESU) (CM18)

Impact AQUA-71: Effects of Urban Stormwater Treatment on Chinook Salmon (Spring-Run ESU) (CM19)

Impact AQUA-72: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Spring-Run ESU) (CM21)

NEPA Effects: As discussed for Alternative 1A and 2A, with the implementation of environmental commitments and conservation measures (Impact AQUA-61 through AQUA-72), the effects would typically be beneficial to spring-run Chinook salmon. Specifically for AQUA-62, the effects of contaminants on spring-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on spring-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Fall-/Late Fall–Run Chinook Salmon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-73 through AQUA-74), the effects described for fall- and late fall-run Chinook salmon under Alternative 1A also appropriately characterize effects under Alternative 2C.

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would not be adverse to fall- and late fall-run Chinook salmon. While construction activities (Impact

AQUA-73) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-73 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on fall- and late fall-run Chinook salmon would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impacts AQUA-75 through AQUA-78), the fish effects described for fall- and late fall-run Chinook salmon also appropriately characterize the effects for Alternative 2C.

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Overall, the effects of water operations vary by location. Similar to effects described in detail under Alternative 2A, Alternative 2C would have an adverse effect on fall-/late fall-run Chinook salmon juvenile survival due to habitat and predation losses at the NDD intakes. Through-delta conditions on the Sacramento River would substantially affect migration conditions relative to NAA while through-Delta conditions on the San Joaquin River would be positive. However, upstream of the Delta, Alternative 2C conditions relative to NAA would not substantially affect migration conditions. The implementation of the conservation and mitigation measures listed below, would reduce the overall effects, but they would still likely remain adverse.

CEQA Conclusion: As described for Alternative 2A, the differences between the CEQA baseline and Alternative 2C vary, depending on location. Through-Delta conditions on the Sacramento River would substantially impact migration conditions relative to Existing Conditions while through-Delta conditions on the San Joaquin River would be positive relative to Existing Conditions. Upstream of the Delta conditions relative to Existing Conditions would be reduced although the impacts are related to climate change. Alternative 2C also has the potential to substantially increase predation and remove important instream habitat as the result of the presence of five NDD structures.

Implementation of *CM6 Channel Margin Enhancement* and *CM15 Localized Reduction of Predatory Fishes (Predator Control)* would address habitat and predation losses, therefore, would potentially minimize impacts to some extent but not to a less than significant level.

CM6 Channel Margin Enhancement. CM6 would entail restoration of 20 linear miles of channel margin by improving channel geometry and restoring riparian, marsh, and mudflat habitats on the waterside side of levees along channels that provide rearing and outmigration habitat for juvenile salmonids.

CM15 Localized Reduction of Predatory Fishes (Predator Control). CM15 would seek to reduce populations of predatory fishes at specific locations or modify holding habitat at selected locations of high predation risk (i.e., predation “hotspots”), including the NDD intakes. This conservation measure seeks to reduce mortality rates of juvenile migratory salmonids that are particularly vulnerable to predatory fishes. Because of uncertainties regarding treatment methods and efficacy, implementation of CM15 would involve discrete pilot projects and research actions coupled with an adaptive management and monitoring program to evaluate effectiveness.

As with the conservation measures, the implementation of the mitigation measures listed below also has the potential to reduce the severity of the impact though not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-78a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Fall-/Late Fall–Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-78a under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78b: Conduct Additional Evaluation and Modeling of Impacts on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-78b under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-78c under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on fall- and late fall-run Chinook salmon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-79 through AQUA-90), the fish effects under Alternative 1A also appropriately characterize effects for fall- and late fall-run Chinook salmon under Alternative 2C.

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM12)

Impact AQUA-83: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM13)

Impact AQUA-84: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM14)

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM15)

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM16)

Impact AQUA-87: Effects of Illegal Harvest Reduction on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM17)

Impact AQUA-88: Effects of Conservation Hatcheries on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM18)

Impact AQUA-89: Effects of Urban Stormwater Treatment on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM19)

Impact AQUA-90: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM21)

NEPA Effects: As discussed in detail for Alternative 1A, these restoration and conservation commitment impact mechanisms (Impact AQUA-79 through AQUA-90) would not be adverse, and would typically be beneficial to fall- and late fall-run Chinook salmon. Specifically for AQUA-80, the effects of contaminants on fall- and late fall-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on fall- and late fall-run Chinook salmon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Steelhead

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on steelhead would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on steelhead would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-91 through AQUA-108), the fish effects described for steelhead under Alternative 1A also appropriately characterize effects for steelhead under Alternative 2C.

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: These impact mechanisms would typically not be adverse to steelhead. While construction activities (Impact AQUA-91) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-91 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of` water conveyance facility operations on steelhead would be similar to those described above under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impact AQUA-93 through AQUA-96), the effects described for steelhead under Alternative 2A also appropriately characterize effects under Alternative 2C.

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

NEPA Effects: As discussed in detail for Alternative 2A for the above listed impact mechanisms (Impact AQUA-93 through AQUA-96) flow reductions and temperature increases under Alternative 2C would affect the quantity and quality of juvenile rearing habitat and would contribute to reduced survival and increased stress. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. However, implementing Mitigation Measures AQUA-95a through AQUA-95c has the potential to reduce the severity of impact though not necessarily to a not adverse level.

CEQA Conclusion: Similar to the detailed discussion provided above for Alternative 2A, flow reductions and temperature increases would have a significant and unavoidable impact on the quantity and quality of juvenile rearing habitat and would contribute to reduced survival and increased stress. Applying mitigation to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-95a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Steelhead to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat.

Please refer to Mitigation Measure AQUA-95a under Alternative 2A for winter-run Chinook salmon.

Mitigation Measure AQUA-95b: Conduct Additional Evaluation and Modeling of Impacts on Steelhead Rearing Habitat Following Initial Operations of CM1.

Please refer to Mitigation Measure AQUA-95b under Alternative 2A for winter-run Chinook salmon.

Mitigation Measure AQUA-95c: Consult with NMFS, USFWS and CDFW to Identify Potentially Feasible Means to Minimize Effects on Steelhead Habitat Consistent with CM1

Please refer to Mitigation Measure AQUA-95c under Alternative 2A for winter-run Chinook salmon.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on steelhead would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C, compared to those described in detail for Alternative 1A (Impact AQUA-97 through AQUA-108), the effects described for steelhead also appropriately characterize the effects under Alternative 2C.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (CM12)

Impact AQUA-101: Effects of Invasive Aquatic Vegetation Management on Steelhead (CM13)

Impact AQUA-102: Effects of Dissolved Oxygen Level Management on Steelhead (CM14)

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (CM15)

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (CM16)

Impact AQUA-105: Effects of Illegal Harvest Reduction on Steelhead (CM17)

Impact AQUA-106: Effects of Conservation Hatcheries on Steelhead (CM18)

Impact AQUA-107: Effects of Urban Stormwater Treatment on Steelhead (CM19)

Impact AQUA-108: Effects of Removal/Relocation of Nonproject Diversions on Steelhead (CM21)

NEPA Effects: As discussed in detail for Alternative 1A and 2A, these impact mechanisms would not be adverse, and would typically be beneficial to steelhead. Specifically for AQUA-98, the effects of contaminants on steelhead with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on steelhead are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Sacramento Splittail

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on Sacramento splittail would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on Sacramento splittail would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-109 and AQUA-110), the fish effects described for Sacramento splittail under Alternative 1A also appropriately characterize effects for Sacramento splittail under Alternative 2C.

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: These impact mechanisms would generally not be adverse to Sacramento splittail. While construction activities (Impact AQUA-109) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-109 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The effects of Impact AQUA-110 would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on Sacramento splittail would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C, compared to those described in detail for Alternative 2A (Impacts AQUA-111 through AQUA-114), the fish effects described would also appropriately characterize the effects under Alternative 2C.

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

NEPA Effects: As discussed in detail for Alternative 2A, the operations impact mechanisms would not be adverse to Sacramento splittail.

CEQA Conclusion: Similar to the discussion provided above for Alternative 2A, these impact mechanisms would be less than significant, and no mitigation would be required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on Sacramento splittail would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impacts AQUA-115 through AQUA-126), the fish effects described also appropriately characterize the effects under Alternative 2C.

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (CM12)

Impact AQUA-119: Effects of Invasive Aquatic Vegetation Management on Sacramento Splittail (CM13)

Impact AQUA-120: Effects of Dissolved Oxygen Level Management on Sacramento Splittail (CM14)

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (CM15)

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (CM16)

Impact AQUA-123: Effects of Illegal Harvest Reduction on Sacramento Splittail (CM17)

Impact AQUA-124: Effects of Conservation Hatcheries on Sacramento Splittail (CM18)

Impact AQUA-125: Effects of Urban Stormwater Treatment on Sacramento Splittail (CM19)

Impact AQUA-126: Effects of Removal/Relocation of Nonproject Diversions on Sacramento Splittail (CM21)

NEPA Effects: As discussed in detail for Alternative 1A and 2A, the restoration and conservation measure impact mechanisms would not be adverse, and would typically be beneficial to Sacramento splittail. Specifically for AQUA-116, the effects of contaminants on Sacramento splittail with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on Sacramento splittail are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Green Sturgeon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on green sturgeon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on green sturgeon would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-127 and AQUA-128), the effects described for green sturgeon under Alternative 1A also appropriately characterize effects for green sturgeon under Alternative 2C.

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: While the maintenance impact mechanism (Impact AQUA-128) would not be adverse to green sturgeon, construction activities (Impact AQUA-127) could result in adverse effects from impact pile driving activities. However, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-127 could result in significant underwater noise effects from impact pile driving, although implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The other impact mechanism would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of operations of water conveyance facilities on green sturgeon would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impacts AQUA-129 through AQUA-132), the fish effects described for green sturgeon also appropriately characterize the effects under Alternative 2C.

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

NEPA Effects: As discussed for Alternative 2A, the expected effects of Impact AQUA-130 and Impact AQUA-132 on green sturgeon spawning and migration habitat under Alternative 2C would be limited, although adverse effects would still be expected from Impact AQUA-132, because it has the potential to substantially interfere with the movement of green sturgeon. This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. Therefore, this would be an unavoidable adverse effect because there is no feasible mitigation available, although the implementation of Mitigation Measures AQUA-132a through AQUA-132c, is expected to reduce the overall effects.

As discussed for Alternative 2A, the expected effects of Alternative 2C on green sturgeon entrainment and rearing habitat (Impact AQUA-129 and Impact AQUA-131) would not be adverse.

CEQA Conclusion: As discussed in detail for Alternative 2A, Impact AQUA-130 through AQUA-132 could result in significant, but unavoidable, effects on water temperature, and green sturgeon rearing and migration habitat conditions under Alternative 2C. These impacts are a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, these impacts are significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation (Mitigation Measure 132a through 132c) that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-132a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Green Sturgeon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-132a under Alternative 2A.

Mitigation Measure AQUA-132b: Conduct Additional Evaluation and Modeling of Impacts on Green Sturgeon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-132b under Alternative 2A.

Mitigation Measure AQUA-132c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Green Sturgeon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-132c under Alternative 2A.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on green sturgeon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-133 through AQUA-144), the fish effects under Alternative 1A would appropriately characterize effects under Alternative 2C.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (CM12)

Impact AQUA-137: Effects of Invasive Aquatic Vegetation Management on Green Sturgeon (CM13)

Impact AQUA-138: Effects of Dissolved Oxygen Level Management on Green Sturgeon (CM14)

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (CM15)

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (CM16)

Impact AQUA-141: Effects of Illegal Harvest Reduction on Green Sturgeon (CM17)

Impact AQUA-142: Effects of Conservation Hatcheries on Green Sturgeon (CM18)

Impact AQUA-143: Effects of Urban Stormwater Treatment on Green Sturgeon (CM19)

Impact AQUA-144: Effects of Removal/Relocation of Nonproject Diversions on Green Sturgeon (CM21)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, the restoration and conservation measure impact mechanisms listed above would not be adverse, and would typically be beneficial to green sturgeon. Specifically for AQUA-134, the effects of contaminants on green sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on green sturgeon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, the impact mechanisms related to restoration and conservation measures would be beneficial or less than significant, and no mitigation would be required.

White Sturgeon

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on white sturgeon would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on white sturgeon would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-145 and AQUA-146), the fish effects described for white sturgeon under Alternative 1A also appropriately characterize effects under Alternative 2C.

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: These impact mechanisms would generally not be adverse to white sturgeon. However, construction activities (Impact AQUA-145) could result in adverse effects from impact pile driving activities, although the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-145 could result in significant underwater noise effects from impact pile driving, implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance operations on white sturgeon would be similar to those described for Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A, the effects described under Alternative 2A (Impacts AQUA-147 through AQUA-150) also appropriately characterize the effects for white sturgeon under Alternative 2C.

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

NEPA Effects: As discussed above under Alternative 2A, the impact mechanisms listed above would not be generally adverse for white sturgeon. However, there is a positive correlation between white sturgeon year class strength and river/Delta flow, such that changes in water operations could result in an adverse effect on white sturgeon migration conditions (Impact AQUA-150). While there is uncertainty regarding the particular responsible mechanisms, this uncertainty will be addressed through targeted research and monitoring conducted in the years leading up to the initiation of north Delta facilities operations. The results of these efforts would be used to determine if changes in flow under Alternative 2C are likely to result in adverse effects, as well as to guide an adaptive management process to minimize or avoid such effects.

CEQA Conclusion: With a few exceptions, these impact mechanisms listed above would be less than significant, and no mitigation would be required. As discussed for Impact AQUA-149 under Alternative 2A, if the expected operational effects are adjusted to exclude sea level rise and climate change, it would not in itself result in a significant impact on rearing habitat for white sturgeon. Therefore, this impact is less than significant and no mitigation is required. However, due to the uncertainty regarding effects of flow changes on migration conditions for white sturgeon (Impact AQUA-150), research and monitoring efforts and an associated adaptive management process is proposed. These efforts are expected to identify any significant effects and develop appropriate mitigation to reduce the effect to be less than significant.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on white sturgeon would be similar to those described under Alternative 1A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-151 through AQUA-162), the effects described under Alternative 1A appropriately characterize effects for white sturgeon under Alternative 2C.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (CM12)

Impact AQUA-155: Effects of Invasive Aquatic Vegetation Management on White Sturgeon (CM13)

Impact AQUA-156: Effects of Dissolved Oxygen Level Management on White Sturgeon (CM14)

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (CM15)

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (CM16)

Impact AQUA-159: Effects of Illegal Harvest Reduction on White Sturgeon (CM17)

Impact AQUA-160: Effects of Conservation Hatcheries on White Sturgeon (CM18)

Impact AQUA-161: Effects of Urban Stormwater Treatment on White Sturgeon (CM19)

Impact AQUA-162: Effects of Removal/Relocation of Nonproject Diversions on White Sturgeon (CM21)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would not be adverse to white sturgeon and would typically be beneficial. Specifically for AQUA-152, the effects of contaminants on white sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on white sturgeon are uncertain.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Pacific Lamprey

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on Pacific lamprey would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on Pacific lamprey would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-163 and AQUA-164), the fish effects described for Pacific lamprey under Alternative 1A also appropriately characterize effects for Pacific lamprey under Alternative 2C.

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: While maintenance activities would generally not be adverse to Pacific lamprey, construction activities (Impact AQUA-163) could result in adverse effects from impact pile driving activities. However, the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, Impact AQUA-163 could result in significant underwater noise effects from impact pile driving. However, implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance operations on Pacific lamprey would be similar to those described under Alternative 2A (Impact AQUA-165 and AQUA-168). Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A, the effects described for Pacific lamprey under Alternative 2A also appropriately characterize effects for Pacific lamprey under Alternative 2C.

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

NEPA Effects: As discussed for Alternative 2A, these impact mechanisms would not be adverse to Pacific lamprey.

CEQA Conclusion: Similar to the discussion provided above for 2A, these impact mechanisms would be less than significant, and no mitigation would be required. While analyses of Impact AQUA-166 and AQUA-167 indicate that the differences between Existing Conditions and Alternative 2A could be significant because of substantial reductions in suitable spawning and rearing habitat and increased egg mortality. However, these differences are generally due to climate change, sea level rise, and future demand, and not the alternative. The impacts of Alternative 2C would be similar, and would therefore be less than significant and no mitigation is required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on Pacific lamprey would be similar to those described under Alternative 1A. Because no differences in effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-169 and through AQUA-180), the effects described for Pacific lamprey under Alternative 1A also appropriately characterize effects for Pacific lamprey under Alternative 2C.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (CM12)

Impact AQUA-173: Effects of Invasive Aquatic Vegetation Management on Pacific Lamprey (CM13)

Impact AQUA-174: Effects of Dissolved Oxygen Level Management on Pacific Lamprey (CM14)

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (CM15)

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (CM16)

Impact AQUA-177: Effects of Illegal Harvest Reduction on Pacific Lamprey (CM17)

Impact AQUA-178: Effects of Conservation Hatcheries on Pacific Lamprey (CM18)

Impact AQUA-179: Effects of Urban Stormwater Treatment on Pacific Lamprey (CM19)

Impact AQUA-180: Effects of Removal/Relocation of Nonproject Diversions on Pacific Lamprey (CM21)

NEPA Effects: Similar to the discussion provided above for Alternative 1A, these impact mechanisms would not be adverse, and would typically be beneficial to Pacific lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

River Lamprey

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on river lamprey would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on river lamprey would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-181 and AQUA-182), the fish effects described for river lamprey under Alternative 1A also appropriately characterize effects for river lamprey under Alternative 2C.

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

NEPA Effects: While construction activities (Impact AQUA-181) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality). Therefore, as discussed for Alternative 1A, these impact mechanisms would not be adverse to river lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, Impact AQUA-181 could result in significant underwater noise effects from impact pile driving, implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. Therefore, the overall effects of these impact mechanisms would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on river lamprey would be similar to those described under Alternative 2A. Because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 2A (Impact AQUA-183 through AQUA-186), the effects described for river lamprey under Alternative 2A also appropriately characterize effects for river lamprey under Alternative 2C.

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

NEPA Effects: As discussed for Alternative 2A, these impact mechanisms would not be adverse to river lamprey.

CEQA Conclusion: Similar to the discussion provided above under Alternative 2A for river lamprey, analyses of Impact AQUA-184, AQUA-185, and AQUA-186 indicate that the differences between Existing Conditions and Alternative 2A could be significant because of substantial reductions in suitable spawning, incubation, rearing, and migration conditions. However, these differences are generally due to climate change, sea level rise, and future water demands, and not the alternative. Thus, the effects of these impact mechanisms under Alternative 2C would be similar to those discussed above under Alternative 2A, and therefore would be less than significant and no mitigation is required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on river lamprey would be similar to those described under Alternative 1A, as no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C (Impact AQUA-187 through AQUA-198), the effects described for river lamprey under Alternative 1A also appropriately characterize effects for river lamprey under Alternative 2C.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (CM12)

Impact AQUA-191: Effects of Invasive Aquatic Vegetation Management on River Lamprey (CM13)

Impact AQUA-192: Effects of Dissolved Oxygen Level Management on River Lamprey (CM14)

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (CM15)

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (CM16)

Impact AQUA-195: Effects of Illegal Harvest Reduction on River Lamprey (CM17)

Impact AQUA-196: Effects of Conservation Hatcheries on River Lamprey (CM18)

Impact AQUA-197: Effects of Urban Stormwater Treatment on River Lamprey (CM19)

Impact AQUA-198: Effects of Removal/Relocation of Nonproject Diversions on River Lamprey (CM21)

NEPA Effects: As discussed for Alternative 1A and 2A, these restoration and conservation measure impact mechanisms would not be adverse, and would typically be beneficial to river lamprey.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Non-Covered Aquatic Species of Primary Management Concern

The potential effects of construction and maintenance of water conveyance facilities, operations of water conveyance facilities, restoration measures and other conservation measures on non-covered species would be similar to those described under Alternative 1A.

Construction and Maintenance of CM1

The potential effects of construction and maintenance activities on non-covered species would be similar to those described under Alternative 1A because no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C compared to those described in detail for Alternative 1A (Impact AQUA-199 and AQUA-200), the fish effects described for non-covered aquatic species of primary management concern under Alternative 1A also appropriately characterize effects for non-covered aquatic species of primary management concern under Alternative 2C.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: While construction activities (Impact AQUA-199) could result in adverse effects from impact pile driving activities, the implementation of Mitigation Measures AQUA-1a and AQUA-1b, would minimize or eliminate adverse effects from impact pile driving (e.g., injury or mortality).

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A, while Impact AQUA-199 could result in significant underwater noise effects from impact pile driving, implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce the severity of impacts to less than significant. The other impact mechanism would be less than significant, so no additional mitigation would be required.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in delta smelt.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in delta smelt.

Water Operations of CM1

The potential effects of water conveyance facility operations on non-covered species would be similar to those described under Alternative 1A, as no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C (Impact AQUA-201 through AQUA-204). Therefore, effects discussed in detail under Alternative 1A also appropriately characterize effects for non-covered aquatic species of primary management concern under Alternative 2C.

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: As discussed for Alternative 2A, the expected effects of Impact AQUA-203 on rearing habitat for several non-covered fish species of primary management concern under Alternative 2C, would be reduced, but would not be adverse. These species are Sacramento tule perch, largemouth bass, hardhead and Sacramento-San Joaquin roach. The other impact mechanisms would not be adverse.

CEQA Conclusion: Similar to the discussion provided above for Alternative 2A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required. However, Impact AQUA-203 could result in significant, but unavoidable effects on rearing habitat conditions for several fish species of primary management concern. There are also no feasible mitigation measures available to mitigate for these impacts. The other impact mechanisms would be less than significant, so no additional mitigation would be required.

Restoration and Conservation Measures

The potential effects of restoration measures and other conservation measures on non-covered species would be similar to those described under Alternative 1A, as no differences in fish effects are anticipated anywhere in the affected environment under Alternative 2C (Impact AQUA-205 through AQUA-217). Therefore, the fish effects described for non-covered aquatic species of primary management concern under Alternative 1A also appropriately characterize effects for non-covered aquatic species of primary management concern under Alternative 2C.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (CM12)

Impact AQUA-209: Effects of Invasive Aquatic Vegetation Management on Non-Covered Aquatic Species of Primary Management Concern (CM13)

Impact AQUA-210: Effects of Dissolved Oxygen Level Management on Non-Covered Aquatic Species of Primary Management Concern (CM14)

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (CM15)

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (CM16)

Impact AQUA-213: Effects of Illegal Harvest Reduction on Non-Covered Aquatic Species of Primary Management Concern (CM17)

Impact AQUA-214: Effects of Conservation Hatcheries on Non-Covered Aquatic Species of Primary Management Concern (CM18)

Impact AQUA-215: Effects of Urban Stormwater Treatment on Non-Covered Aquatic Species of Primary Management Concern (CM19)

Impact AQUA-216: Effects of Removal/Relocation of Nonproject Diversions on Non-Covered Aquatic Species of Primary Management Concern (CM21)

NEPA Effects: As discussed for Alternative 1A, these impact mechanisms would not be adverse to the non-covered species of primary management concern, and with the implementation of environmental commitments and conservation measures, the effects would typically be beneficial.

CEQA Conclusion: Similar to the discussion provided above for Alternative 1A and 2A, most of these impact mechanisms would be beneficial or less than significant, and no mitigation would be required.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: Similar to the description for Alternative 2A, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 2C would not be substantially reduced when compared to NAA.

CEQA Conclusion: Similar to the description for Alternative 2A, Alternative 2C would reduce the quantity of coldwater fish habitat in the CVP and SWP. However, if adjusted to exclude sea level rise and climate change, similar to the NEPA conclusion, the effect would not in itself result in a significant impact on coldwater habitat in upstream reservoirs. Therefore, this impact is found to be less than significant and no mitigation is required.

11.3.4.8 Alternative 3—Dual Conveyance with Pipeline/Tunnel and Intakes 1 and 2 (6,000 cfs; Operational Scenario A)

Alternative 3 would result in the same potential construction impacts as Alternative 1A, except that only Intakes 1 and 2 would be constructed. Consequently, the intensity and extent of impacts related to the construction of the intakes would be similar but less under Alternative 3 compared to those under Alternative 1A. The total permanent in-water footprint of the two intakes would be about 8.3 acres (13.5 acres smaller under Alternative 3 than under Alternative 1A), and the total length of permanent bank protection would be approximately 4,450 feet (7,450 feet less than Alternative 1A) (See Table 11-7). The six barge landings under Alternative 3 would be in the same locations, and operate the same as the landings under Alternative 1A. The effects of the landing construction and operation would be identical to those described for Alternative 1A. All other upland construction, except for the pipelines between Intakes 1 and 2 and the intermediate forebay, are identical to Alternative 1A. The conveyance system would be the same under Alternative 3 as under Alternative 1A; therefore, all impacts related to construction of the conveyance tunnel and pipelines, including those associated with barge landings would be the same. All other aspects of construction would be similar but typically less than for Alternative 3 as for Alternative 1A.

The Sacramento River channel and bank would be affected by construction of the two north Delta intake facilities (Intakes 1 and 2) between RM 44 (south of Freeport) and approximately RM 39 (at the town of Courtland). The locations, dimensions, and construction footprints of the intakes considered in Alternative 3 are presented in Table 11-5.

The number of barge trips required under Alternative 3 would be somewhat less than the estimated 3,000 barge trips under Alternative 1A, because two intake facilities would be constructed under Alternative 3 compared to five intakes under Alternative 1A. All other aspects of construction would typically be less under Alternative 3 as described for Alternative 1A.

Delta Smelt

Construction and Maintenance of CM1

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

The potential effects of construction of water conveyance facilities on delta smelt or designated critical habitat under Alternative 3 would be the same as those described for Alternative 1A (see Impact AQUA-1), except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-1, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for delta smelt or critical habitat.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-1, the impact of the construction of water conveyance facilities on delta smelt or critical habitat would be less than significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only two intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce the noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 3 would be the same as those described for Alternative 1A (see Impact AQUA-2) except that only two intakes would need to be maintained under Alternative 3 rather than five as under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-2, the effect on delta smelt or critical habitat would not be adverse.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-2, the impact of the maintenance of water conveyance facilities on delta smelt would be less than significant and no mitigation would be required.

Water Operations of CM1

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Water Exports from SWP/CVP South Delta Facilities

Under Alternative 3, average proportional entrainment would increase for larvae and juveniles (Figure 11-3-1), and decrease for adults (Figure 11-3-2).

Proportional entrainment of larval/juvenile delta smelt (March-June) under Alternative 3 would average 0.16(16% of the juvenile population) (Figure 11-3-1). This is an increase of 0.013 (1.3% of the juvenile population, a 9% relative increase) compared to NAA (Table 11-3-1). The greatest increase would occur in above normal years (0.024 more proportional entrainment, a 22% relative increase compared to NAA).

For adult delta smelt (December-March), average proportional entrainment would be no greater than 0.08 (i.e., 8% of the adult population) (Figure 11-3-2). Proportional entrainment under

Alternative 3 would be reduced compared to NAA for all water year types (average 0.010 lower, a 13% relative decrease), with the greatest reduction in wet (28% relative decrease) and above normal years (14% relative decrease) (Figure 11-3-2, Table 11-3-1).

Table 11-3-1. Differences in Proportional Entrainment Index of Delta Smelt at SWP/CVP South Delta Facilities

	Proportional Entrainment[a] Difference in Proportions (Relative Change in Proportions)	
Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Total Population (December–June)		
Wet	0.011 (10%)	-0.015 (-11%)
Above Normal	0.041 (25%)	0.013 (7%)
Below Normal	0.043 (20%)	0.014 (5%)
Dry	0.030 (11%)	0.011 (4%)
Critical	0.012 (4%)	0.013 (4%)
All Years	0.025 (13%)	0.004 (2%)
Juvenile Delta Smelt (March–June)		
Wet	0.031 (81%)	0.005 (7%)
Above Normal	0.053 (65%)	0.024 (22%)
Below Normal	0.052 (38%)	0.020 (12%)
Dry	0.034 (19%)	0.014 (7%)
Critical	0.019 (8%)	0.014 (6%)
All Years	0.037 (30%)	0.013 (9%)
Adult Delta Smelt[b] (December–March)		
Wet	-0.020 (-29%)	-0.019 (-28%)
Above Normal	-0.012 (-15%)	-0.011 (-14%)
Below Normal	-0.008 (-10%)	-0.006 (-8%)
Dry	-0.004 (-6%)	-0.003 (-4%)
Critical	-0.007 (-9%)	-0.001 (-2%)
All Years	-0.012 (-15%)	-0.010 (-13%)

Shading indicates 5% or more increase in entrainment.

Note: Negative values indicate lower entrainment loss under Alternative than under existing biological conditions.

[a] Proportional entrainment index calculated in accordance with USFWS BiOp (U.S. Fish and Wildlife Service 2008a).

[b] Adult proportional entrainment adjusted according to Kimmerer (2011).

Water Exports from SWP/CVP North Delta Intake Facilities

As described for Alternative 1A, potential entrainment and impingement risks at the proposed north Delta facilities would be limited since delta smelt rarely occur in the vicinity of the proposed intake site. The intake would be screened to exclude fish larger than 15 mm SL. Alternative 3 would have only two intakes, and therefore potential entrainment and impingement risks would be even lower than for Alternative 1A with five intakes (0–2% particle entrainment).

Water Exports with a Dual Conveyance for the SWP North Bay Aqueduct

Potential entrainment of larval delta smelt at the NBA, as estimated by particle tracking modeling, was low, averaging 1.3% under Alternative 3 compared to 2.0% under NAA (a 35% relative decrease) (Table 11-3-2).

Table 11-3-2. Average Percentage (and Difference) of Particles Representing Larval Delta Smelt Entrained by the North Bay Aqueduct under Alternative 3 and Baseline Scenarios

Average Percent Particles Entrained at NBA			Difference (and Relative Difference)	
EXISTING CONDITIONS	NAA	A3_LLT	A3_LLT vs. EXISTING CONDITIONS	A3_LLT vs. NAA
2.1	2.0	1.3	-0.80 (-38%)	-0.70 (-35%)

Note: 60-day DSM2-PTM simulation. Negative difference indicates lower entrainment under the alternative compared to the baseline scenario.

Predation Associated with Entrainment

Pre-screen loss of delta smelt at the south Delta facilities is typically attributed to predation (as described in Impact AQUA-3 for Alternative 1) and is expected to change commensurate with changes in entrainment. Predation risk at the proposed north Delta intake screens and structures would be very low because delta smelt rarely occur this far upstream and risk associated with the dual conveyance option of the NBA would likely be low because this alternative intake on the Sacramento is located upstream of the main delta smelt range.

NEPA Effects: In summation, under Alternative 3 average proportional entrainment at the south Delta facilities would increase slightly for larval/juvenile delta smelt and decrease for adults, but this change would be a small proportion of the population. Any potential effects would be reduced by real-time monitoring and adaptive management response by the Real-Time Response Team. Entrainment and impingement could potentially occur at the proposed north Delta intakes, but the risk would be low due to the location, design, and operation of intakes, and offset by reduced entrainment at the south Delta facilities.

Overall, the effect of Alternative 3 on entrainment at SWP/CVP facilities would not be adverse due to the minimal amount and risk.

CEQA Conclusion: Under Alternative 3, average proportional entrainment for adults would decrease 0.012 (15% relative decrease), with the greatest decrease in wet years (0.020 less, 29% relative decrease) (Table 11-3-1, Figure 11-3-2). Average larval/juvenile proportional entrainment and associated predation loss at the south Delta facilities would increase 0.037 (a 30% relative increase) compared to Existing Conditions, with greatest increase in above normal (0.053 more, 65% relative increase) and wet years (0.031 more, 81% relative increase) (Table 11-3-1, Figure 11-3-1). However, this represents a small proportion of the larval/juvenile population (3.7% on average, 5.3% in above normal years). Furthermore, as described for Alternative 1A (Impact AQUA-3), monitoring and adaptive management by the Real-Time Response Team would reduce such modeled potential impacts.

Note that the CEQA interpretation of the larval/juvenile proportional entrainment differs from the NEPA analysis, which is likely due to different modeling assumptions (as described in Section 11.3.3

and Alternative 1A Impact AQUA-3). Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. Note that the analysis for larvae and juveniles includes both OMR flows and X2 as predictors of proportional entrainment; primarily because of sea level rise assumptions, X2 would be further upstream in the ELT and LLT even with similar water operations, so that the comparison of the action alternative in the ELT and LLT to Existing Conditions is confounded.

Therefore, the impact analysis is better informed by the results from the NEPA analysis presented above, which accounts for sea level rise by considering the NAA in the LLT. When climate change is factored in, larval-juvenile delta smelt proportional entrainment would still increase compared to conditions without BDCP, but to a smaller degree: 0.013 more entrainment (a 9% relative increase) averaged across all years, and 0.024 more entrainment (22% relative increase) in above normal years (Table 11-2A-1). This represents a small proportion of the modeled larval-juvenile population (1.3% average, 2.4% in above normal water years)

The proposed north Delta intake facilities have the potential for entrainment and impingement, but this risk would be minimized due to low abundances of delta smelt in the vicinity, fewer intakes (two intakes for Alternative 3), and state-of-the-art screens. Potential entrainment of larvae would be slightly decreased (1%) at the NBA compared to Existing Conditions (Table 11-3-2).

Overall, the impact is considered less than significant because overall entrainment of delta smelt would be similar to conditions without BDCP, and only a small proportion of the population would be affected. Furthermore, any potential impacts would be reduced by monitoring and adaptive management by the Real-Time Response Team. No mitigation would be required.

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

NEPA Effects: The effects of operations under Alternative 3 on abiotic spawning habitat would be about the same as described for Alternative 1A (Impact AQUA-4). Flow reductions below the north Delta intakes would not reduce available spawning habitat. In-Delta water temperatures, which can affect spawning timing, would not change across alternatives, because they would be in thermal equilibrium with atmospheric conditions and not strongly influenced by the flow changes. The effect of Alternative 3 operations on spawning would not be adverse, because there would be little change in abiotic spawning conditions for delta smelt.

CEQA Conclusion: Operations under Alternative 3 would not reduce abiotic spawning habitat availability or change spawning temperatures for delta smelt (see discussion in Alternative 1A, Impact AQUA-4). Consequently, the impact would be less than significant, and no mitigation would be required.

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

NEPA Effects: As described for Alternative 1A (Impact AQUA-5), rearing habitat conditions for juvenile delta smelt are considered with respect to a fall abiotic habitat index with and without the assumption that habitat restoration benefits are realized. Similar to Alternative 1A, Alternative 3 does not include the USFWS BiOp Fall X2 requirements. The average abiotic habitat index under Alternative 3 without restoration (A3_LLT would be 21% less, relative to NAA (Table 11-3-3).

However, habitat restoration has the potential to increase spawning and rearing habitat and is expected to supplement food production and export to rearing areas. With habitat restoration, Alternative 3 could provide delta smelt with additional habitat (CM2, CM4,), particularly in the Suisun Marsh, West Delta, and Cache Slough ROAs, which are closer to delta smelt's main range. The average abiotic habitat index for Alternative 3 with habitat restoration would be about the same as NAA assuming 100% habitat occupancy by delta smelt. Under Alternative 3 the delta smelt abiotic habitat index without restoration would remain fairly constant (~5,000 hectares) across wet to below normal water year types (Figure 11-3-3).

Assuming habitat benefits are realized, the abiotic habitat index under Alternative 3 would be 25% lower than NAA in wet water year types, 8% lower in above normal water year types, but 24–35% greater than baseline in other water year types (Table 11-3-3).

CEQA Conclusion: As discussed under Alternative 1A, Alternative 3 would not result in less rearing habitat area, compared to Existing Conditions. However, without BDCP habitat restoration efforts, the delta smelt fall abiotic habitat index under Alternative 3 would be similar under most water year types (about 4% difference) compared to Existing Conditions. In wet water years, the abiotic habitat index would decrease 13% in wet water years, but would be the same or slightly increased relative to Existing Conditions in all other water year types. With the implementation of the BDCP habitat restoration actions, the average abiotic habitat index under Alternative 3 would increase by 22% compared to Existing Conditions. The abiotic habitat index would increase 22% on average (10–32% more in wetter years and 24–32% more in drier years) compared to Existing Conditions.

Note that the CEQA analysis predicts a greater increase in the abiotic habitat index relative to baseline than the NEPA analysis. It is unclear whether this increase under Alternative 3 compared to Existing Conditions is a function of Project operations, or attributable to differences in modeling assumptions (Existing Conditions does not include Fall X2). The NEPA analysis is a better approach for isolating the effect of the Alternative from the effects of sea level rise, climate change, future water demands, and implementation of required actions under the BiOps. When compared to the NAA and informed by the NEPA analysis, the average delta smelt abiotic habitat index under Alternative 3 without restoration would be 21% lower to NAA, and similar to NAA with restoration (Table 11-3-3).

Overall, there would be a minor beneficial impact on the species compared to existing conditions without Fall X2, primarily from implementation of habitat restoration. The benefits of restored habitat for this species will depend on the success of restoration in creating physical habitat for smelt and in fostering ecological conditions that favor good feeding conditions and production of food upon which smelt can feed. The magnitude of restored habitat benefits is uncertain. As such, BDCP water operations will be subject to adjustment via adaptive management, in order to ensure the impacts of water operations on rearing habitat for delta smelt are not significant and to support a contribution to recovery of this species. The Adaptive Management Program will evaluate the effects of water operations and habitat restoration on the delta smelt population, including adjustments as appropriate to improve water supply reliability. In conclusion, the impact of Alternative 3 without habitat restoration on delta smelt rearing habitat would be considered less than significant, because the amount of abiotic habitat would be similar to Existing Conditions. The impact would be less than significant and may be beneficial when habitat restoration is included. No mitigation would be required.

Table 11-3-3. Differences in Delta Smelt Fall Abiotic Index (hectares) between Alternative 3 and Existing Biological Conditions Scenarios, with Habitat Restoration, Averaged by Prior Water Year Type

	Without Restoration		With Restoration	
Water Year	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
All	-147 (-4%)	-1,033 (-21%)	867 (22%)	-18 (0%)
Wet	-632 (-13%)	-2,828 (-41%)	462 (10%)	-1,734 (-25%)
Above Normal	135 (4%)	-1,533 (-28%)	1,224 (32%)	-443 (-8%)
Below Normal	-3 (0%)	146 (4%)	1,130 (27%)	1,278 (32%)
Dry	157 (4%)	249 (7%)	1,132 (32%)	1,224 (35%)
Critical	18 (1%)	17 (1%)	713 (24%)	713 (24%)
	Shading indicates >5% decrease in estimated abiotic habitat acres from baseline.			

Note: Negative values indicate lower habitat indices under preliminary proposal scenarios. Water year 1922 was omitted because water year classification for prior year was not available.

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

NEPA Effects: As described for previous alternatives, Alternative 3 may decrease sediment supply to the estuary by 8 to 9%, with the potential for decreased habitat suitability for delta smelt in some locations.

***CEQA Conclusion*:** Operations under Alternative 3 would not substantially alter the turbidity cues associated with winter flush events that may initiate migration, nor would there be appreciable changes in water temperatures (see Alternative 1A, Impact AQUA-6). Consequently, the impact on adult delta smelt migration conditions would be less than significant, and no mitigation would be required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related effects on fish are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the effects of restoration measures on fish as described for delta smelt under Alternative 1A (Impact AQUA-7 through AQUA-9) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

NEPA Effects: All of these impact mechanisms have been determined to result in no adverse effects on delta smelt, for the reasons identified for Alternative 1A. Specifically for AQUA-8, the effects of contaminants on delta smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on delta smelt are uncertain.

CEQA Conclusion: All of these impact mechanisms would be considered less than significant, for the reasons identified for Alternative 1A, and no mitigation would be required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related effects on fish are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the effects of other conservation measures on fish described for delta smelt under Alternative 1A (Impact AQUA-10 through AQUA-18) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (CM12)

Impact AQUA-11: Effects of Invasive Aquatic Vegetation Management on Delta Smelt (CM13)

Impact AQUA-12: Effects of Dissolved Oxygen Level Management on Delta Smelt (CM14)

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (CM15)

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (CM16)

Impact AQUA-15: Effects of Illegal Harvest Reduction on Delta Smelt (CM17)

Impact AQUA-16: Effects of Conservation Hatcheries on Delta Smelt (CM18)

Impact AQUA-17: Effects of Urban Stormwater Treatment on Delta Smelt (CM19)

Impact AQUA-18: Effects of Removal/Relocation of Nonproject Diversions on Delta Smelt (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on delta smelt for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on delta smelt, for the reasons identified for Alternative 1A, and no mitigation is required.

Longfin Smelt

Construction and Maintenance of CM1

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

The potential effects of construction of water conveyance facilities on longfin smelt under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-19) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-19, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for longfin smelt.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-19, the impact of the construction of water conveyance facilities on longfin smelt would be less than significant except for construction noise associated with pile driving which would only occur for two intakes rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce the noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 3 would be the same as those described for Alternative 1A except that only two intakes would need to be maintained under Alternative 3 instead of five as under Alternative 1A (see Impact AQUA-20). As concluded in Alternative 1A, Impact AQUA-20, the effect on longfin smelt would not be adverse.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-20, the impact of the maintenance of water conveyance facilities on longfin smelt would be less than significant and no mitigation would be required.

Water Operations of CM1

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Water Exports from SWP/CVP South Delta Facilities

For larval longfin smelt, entrainment risk was simulated using particle tracking modeling. Entrainment loss of longfin smelt larvae to the south Delta facilities under the wetter starting distribution was 1.1% for Alternative 3 compared to 1.6% for NAA, a 35% decrease in relative terms (Table 11-3-4). Under the drier starting distribution, average entrainment was 1.4% under Alternative 3 compared to 2.2% for NAA, a 38% relative decline. Overall, larval longfin smelt entrainment at the south Delta intakes would be reduced under Alternative 3 compared to baseline conditions (NAA).

Table 11-3-4. Percentage of Particles (and Difference) Representing Longfin Smelt Larvae Entrained by the South Delta Facilities under Alternative 3 and Baseline Scenarios

	Percent Particles Entrained			Difference (and Relative Difference)	
Starting Distribution	EXISTING CONDITIONS	NAA	A3_LLT	A3_LLT vs. EXISTING CONDITIONS	A3_LLT vs. NAA
Wetter	1.9	1.6	1.1	-0.77 (-41%)	-0.59 (-35%)
Drier	2.5	2.2	1.4	-1.13 (-45%)	-0.86 (-38%)

For juvenile longfin smelt, entrainment at the south Delta facilities (salvage index, averaged across all water year types) would increase under Alternative 3 by 61% (compared to NAA) (Table 11-3-5). The increase in juvenile entrainment is related to substantial increases in reverse OMR flows in April and May during dry and wetter water year types. Under Alternative 3, juvenile entrainment would be highest in dry water year types. In critical water year types, juvenile entrainment would be reduced 11% compared to NAA.

For adult longfin smelt, entrainment at the south Delta facilities (salvage index, averaged across all water year types) would be reduced by 29% compared to NAA (Table 11-3-5). The reduction in entrainment for adult longfin smelt is due to substantial reductions in reverse OMR flows during January–March under Alternative 3 (Figure 11-3-1). For adult longfin smelt, the reduction in entrainment is 1–2 orders of magnitude greater in critical years. Under Alternative 3, adult entrainment in critical water year types would be reduced 22% compared to NAA.

Table 11-3-5. Longfin Smelt Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences (Absolute and Percentage) between Model Scenarios for Alternative 3

Life Stage	Water Year Types	Absolute Difference (Percent Difference) EXISTING CONDITIONS vs. A3_LLT	Absolute Difference (Percent Difference) NAA vs. A3_LLT
Juvenile (March–June)	Wet	56,797 (89%)	51,355 (74%)
	Above Normal	5,808 (128%)	5,519 (115%)
	Below Normal	2,311 (75%)	2,103 (64%)
	Dry	186,501 (35%)	128,194 (22%)
	Critical	-127,067 (-22%)	-53,197 (-11%)
	All Years	202,565 (76%)	177,554 (61%)
Adult (Dec–March)	Wet	-38 (-30%)	-42 (-31%)
	Above Normal	-85 (-13%)	-125 (-18%)
	Below Normal	-143 (-7%)	-66 (-4%)
	Dry	-170 (-14%)	-105 (-9%)
	Critical	-6,958 (-29%)	-4,824 (-22%)
	All Years	-1,059 (-29%)	-1,024 (-29%)
	Shading indicates >5% increase in entrainment index.		

[a] Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

The proposed north Delta intakes could increase entrainment potential and locally attract piscivorous fish predators, but entrainment and predation losses of longfin smelt at the north Delta would be extremely low because this species is not expected to occur this far upstream.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

Particle entrainment at the NBA, representing potential larval longfin smelt entrainment, was low for both starting distributions (wetter and drier), averaged 0.13-0.16% under Alternative 3, which was 0.05% less than NAA, or 47-56% lower in relative terms (Table 11-3-6).

Table 11-3-6. Average Percentage (and Difference) of Particles Representing Larval Longfin Smelt Entrained by the North Bay Aqueduct under Alternative 3 and Baseline Scenarios

	Percent Particles Entrained			Difference (and Relative Difference)	
Distribution	EXISTING CONDITIONS	NAA	A3_LLT	A3_LLT vs. EXISTING CONDITIONS	A3_LLT vs. NAA
Wetter	0.20	0.08	0.13	-0.08 (-38.4%)	0.05 (56.1%)
Drier	0.25	0.11	0.16	-0.09 (-36.7%)	0.05 (47.1%)

Note: 60-day runs of PTM. Negative difference values indicate lower entrainment under the alternative compared to the baseline scenario.

In summation, at the SWP/CVP south Delta facilities juvenile longfin smelt entrainment would increase substantially under Alternative 3 compared to NAA. Adult entrainment at the south Delta facilities would be reduced, especially in critical water year types when longfin smelt distribution extends further into the Delta. Longfin smelt entrainment to the NBA would increase negligibly compared to NAA. Entrainment loss of longfin smelt at the proposed north Delta intakes would be low since longfin smelt would occur only rarely in that area of the Sacramento River.

Predation Associated with Entrainment

Under Alternative 3, pre-screen loss of juvenile longfin smelt at the south Delta facilities, typically attributed to predation (as described for Impact AQUA-3 for Alternative 1), is expected to increase for juveniles and decrease for adults commensurate with entrainment. Predation loss at the proposed north Delta intakes and the alternate NBA intake would be limited because longfin smelt only rarely occur that far upstream.

NEPA Effects: Overall, the effect of water operations on entrainment and entrainment-related predation loss of longfin smelt under Alternative 3 would be adverse, particularly because of the substantial increase in south Delta entrainment and predation loss of juvenile longfin smelt.

CEQA Conclusion**:** The results of the PTM model indicate slightly lower larval entrainment at the south Delta facilities, agricultural diversions, and the NBA for all distributions (wetter and drier) compared to Existing Conditions. At the south Delta facilities, juvenile entrainment would increase 76% while adult entrainment would be reduced 29% compared to Existing Conditions. Entrainment to the north Delta intakes would be low since longfin smelt would not occur in the vicinity of the intakes.

Predation loss of juveniles would be increased 76% compared to Existing Conditions (based on salvage data) while predation loss of adults would be reduced by 29%. Predation risk at the SWP/CVP north Delta intakes would be low because longfin smelt rarely occur in that vicinity.

Under Alternative 3, the impact of water operations on longfin smelt would be significant because the increase in entrainment and predation loss for juveniles would be much greater than the reduction predicted for adult longfin smelt. As a result, this impact is significant and unavoidable. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-21a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Longfin Smelt to Determine Feasibility of Mitigation to Reduce Entrainment Impacts

Although analysis conducted as part of the EIR/EIS determined that Alternative 3 would have significant and unavoidable adverse effects on entrainment of longfin smelt, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on entrainment in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 3.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 3 operations only. Development of mitigation actions for the incremental impacts on entrainment attributable to climate change/sea level rise, are not required because these changed conditions would occur with or without implementation of Alternative 3.

Mitigation Measure AQUA-21b: Conduct Additional Evaluation and Modeling of Impacts on Longfin Smelt Entrainment Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to entrainment under Alternative 3. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-21c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Longfin Smelt Entrainment Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on longfin smelt, the BDCP proponents will consult with USFWS and CDFW to identify and implement any feasible operational means to minimize effects on entrainment Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-21a.

If feasible means are identified to reduce impacts on entrainment consistent with the overall operational framework of Alternative 3 without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on longfin smelt habitat is not feasible under Alternative 3 operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on longfin smelt would remain significant and unavoidable.

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

NEPA Effects: Predicted average longfin smelt relative abundance would be reduced under Alternative 3, resulting in 7% less (based on Fall Midwater Trawl estimates) to 8% less (based on Bay Otter Trawl estimates) compared to NAA (Table 11-3-7). Under Alternative 3 longfin smelt relative abundance would be reduced 14–17% in above normal water year types, and reduced 13–15% in below normal water year types compared to NAA.

Table 11-3-7. Estimated Differences between Scenarios for Longfin Smelt Relative Abundance in the Fall Midwater Trawl or Bay Otter Trawl

	Fall Midwater Trawl Relative Abundance		Bay Otter Trawl Relative Abundance	
Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
All	-1,724 (-33%)	-247 (-7%)	-5,518 (-39%)	-763 (-8%)
Wet	-6,441 (-35%)	-77 (-1%)	-26,449 (-41%)	-300 (-1%)
Above Normal	-3,650 (-43%)	-817 (-14%)	-12,781 (-49%)	-2,736 (-17%)
Below Normal	-1,685 (-39%)	-386 (-13%)	-5,154 (-45%)	-1,134 (-15%)
Dry	-601 (-28%)	-108 (-7%)	-1,621 (-33%)	-284 (-8%)
Critical	-169 (-18%)	-34 (-4%)	-393 (-21%)	-79 (-5%)
	Shading indicates10% or greater decrease in relative abundance.			
Note: Based on the X2-Relative Abundance Regressions of Kimmerer et al. (2009).				

The differences in predicted abundance described above result from differences in predicted Delta outflow in January through June between Alternative 3 and NAA. Averaged across all water years, predicted Delta outflow under Alternative 3 showed <10% difference relative to NAA during the peak larval longfin smelt transport period from January-March. During April-June however, Delta outflows would be reduced 15–25% compared to NAA. The largest differences would occur in above and below normal water years in April (23–25% reduction in outflow) and in wet, above normal, and below normal water years in May (25–31% reduction in outflow).

Longfin smelt may benefit from habitat restoration which includes *CM2 Yolo Bypass Fisheries Enhancement* for smelt present in Cache Slough region, and *CM4 Tidal Natural Communities Restoration* for smelt in the west Delta and Suisun Bay*.* This restored habitat is intended to provide additional food production and export to rearing areas, which may provide benefits to longfin smelt, particularly from Suisun Marsh, West Delta, and Cache Slough ROAs.

CEQA Conclusion: Under Alternative 3, average Delta outflows would be increased 7% in January and February, similar to Existing Conditions in March, and reduced in spring (15-16% decrease in April and June, 25% decrease in May) compared to Existing Conditions.

Average relative longfin smelt abundance, based on Kimmerer et al.2009, decreased 33–39% compared to Existing Conditions (Table 11-3-7). Relative longfin smelt abundances decreased under Alternative 3 in all water year types, with the largest reduction (35–49% decrease) in wet, above normal, and below normal water year types, based on Bay Otter Trawl indices.

It is worth noting that this CEQA analysis predicts a greater decrease in juvenile relative abundance than estimated under the NEPA analysis set forth above. This interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed above (Section 11.3.3), because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA) models anticipated future conditions that would occur in 2060 (LLT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the NEPA analysis, which compares results between the alternative and NAA, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA and informed by the NEPA analysis, above, the average longfin smelt abundance, based on Kimmerer et al. (2009), under Alternative 3 decreased 7–8% compared to NAA (Table 11-3-7), with the greatest reduction (13-17%) in above normal and below normal water year types. These results represent the increment of change attributable to the alternative, and address the limitations of the comparison the CEQA baseline (Existing Conditions).

Overall, Alternative 3 could have a significant impact because reduced Delta outflows in the spring would have the potential to contribute to reductions in longfin smelt abundances. As a result, this impact is considered significant, and mitigation would be required. Implementation of Mitigation Measures AQUA-22a through 22c, habitat restoration and adaptive management would reduce this impact to less than significant.

Mitigation Measure AQUA-22a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Longfin Smelt to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Although analysis conducted as part of the EIR/EIS determined that Alternative 3 would have significant and unavoidable adverse effects on rearing habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on rearing habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 3.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 3 operations only. Development of mitigation actions for the incremental impact on rearing habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 3.

Mitigation Measure AQUA-22b: Conduct Additional Evaluation and Modeling of Impacts on Longfin Smelt Rearing Habitat Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to rearing habitat under Alternative 3. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-22c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Longfin Smelt Rearing Habitat Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on longfin smelt habitat, the BDCP proponents will consult with NMFS, USFWS and CDFW to identify and implement any feasible operational means to minimize effects on rearing habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-22a.

If feasible means are identified to reduce impacts on rearing habitat consistent with the overall operational framework of Alternative 3 without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on longfin smelt habitat is not feasible under Alternative 3 operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under Alternative 3, and the impact on longfin smelt would remain significant and unavoidable.

Impact AQUA-23: Effects of Water Operations on Rearing Habitat for Longfin Smelt

The analysis, NEPA Effects and CEQA Conclusion for effects of water operations on rearing habitat for longfin smelt is included in Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt.

Impact AQUA-24: Effects of Water Operations on Migration Conditions for Longfin Smelt

The analysis, NEPA Effects and CEQA Conclusion for effects of water operations on migration conditions for longfin smelt is included in Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related effects on fish are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the effects of restoration measures on longfin smelt described under Alternative 1A (Impact AQUA-25 through AQUA-27) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

NEPA Effects: All of these effects have been determined to result in no adverse effects on longfin smelt. Specifically for AQUA-26, the effects of contaminants on longfin smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on longfin smelt are uncertain.

CEQA Conclusions: The overall effects of the restoration measures is considered less than significant for CEQA purposes for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related effects on fish are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the effects of other conservation measures on longfin smelt described under Alternative 1A (Impact AQUA-28 through AQUA-36) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (CM12)

Impact AQUA-29: Effects of Invasive Aquatic Vegetation Management on Longfin Smelt (CM13)

Impact AQUA-30: Effects of Dissolved Oxygen Level Management on Longfin Smelt (CM14)

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (CM15)

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (CM16)

Impact AQUA-33: Effects of Illegal Harvest Reduction on Longfin Smelt (CM17)

Impact AQUA-34: Effects of Conservation Hatcheries on Longfin Smelt (CM18)

Impact AQUA-35: Effects of Urban Stormwater Treatment on Longfin Smelt (CM19)

Impact AQUA-36: Effects of Removal/Relocation of Nonproject Diversions on Longfin Smelt (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on longfin smelt, for the reasons identified for Alternative 1A.

CEQA Conclusions: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on longfin smelt, for the reasons identified for Alternative 1A, and no mitigation is required.

Winter-Run Chinook Salmon

Construction and Maintenance of CM1

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

The potential effects of construction of water conveyance facilities on Chinook salmon under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-37) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-37, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-37, the impact of the construction of water conveyance facilities on Chinook salmon would be less than significant except for construction noise associated with pile driving which would only occur for two intakes rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 3 would be the similar to those described for Alternative 1A except that only two intakes would need to be maintained under Alternative 3 instead of five under Alternative 1A (see Impact AQUA-2, delta smelt). As concluded in Alternative 1A, Impact AQUA-38, the effect would not be adverse for Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-38, the impact of the maintenance of water conveyance facilities on Chinook salmon would be less than significant and no mitigation would be required.

Water Operations of CM1

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Alternative 3 would reduce the overall entrainment of juvenile winter-run Chinook salmon at the south Delta export facilities. Average entrainment would decrease 22% across all water year types compared to NAA (Table 11-3-8), with the greatest reductions in wetter years (18% to 33% less compared to NAA). Pre-screen losses, typically attributed to predation, would be expected to decrease commensurate with decreased entrainment at the south Delta facilities.

Table 11-3-8. Juvenile Chinook Salmon Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Winter-Run Chinook Salmon		
Wet	-3,467 (-30%)	-3,888 (-33%)
Above Normal	-1,582 (-24%)	-1,707 (-25%)
Below Normal	-1,626 (-23%)	-1,202 (-18%)
Dry	-337 (-9%)	-30 (-1%)
Critical	-195 (-15%)	-56 (-5%)
All Years	-1,546 (-23%)	-1,486 (-22%)
	Shading indicates entrainment increased 5% or more.	

[a] Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

As described under Alternative 1A (Impact AQUA-39), potential entrainment of juvenile salmonids at the north Delta intakes would be greater than baseline, but the effects would be minimal because the north Delta intakes would have state-of-the-art screens to exclude juvenile fish.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

As described under Alternative 1A (Impact AQUA-39), potential entrainment and impingement effects for juvenile salmonids would be minimal because intakes would have state-of-the-art screens installed.

NEPA Effects: In conclusion, Alternative 3 would reduce the overall entrainment of juvenile winter Chinook salmon compared to baseline conditions, which would be a beneficial impact.

***CEQA Conclusion*:** As discussed above, entrainment losses of juvenile winter-run Chinook salmon at the south Delta export facilities would decrease under Alternative 3 compared to Existing Conditions (Table 11-3-8). Impacts at the north Delta intake facilities would be similar to Alternative 1A but less because Alternative 3 has only two intakes. Overall, impacts would be less than significant and may be beneficial due to reductions in entrainment at the south Delta export facilities and at the north Delta intake facilities. No mitigation would be required.

The impact and conclusion for predation associated with entrainment is the same as described above, because although combined predation losses at the south Delta and the proposed north Delta intakes would increase for all races of juveniles, there would not be substantial effects on population levels. The impacts would be less than significant, no mitigation would be required.

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

In general, effects of Alternative 3 on spawning and egg incubation habitat for winter-run Chinook salmon relative to NAA are uncertain.

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam were examined during the May through September winter-run Chinook salmon spawning period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation. Flows under A3_LLT during May through July would generally be similar to or greater than flows under NAA except in dry years during July (9% at both locations). Flows during August and September under A3_LLT would be mostly lower than flows under NAA (up to 45% lower depending on month, location, and water year type).

Shasta Reservoir storage volume at the end of May influences flow rates below the dam during the May through September winter-run spawning and egg incubation period. May Shasta storage volume under A3_LLT would be similar to or greater than storage under NAA for all water year types except below normal (8% lower) and dry (6% lower) (Table 11-3-9).

These results indicate that there would be small to moderate effects of Alternative 3 relative to NAA.

Table 11-3-9. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	-78 (-2%)	-44 (-1%)
Above Normal	-161 (-4%)	-75 (-2%)
Below Normal	-518 (-13%)	-320 (-8%)
Dry	-634 (-17%)	-190 (-6%)
Critical	-593 (-24%)	-9 (0%)

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-40, which indicates that there would generally be no effects on water temperature in the Sacramento River.

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under A3_LLT would be similar to mortality under NAA in wet and critical years (<5% difference). Egg mortality under A3_LLT would be 12% to 97% greater than mortality under NAA in above normal, below normal, and dry water years, although these increases represent a 0.3 to 2% absolute scale change in the winter-run Chinook salmon population (Table 11-3-10). Therefore, this effect is considered negligible to the winter-run population. These results indicate that climate change would cause the majority of the increase in winter-run egg mortality.

Table 11-3-10. Difference and Percent Difference in Percent Mortality of Winter-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	1 (270%)	-0.03 (-2%)
Above Normal	2 (413%)	0.3 (13%)
Below Normal	3 (267%)	2 (97%)
Dry	7 (440%)	1 (12%)
Critical	43 (159%)	-1 (-2%)
All	9 (190%)	0.3 (2%)

SacEFT predicts that there would be a 22% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A3_LLT relative to NAA (Table 11-3-11). This reduction would be 7% on an absolute scale and, therefore, is considered a small effect. SacEFT predicts that the percentage of years with good (lower) redd scour risk under A3_LLT would be identical to the percentage of years under NAA. SacEFT predicts that the percentage of years with good egg incubation conditions under A3_LLT would be similar to (<5% difference) that under NAA. SacEFT predicts that the percentage of years with good (lower) redd dewatering risk under A3_LLT would be 10% lower than risk under NAA, which is negligible (3%) on an absolute scale.

The biological significance of a reduction in available suitable spawning habitat varies at the population level in response to a number of factors, including adult escapement. For those years when adult escapement is less than the carrying capacity of the spawning habitat, a reduction in area would have little or no population level effect. In years when escapement exceeds carrying capacity of the reduced habitat, competition among spawners for space (e.g., increased redd superimposition) would increase, resulting in reduced reproductive success. The reduction in the frequency of years in which spawning habitat availability is considered to be good by SacEFT could result in reduced reproductive success and abundance of winter-run Chinook salmon if the number of spawners is limited by spawning habitat quantity

Table 11-3-11. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Winter-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Spawning WUA	-33 (-57%)	-7 (-22%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-25 (-26%)	-2 (-3%)
Redd Dewatering Risk	1 (4%)	-3 (-10%)
Juvenile Rearing WUA	-10 (-20%)	15 (60%)
Juvenile Stranding Risk	-14 (-70%)	-25 (-81%)
WUA = Weighted Usable Area.		

NEPA Effects: Available analytical tools show conflicting results regarding the temperature effects of relatively small changes in predicted summer and fall flows. Several models (CALSIM, SRWQM, and Reclamation Egg Mortality Model) generally show no change in upstream conditions as a result of Alternative 3. However, one model, SacEFT, shows adverse effects under some conditions. After extensive investigation of these results, they appear to be a function of high model sensitivity to relatively small changes in estimated upstream conditions, which may or may not accurately predict adverse effects. The new NDD structures allow for spring time deliveries of water south of the Delta that are currently constrained under the NAA. For this reason, additional spring storage criteria may be necessary to ensure Shasta Reservoir operations similar to what was modeled. These discussions will occur in the Section 7 consultation with Reclamation on Shasta Reservoir and system-wide operations, which is outside the scope of BDCP. In conclusion, Alternative 3 modeling results support a finding that effects are uncertain, but modeled results are mixed and operations that match the CALSIM modeling are not assured. Model results will be submitted to independent peer review to confirm that adverse effects are not reasonably anticipated to occur.

CEQA Conclusion: In general, Alternative 3 would not affect spawning and egg incubation habitat for winter-run Chinook salmon relative to the Existing Conditions.

CALSIM flows in the Sacramento River between Keswick and upstream of Red Bluff were examined during the May through September winter-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT during May through July would generally be similar to or greater than flows under Existing Conditions, except in wet years during May (14% to 18% lower depending on location) and in dry and critical years during July (6% to 11% lower depending on month and location) and August (21% to 25% lower depending on location). Flows under A3_LLT during August and September would generally be lower than flows under Existing Conditions by up to 27% depending on month, water year type, and location.

Shasta Reservoir storage volume at the end of May under A3_LLT would be similar to Existing Conditions in wet and above normal water years, but lower by 13% to 24% in below normal, dry, and critical water years (Table 11-3-9). This indicates that there would be a small to moderate effect of Alternative 3 on flows during the spawning and egg incubation period.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-40, which indicates that there would be increased exceedances of NMFS temperature thresholds in the Sacramento River relative to Existing Conditions.

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under A3_LLT would be 159% to 440% greater than mortality under Existing Conditions depending on water year type (Table 11-3-10). These increases would only affect the winter-run population during dry and critical years, in which the absolute percent increase of the winter-run population would be 7% and 43%, respectively. These results indicate that Alternative 3 would cause substantially increased winter-run Chinook salmon mortality in drier years in the Sacramento River.

SacEFT predicts that there would be a 57% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A3_LLT relative to Existing Conditions (Table 11-3-11). SacEFT predicts that the percentage of years with good (lower) redd scour risk under A3_LLT would be identical to the percentage of years under Existing Conditions. SacEFT predicts that the percentage of years with good egg incubation conditions under A3_LLT would be 26% lower than under Existing Conditions. SacEFT predicts that the percentage of years with good (lower) redd dewatering risk under A3_LLT would be similar (<5% difference) to the percentage of years under Existing Conditions. These results indicate that Alternative 3 would cause moderate to substantial reductions in spawning WUA and egg incubation conditions.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-40 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, when compared to the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above. Flows and water temperature conditions would be degraded in the Sacramento River under Alternative 3 relative to Existing Conditions. Egg mortality in drier years, during which winter-run Chinook salmon would already be stressed due to reduced flows and increased temperatures, would be up to 43% greater (on an absolute scale) due to Alternative 3 compared to the Existing Conditions (Table 11-3-10). Further, the extent of spawning habitat would be 33% lower (absolute scale) and egg incubation would be reduced by 25% (absolute scale) under Alternative 3 compared to the Existing Conditions (Table 11-3-11), which represent a substantial reductions spawning and egg incubation conditions for winter-run Chinook salmon.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow and reservoir storage outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between future conditions without the alternative (NAA) and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for winter-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

In general, Alternative 3 would reduce the quality of rearing habitat for fry and juvenile winter-run Chinook salmon relative to NAA.

Sacramento River flows upstream of Red Bluff were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can lead to reduced extent and quality of fry and juvenile rearing habitat. Flows under A3_LLT would generally be similar to or greater than flows under NAA during October and December, but up to 43% lower than flows under NAA during August, September, and November depending on month and water year type. This indicates that both climate change and

Alternative 3 would cause small to moderate reductions in flows in the Sacramento River during most months of the winter-run upstream fry and juvenile rearing period.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-41, which indicates that there would be no effect on mean monthly temperatures during the winter-run juvenile rearing period.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under A3_LLT would be 60% greater (15% higher on an absolute scale) than that under NAA (Table 11-3-10). In addition, the percentage of years with good (low) juvenile stranding risk under A3_LLT is predicted to be 81% lower (25% lower on an absolute scale) than that under NAA. This indicates that, although the quantity of juvenile rearing habitat in the Sacramento River under Alternative 3 would be substantially similar to or higher than NAA, the quality of this habitat, measured as stranding risk, would be substantially lower.

SALMOD predicts that mean winter-run smolt equivalent habitat-related mortality under A3_LLT would be similar (<5% difference) to mortality under NAA.

NEPA Effects: Collectively, these results indicate that the effect would be adverse because it has the potential to substantially reduce the amount of suitable rearing habitat. Under Alterative 3, there would be large flow reductions during 3 months of the 5-month the larval and juvenile rearing period. Also, stranding risk of larvae and juveniles would be substantially higher under Alternative 3relative to NAA (Table 11-3-11). This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect. Even so, proposed mitigation (Mitigation Measure AQUA-41a through AQUA-41c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 3 would reduce the quantity and quality of fry and juvenile rearing habitat for winter-run Chinook salmon relative to the Existing Conditions.

Sacramento River flows upstream of Red Bluff were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). During September, October, and December, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions, except in wet and dry water years during September (23% and 20% lower, respectively). During August and November, flow would be nearly always lower than under Existing Conditions by up to 24% depending on month and water year type.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-41, which indicates that there would be small temperature increases under Alternative 1A during some months in the Sacramento River.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under A3_LLT would be 20% lower than under Existing Conditions (Table 11-3-11). In addition, the percentage of years with good (low) juvenile stranding risk under A3_LLT is predicted to be 70% lower than under Existing Conditions. These results indicate that there would be a small reduction in the amount of juvenile rearing habitat and a moderate reduction in the quality of juvenile rearing habitat in the Sacramento River, measured as stranding risk, under Alternative 3 relative to Existing Conditions.

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under A3_LLT would be 9% higher than under Existing Conditions.

Summary of CEQA Conclusion

These results indicate that the impact would be significant because it has the potential to substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish. Differences in flows are moderately large during August and November. Temperatures would increase in the Sacramento River during the winter-run rearing period under Alternative 3. Further, a 20% reduction (10% on an absolute scale) in rearing habitat quantity and 70% increase (14% on an absolute scale) in stranding risk would reduce upstream habitat conditions for winter-run fry and juveniles. SALMOD predicts that habitat-related mortality will increase due to Alternative 3. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-41a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat

Although analysis conducted as part of the EIR/EIS determined that Alternative 3 would have significant and unavoidable adverse effects on rearing habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on rearing habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 3.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 3 operations only. Development of mitigation actions for the incremental impact on spawning habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 3.

Mitigation Measure AQUA-41b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Rearing Habitat Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to rearing habitat under Alternative 3. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-41c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Rearing Habitat Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on Chinook salmon habitat, the BDCP proponents will consult with NMFS, USFWS, and CDFW to identify and implement any feasible operational means to minimize effects on rearing habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-41a.

If feasible means are identified to reduce impacts on rearing habitat consistent with the overall operational framework of Alternative 3 without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on winter-run Chinook salmon habitat is not feasible under Alternative 3 operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on winter-run Chinook salmon would remain significant and unavoidable.

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

In general, Alternative 3 would reduce migration conditions for winter-run Chinook salmon relative to NAA.

Upstream of the Delta

Flows in the Sacramento River upstream of Red Bluff were examined for the July through November juvenile emigration period. A reduction in flow may reduce the ability of juvenile winter-run Chinook salmon to migrate effectively down the Sacramento River. Flows under A3_LLT would generally be similar to flows under NAA during July, up to 43% lower under NAA during July, August, and November, and up to 33% greater during October (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This indicates that Alternative 3 would cause small to moderate reductions in flows in the Sacramento River during the majority of months during the winter-run migration period.

Flows in the Sacramento River upstream of Red Bluff were examined during the adult winter-run Chinook salmon upstream migration period (December through August). A reduction in flows may reduce the olfactory cues needed by adult winter-run Chinook salmon to return to natal spawning grounds in the upper Sacramento River. Flows under A3_LLT would generally be similar to flows under NAA, except during May, in which flows would be up to 15% greater, and during August, in which flows would be up to 43% lower.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-42, which indicates there would be no differences in water temperatures between NAA and Alternative 1A.

Through-Delta

The effects on through-Delta migration were evaluated using the approach described in Alternative 1A, Impact AQUA-42.

Juveniles

Juvenile salmonids migrating down the Sacramento River would generally experience lower flows below the north Delta intakes by up to 26% averaged over all water year types compared to baseline conditions. The two intake structures of Alternative 3 would replace aquatic habitat and likely attract piscivorous fish around the intake structures, as described above in Impact AQUA-42. The two intakes would remove or modify habitat along that portion of the migration corridor (8.3 acres aquatic habitat and 4,450 linear feet of shoreline). Potential predation losses at the north Delta intakes, as estimated by the bioenergetics model for two intakes with median density of predators (119 striped bass per 1,000 feet of intake), would be 0.7% of the annual juvenile production estimated for the Sacramento Valley (Table 11-3-12). A conservative assumption of 5% loss per intake would yield a cumulative loss of 8% of juvenile winter-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate.

Table 11-3-12. Chinook Salmon Predation Loss at the Proposed North Delta Diversion Intakes for Alternative 3 (Two Intakes)

Striped Bass Numbers		Estimated Number of Juvenile Salmon Consumed				Percentage of Annual Juvenile Production (%) Consumed			
Per 1,000 ft. of Intake	Total Bass	Winter	Spring	Fall	Late Fall	Winter	Spring	Fall	Late Fall
18 (Low)	52	2,651	3,709	56,870	10,760	0.10%	0.09%	0.09%	0.25%
119 (Median)	345	17,525	24,520	375,972	71,138	0.67%	0.58%	0.61%	1.65%
219 (High)	635	32,252	45,125	691,916	130,918	1.24%	1.07%	1.12%	3.04%

Through-Delta survival by emigrating juvenile winter-run Chinook salmon under Alternative 3 (A3_LLT) l would be similar to NAA (Table 11-3-13).

Table 11-3-13. Through-Delta Survival (%) of Emigrating Juvenile Winter-Run Chinook Salmon under Alternative 3

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Month	EXISTING CONDITIONS	NAA	A3_LLT	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wetter Years	46.3	46.1	45.3	-1.0 (-2%)	-0.8 (-2%)
Drier Years	28.0	27.1	26.4	-1.6 (-6%)	-0.7 (-3%)
All Years	34.9	34.2	33.5	-1.4 (-4%)	-0.7 (-2%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and Above Normal WYs (6 years).
Drier = Below Normal, Dry and Critical WYs (10 years).

Adults

Adult salmonids migrating through the Delta use flow and olfactory cures for navigation to their natal streams (Marston et al. 2012). Attraction flow, as estimated by the percentage of Sacramento River water at Collinsville (DSM2 fingerprinting), would decrease less than 10% compared to NAA during the adult winter-run upstream migration from December-July (Table 11-3-14). The reductions in percentage are small in comparison with the magnitude of change in dilution (20%) reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect adult Chinook salmon migration. Therefore, it is expected that olfactory cues for adult winter-run Chinook salmon from the Sacramento River would be adequate and not substantially affected by flow operations under Alternative 3. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 for Alternative 1A.

Table 11-3-14. Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Adult Chinook Migration Period for Alternative 3

Month	EXISTING CONDITIONS	NAA	A3_LLT	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Sacramento River					
September	60	65	54	-6	-11
October	60	68	66	6	-2
November	60	66	63	3	-3
December	67	66	64	-3	-2
January	76	75	73	-3	-2
February	75	72	69	-6	-3
March	78	76	69	-9	-7
April	77	75	69	-8	-6
May	69	65	63	-6	-2
San Joaquin River					
September	0.3	0.1	0.8	0.5	0.7
October	0.2	0.3	0.9	0.7	0.6
November	0.4	1.0	1.8	1.4	0.8
December	0.9	1.0	1.1	0.2	0.1
January	1.6	1.7	2.2	0.6	0.5
February	1.4	1.5	2.4	1.0	0.9
March	2.6	2.8	4.5	1.9	1.7
April	6.3	6.6	7.3	1.0	0.7
	Shading indicates 10% or greater absolute difference.				

NEPA Effects: Overall, the results indicate that the effect of Alternative 3 is adverse because it has the potential to substantially decrease winter-run Chinook salmon migration habitat conditions in the Sacramento River.

Upstream of the Delta in the Sacramento River, flows would be up to 43% lower during the majority of the juvenile migration period. These reductions in flow may impact the condition and survival of juvenile winter-run Chinook salmon as they migrate downstream. There would be no differences between Alternative 3 and NAA in upstream flows during the adult migration period or in water temperatures during both juvenile and adult migration periods.

Adult attraction flows in the Delta under Alternative 3 would be lower than those under NAA, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 3 NDD on winter-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating winter-run Chinook salmon, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus the level of impacts associated with 2 new intakes would be considerably lower than those expected from having 5 new intakes in the river. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 8% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the 2 new intake structures will be implemented as part of the final NDD screen design effort. Alternative 3 also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for winter-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 3 predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 3 would be similar to those estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of, the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon.

Because upstream effects would be adverse, it is concluded that the overall effect of Alternative 3 on winter-run Chinook salmon migration conditions would be adverse.

This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this effect is adverse and unavoidable because there is no feasible mitigation available.

CEQA Conclusion: In general, Alternative 3 would not affect migration conditions for winter-run Chinook salmon relative to the Existing Conditions.

Upstream of the Delta

Flows in the Sacramento River upstream of Red Bluff were examined during the July through November juvenile emigration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT for juvenile migrants would generally be greater than or similar to flows under Existing Conditions during August and November, in which flows would be up to 24% lower depending on month and water year type.

Flows in the Sacramento River upstream of Red Bluff were examined during the December through August adult migration period. Flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions, except during August in which flows would be up to 24% lower under A3_LLT.

Water temperatures in the Sacramento River under Alternative3 would be the same as those under Alternative 1A, Impact AQUA-42, which indicates that there would be small increase in water temperatures under Alternative 3 during large portions of the juvenile and adult migration periods, compared to Existing Conditions.

Through-Delta

Through-Delta survival of juvenile winter-run Chinook salmon would be similar compared to Existing Conditions when averaged across all water years (<4% relative decrease) (Table 11-3-13. Predation of migrating juveniles would increase at the north Delta intakes, with loss hypothetically estimated of 0.7% to 8% of juveniles reaching the Delta. Attraction flows and olfactory cues for migrating adult winter-run Chinook salmon under Alternative 3, as indicated by the proportion of Sacramento River flows (54–73% of Delta water), would be similar (<10% difference) to Existing Conditions for (Table 11-3-14).

Summary of CEQA Conclusion

Due to the similarity in migration flows and water temperatures between Alternative 3 and the CEQA baseline for all months except November, upstream habitat and movement conditions are not substantially reduced for juvenile or adult winter-run Chinook salmon. Through-Delta survival of juvenile winter-run Chinook salmon would be similar compared to Existing Conditions. Further, based on the proportion of Sacramento River flows, olfactory cues would be similar (<10% difference) to Existing Conditions for adult winter-run Chinook salmon migrating through the Delta. Therefore, the overall impact of Alternative 3 on winter-run Chinook salmon would be less than significant, and no mitigation would be required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for winter-run Chinook salmon under Alternative 1A (Impact AQUA-43 through AQUA-45) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

NEPA Effects: All of these effects have been determined to result in no adverse effects on winter-run Chinook salmon for NEPA purposes. Specifically for AQUA-44, the effects of contaminants on winter-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on winter-run Chinook salmon are uncertain.

CEQA Conclusions: As described under Alternative 1A, the overall effect of these restoration measures would be considered less than significant for CEQA purposes for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related effects on fish are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the effects of other conservation measures on winter-run Chinook salmon as described under Alternative 1A (Impact AQUA-46 through AQUA-54) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (CM12)

Impact AQUA-47: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Winter-Run ESU) (CM13)

Impact AQUA-48: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Winter-Run ESU) (CM14)

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (CM15)

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (CM16)

Impact AQUA-51: Effects of Illegal Harvest Reduction on Chinook Salmon (Winter-Run ESU) (CM17)

Impact AQUA-52: Effects of Conservation Hatcheries on Chinook Salmon (Winter-Run ESU) (CM18)

Impact AQUA-53: Effects of Urban Stormwater Treatment on Chinook Salmon (Winter-Run ESU) (CM19)

Impact AQUA-54: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Winter-Run ESU) (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on winter-run Chinook salmon for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusions: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on winter-run Chinook salmon, for the reasons identified for Alternative 1A, and no mitigation is required.

Spring-Run Chinook Salmon

Construction and Maintenance of CM1

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

The potential effects of construction of water conveyance facilities on spring-run Chinook salmon under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-55) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-55, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for spring-run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-55, the impact of the construction of water conveyance facilities on spring-run Chinook salmon would be less than significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only two intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

The maintenance-related effects of Alternative 3 would be identical for all four Chinook salmon ESUs. Accordingly, for a discussion of the impacts, please refer to the discussion for winter-run Chinook salmon (Alternative 3, Impact AQUA-38).

Water Operations of CM1

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Alternative 3 would increase overall entrainment of juvenile spring-run Chinook salmon at the south Delta export facilities, estimated as salvage density, by 45% (Table 11-3-15) across all water years compared to NAA. Entrainment would be highest in above normal years and lowest in critical years. Under Alternative 3, entrainment would increase 143% in above normal water years and increase 107% in below normal water years compared to NAA. Pre-screen losses, typically attributed to predation, would be expected to increase commensurate with increased entrainment at the south Delta facilities.

The average proportion of the annual spring-run Chinook salmon population (assumed to be 750,000 juveniles approaching the Delta) lost at the south Delta facilities would increase about 2% under Alternative 3 compared to NAA.

Table 11-3-15. Juvenile Spring-Run Chinook Salmon Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Spring-Run Chinook Salmon		
Wet	16,688 (19%)	13,060 (14%)
Above Normal	37,640 (141%)	34,571 (116%)
Below Normal	6,782 (106%)	5,987 (84%)
Dry	9,577 (58%)	8,383 (48%)
Critical	-626 (-5%)	995 (10%)
All Years	19,379 (51%)	17,769 (45%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

As described for winter-run Chinook salmon under Alternative 1A (Impact AQUA-39), potential entrainment of juvenile salmonids at the north Delta intakes would be greater than baseline, but the effects would be minimal because the north Delta intakes would have state-of-the-art screens to exclude juvenile fish.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

As described for winter-run Chinook salmon under Alternative 1A (Impact AQUA-39), potential entrainment and impingement effects for juvenile salmonids would be minimal because intakes would have state-of-the-art screens installed.

NEPA Effects: In conclusion, due to increased entrainment (average 45% increase) of juvenile spring-run Chinook salmon at the south Delta facilities, the effect of Alternative 3 would be adverse.

CEQA Conclusion: Due to increased entrainment (average 51% increase) compared to Existing Conditions, the impact of Alternative 3 on spring-run Chinook entrainment would be significant.

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

In general, Alternative 3 would reduce spawning and egg incubation habitat for spring-run Chinook salmon relative to NAA.

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were examined during the spring-run Chinook salmon spawning and incubation period (September through January). Flows under A3_LLT would be generally greater than and similar to flows NAA in October, December, and January, except in critical water years during January (8% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Shasta Reservoir storage volume at the end of September influences flows downstream of the dam during the spring-run spawning and egg incubation period (September through January). Storage volume at the end of September would be 9% lower than under NAA in below normal water years, but would be similar to or greater than storage under NAA in other water year types depending on water year type (Table 11-3-16).

Table 11-3-16. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	-286 (-9%)	226 (8%)
Above Normal	-484 (-15%)	131 (5%)
Below Normal	-587 (-20%)	-233 (-9%)
Dry	-544 (-22%)	-33 (-2%)
Critical	-392 (-33%)	-10 (-1%)

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-58, which indicates that there would generally be no effects of Alternative 3 on water temperatures during the spring-run spawning and egg incubation period in the Sacramento River, compared to NAA.

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under A3_LLT would be lower than or similar to mortality under NAA in dry and critical years, but greater in wet (39% greater), above normal (20% greater), and below normal (33% greater) water years (Table 11-3-17).

Table 11-3-17. Difference and Percent Difference in Percent Mortality of Spring-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	24 (241%)	10 (39%)
Above Normal	29 (219%)	7 (20%)
Below Normal	43 (361%)	14 (33%)
Dry	55 (278%)	-2 (-3%)
Critical	22 (30%)	0 (0%)
All	35 (155%)	6 (12%)

SacEFT predicts that there would be a 69% increase in the percentage of years with good spawning availability, measured as weighted usable area, under A3_LLT relative to NAA (Table 11-3-18). SacEFT predicts that there would be no differences in the percentage of years with good (lower) redd scour risk under A3_LLT relative to NAA. SacEFT predicts that there would be a 41% decrease in the percentage of years with good (lower) egg incubation conditions under A3_LLT relative to NAA. SacEFT predicts that there would be an 18% increase in the percentage of years with good (lower) redd dewatering risk under A3_LLT relative to NAA. These results indicate that all spawning and egg habitat metrics except egg incubation conditions would improve or not change under Alternative 3 relative to NAA.

Table 11-3-18. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Spring-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Spawning WUA	13 (19%)	34 (69%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-66 (-77%)	-14 (-41%)
Redd Dewatering Risk	-9 (-18%)	6 (18%)
Juvenile Rearing WUA	-2 (-9%)	-2 (-9%)
Juvenile Stranding Risk	-5 (-26%)	0 (0%)

WUA = Weighted Usable Area.

Clear Creek

Flows in Clear Creek were examined during the spring-run Chinook salmon spawning and egg incubation period (September through January). Flows under A3_LLT would be similar to or greater than flows under NAA except in critical years during September (13% decrease) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest reduction in flows under A3_LLT would be the same or of a lower magnitude as that under NAA in all water year types (Table 11-3-19).

Water temperatures were not modeled in Clear Creek.

Table 11-3-19. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	0 (NA)	0 (NA)
Above Normal	-27 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-67 (NA)	0 (0%)
Critical	-33 (-50%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) where spring-run primarily spawn during September through January (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would not differ from NAA because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006).

Oroville Reservoir storage volume at the end of September influence flows downstream of the dam during the spring-run spawning and egg incubation period. Storage under A3_LLT would be 17% to 32% greater than storage under NAA depending on water year type (Table 11-3-20).

Table 11-3-20. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	-477 (-16%)	537 (28%)
Above Normal	-482 (-20%)	309 (20%)
Below Normal	-372 (-18%)	237 (17%)
Dry	-30 (-2%)	323 (32%)
Critical	-40 (-4%)	148 (19%)

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the egg incubation period compared to the flow in September when spawning is assumed to occur. Minimum flows in the low-flow channel during October through January were identical among A3_LLT and NAA (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Therefore, there would be no effect of Alternative 3 on redd dewatering in the Feather River low-flow channel.

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-58, which indicates that there would be no effect of Alternative 3 on water temperatures in the Feather River relative to NAA during the spring-run spawning and egg incubation period, compared to NAA.

NEPA Effects: Collectively, these results indicate that the effect is adverse because it has the potential to substantially reduce the quantity and quality of spawning and egg incubation habitat. Although comparisons of mean flows and water temperatures in the Sacramento River indicate that there would not be differences between NAA and Alternative 3, the Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under Alternative 3 would be higher than mortality under NAA by up to 14% (absolute scale) depending on water year type and by 6% (absolute scale) with all water years combined (Table 11-3-17). Further, SacEFT predicts that the number of years with good egg incubation conditions would decline under Alternative 3 by 41% (14% on an absolute scale) (Table 11-3-18). There would be no biologically meaningful effects on spring-run Chinook salmon in Clear Creek or the Feather River.

This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. Even so, proposed mitigation (Mitigation Measure AQUA-58a through AQUA-58c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 3 would reduce spawning and egg incubation habitat conditions for spring-run Chinook salmon relative to the Existing Conditions.

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were examined during the spring-run Chinook salmon spawning and incubation period (September through January). Flows under A3_LLT would be similar to or greater than flows under Existing Conditions during October, December, and January (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would be mostly lower by up to 23% than those under Existing Conditions during September and November depending on water year type.

Shasta Reservoir Storage volume at the end of September under A3_LLT would be 9% to 33% lower relative to Existing Conditions depending on water year type (Table 11-3-16).

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-58, which indicates that there would be substantial increases in the exceedances of NMFS temperature thresholds under Alternative 3 relative to Existing Conditions.

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under A3_LLT would be 30% to 361% greater than mortality under Existing Conditions depending on water year type (Table 11-3-17).

SacEFT predicts that there would be a 19% increase in the percentage of years with good spawning availability, measured as weighted usable area, under A3_LLT relative to Existing Conditions (Table 11-3-18). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under A3_LLT relative to Existing Conditions. SacEFT predicts that there would be a 77% decrease in the percentage of years with good (lower) egg incubation conditions under A3_LLT relative to Existing Conditions, respectively. SacEFT predicts that there would be an 18% decrease in the percentage of years with good (lower) redd dewatering risk under A3_LLT relative to Existing Conditions. These results indicate that spawning and egg habitat conditions for spring-run Chinook salmon would be better for some metrics and worse for other metrics under Alternative 3 relative to the Existing Conditions.

Clear Creek

Water temperatures were not modeled in Clear Creek.

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under A3_LLT would generally be similar to or greater than flows under Existing Conditions except in critical years during September (37% reduction) (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*).

The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest reduction in flows under A3_LLT would be similar to or lower magnitude than that under Existing Conditions in wet and below normal water years (Table 11-3-19). The greatest reduction in flows under A3_LLT would be 27–67% lower (more negative) than Existing Conditions in above normal, dry, and critical water years.

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-58, which indicates that there would be increases in the exceedances of NMFS temperature thresholds under Alternative 3 relative to Existing Conditions.

Flows in the Feather River low-flow channel under A3_LLT are not different from Existing Conditions during the spring-run spawning and egg incubation period (September through January) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows in October through January (800 cfs) would be equal to or greater than the spawning flows in September (773 cfs) for all model scenarios.

Oroville Reservoir storage volume at the end of September under A3_LLT would be similar to storage under Existing Conditions in dry and critical years but 16–20% lower in wet, above normal, and below normal years depending on water year type (Table 11-3-20).

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. Minimum flows in the low-flow channel during October through January were identical between A3_LLT and Existing Conditions (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Therefore, Alternative 3 would have no impact on redd dewatering in the Feather River low-flow channel.

Summary of CEQA Conclusion

Collectively, these results indicate that the effect is significant because it has the potential to substantially reduce the quantity and quality of spawning and egg incubation habitat. The Reclamation egg mortality model predicts that egg mortality would increase in the Sacramento River by up to 22% to 55% (absolute scale) depending on water year type (Table 11-3-17). SacEFT predicts that the number of years with good egg incubation conditions would decline under Alternative 3 by 77% (66% on an absolute scale) (Table 11-3-18). There would be no biologically meaningful effects in Clear Creek or the Feather River.

This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-58a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat.

Although analysis conducted as part of the EIR/EIS determined that Alternative 3 would have significant and unavoidable adverse effects on spawning habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on rearing habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 3.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 3 operations only. Development of mitigation actions for the incremental impact on spawning habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 3.

Mitigation Measure AQUA-58b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Spawning Habitat Following Initial Operations of CM1.

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to spawning habitat under Alternative 3. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-58c: Consult With NMFS, USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Spawning Habitat Consistent With CM1

In order to determine the feasibility of reducing the effects of CM1 operations on spring-run Chinook salmon habitat, the BDCP proponents will consult with NMFS, USFWS, and CDFW to identify and implement any feasible operational means to minimize effects on spawning habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-58a Alternative 3.

If feasible means are identified to reduce impacts on spawning habitat consistent with the overall operational framework of Alternative 3 without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on steelhead habitat is not feasible under Alternative 3 operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on spring-run Chinook salmon would remain significant and unavoidable.

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

In general, Alternative 3 would not affect the quantity and quality of rearing habitat for fry and juvenile spring-run Chinook salmon relative to NAA.

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows during November are lower than under NAA in both locations and generally similar to those under NAA in all other months.

As reported in Impact AQUA-40, May Shasta storage volume under A3_LLT would similar to or greater than storage under NAA for all water year types except below normal (8% lower) and dry (6% lower) (Table 11-3-9).

As reported in Impact AQUA-58, September Shasta storage volume under A3_LLT would be 9% lower than under NAA in below normal water years, but would be similar to or greater than storage under NAA in other water year types depending on water year type (Table 11-3-16).

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-59, which indicates that there would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 3 in any month or water year type throughout the period.

SacEFT predicts that the percentage of years with good juvenile rearing WUA conditions under A3_LLT would be 9% lower (2% on an absolute scale) than that under NAA (Table 11-3-18). The percentage of years with good (lower) juvenile stranding risk conditions under A3_LLT would not be different than the percentage of years under NAA. These results indicate that there would be no effect on juvenile rearing habitat.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality would be similar (<5% difference) between A3_LLT and NAA.

Clear Creek

Flows in Clear Creek during the November through March rearing period under A3_LLT would generally be similar to or greater than flows under NAA, except in below normal water years during March (6% lower) and critical years in February (6% lower) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during November through June were reviewed to determine flow-related effects on larval and juvenile spring-run Chinook salmon rearing period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Relatively constant flows in the low-flow channel throughout this period under A3_LLT would not differ from those under NAA. In the high-flow channel, flows under A3_LLT would be generally be similar to or greater than flows under NAA except in above normal water years during November (8% lower) and in critical years during January (20% lower).

May Oroville storage under A3_LLT would be similar to (<5% difference) storage under NAA in all water year types (Table 11-3-21).

As reported in Impact AQUA-58, September Oroville storage volume would be 17% to 32% greater than storage under NAA depending on water year type (Table 11-3-20).

Table 11-3-21. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	-83 (-2%)	-37 (-1%)
Above Normal	-217 (-6%)	-61 (-2%)
Below Normal	-343 (-11%)	10 (0%)
Dry	-444 (-16%)	76 (3%)
Critical	-255 (-14%)	61 (4%)

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A Impact AQUA-59, which indicates that mean monthly water temperatures would generally be similar between NAA and Alternative 3 during the period.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because habitat would not be substantially reduced. There would be no effect of Alternative 3 compared to NAA on flows in the Sacramento and Feather Rivers or in Clear Creek. Further, there would be no effects of Alternative 3 compared to NAA on water temperatures in the Sacramento or Feather Rivers.

CEQA Conclusion: In general, Alternative 3 would not affect the quantity and quality of rearing habitat for fry and juvenile spring-run Chinook salmon relative to Existing Conditions.

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would be generally similar to or greater than those under Existing Conditions with some exceptions, although flows during November would be lower (up to 27% lower depending on month, water year type, and location) than those under Existing Conditions.

As reported in Impact AQUA-40, Shasta Reservoir storage volume at the end of May under A3_LLT would be similar to Existing Conditions in wet and above normal water years, but lower by 13% to 24% in below normal, dry, and critical water years (Table 11-3-9). As reported in Impact AQUA-59, storage volume at the end of September under A3_LLT would be 9% to 33% lower relative to Existing Conditions depending on water year type (Table 11-3-16).

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-59, which indicates that there would be no differences in mean monthly water temperature between Existing Conditions and Alternative 3.

SacEFT predicts that the percentage of years with good juvenile rearing WUA conditions under A3_LLT would be 9% lower (2% on an absolute scale) than that under Existing Conditions, which would be negligible (Table 11-3-18). The percentage of years with good (lower) juvenile stranding risk conditions under A3_LLT would be 26% lower (5% reduction on an absolute scale) than under Existing Conditions, which would be a small effect.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality under A3_LLT would be 7% greater than under Existing Conditions.

Clear Creek

Flows in Clear Creek during the November through March rearing period under A3_LLT would generally be similar to or greater than flows under Existing Conditions (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during November through June were reviewed to determine flow-related effects on larval and juvenile spring-run rearing period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Relatively constant flows in the low flow channel throughout this period under A3_LLT would not differ from those under Existing Conditions. In the high flow channel, flows under A3_LLT would generally be greater than or similar to flows under Existing Conditions with some exceptions, during which flows would be up to 36% lower under A3_LLT.

May Oroville storage volume under A3_LLT would be 6% to 16% lower than storage under Existing Conditions in all but wet years, in which storage would be similar to Existing Conditions (Table 11-3-21).

As reported in Impact AQUA-58, Oroville Reservoir storage volume at the end of September under A3_LLT would be similar to storage under Existing Conditions in dry and critical years but 16% to 20% lower in wet, above normal, and below normal years depending on water year type (Table 11-3-20).

Collectively, these results indicate that the impact would be less than significant and no mitigation would be necessary because habitat would not be substantially reduced. Although rearing habitat conditions in the Sacramento River would be slightly reduced by Alternative 3as predicted by SacEFT and SALMOD, there would be no other effects of Alternative 3 in any waterway.

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

Upstream of the Delta

In general, the effects of Alternative 3 on spring-run Chinook salmon migration conditions relative to the NAA are uncertain.

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were evaluated during the December through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than flows under NAA, except in critical years during January (8% lower).

Flows in the Sacramento River upstream of Red Bluff were evaluated during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during April through July under A3_LLT would generally be similar to or greater than NAA except in dry water years during July (14% lower). Flows during August under A3_LLT would generally be lower than NAA by up to 18%.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A Impact AQUA-60, which indicates that there would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 3.

Clear Creek

Flows in Clear Creek during the November through May juvenile Chinook salmon spring-run migration period under A3_LLT would generally be similar to or greater than flows under NAA except in critical water years during February and below normal water years during March (6% lower in both) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek during the April through August adult spring-run Chinook salmon upstream migration period under A3_LLT would be similar to or greater than flows under NAA in all months and water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be greater than or similar to flows under NAA, except in above normal water years during November (6% lower) and in critical water years during January (8% lower).

Flows in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT during April through June would generally be similar to or greater than flows under NAA, except in critical years during June (8% lower). Flows under A3_LLT during July and August would be lower than flows under NAA by up to 48% regardless of water year type.

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A Impact AQUA-60, which indicates that there would be no differences in mean monthly water temperature between NAA and Alternative 3.

Through-Delta

The effects on through-Delta migration were evaluated using the approach described in Alternative 1A, Impact AQUA-42.

Juveniles

Juvenile salmonids migrating down the Sacramento River would generally experience lower flows below the north Delta intakes compared to baseline conditions. The two intake structures of Alternative 3 would replace aquatic habitat and likely attract piscivorous fish around the intake structures, as described above in Impact AQUA-42. Potential predation losses, as estimated by the bioenergetics model, would be 0.6% of the annual juvenile production estimated for the Sacramento Valley (Impact AQUA-42, Table 11-3-12). A conservative assumption of 5% loss per intake would yield a cumulative loss of 8.3% of juvenile spring-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate.

Through-Delta survival to Chipps Island (DPM) by emigrating juvenile spring-run Chinook salmon under Alternative 3 would average 29.5% across all years, 24.1% in drier years, and 38.3% in wetter years (Table 11-3-22). Compared to NAA, juvenile survival would be similar or slightly lower under Alternative 3 (up to 2.1% lower in wetter years, a 5% relative decrease).

Table 11-3-22. Through-Delta Survival (%) of Emigrating Juvenile Spring-Run Chinook Salmon under Alternative 3

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Month	EXISTING CONDITIONS	NAA	A3_LLT	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wetter Years	42.1	40.4	38.3	-3.8 (-9%)	-2.1 (-5%)
Drier Years	24.8	24.3	24.1	-0.6 (-2%)	-0.2 (-1%)
All Years	31.3	30.3	29.5	-1.8 (-6%)	-0.9 (-3%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and Above Normal WYs (6 years).
Drier = Below Normal, Dry and Critical WYs (10 years).

Adults

During the overall spring-run upstream migration from March-June, the proportion of Sacramento River in the Delta would be similar to NAA throughout the adult migration period (Table 11-3-14). Olfactory cues for spring-run Chinook salmon adults would be strong, as the proportion of Sacramento River under Alternative 3 would represent 61–69% of Delta outflows. This topic is discussed further in Impact AQUA-42 for Alternative 1A.

NEPA Effects: Upstream of the Delta, these results indicate that the effect would not be adverse because it does not have the potential to substantially interfere with the movement of fish. There would be decreases in flows during 2 of 5 months of the adult upstream migration period in the Feather River. However, there would be no other effects of Alternative 3 in the Feather River and no effects on flows or temperatures in the Sacramento River and in Clear Creek.

Near-field effects of Alternative 3 NDD on spring-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating spring-run Chinook salmon, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus the level of impacts associated with 2 new intakes would be considerably lower than those expected from having 5 new intakes in the river. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 8% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the 2 new intake structures will be implemented as part of the final NDD screen design effort. Alternative 3 also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for spring-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 3 predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 3 would be similar to those estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of, the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon. However, until these efforts are completed and their results are fully analyzed, the overall cumulative effect of Alternative 3 on spring-run Chinook salmon migration remains uncertain.

CEQA Conclusion: In general, under Alternative 3 water operations, the quantity and quality of migration habitat for spring-run Chinook salmon would not be affected relative to the CEQA baseline.

Upstream of the Delta

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were evaluated during the December through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions except in wet water years during May (14% lower).

Flows in the Sacramento River upstream of Red Bluff were evaluated during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during April through July under A3_LLT would generally be similar to or greater than Existing Conditions, except in wet years during May (14% lower) and in dry and critical water years during July (6% and 10% lower, respectively). Flows under A3_LLT during August are mostly lower than Existing Conditions by up to 24%.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-60, which indicates that there would be negligible differences in mean monthly water temperature between NAA and Alternative 1A.

Clear Creek

Flows in Clear Creek during the November through May juvenile Chinook salmon spring-run migration period under A3_LLT would be similar to or greater than flows under Existing Conditions in all water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek during the April through August adult spring-run Chinook salmon upstream migration period under A3_LLT would generally be similar to or greater than flows under Existing Conditions with exceptions during August of critical water years (17% reduction) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows were examined for the Feather River at the confluence with the Sacramento River during the November through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions, except in wet years during November and May (12% and 24% lower, respectively) and in below normal water years during November, January, and March (11%, 10%, and 12% lower, respectively).

Flows were examined for the Feather River at the confluence with the Sacramento River during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during April and May under A3_LLT would generally be similar to or greater than flows under Existing Conditions except in wet years during May (24% lower). Flows during June through August would generally be lower than flows under Existing Conditions by up to 54%.

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-60, which indicates that there would be negligible differences in mean monthly water temperature between Existing Conditions and Alternative 1A.

Through-Delta

Please see the *CEQA Conclusion* above for winter-run Chinook salmon (Alternative 3, Impact AQUA-42). As described above for adult Chinook salmon winter-run upstream migration, the impact on emigrating spring-run Chinook salmon juveniles through the Delta under Alternative 3 would be less than significant.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-60 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce migration habitat and substantially interfere with the movement of fish, contrary to the NEPA conclusion set forth above. There would generally be no effects of Alternative 3 on flows in the Sacramento River and Clear Creek and temperatures in the Sacramento and Feather rivers. However, flows in the Feather River would be up to 54% lower during 3 of the 5 months of the adult migration period. There would also be no substantial effects of Alternative 3 on through-Delta migration conditions for winter-run Chinook salmon.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration habitat for winter-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for spring-run Chinook salmon under Alternative 1A (Impact AQUA-61 through AQUA-63) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

NEPA Effects: All of these effects have been determined to result in no adverse effects on spring-run Chinook salmon for NEPA purposes, for the reasons identified for Alternative 1A. Specifically for AQUA-62, the effects of contaminants on spring-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on spring-run Chinook salmon are uncertain.

CEQA Conclusions**:** Overall the effects would be considered less than significant for CEQA purposes for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for spring-run Chinook salmon under Alternative 1A (Impact AQUA-64 through AQUA-72) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (CM12)

Impact AQUA-65: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Spring-Run ESU) (CM13)

Impact AQUA-66: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Spring-Run ESU) (CM14)

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (CM15)

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (CM16)

Impact AQUA-69: Effects of Illegal Harvest Reduction on Chinook Salmon (Spring-Run ESU) (CM17)

Impact AQUA-70: Effects of Conservation Hatcheries on Chinook Salmon (Spring-Run ESU) (CM18)

Impact AQUA-71: Effects of Urban Stormwater Treatment on Chinook Salmon (Spring-Run ESU) (CM19)

Impact AQUA-72: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Spring-Run ESU) (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on spring-run Chinook salmon for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusions: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on spring-run Chinook salmon, for the reasons identified for Alternative 1A, and no mitigation is required.

Fall-/Late Fall–Run Chinook Salmon

Construction and Maintenance of CM1

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

The potential effects of construction of water conveyance facilities on fall-run/late fall run Chinook salmon under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-73) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-73, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for fall-run/late fall run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-73, the impact of construction of the water conveyance facilities on fall-run/late fall-run Chinook salmon would be less than significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only two intakes would be constructed under Alternative 3 rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

The maintenance-related effects of Alternative 3 would be identical for all four Chinook salmon ESUs. Accordingly, for a discussion of the impacts, please refer to the discussion for winter-run Chinook (Alternative 3, Impact AQUA-38).

Water Operations of CM1

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Fall-Run Chinook Salmon

Water Exports from SWP/CVP South Delta Facilities

Entrainment at Delta export facilities would increase 19% (11,000 more fish entrained) across all water year types compared to NAA (Table 11-3-23). When compared to NAA entrainment would be highest in above normal water years, increasing by 52–58%, and lowest in critical water year types, decreasing by 11–18% (Table 11-3-23). Pre-screen losses, typically attributed to predation, would be expected to change commensurate with entrainment at the south Delta facilities.

Under the assumption that the annual number of juvenile fall-run Chinook salmon juveniles approaching the Delta was 23 million fish, the percentage of the population lost to entrainment across all years averaged 0.24% under baseline scenarios and increased slightly (0.05%) under Alternative 3.

Water Exports from SWP/CVP North Delta Intake Facilities

As described for winter-run Chinook salmon under Alternative 1A (Impact AQUA-39), potential entrainment of juvenile salmonids at the north Delta intakes would be greater than baseline, but the effects would be minimal because the north Delta intakes would have state-of-the-art screens to exclude juvenile fish.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

As described for winter-run Chinook salmon under Alternative 1A (Impact AQUA-39), potential entrainment and impingement effects for juvenile salmonids would be minimal because intakes would have state-of-the-art screens installed.

Late Fall–Run Chinook Salmon

Water Exports from SWP/CVP South Delta Facilities

Alternative 3 would reduce the overall entrainment of juvenile late fall–run Chinook salmon at the south Delta export facilities by 14% (~260 fish) across all water year types compared to NAA (Table 11-3-23). Entrainment for late fall–run Chinook salmon would be greatest in wet years and one to two orders of magnitude less in other water year types (Table 11-3-23). Under Alternative 3, entrainment of juvenile late fall–run Chinook salmon in wet years would decrease 20% compared to NAA. The greatest relative reductions for late fall–run Chinook salmon would occur in critical water years (decreased by 22%). Pre-screen loss at the south Delta facilities, which is typically attributed to predation, would decrease commensurate with reductions in entrainment.

The proportion of the annual late fall–run Chinook population (assumed to be 1 million juveniles approaching the Delta) lost at the south Delta facilities would be very low and similar under baseline (0.2%) and Alternative 3 (0.2%).

Table 11-3-23. Juvenile Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Fall-Run Chinook Salmon		
Wet	-4,379 (-3%)	-4,556 (-4%)
Above Normal	17,981 (55%)	17,507 (52%)
Below Normal	4,718 (35%)	4,359 (31%)
Dry	8,768 (45%)	7,120 (33%)
Critical	-9,249 (-23%)	-4,071 (-11%)
All Years	10,718 (20%)	10,662 (19%)
Late Fall–Run Chinook Salmon		
Wet	-1,244 (-21%)	-1,157 (-20%)
Above Normal	-89 (-15%)	-75 (-13%)
Below Normal	-3 (-6%)	0.4 (1%)
Dry	-8 (-6%)	8 (6%)
Critical	-46 (-28%)	-34 (-22%)
All Years	-342 (-18%)	-261 (-14%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

As described for winter-run Chinook salmon under Alternative 1A (Impact AQUA-39), potential entrainment of juvenile salmonids at the north Delta intakes would be greater than baseline, but the effects would be minimal because the north Delta intakes would have state-of-the-art screens to exclude juvenile fish.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

As described for winter-run Chinook salmon under Alternative 1A (Impact AQUA-39), potential entrainment and impingement effects for juvenile salmonids would be minimal because intakes would have state-of-the-art screens installed.

NEPA Effects: Under Alternative 3 the entrainment losses at the south Delta facilities would increase for fall-run Chinook salmon and decrease for late fall–run Chinook salmon compared to baseline conditions. This effect would be adverse for fall-run.

CEQA Conclusion: Entrainment losses of juvenile fall-run Chinook salmon at the south Delta export facilities would increase by approximately 20% across all water year types under Alternative 3 compared to Existing Conditions (Table 11-3-23). However, entrainment of juvenile late fall–run Chinook salmon is expected to decrease by approximately 18% across all water year types under Alternative 3 compared to Existing Conditions (Table 11-3-23). Relative impacts at the north Delta intakes and the North Bay Aqueduct would be the same as under Alternative 1A. Overall, impacts would be significant for fall-run Chinook salmon and may be beneficial for late fall–run.

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 3 would have negligible effects on the quantity and quality of spawning and egg incubation habitat for fall-/late fall–run Chinook salmon relative to NAA.

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would generally be greater than or similar to NAA during October, December, and January, except for critical water years during January (8% lower). Flows during November would be lower by up to 29% in all water years.

Shasta Reservoir storage at the end of September would affect flows during the fall-run spawning and egg incubation period. Storage under A3_LLT would be 9% lower than under NAA in below normal water years, but would be similar to or greater than storage under NAA in other water year types depending on water year type (Table 11-3-16).

Water temperatures in the Sacramento River for Alternative 3 are not different from those for Alternative 1A, Impact AQUA-76, which indicates there would be no differences in mean monthly water temperature between NAA and Alternative 1A.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under A3_LLT would lower than or similar to mortality under NAA in all water year types except below normal years (21% greater, and absolute increase of 5% of fall-run population) (Table 11-3-24). These results indicate that climate change would increase fall-run Chinook salmon egg mortality, but Alternative 3 would have small to negligible effects.

Table 11-3-24. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	10 (103%)	0 (2%)
Above Normal	12 (110%)	1 (4%)
Below Normal	16 (148%)	5 (21%)
Dry	17 (120%)	1 (2%)
Critical	9 (30%)	-1 (-2%)
All	13 (91%)	1 (4%)

SacEFT predicts that there would be a 14% increase (5% absolute scale) in the percentage of years with good spawning availability for fall-run Chinook salmon, measured as weighted usable area, under A3_LLT relative to NAA (Table 11-3-25). SacEFT predicts that there would be a 12% reduction (8% absolute scale) in the percentage of years with good (lower) redd scour risk under A3_LLT, relative to NAA. SacEFT predicts that there would be no effect of A3_LLT relative to NAA. SacEFT predicts that there would be a 7% increase (2% absolute scale) in the percentage of years with good (lower) redd dewatering risk under A3_LLT relative to NAA, which is negligible. These results indicate that there would be a small increase in years in which spawning WUA would be considered "good" and small decrease in year in which redd scour risk would be considered "good".

Table 11-3-25. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Fall-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Spawning WUA	-8 (-17%)	5 (14%)
Redd Scour Risk	-3 (-5%)	-8 (-12%)
Egg Incubation	-25 (-27%)	0 (0%)
Redd Dewatering Risk	2 (7%)	2 (7%)
Juvenile Rearing WUA	2 (6%)	-5 (-13%)
Juvenile Stranding Risk	-3 (-10%)	8 (40%)
WUA = Weighted Usable Area.		

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis. Flows under A3_LLT would be greater than or similar to flows under NAA throughout the period.

Shasta Reservoir storage at the end of September would affect flows during the late fall–run spawning and egg incubation period. As reported in Impact AQUA-58, end of September Shasta Reservoir storage would be 9% lower than under NAA in below normal water years, but would be similar to or greater than storage under NAA in other water year types depending on water year type (Table 11-3-16).

The Reclamation egg mortality model predicts that late fall–run Chinook salmon egg mortality in the Sacramento River under A3_LLT would be similar to mortality under NAA in all water years, including below normal water years in which, although there would be an 17% relative increase, the absolute increase would be 1% of the late fall–run population (Table 11-3-26).

Table 11-3-26. Difference and Percent Difference in Percent Mortality of Late fall–Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	3 (167%)	-1 (-13%)
Above Normal	4 (155%)	-1 (-11%)
Below Normal	5 (336%)	1 (17%)
Dry	4 (160%)	-1 (-8%)
Critical	2 (127%)	0 (-7%)
All	4 (178%)	0 (-6%)

SacEFT predicts that there would be a 6% decrease (3% absolute scale) in the percentage of years with good spawning availability for late fall–run Chinook salmon, measured as weighted usable area, under A3_LLT relative to NAA (Table 11-3-27). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under A3_LLT, relative to NAA. SacEFT predicts that there would be a negligible (<5%) difference in the percentage of years with good (lower) egg incubation conditions between A3_LLT and NAA. SacEFT predicts that there would be a 5% decrease (3% absolute scale) in the percentage of years with good (low) redd dewatering risk under A3_LLT, relative to NAA. These results indicate that there would be negligible effects of Alternative 3 on spawning and egg incubation conditions for late fall-run Chinook salmon in the Sacramento River

Table 11-3-27. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Late Fall–Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Spawning WUA	-7 (-13%)	-3 (-6%)
Redd Scour Risk	-6 (-7%)	0 (0%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	-8 (-13%)	-3 (-5%)
Juvenile Rearing WUA	-10 (-22%)	-28 (-44%)
Juvenile Stranding Risk	-27 (-38%)	-1 (-2%)

WUA = Weighted Usable Area.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Clear Creek flows below Whiskeytown Reservoir were examined for the September through February fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would be similar to or greater than flows under NAA throughout the period.

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest monthly reduction in Clear Creek flows during September through February under A3_LLT would be the same as the reduction under NAA in all water years (Table 11-3-28).

Table 11-3-28. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through February Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	0 (NA)	0 (NA)
Above Normal	-27 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-67 (NA)	0 (0%)
Critical	-33 (-50%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-76, which indicates that temperatures conditions under Alternative 1A would be similar to or better than those under NAA.

Fall-Run

Flows in the Feather River in the low flow and high flow channels were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows in the low-flow channel under A3_LLT would be identical to those under NAA. Flows in the high-flow channel under A3_LLT would generally be similar to or greater than those under NAA except in above normal water years during November (8% lower) and critical years during January (20% lower). These results indicate that Alternative 3 would generally improve flow conditions for fall-run spawning and egg incubation conditions in the Feather River high flow channel.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel during November through January were identical between A3_LLT and NAA (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Therefore, there would be no effect of Alternative 3 on redd dewatering in the Feather River low-flow channel.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under A3_LLT would be similar to or lower than mortality under NAA in all water years, indicating a small beneficial effect of Alternative 3 on temperature conditions for incubating eggs in the Feather River (Table 11-3-29).

Table 11-3-29. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Feather River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	5 (390%)	-14 (-67%)
Above Normal	5 (463%)	-7 (-53%)
Below Normal	12 (683%)	-1 (-6%)
Dry	15 (690%)	-4 (-17%)
Critical	21 (437%)	-2 (-7%)
All	11 (523%)	-7 (-33%)

American River

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, which indicates that there would be no differences in mean monthly water temperature between NAA and Alternative 1A.

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would generally be similar to or greater than flows under NAA, except for above normal water years during November (16% lower). These results indicate that these differences are primarily due to climate change and not Alternative 3.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. The greatest reduction under A3_LLT would be 18% to 53% greater than that under NAA depending on water year type (Table 11-3-30).

Table 11-3-30. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in the American River at Nimbus Dam during the October through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	-41 (-189%)	-16 (-35%)
Above Normal	-17 (-57%)	-7 (-18%)
Below Normal	-42 (-219%)	-15 (-32%)
Dry	-6 (-12%)	-8 (-18%)
Critical	-9 (-18%)	-21 (-53%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in October, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under A3_LLT would be similar to mortality under NAA in all water years (Table 11-3-31).

Table 11-3-31. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the American River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	25 (165%)	1 (3%)
Above Normal	22 (209%)	-1 (-2%)
Below Normal	20 (165%)	-2 (-5%)
Dry	16 (101%)	0 (0%)
Critical	9 (45%)	0 (-1%)
All	20 (129%)	0 (0%)

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to flows under NAA throughout the period.

Water temperatures in the Stanislaus River under Alternative 3 would be the same as those under Alternative 1A, which indicates that there would be no differences (<5%) in mean monthly water temperature between NAA and Alternative 1A.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, it is concluded that the effect is not adverse because habitat conditions are not substantially reduced. There are no reductions in flows under Alternative 3 or increases in temperatures in the rivers evaluated that would translate into biologically meaningful effects on fall-/late fall-run Chinook salmon.

CEQA Conclusion: In general, under Alternative 3 water operations, spawning and egg incubation habitat for fall-/late fall-run Chinook salmon would not be affected relative to the CEQA baseline.

Sacramento River

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-76, which indicates that there would be moderate to large increases in water temperatures under of Alternative 1A relative to Existing Conditions in the Sacramento River.

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would be greater than or similar to Existing Conditions in all water year types during October, December, and January (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). However, flows in November under A3_LLT would be lower in all water year types by 5% to 21%.

As indicated in Impact AQUA-58, Shasta Reservoir Storage volume at the end of September under A3_LLT would be 9% to 33% lower relative to Existing Conditions depending on water year type (Table 11-3-16).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under A3_LLT would be 30% to 148% greater than mortality under Existing Conditions (Table 11-3-24).

SacEFT predicts that there would be an 8% increase in the percentage of years with good spawning availability, measured as weighted usable area, under A3_LLT relative to Existing Conditions (Table 11-3-25). SacEFT predicts that there would be a 5% reduction in the percentage of years with good (lower) redd scour risk under A3_LLT relative to Existing Conditions. SacEFT predicts that there would be a 27% reduction in the percentage of years with good (lower) egg incubation conditions under A3_LLT relative to Existing Conditions. SacEFT predicts that there would be a 7% increase in the percentage of years with good (lower) redd dewatering risk under A3_LLT relative to Existing Conditions.

Late Fall–Run

Flows in the Sacramento River upstream of Red Bluff were examined during the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would generally be greater than or similar to flows under Existing Conditions, except in wet years during May (14% lower).

Shasta Reservoir Storage volume at the end of September under A3_LLT would be 9% to 33% lower relative to Existing Conditions depending on water year type (Table 11-3-16).

The Reclamation egg mortality model predicts that late fall–run Chinook salmon egg mortality in the Sacramento River under A3_LLT would be 127% to 336% greater than mortality under Existing Conditions (Table 11-3-26). However, absolute differences in the percent of the late-fall population subject to mortality would be minimal in all but below normal years, in which there is a 5% increase.

SacEFT predicts that there would be a 13% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A3_LLT relative to Existing Conditions (Table

11-3-23). SacEFT predicts that there would be a 7% decrease in the percentage of years with good (lower) redd scour risk under A3_LLT relative to Existing Conditions. SacEFT predicts that there would be no difference in the percentage of years with good (lower) egg incubation conditions between A3_LLT and Existing Conditions. SacEFT predicts that there would be a 13% decrease in the percentage of years with good (lower) redd dewatering risk under A3_LLT relative to Existing Conditions.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run flows in Clear Creek below Whiskeytown Reservoir were reviewed during the September through February fall-run spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would always be similar to or greater than flows under Existing Conditions throughout the period.

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning occurred. The greatest monthly reduction in Clear Creek flows during October through February under A3_LLT would be similar to or lower magnitude than those under Existing Conditions in wet and below normal water years, but the reduction would be 27%, 67%, and 33% greater (absolute, not relative, differences) under A3_LLT in above normal, dry, and critical water years, respectively (Table 11-3-28).

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, which indicates that there would be moderate to large effects of Alternative 1A on temperatures.

Fall-Run flows in the Feather River in the low flow and high flow channels were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows in the low-flow channel A3_LLT would be identical to those under Existing Conditions. Flows in the high-flow channel during October through December under A3_LLT would be similar to or greater than flows under Existing Conditions, except in wet years during November and December (16% lower in both years) and in below normal years during October and November (7% and 13% lower, respectively). During January, flows would generally be lower by up to 36% than flows under Existing Conditions, although there would be increase flows in wet and dry years of 27% and 34%, respectively, which would outweigh reductions in other years.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel would be identical between A3_LLT and Existing Conditions (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Therefore, there would be no effect of Alternative 3 on redd dewatering in the Feather River low-flow channel.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under A3_LLT would be 390% to 690% greater than mortality under Existing

Conditions, which would be a 5% to 21% increase in egg mortality on an absolute scale (Table 11-3-29).

American River

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-76, which indicates that there would be moderate to large effects of Alternative 1A on temperatures.

Fall-Run Flows in the American River at the confluence with the Sacramento River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows during November and December in the American River at the confluence with the Sacramento River under A3_LLT would generally be lower by up to 37% than flows under NAA during November through January (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows during January would generally be similar to or greater than flows under Existing Conditions, except in dry and critical water years (12% and 17% lower, respectively).

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. The greatest monthly reduction in American River flows under A3_LLT during November through January would be of greater magnitude than that under Existing Conditions in all water year types by 12% to 219% (Table 11-3-30).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under A3_LLT would be 45% to 209% greater than mortality under Existing Conditions, which would be 9% to 25% higher on an absolute scale (Table 11-3-31).

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be up to 18% lower than those under Existing Conditions throughout the period.

Water temperatures in the Stanislaus River for Alternative 3 are not different from those for Alternative 1A, Impact AQUA-76, which indicates that there would be no effects of Alternative 1A on temperatures.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be up to 8% lower than Existing Conditions in most water years during October, similar to Existing Conditions in November and December, and up to 6% higher than Existing Conditions during January.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be up to 14% lower than flows under Existing Conditions during October and November, up to 15% greater than flows under Existing Conditions during December and January.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-76 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat for fish, contrary to the NEPA conclusion set forth above. There would be flow reductions and water temperature increases in the Sacramento River that would affect fall- and late fall–run Chinook salmon, as evidenced by Reclamation Egg Mortality model results for fall-run and SacEFT results for fall- and late fall–run Chinook salmon. Water temperatures would also be higher in the Feather and American Rivers under Alternative 3 than under the Existing Conditions that would lead to moderately higher egg mortality as predicted by the Reclamation Egg Mortality Model. Flows would be lower and water temperatures would be lower in the Stanislaus River under Alternative 3.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for fall-/late fall-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 3 would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall–run Chinook salmon relative to NAA.

Sacramento River

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-77, which indicates that there would be no effects of Alternative 1A on temperature.

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Sacramento River upstream of Red Bluff under A3_LLT would be greater than or similar to flows under NAA, except in critical water years during January (8% lower).

Shasta Reservoir storage at the end of September would affect flows during the fall-run larval and juvenile rearing period. Storage volume at the end of September would be 9% lower than under NAA in below normal water years, but would be similar to or greater than storage under NAA in other water year types depending on water year type (Table 11-3-13).

SacEFT predicts that there would be a 13% reduction (5% absolute scale) in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under A3_LLT relative to NAA (Table 11-3-25). SacEFT predicts that there would be a 40% increase (8% absolute scale) in the percentage of years with "good" (lower) juvenile stranding risk under A3_LLT relative to NAA.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under A3_LLT would be 7% lower than under NAA.

Late Fall–Run

Year-round Sacramento River flows upstream of Red Bluff were examined for the late fall–run Chinook salmon juvenile March through July rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during this period under A3_LLT were generally similar to or greater than those under NAA.

Shasta Reservoir storage at the end of September and May would affect flows during the late fall–run larval and juvenile rearing period. End of September Shasta storage volume would be 9% lower than under NAA in below normal water years, but would be similar to or greater than storage under NAA in other water year types depending on water year type (Table 11-3-16).

May Shasta storage volume under A3_LLT would be similar to or greater than storage under NAA for all water year types except below normal (8% lower) and dry (6% lower) (Table 11-3-9).

SacEFT predicts that there would be a 44% decrease (28% absolute scale) in the percentage of years with good juvenile rearing availability for late fall–run Chinook salmon, measured as weighted usable area, under A3_LLT relative to NAA (Table 11-3-27). SacEFT predicts that the percentage of years with "good" (lower) juvenile stranding risk under A3_LLT would be similar (<5% difference) to NAA.

SALMOD predicts that late fall–run smolt equivalent habitat-related mortality under A3_LLT would be similar to (<5% difference) mortality under NAA.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined the January through May fall-run Chinook salmon rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to or greater than flows under NAA, except in critical water years during February (6% lower) and in below normal years during March (6% reduction).

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-77, which indicates that there would be no effects of Alternative 1A on temperature.

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Relatively constant flows in the low flow channel throughout this period under A3_LLT would not differ from those under NAA. In the high flow channel, flows under A3_LLT would nearly always be similar to or greater than flows under NAA, except in critical water years during January (20% lower). These results indicate that Alternative 3 would provide moderate benefits to fall-run Chinook salmon in the Feather River.

As reported in Impact AQUA-59, May Oroville storage under A3_LLT would be similar to (<5% difference) storage under NAA in all water year types (Table 11-3-22).

As reported in Impact AQUA-58, September Oroville storage volume would be 17% to 32% greater than storage under NAA depending on water year type (Table 11-3-20).

American River

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-77, which indicates that there would be no effects on temperature, compared to NAA.

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during January through April under A3_LLT would generally be similar to or greater than flows under NAA except in dry and critical years during March (7% and 9% lower, respectively). Flows during May under A3_LLT would be mostly higher than flows under NAA (up to 36% lower).

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for Alternative 3 are not different from those under NAA, for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures in the Stanislaus River for Alternative 3 are not different from those for Alternative 1A, which indicates that there would be no effects on temperature or flow, relative to NAA.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis for Alternative 3 are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta for Alternative 3 are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Taken together, these results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat of fish. Fall-run Chinook salmon would experience beneficial effects of Alternative 3 in the Sacramento River and would not be affected in any upstream waterway. SacEFT predicts that there would be a 44% decrease (28% on an absolute scale) in the percentage of years with good juvenile rearing availability for late fall-run, although modeling outputs predict that flows, which drive rearing habitat availability, would be similar or would increase during the rearing period. In addition, the number of years with good juvenile stranding risk for late fall-run Chinook salmon as predicted by SacEFT would not differ between Alternative 3 and the NEPA baseline, nor would water temperatures or smolt equivalent habitat-related mortality as predicted by SALMOD. There are no effects of Alternative 3 on fall-run or late-fall-run Chinook salmon in other waterways.

CEQA Conclusion: In general, Alternative 3 would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall–run Chinook salmon relative to the Existing Conditions.

Sacramento River

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-77 which indicates that there would be no effects on temperatures during the evaluated period, relative to Existing Conditions.

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would generally be greater than or similar to flows under Existing Conditions, except in wet years during May (14% lower).

As reported in Impact AQUA-58, end of September Shasta Reservoir storage under A3_LLT would be 9% to 33% lower relative to Existing Conditions depending on water year type (Table 11-3-16).

SacEFT predicts that there would be a 6% increase in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under A3_LLT relative to Existing Conditions (Table 11-3-25). SacEFT predicts that there would be a 10% reduction in the percentage of years with "good" (lower) juvenile stranding risk under A3_LLT relative to Existing Conditions.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under A3_LLT would be 14% lower than mortality under Existing Conditions.

Late Fall–Run

Year-round Sacramento River flows upstream of Red Bluff were examined for the late fall–run Chinook salmon juvenile March through July rearing period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows during the period under A3_LLT were generally similar to or greater than those under Existing Conditions except for lower flows in some water years in July (up to 10% lower).

As reported in Impact AQUA-58, end of September Shasta Reservoir storage under A3_LLT would be 9% to 33% lower relative to Existing Conditions depending on water year type (Table 11-3-16).

As reported in Impact AQUA-40, end of May Shasta storage under A3_LLT would be similar to Existing Conditions in wet and above normal water years, but lower by 13% to 24% in below normal, dry, and critical water years (Table 11-3-9).

SacEFT predicts that there would be a 10% reduction in the percentage of years with good juvenile rearing availability for late fall–run Chinook salmon, measured as weighted usable area, under A3_LLT relative to Existing Conditions (Table 11-3-27). SacEFT predicts that there would be a 38% reduction in the percentage of years with "good" (lower) juvenile stranding risk under A3_LLT relative to Existing Conditions.

SALMOD predicts that late fall–run smolt equivalent habitat-related mortality under A3_LLT would be 7% higher than mortality under Existing Conditions.

Clear Creek

No temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined the January through May fall-run Chinook salmon rearing period (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under A3_LLT would be similar to or greater than flows under Existing Conditions for the entire period.

Feather River

Fall-Run

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-77, which indicates that temperatures would be higher than under Existing Conditions during substantial portions of the periods evaluated.

Fall-run flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low flow channel throughout the period under A3_LLT would not differ from those under Existing Conditions. In the high flow channel, flows under A3_LLT would be mostly lower (up to 36%) during January and mostly similar to or greater than flows under NAA during December and February through June with few exceptions during which flows would be up to 33% lower under A3_LLT. Overall, the increases in flows would outweigh the reductions in flows under Alternative 3 relative to the Existing Conditions.

As reported under Impact AQUA-59, May Oroville storage volume under A3_LLT would be 6% to 16% lower than storage under Existing Conditions in all but wet years, in which storage would be similar to Existing Conditions (Table 11-3-21).

As reported in Impact AQUA-58, Oroville Reservoir storage volume at the end of September under A3_LLT would be similar to storage under Existing Conditions in dry and critical years but 16% to 20% lower in wet, above normal, and below normal years depending on water year type (Table 11-3-20).

American River

Fall-Run

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-77, which indicates that temperatures would be higher than under Existing Conditions in 3 months during the 5-month period evaluated.

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during January through April under A3_LLT would generally be similar to or greater than flows under Existing Conditions, with few exceptions during which flows would be up to 17% lower. Flows during May under A3_LLT would be mostly lower (by up to 27%) than flows under Existing Conditions.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for Alternative 3 would be up to 36% lower than Existing Conditions in January through May fall-run larval and juvenile rearing period in most water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures in the Stanislaus River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-77, which indicates that temperatures would be higher than under Existing Conditions throughout the period evaluated.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to flows under Existing Conditions during January and February and lower by up to 15% during March through May, particularly in drier water year types.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be up to 18% greater than those under Existing Conditions during January and February, similar to flows under Existing Conditions during March, and lower by up to 18% than flows under Existing Conditions during April and May.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-77 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce the fall-/late fall-run Chinook salmon rearing habitat, contrary to the NEPA conclusion set forth above. Fall-run Chinook salmon would experience higher egg mortality in the Sacramento River under Alternative 3 relative to Existing Conditions. Late fall–run Chinook salmon in the Sacramento River experience small to moderate (up to 24%) reductions in flow during August, September, and November in most water year types relative to the Existing Conditions. SacEFT predicts that there would be a 22% reduction (10% on an absolute scale) in years with good late fall-run Chinook salmon juvenile rearing WUA and a 38% reduction (27% on an absolute scale) in years with low juvenile stranding risk. Despite small or intermittent flow reductions, there are no impacts of Alternative 3 on flows during the fall-run or late fall–run Chinook salmon periods in the Feather, American, San Joaquin, and Mokelumne Rivers. However, water temperatures would be increased in both the Feather and American Rivers. In the Stanislaus River, flows would be reduced and water temperatures would increase throughout the period.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing incubation habitat for fall-/late fall-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 3 would reduce migration conditions for fall-/late fall–run Chinook salmon relative to NAA.

Upstream of the Delta

Sacramento River

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-78, which indicates that there would be no effect on temperatures throughout the periods evaluated, relative to NAA.

Fall-Run

Fall-run flows in the Sacramento River upstream of Red Bluff were examined for juvenile fall-run migrants during February through May. Flows under A3_LLT would be similar to or greater than flows under NAA throughout the juvenile fall-run migration period in all water year types (Appendix 11C*, CALSIM II Model Results utilized in the Fish Analysis*).

Flows in the Sacramento River upstream of Red Bluff were examined during the adult fall-run Chinook salmon upstream migration period (September through October). Flows during September under A3_LLT would generally be lower by up to 43% than those under NAA. Flows during October under A3_LLT would be greater than those under NAA. Because flow reductions are negligible or small in dry and critical water years, these flow reductions would not affect fall-run Chinook salmon in a biologically meaningful way.

Late Fall–Run

Flows in the Sacramento River upstream of Red Bluff were reviewed for juvenile late fall–run migration period (January through March). Flows under A3_LLT would generally be similar to or greater than flows under NAA except in critical water years during January (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in the Sacramento River upstream of Red Bluff were reviewed for the adult late fall–run Chinook salmon upstream migration period (December through February). Flows under A3_LLT would generally be similar to or greater than flows under NAA except in critical water years during January (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-run flows in the Clear Creek below Whiskeytown Reservoir were examined for juvenile fall-run migrants during February through May. Flows under A3_LLT would generally be similar to or greater than flows under NAA except in critical years during February (6% lower) and in below normal water years during March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek below Whiskeytown Reservoir during the adult fall-run Chinook salmon upstream migration period (September through October) under A3_LLT would be similar to or greater than those under NAA, except in critical water years during September (13% lower). (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-78, which indicates that there would be no effect on temperatures throughout the periods evaluated relative to NAA.

Fall-run Flows in the Feather River at the confluence with the Sacramento River were reviewed during the February through May fall-run juvenile migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than flows under NAA throughout the February to May juvenile migration period.

Flows in the Feather River at the confluence with the Sacramento River were reviewed during the September through October fall-run Chinook salmon adult migration period. Flows in September under A3_LLT would generally be up to 84% lower than flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during October under A3_LLT would be similar to or greater than flows under NAA in all water year types.

American River

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-78, which indicates that there would be no effect on temperatures throughout the periods evaluated relative to NAA.

Fall-Run

Fall-run Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT during February through May would be generally similar to or greater than flows under NAA, except for dry and critical water years during March (7% and 9% lower, respectively).

Flows in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during September under A3_LLT would be up to 58% lower than flows under NAA. During October, flows under A3_LLT would be 40% greater than flows under NAA.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to those under NAA in all months and water year types throughout the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to those under NAA in all months and water year types throughout the period.

Water temperatures in the Stanislaus River for Alternative 3 are not different from those for Alternative 1A, which indicates that there would be no effect on temperatures throughout the period evaluated, relative to NAA.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to those under NAA in all months and water year types throughout the period.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to those under NAA in all months and water year types throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to those under NAA in all months and water year types throughout the period.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to those under NAA in all months and water year types throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Sacramento River

Fall-Run

Juveniles

Juvenile salmonids migrating down the Sacramento River would generally experience lower flows below the north Delta intakes compared to Existing Conditions. The two intakes would replace aquatic habitat and likely attract piscivorous fish around the intake structures. Estimates of potential predation losses ranged from 0.6% (bioenergetics model, Table 11-1A-17) up to 8.8% (conservative assumption of 5% loss per intake) of fall-run annual production. Through-Delta survival by juvenile fall-run Chinook salmon under Alternative 3 was similar to NAA (Table 11-3-32).

Table 11-3-32. Through-Delta Survival (%) of Emigrating Juvenile Fall-Run Chinook Salmon under Alternative 3

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Month	EXISTING CONDITIONS	NAA	A3_LLT	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Sacramento River					
Wetter Years	34.5	31.1	29.5	-5.1 (-15%)	-1.7 (-5%)
Drier Years	20.6	20.8	21.7	1.1 (5%)	0.9 (4%)
All Years	25.8	24.7	24.6	-1.2 (-5%)	-0.1 (<-1%)
Mokelumne River					
Wetter Years	17.2	15.7	14.7	-2.5 (-15%)	-1.1 (-7%)
Drier Years	15.6	15.9	15.4	-0.2 (-1%)	-0.6 (-4%)
All Years	16.2	15.9	15.1	-1.1 (-7%)	-0.7 (-5%)
San Joaquin River					
Wetter Years	19.3	20.3	20.9	1.6 (8%)	0.7 (3%)
Drier Years	10.0	9.5	10.6	0.7 (7%)	1.1 (11%)
All Years	13.5	13.6	14.5	1.0 (8%)	0.9 (7%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and Above Normal WYs (6 years).
Drier = Below Normal, Dry and Critical WYs (10 years).

Adults

River water in the Delta under Alternative 3 would be similar (<10% change) to NAA from October to December, but would be reduced by 13% in September (Table 11-3-14). Although reduction in the proportion of Sacramento River flows during September would be substantial, it would not occur during the peak migration period (October–December), and olfactory cues for fall-run adults would still be strong. The proportion of Sacramento River under Alternative 3 would still represent 54–66% of Delta outflows. The reductions in percentage are less than the magnitude of change in dilution reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect adult Chinook salmon migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 for Alternative 1A.

Mokelumne River

Fall-Run

Juveniles

Through-Delta survival by juvenile fall-run Chinook salmon under Alternative 3 averaged across years would be 15.1% from the Mokelumne River, which is 0.7% less (5% relative decrease) compared to NAA (Table 11-2A-32). In wetter years, mean survival would be 1.1% lower (7% relative decrease) compared to NAA.

San Joaquin River

Fall-Run

Juveniles

The only changes to San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. Through-Delta survival of juvenile fall-run Chinook salmon emigrating from the San Joaquin river under Alternative 3 averaged 14.5% across all years, which is 0.9% greater (7% relative increase) compared to NAA (Table 11-4-32).

Adults

Alternative 3 would slightly increase the proportion of San Joaquin River water in the Delta in September through December by 1.2 % (compared to NAA) (Table 11-3-14). The proportion of San Joaquin River water would be slightly increased compared NAA. Therefore migration conditions under Alternative 3 would be slightly improved.

Late Fall–Run

Juveniles

Through-Delta survival by emigrating juvenile late fall–run Chinook salmon under Alternative 3 (A3_LLT) would average 23% across all years, ranging from 21% in drier years to 26% in wetter years. Under Alternative 3, juvenile survival would increase slightly in drier years (0.4% greater survival, or 12% more in relative percentage) compared to NAA (Table 11-3-33).

Table 11-3-33. Through-Delta Survival (%) of Emigrating Juvenile Late Fall-Run Chinook Salmon under Alternative 3

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Month	EXISTING CONDITIONS	NAA	A3_LLT	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wetter Years	28.8	27.3	27.7	-1.1 (-4%)	0.3 (1%)
Drier Years	18.8	20.2	20.6	1.9 (10%)	0.4 (2%)
All Years	22.5	22.9	23.3	0.8 (3%)	0.4 (2%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and Above Normal WYs (6 years).
Drier = Below Normal, Dry and Critical WYs (10 years).

Adults

The adult late fall–run migration is from November through March, peaking in January through March. The proportion of Sacramento River water in the Delta would be similar (<10%) to NAA throughout the migration period (Table 11-3-14).

Because the proportion of Sacramento River water in the Delta would not substantially change during much of the adult and juvenile fall-run Chinook salmon migration periods under Alternative 3, it would not have an adverse effect on Sacramento or San Joaquin River fall-run Chinook salmon migration success through the Delta. Similarly, Alternative 3 would not have an adverse effect on adult or juvenile late fall–run Chinook salmon migration or survival.

NEPA Effects: Collectively, these results indicate that the effect would be adverse because it has the potential to substantially reduce the availability of suitable migration habitat or substantially interfere with the movement of fish. Flows in the Feather and American rivers during one of the two months of the fall-run Chinook salmon adult migration period would be substantially lower (up to 84% and up to 58%, respectively).Flows in other upstream waterways under Alternative 3 would generally be similar to or greater than those under NAA during juvenile fall- and late fall-run Chinook salmon migration periods.

Near-field effects of Alternative 3 NDD on fall- and late fall-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating fall- and late fall-run Chinook salmon, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus the level of impacts associated with 2 new intakes would be considerably lower than those expected from having 5 new intakes in the river. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 9% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the 2 new intake structures will be implemented as part of the final NDD screen design effort. Alternative 3 also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for fall- and late fall-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 3 predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 3 would be similar to those estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of, the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon.

Because upstream effects would be adverse, it is concluded that the overall effect of Alternative 3 on fall-/late fall-run Chinook salmon migration conditions would be adverse.

This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. Even so, proposed mitigation (Mitigation Measure AQUA-78a through AQUA-78c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 3 would reduce migration conditions for fall-/late fall-run Chinook salmon relative to Existing Conditions

Upstream of the Delta

Sacramento River

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-78, which indicates that temperatures would generally not change relative to Existing Conditions during the periods evaluated.

Fall-Run

Flows in the Sacramento River upstream of Red Bluff for juvenile fall-run migrants were evaluated during February through May under A3_LLT. Results indicate that flows would generally be similar to or greater than those under Existing Conditions, except in wet years during May (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in the Sacramento River upstream of Red Bluff were evaluated during the adult fall-run Chinook salmon upstream migration period (September through October). Flows under A3_LLT would generally be similar to or greater than those under Existing Conditions by except in wet and dry water years during September (23% and 20% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Late Fall–Run

Flows in the Sacramento River upstream of Red Bluff were examined for juvenile late fall–run migrants (January through March). Flows under A3_LLT during this period would be similar to or greater than flows under Existing Conditions in all months and water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in the Sacramento River upstream of Red Bluff were examined during the adult late fall–run Chinook salmon upstream migration period (December through February). Flows under A3_LLT during this period would be similar to or greater than flows under Existing Conditions in all months and water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir during the juvenile fall-run Chinook salmon upstream migration period (February through May) under A3_LLT would be similar to or greater than those under Existing Conditions throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Flows in Clear Creek below Whiskeytown Reservoir during the adult fall-run Chinook salmon upstream migration period (September through October) under A3_LLT would generally be similar to or greater than those under Existing Conditions except in critical years during September (37% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-78, which indicates that there would be no differences in temperatures during the periods evaluated, compared to Existing Conditions.

Fall-Run

Flows in the Feather River at the confluence with the Sacramento River were evaluated during the fall-run juvenile migration period (February through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during February through April, except in below normal years during March (12% lower) and in wet years during May (24% lower).

Flows in the Feather River at the confluence with the Sacramento River were evaluated during the September through October fall-run Chinook salmon adult migration period. Flows during September under A3_LLT would generally be lower than flows under Existing Conditions by up to 24% (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Although flow reductions would be moderate, they would occur in the majority of years, including dry and below normal years when flow reductions have a larger effect on Chinook salmon. Flows during October under A3_LLT would generally be similar to or greater than flows under Existing Conditions except in below normal water years (6% lower).

American River

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-78, which indicates that temperatures would be higher relative to Existing Conditions during substantial portions of the periods evaluated.

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis* Flows under A3_LLT during February through April would generally be similar to or greater than flows under Existing Conditions, except for critical years during February and March (14% and 12% lower, respectively) and in above normal years during April (8% lower). Flows under A3_LLT during May would generally be lower than flows under Existing Conditions by up to 27%.

Flows in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT during September would be 44% to 55% lower than flows under Existing Conditions. Flows under A3_LLT during October would be 9% to 30% greater than those under Existing Conditions.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT throughout this period would generally be lower than Existing Conditions (up to 36% lower), except for March in wet water years (7% greater).

Water temperatures in the Stanislaus River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-78, which indicates that temperatures would be higher than under Existing Conditions during substantial portions of the juvenile migration period evaluated.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to flows under Existing Conditions during September, except in wet and above normal years (17% and 6% lower, respectively). During October, flows would be 6% to 11% lower depending on water year type.

Water temperatures in the Stanislaus River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-78, which indicates that temperatures would be higher than under Existing Conditions during September, but not October.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to Existing Conditions but with 8% to 13% lower flows in two water years during February, and would be lower than Existing Conditions by up to 16% during March, April, and May.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be lower than Existing Conditions by up to 11% during both months.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than those under Existing Conditions during February and March, but up to 18% lower than flows under Existing Conditions during April and May.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be up to 29% lower than those under Existing Conditions depending on the month and water year type.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Through-Delta survival of juvenile fall-run Chinook salmon under Alternative 3 compared to Existing Conditions would be slightly increased in drier years (5% relative increase) and decreased in wetter years (15% relative decrease) from the Sacramento River, decreased from the Mokelumne River, especially in wetter years (15% relative decrease); and increased for juveniles from the San Joaquin River (8% relative increase) (Table 11-3-32).

Patterns in adult attraction flow would be similar (within 3% to 6%) for Sacramento River adults, and increased slightly for San Joaquin River adults compared to Existing Conditions (Table 11-3-14).

Summary of CEQA Conclusion

Collectively, the results indicate that Alternative 3 would be significant because the alternative would substantially reduce the fall-/late fall-run Chinook salmon migration habitat and substantially interfere with the movement of fish. There would be flow reductions under Alternative 3 relative to Existing Conditions during substantial portions of the migration periods evaluated in the Feather, American, Stanislaus, and San Joaquin Rivers. Further, there would be water temperature increases during substantial portions of the periods evaluated in the American and Stanislaus Rivers. There would be negligible effects of Alternative 3 on juvenile and adult fall-/late fall-run Chinook salmon migration through the Delta.

Although the CEQA analyses indicate some significant effects of water operations on juvenile fall-/late fall-run Chinook salmon migrations, the implementation of the mitigation measures listed below has the potential to reduce the severity of the impact, although not necessarily to a less-than-significant level. These mitigation measures would provide an adaptive management process, that may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6), for assessing impacts and developing appropriate minimization measures.

Mitigation Measure AQUA-78a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Fall-/Late Fall–Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-78a under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78b: Conduct Additional Evaluation and Modeling of Impacts on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Following Initial Operations of CM1

Please refer to Mitigation Measure AQUA-78b under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78c: Consult with USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Consistent with CM1

Please refer to Mitigation Measure AQUA-78c under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for fall- and late fall–run Chinook salmon under Alternative 1A (Impact AQUA-79 through AQUA-81) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: All of these effects have been determined to result in no adverse effects on fall-run/late fall-run Chinook salmon for NEPA purposes, for the reasons identified for Alternative 1A. Specifically for AQUA-80, the effects of contaminants on fall- and late fall-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on fall- and late fall-run Chinook salmon are uncertain.

CEQA Conclusion: All of these effects would be considered less than significant for CEQA purposes, for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for fall- and late fall–run Chinook salmon under Alternative 1A (Impact AQUA-82 through AQUA-90) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM12)

Impact AQUA-83: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM13)

Impact AQUA-84: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM14)

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM15)

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM16)

Impact AQUA-87: Effects of Illegal Harvest Reduction on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM17)

Impact AQUA-88: Effects of Conservation Hatcheries on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM18)

Impact AQUA-89: Effects of Urban Stormwater Treatment on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM19)

Impact AQUA-90: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on fall- and late fall-run Chinook salmon for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusions: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on fall- and late fall-run Chinook salmon, for the reasons identified for Alternative 1A, and no mitigation is required.

Steelhead

Construction and Maintenance of CM1

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

The potential effects of construction of water conveyance facilities steelhead under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-91) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-91, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for steelhead.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-91, the impact of the construction of the water conveyance facilities on steelhead would be less than significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only two intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: The potential impacts of the maintenance of water conveyance facilities under Alternative 3 would be similar to those described for Alternative 1A except that only two intakes would need to be maintained under Alternative 3 instead of five under Alternative 1A (see Impact

AQUA-92). As concluded in Alternative 1A, Impact AQUA-92, the effect would not be adverse for steelhead.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-92, the impact of the maintenance of water conveyance facilities on steelhead would be less than significant and no mitigation would be required.

Water Operations of CM1

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Water Exports from SWP/CVP South Delta Facilities

Alternative 3 would reduce entrainment losses of juvenile steelhead at the SWP/CVP south Delta facilities, similar to Alternative 1A (Impact AQUA-93). Entrainment, estimated as salvage density, would be highest in above normal and below normal water year types, but would decrease 20–22% (~2,000 fish; Table 11-3-34) across all water year types compared to NAA. Under Alternative 3, entrainment in above and below normal water years would decrease 17–22% (~1,900–2,600 fish) compared to NAA. The greatest relative reductions would occur in wet years (~1,800 fish; decrease 27–28%). This effect is not adverse and may be beneficial to steelhead.

Water Exports from SWP/CVP North Delta Intake Facilities

The effect would be similar in type to Alternative 1A (with five intakes), but the degree is less because Alternative 3 has only two intakes. Therefore, under Alternative 3 there would be a 60% reduction in impingement and predation risk associated with the north Delta facilities relative to Alternative 1A. The conclusions are the same as for Alternative 1A, Impact AQUA-93, and the effect would not be adverse.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The effects and conclusion are the same as for Impact AQUA-93 for Alternative 1A. Entrainment and impingement effects on juvenile steelhead would be minimal for Alternative 3 because intakes would have state-of-the-art screens installed. Overall, the effect on steelhead under Alternative 3 would not be adverse and may provide a small benefit to the species because entrainment would be reduced, especially at the south Delta facilities.

Predation Associated with Entrainment

Steelhead predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Average pre-screen predation loss for steelhead entrained at the Clifton Court Forebay is about 80% (Clark et al. 2009) while predation loss for fish entrained at the CVP is assumed to be 15%. Predation loss at the south Delta for steelhead would be reduced by 20–22% compared to NAA. The effects and conclusion for the risk of predation associated with the NPB structures would be the same as described for Alternative 1A (Impact AQUA-93).

Predation at the north Delta would be increased due to the construction of the proposed SWP/CVP water export facilities on the Sacramento River. It is assumed that per capita steelhead predation losses would be similar to those predicted for spring-run Chinook salmon, although slightly reduced because of the larger size of steelhead outmigrants. Bioenergetics modeling with a median predator density of 0.12 predators per foot (0.39 predators per meter) of intake predicts a predation loss of about 0.6% of the juvenile spring-run juvenile population (Table 11-3-12).

NEPA Effects: The overall predation and entrainment losses would likely have a very minor impact on the overall steelhead population, Therefore, the effect under Alternative 3 would not be adverse.

CEQA Conclusion: Entrainment losses of juvenile steelhead would be less under Alternative 3 compared to Existing Conditions (Table 11-3-34). Impacts of water operations on entrainment of steelhead would be less than significant and may be beneficial to the species because of the reduction in entrainment loss and mortality. No mitigation would be required.

Table 11-3-34. Juvenile Steelhead Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	-1,644 (-26%)	-1,736 (-27%)
Above Normal	-2,117 (-16%)	-2,461 (-18%)
Below Normal	-2,586 (-22%)	-1,856 (-17%)
Dry	-267 (-4%)	324 (5%)
Critical	-678 (-12%)	-327 (-6%)
All Years	-1,919 (-21%)	-1,777 (-20%)

[a] Estimated annual number of fish lost, based on non-normalized data.

The impact and conclusion for predation associated with entrainment would be the same as described above as predation loss would be reduced at the south Delta (21% compared to Existing Conditions), but increased slightly at the north Delta intakes. There would likely be a minor increase in predation loss under Alternative 3, but the population level effect would likely be small (<1% of the population). Therefore, the impact would be less than significant and no mitigation would be required.

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

In general, the effects of Alternative 3 on steelhead spawning conditions would be negligible relative to NAA.

Sacramento River

Water temperatures in the Sacramento River for Alternative 3 are not different from those for Alternative 1A, Impact AQUA-94, which indicates that temperatures would be similar to those under NAA.

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam, where the majority of steelhead spawning occurs, were examined during the primary steelhead spawning and egg incubation period of January through April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds, leading to mortality. Flows under A3_LLT throughout the period would generally be similar to those under NAA except during January during critical water years (8% lower flow).

SacEFT predicts that there would be a 6% decrease (3% on an absolute scale) in the percentage of years with good spawning availability, measured as weighted usable area, under A3_LLT relative to NAA (Table 11-3-35). SacEFT predicts that there would be negligible (<5%) differences between NAA and A3_LLT in the percentage of years with good (lower) redd scour risk, good (lower) egg incubation conditions, and good (lower) redd dewatering risk. These results indicate that there would be no effect of Alternative 3 on spawning habitat quantity, redd scour risk or temperature-related egg incubation conditions.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-94. Conclusions for Alternative 1A are that the predicted magnitude and frequency of water temperatures potentially affecting the quantity and quality of spawning and incubation habitat under Alternative 1A and baseline conditions would be comparable and would therefore not affect long-term habitat conditions relative to baseline conditions.

Overall, these results indicate that the effects of Alternative 3 on steelhead spawning and egg incubation habitat in the Sacramento River would be negligible.

Table 11-3-35. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Steelhead Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Spawning WUA	0 (0%)	-3 (-6%)
Redd Scour Risk	-3 (-4%)	0 (0%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	-1 (-2%)	2 (4%)
Juvenile Rearing WUA	-3 (-7%)	-7 (-16%)
Juvenile Stranding Risk	-17 (-50%)	-3 (-15%)

WUA = Weighted Usable Area.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Flows in Clear Creek were examined during the steelhead spawning and egg incubation period (January through April). Flows under A3_LLT would generally be similar to flows under NAA throughout the period, except in critical years during February (6% lower), below normal years during March (6% lower), and critical years during January (7% higher) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Results of the flow analyses for the risk of redd dewatering for Clear Creek indicate that the greatest monthly flow reduction would be identical between NAA and A3_LLT for all water year types except for substantial flow reductions in some critical years (100% reduction, to 0 cfs) (Table 11-3-36), which would pose substantial redd dewatering risk for that time-frame.

Overall, these results indicate that the effects of Alternative 3 on steelhead spawning and egg incubation habitat in Clear Creek would be negligible except in some critical years.

Table 11-3-36. Comparisons of Greatest Monthly Reduction (Percent Change) in Instream Flow under Model Scenarios in Clear Creek during the January–April Steelhead Spawning and Egg Incubation Period[a]

Water Year Type	A3_LLT vs. EXISTING CONDITIONS	A3_LLT vs. NAA
Wet	-25 (-38%)	0 (0%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	-100 (NA)	-100 (NA)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in the month when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) during the steelhead spawning and egg incubation period (January through April) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the low-flow channel under A3_LLT would not differ from NAA because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006). Flows under A3_LLT at Thermalito Afterbay would generally be much greater than flows under NAA (5% to 70%), except for the occurrence of a decrease in critical years during January (20% lower).

Oroville Reservoir storage volume at the end of September and end of May influences flows downstream of the dam during the steelhead spawning and egg incubation period. Storage volume at the end of September under A3_LLT would be up to 32% greater than storage under NAA depending on water year type (Table 11-3-20). May Oroville storage under A3_LLT would be similar to storage under NAA (Table 11-3-21).

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-94. Conclusions for Alternative 1A are that water temperatures would be comparable and would therefore not affect long-term habitat conditions relative to NAA.

Overall, these results indicate that the effects of Alternative 3 on steelhead spawning and egg incubation habitat in the Feather River would be beneficial.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to flows under NAA during the period except in dry and critical years during March (7% and 9% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-94, which indicates that there would be no effects of Alternative 3 on temperatures during the periods evaluated.

Overall, these results indicate that the effects of Alternative 3 on steelhead spawning and egg incubation habitat in the American River would be negligible.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT throughout this period would generally be identical to flows under NAA.

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-94, which indicates that there would be no effects on temperatures during the periods evaluated, relative to NAA.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT throughout this period would generally be identical to flows under NAA.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, these results indicate that the effect of Alternative 3 would not be adverse because it would not substantially reduce suitable spawning or egg incubation habitat or substantially reduce the number of fish as a result of egg mortality. Project-related effects on steelhead egg incubation and spawning conditions based on mean monthly flow consist primarily of negligible effects (<5%), small decreases in mean monthly flow (to -12%) that would not adversely affect steelhead spawning conditions in any of the locations analyzed. There would be beneficial effects from substantial increases in mean monthly flow for some months and water year types in the Feather River (primarily of increases in mean monthly flow ranging from 5% to 70% throughout the spawning period). SacEFT predicts there would be no effects of Alternative 3 on spawning and egg incubation habitat in the Sacramento River.

CEQA Conclusion: In general, Alternative 3 would not reduce the quantity and quality of steelhead spawning habitat relative to the Existing Conditions.

Sacramento River

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam, where the majority of steelhead spawning occurs, were examined during the primary steelhead spawning and egg incubation period of January through April. (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds, leading to mortality. At Keswick, flows under A3_LLT would generally be similar to flows under Existing Conditions in March and April, and higher than flows under Existing Conditions in January and February with some exceptions. Upstream of Red Bluff Diversion Dam, flows would generally be similar between Existing Conditions and A3_LLT throughout the period with somewhat better conditions in January.

SacEFT predicts no differences in spawning habitat and egg incubation and negligible changes (<5%) in redd scour and dewatering risk between Existing Conditions and Alternative 3 (Table 11-3-35).

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-94. Conclusions for Alternative 1A are that water temperatures under NAA and Alternative 1A would be comparable and would therefore not affect long-term habitat conditions relative to NAA.

Overall, these results indicate that the effects of Alternative 3 on steelhead spawning and egg incubation habitat in the Sacramento River would be negligible

Clear Creek

Flows in Clear Creek were examined during the steelhead spawning and egg incubation period (January through April). Flows under A3_LLT would be similar to or greater than flows under Existing Conditions throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Results of the flow analyses for the risk of redd dewatering for Clear Creek indicate that the greatest monthly flow reduction would be identical between Existing Conditions and A3_LLT for all water year types except wet, in which the greatest reduction would be 38% lower (worse) under A3_LLT than under Existing Conditions (Table 11-3-36).

No water temperature modeling was conducted in Clear Creek.

Overall, these results indicate that the effects of A3_LLT on steelhead spawning and egg incubation habitat in Clear Creek would be negligible.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) during the steelhead spawning and egg incubation period (January through April) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the low-flow channel under A3_LLT would not differ from Existing Conditions because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006). Flows under A3_LLT at Thermalito Afterbay would generally be greater than flows under Existing Conditions, except in above and below normal water years during January (6% and 36% lower, respectively), below normal years during February and March (22% and 33% lower, respectively), and wet water years during April (30% lower).

Oroville Reservoir storage volume at the end of September and end of May influences flows downstream of the dam during the steelhead spawning and egg incubation period. Oroville Reservoir storage volume at the end of September would be 2% to 20% lower under A3_LLT relative to Existing Conditions depending on water year type (Table 11-3-20). May Oroville storage volume under A3_LLT would be lower than Existing Conditions by 2% to 16% depending on water year type (Table 11-3-21).

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-94 which indicates that there would be substantial increases in temperatures relative to Existing Conditions during portions of the periods evaluated.

Overall, these results indicate that there would be negligible effects of Alternative 3 on mean monthly flows in the low-flow channel, but that flows in the high-flow channel would be substantially lower in some water year types and months. Alternative 3 would increase exposure of spawning steelhead and their eggs to critical water temperatures, in some water years, a result of reduced coldwater pool availability in Oroville Reservoir.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions in January through April except that they would be substantially lower in dry and critical years in January, critical years in February and March and above normal years in April. Overall, these results indicate that the effects of Alternative 3 on steelhead spawning and egg incubation habitat in the American River would be negligible to minor.

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, which indicates that there would be substantial increases in temperatures during the periods evaluated, compared to Existing Conditions.

Stanislaus River

Flows in the Stanislaus River for Alternative 3 are substantially below those under Existing Conditions in all months.

Water temperatures in the Stanislaus River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-94, which indicates that temperatures would be greater than those under Existing Conditions during the entire period evaluated.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River for Alternative 3 would be similar to or higher than under Existing Conditions in January and February (up to 18% higher), similar to Existing Conditions in March except for being lower in dry years (8% lower), and substantially lower in most water year types in April (up to 14%).

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-94 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above. Flows under Alternative 3 would be similar to flows under Existing Conditions in all rivers except the Stanislaus River, Mokelumne River and in the Feather River high flow channel. However, only a small number of steelhead spawn in this reach of the Feather River (Cavallo et al. 2003). The majority of steelhead spawning occurs in Hatchery Ditch and the low-flow channel in the general vicinity of the Feather River Hatchery. In addition, there would be substantial negative effects on water temperatures in the Feather, American, and Stanislaus Rivers.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for steelhead. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

In general, Alternative 3 would reduce the quantity and quality of steelhead rearing habitat relative to NAA.

Sacramento River

Juvenile steelhead rear within the Sacramento River for 1 to 2 years before migrating downstream to the ocean. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry or juveniles leading to mortality. Year-round Sacramento River flows within the reach where the majority of steelhead spawning and juvenile rearing occurs (Keswick Dam to upstream of RBDD) were evaluated (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during September, October, and between December and July under A3_LLT would generally be similar to or greater than those under NAA. Flows during August and November would generally be lower under A3_LLT than under NAA.

SacEFT predicts that the percentage of years with good juvenile steelhead rearing WUA conditions under A3_LLT would be 16% lower (7% on an absolute scale) than that under NAA (Table 11-3-35). Also, the percentage of years with good (lower) juvenile stranding risk conditions under A3_LLT would be 15% lower (3% on an absolute scale) than under NAA. These results indicate that Alternative 3 would cause a small decrease in rearing habitat availability in the Sacramento River.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-95. Conclusions for Alternative 1A are that the predicted magnitude and frequency of water temperatures potentially affecting the quantity and quality of rearing habitat under NAA and Alternative 1A would be comparable and would therefore not affect long-term habitat conditions relative to NAA.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Flows in Clear Creek below Whiskeytown during the year-round steelhead rearing period under A3_LLT would generally be similar to or greater than flows under NAA, except for critical years in February, October and December and above normal years in March in which flows would be 6% to 9% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).Water temperatures were not modeled in Clear Creek.

It was assumed that habitat for juvenile steelhead rearing would be constrained by the month having the lowest instream flows. Juvenile rearing habitat is assumed to increase as instream flows increase, and therefore the lowest monthly instream flow was used as an index of habitat constraints for juvenile rearing. Results of the analysis indicate that juvenile steelhead rearing habitat, based on minimum instream flows, is comparable for Alternative 3 relative to NAA in wet, above normal, below normal and dry water year types (Table 11-3-37). Minimum flows would be 10% higher in critical years.

Denton (1986) developed flow recommendations for steelhead in Clear Creek using IFIM (Figure 11-1A-4). The current Clear Creek management regime uses flows slightly lower than those recommended by Denton. Results from a new IFIM study on Clear Creek are currently being analyzed. Depending on results of this study the flow regime could be adjusted in the future. We expect that the modeled flows will be suitable for the existing steelhead populations in Clear Creek. No change in effect on steelhead in Clear Creek is anticipated.

Table 11-3-37. Minimum Monthly Instream Flow (cfs) for Model Scenarios in Clear Creek during the Year-Round Juvenile Steelhead Rearing Period

Water Year Type	A3_LLT vs. EXISTING CONDITIONS	A3_LLT vs. NAA
Wet	0 (0%)	0 (0%)
Above Normal	0 (0%)	0 (0%)
Below Normal	0 (0%)	0 (0%)
Dry	0 (0%)	0 (0%)
Critical	-7 (-8%)	7 (10%)

Note: Minimum flows occurred between October and March.

Feather River

Year-round flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were reviewed to determine flow-related effects on steelhead juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The low-flow channel is the primary reach of the Feather River utilized by steelhead spawning and rearing (Cavallo et al. 2003). Relatively constant flows in the low flow channel throughout the year under A3_LLT would not differ from those under NAA. In the high flow channel, flows under A3_LLT would be mostly lower (up to 84%) during July through September and in critical water years during January and mostly greater (up to 72%) than flows under Existing Conditions in other months.

May Oroville storage under A3_LLT would be similar to storage under NAA (Table 11-3-21). September Oroville storage volume would be greater, up to 28% higher than under NAA depending on water year type (Table 11-3-20).

Water temperatures in the Feather River low-flow and high-flow channel under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-95. Conclusions for Alternative 1A are that water temperatures potentially affecting the quantity and quality of rearing habitat under NAA and Alternative 1A would be comparable and would therefore not affect long-term habitat conditions relative to NAA.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be similar to flows under NAA during January through April and October through December, greater than flows under NAA during May, June and October, and lower than flows under NAA during July through September.

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-95. Conclusions for Alternative 1A are that the predicted magnitude and frequency of water temperatures potentially affecting the quantity and quality of rearing habitat under NAA and Alternative 1A would be comparable and would therefore not affect long-term habitat conditions relative to NAA.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to flows under NAA for the entire year except for increases in dry and critical water years during June.

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-95, which indicates that there would be no effect, relative to NAA, during the period evaluated.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River for Alternative 3 were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) and the flows are not different from those under NAA.

NEPA Effects: Collectively, these results indicate the effect would be adverse because it has the potential to substantially reduce rearing habitat for larval and juvenile steelhead. SacEFT predicts that there would be a reduction in rearing habitat availability in the Sacramento River. Further, there would be reductions during July through September in instream flows in the Sacramento, Feather, and American Rivers under Alternative 3 relative to the NEPA baseline, which would reduce the quality and quantity of rearing habitat for larval and juvenile steelhead. There would be no effects on temperatures in the Sacramento, Feather, American, or Stanislaus Rivers. There would be no effects on flows in the Stanislaus, San Joaquin, or Mokelumne Rivers. There would be beneficial effects from increases in mean monthly flow for some months and water year types in Clear Creek, the Feather River, and the American River. However, these would not offset the negative effects of more persistent and/or more critically timed reductions in flow (e.g., during summer months and/or in drier water year types). This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. Even so, proposed mitigation (Mitigation Measure AQUA-95a through AQUA-95c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 3 would not affect the quantity and quality of steelhead rearing habitat relative to the Existing Conditions.

Sacramento River

Year-round Sacramento River flows within the reach where the majority of steelhead spawning and juvenile rearing occurs (Keswick Dam to upstream of RBDD) were evaluated (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during October and between December and June under A3_LLT would generally be similar to or greater than those under Existing Conditions. Flows during August, September and November would generally be lower under A3_LLT than under Existing Conditions.

SacEFT predicts that there would be a 7% decrease in the percentage of years with good rearing availability, measured as weighted usable area, under A3_LLT relative to Existing Conditions (Table 11-3-35). SacEFT predicts that there would be a substantial reduction (-50%) in the number of years with good (lower) juvenile stranding risk under A3_LLT relative Existing Conditions.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-95, which indicates that temperatures would generally not be affected by Alternative 3 relative to Existing Conditions.

Clear Creek

Flows in Clear Creek during the year-round rearing period under A3_LLT would generally be similar to or greater than flows under Existing Conditions, except for critical years in August and September in which flows would be 17% to 37% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

No temperature modeling was conducted in Clear Creek.

Juvenile rearing habitat is assumed to increase in Clear Creek as instream flows increase, and therefore the use of the lowest monthly instream flow as an index of habitat constraints for juvenile rearing was selected for use in this analysis. Results of the analysis of minimum monthly instream flows affecting juvenile rearing habitat are shown in Table 11-3-37. Results indicate that Alternative 3 would have no effect on juvenile rearing habitat, based on minimum instream flows, compared to Existing Conditions in wet, above normal, below normal and dry water years. Minimum flows would be 8% lower in critical years (reduction from 50 cfs to 43 cfs).

Denton (1986) developed flow recommendations for steelhead in Clear Creek using IFIM (Figure 11-1A-4). The current Clear Creek management regime uses flows slightly lower than those recommended by Denton. Results from a new IFIM study on Clear Creek are currently being analyzed. Depending on results of this study the flow regime could be adjusted in the future. We expect that the modeled flows will be suitable for the existing steelhead populations in Clear Creek. No change in effect on steelhead in Clear Creek is anticipated.

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-95 which indicate that temperatures would increase relative to Existing Conditions during the year-round period.

The low-flow channel is the primary reach of the Feather River utilized by steelhead spawning and rearing (Cavallo et al. 2003). There would be no change in flows for Alternative 3 relative to Existing Conditions in the low-flow channel during the year-round steelhead juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). In the high flow channel (at Thermalito Afterbay), flows under A3_LLT would be lower (up to 51%) during July and August and some water year types in November, and mostly greater (up to 149%) than flows under Existing Conditions in other months.

May Oroville storage volume under A3_LLT would be lower than Existing Conditions by 2% to 16% depending on water year type (Table 11-3-21). September Oroville storage volume would be 2% to 20% lower under A3_LLT relative to Existing Conditions depending on water year type (Table 11-3-20).

American River

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-95, which indicates that temperatures would increase relative to Existing Conditions during the year-round period.

Flows in the American River at the confluence with the Sacramento River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be up to 28% greater than to flows under Existing Conditions during February, March, and October, similar to flows under Existing Conditions during April, and up to 58% lower than flows under Existing Conditions during the remaining eight months of the year.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to flows under Existing Conditions during August, September, and November and up to 26% lower than flows under Existing Conditions during the remaining 9 months.

Water temperatures in the Stanislaus River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-95, which indicates that temperatures would increase relative to Existing Conditions during most of the year-round period.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be up to 6% higher than Existing Conditions during January, generally similar to Existing Conditions during February except for being lower in two water years, lower in most water years than Existing Conditions during March through October (up to 38% lower), and similar to Existing Conditions during November and December.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to flows under Existing Conditions during January through March, up to 15% greater than flows under Existing Conditions during December, and up to 52% lower than flows under Existing Conditions during the remaining 8 months.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, these results indicate that the impact on rearing habitat for steelhead would be significant because there would be the potential to substantially reduce rearing habitat and substantially reduce the number of fish as a result of mortality. Alternative 3 would cause reductions in mean monthly flow (to -58%) for much of the rearing period in most locations analyzed that would affect the quantity and quality of juvenile rearing habitat and would contribute to reduced survival and increased stress. Alternative 3 would have negative effects on water temperature conditions during the year-round steelhead rearing period in the Feather, American, and Stanislaus Rivers relative to Existing Conditions, but not in the Sacramento River. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-95a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Steelhead to Determine Feasibility of Mitigation to Reduce Impacts to Rearing Habitat.

Although analysis conducted as part of the EIR/EIS determined that Alternative 3 would have significant and unavoidable adverse effects on rearing habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on rearing habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 3.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 3 operations only. Development of mitigation actions for the incremental impact on spawning habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 3.

Mitigation Measure AQUA-95b: Conduct Additional Evaluation and Modeling of Impacts on Steelhead Rearing Habitat Following Initial Operations of CM1.

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to rearing habitat under Alternative 3. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-95c: Consult With NMFS, USFWS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Steelhead Rearing Habitat Consistent With CM1

In order to determine the feasibility of reducing the effects of CM1 operations on steelhead habitat, the BDCP proponents will consult with NMFS, USFWS, and CDFW to identify and implement any feasible operational means to minimize effects on rearing habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-95a Alternative 3.

If feasible means are identified to reduce impacts on rearing habitat consistent with the overall operational framework of Alternative 3 without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on steelhead habitat is not feasible under Alternative 3 operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on steelhead would remain significant and unavoidable.

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

In general, the effects of Alternative 3 on steelhead migration conditions relative to the NAA are uncertain.

Upstream of the Delta

Sacramento River

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, which indicates that temperatures would not be different during the periods evaluated relative to NAA.

Juveniles

Flows in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period. Flows under A3_LLT would be 10% to 37% lower than flows under NAA during November depending on water year type, they would be up to 22% higher during October, December, April, and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT in the January and February would be similar to flows under NAA with some higher and lower flows in certain water years.

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, which indicates that temperatures would not be different during the periods evaluated relative to NAA.

Adults

Flows in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be lower than flows under NAA during September depending on water year type, lower by 10% to 37% in November, and generally similar to flows under NAA in the remaining six months of the period.

Kelts

Flows in the Sacramento River upstream of Red Bluff were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during March would be similar to NAA flows but higher in below normal, critical and above normal years (up to 13% higher) and flow would be higher during April (up to 13% higher) except for being similar to NAA in critical years.

Overall in the Sacramento River, Alternative 3 would not result in biologically meaningful effects on juvenile, adult, or kelt steelhead migration based on mean monthly flows and water temperatures.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Juveniles

Flows in Clear Creek during the October through May juvenile steelhead migration period under A3_LLT would be similar to flows under NAA except in critical years during October, November and January (7%, 9% and 7% higher, respectively), in critical years in February (6% lower), and in below normal years in March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows in Clear Creek during the September through March adult steelhead migration period under A3_LLT would similar to flows under NAA except in critical years during September, October, November and January (13%, 7%, 9% and 7% higher, respectively), in critical years in February (6% lower), and in below normal years in March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Kelts

Flows in Clear Creek during the March through April steelhead kelt downstream migration period under A3_LLT would be similar to or greater flows under NAA except for lower flows in below normal years in March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall in Clear Creek, Alternative 3 would not have biologically meaningful effects on juvenile, adult, or kelt steelhead migration.

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, which indicates that temperatures would not be different during the periods evaluated relative to NAA.

Juveniles

Flows in the Feather River at the confluence with the Sacramento River were examined during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than flows under NAA in all months and water years except during October in above normal years (6% lower) and January in critical years (8% lower).

Adults

Flows in the Feather River at the confluence with the Sacramento River were examined during the September through March adult steelhead upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than flows under NAA in all months and water years except during September in below normal years (31% lower), October in above normal years (6% lower) and January in critical years (8% lower).

Kelts

Flows in the Feather River at the confluence with the Sacramento River were examined during the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would generally be greater than those under NAA in both months (up to 22% higher).

Overall in the Feather River, project-related effects of Alternative 3 consist of negligible changes in water temperature, and negligible effects (<5%) on mean monthly flow or increases in flow that would have a beneficial effect on migration conditions for juvenile, adult and kelt steelhead.

American River

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, which indicates that temperatures would not be different during the periods evaluated relative to NAA.

Juveniles

Flows in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than flows under NAA during the entire period except for lower flows in dry and critical years in March (7% and 9% lower).

Adults

Flows in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than flows under NAA during the entire period except for lower flows in dry and critical years in March (7% and 9% lower) and would be lower during September for all water year types except dry and critical years (16% to 50% lower).

Kelts

Flows in the American River at the confluence with the Sacramento River were evaluated for the March and April kelt migration period. Flows under A3_LLT would generally be similar to flows under NAA except in dry and critical years during March (7% and 9% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall in the American River, results indicate that project-related effects of Alternative 3 consist of negligible effects on temperature, negligible effects (<5%) on flow or increases in flow that would have beneficial effects on migration conditions, with decreases in flow that would be infrequent, of small magnitude, or would occur in wetter water years that would not have biologically meaningful effects on juvenile, adult, or kelt steelhead migration conditions in the American River.

Stanislaus River

Water temperatures in the Stanislaus River under Alternative 3 would be the same as those under Alternative 1A, which indicates that temperatures would not be different during the periods evaluated relative to NAA.

Juveniles

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the October through May juvenile steelhead migration period. Flows under A3_LLT would be similar to flows under NAA during the entire period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar flows under NAA during the entire period.

Kelts

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the March and April kelt migration period. Flows under A3_LLT would be similar to under NAA for both months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall in the Stanislaus River, there would be no effects of Alternative 3 on flows or water temperatures during the juvenile, adult, or kelt steelhead migration periods.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Juveniles

Flows in the San Joaquin River at Vernalis were evaluated during the October through May juvenile steelhead migration period. Flows under A3_LLT would be similar to flows under NAA during the entire period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows in the San Joaquin River at Vernalis were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar flows under NAA during the entire period.

Kelts

Flows in the San Joaquin River at Vernalis were evaluated for the March and April kelt migration period. Flows under A3_LLT would be similar to under NAA for both months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mokelumne River

Water temperature modeling was not conducted in the Mokelumne River.

Juveniles

Flows in the Mokelumne River were evaluated during the October through May juvenile steelhead migration period. Flows under A3_LLT would be similar to flows under NAA during the entire period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows in the Mokelumne River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar flows under NAA during the entire period.

Kelts

Flows in the Mokelumne River were evaluated for the March and April kelt migration period. Flows under A3_LLT would be similar to under NAA for both months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

The through-Delta methodology for assessing steelhead Delta migration habitat conditions is fully described in the analysis of Alternative 1A.

Sacramento River

Juveniles

Based on DPM results for Chinook salmon (Impact AQUA-42 for Alternative 3), steelhead survival would not be expected to decrease more than 0.5% under Alternative 3.

Adults

The upstream adult steelhead migration occurs from September–March, peaking during December-February. The steelhead kelt downstream migration occurs from January–April. The proportion of Sacramento River water in the Delta under Alternative 3 would to be similar (<10% difference) to NAA during the majority (October–March) of the adult steelhead upstream migration, including during the peak migration months (Table 11-3-14). The proportion of Sacramento River water decreases in September compared to NAA (13%). Based on the overall similarity in Sacramento River flow olfactory cues, especially during the adult upstream and kelt downstream migration periods, the effects would be expected to be similar. Alternative 3 would not have an adverse effect on adult and kelt steelhead migration through the Delta.

San Joaquin River

Juveniles

The only changes to San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. There no flow changes associated with the Alternatives. Alternative 3 would have no effect on steelhead migration success through the Delta.

Adults

Alternative 3 would slightly increase the proportion of San Joaquin River water in the Delta in September through December by 1.9% compared to NAA (Table 11-3-14). Therefore, Alternative 3 would have no effect on the adult steelhead and kelt migration because olfactory cues and flow conditions would be relatively unchanged.

Based on DPM, through-Delta juvenile steelhead survival would not be expected to decrease more than 0.5% under Alternative 3. Alternative 3 would also not have an adverse effect on Sacramento River adult and kelt steelhead migration through the Delta. Alternative 3 would also have no effect on the San Joaquin River juvenile and adult steelhead and kelt through-Delta migrations because olfactory cues and flow conditions would be relatively unchanged.

NEPA Effects: Upstream of the Delta, the results indicate that the effect would not be adverse because the alternative does not have the potential to substantially reduce migration habitat or substantially interfere with the movement of fish. Alternative 3 would have negligible effects on water temperatures in the Sacramento, Feather, American, and Stanislaus Rivers, and effects on flow would consist of negligible effects (<5% difference), beneficial effects (increases in flow to 84%), or reductions in flow that would not have biologically meaningful effects on migration conditions based on the infrequency of occurrence throughout a relatively long migration period (to -68%), moderate magnitude (i.e., more routine reductions in flow to -16%), and/or timing of the reduction (i.e., larger reductions in wetter water years when effects on migration would not be critical).

Near-field effects of Alternative 3 NDD on Sacramento River steelhead related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating steelhead, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus the level of impacts associated with 2 new intakes would be considerably lower than those expected from having 5 new intakes in the river. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 12% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the 2 new intake structures will be implemented as part of the final NDD screen design effort. Alternative 3 also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for steelhead. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 3 predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 3 would be similar to those estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of, the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for steelhead. However, until these efforts are completed and their results are fully analyzed, the overall cumulative effect of Alternative 3 on steelhead migration remains uncertain.

CEQA Conclusion: In general, under Alternative 3, migration conditions for steelhead would not be reduced relative to Existing Conditions.

Upstream of the Delta

Sacramento River

Water temperatures in the Sacramento River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-96, which indicates that temperatures would not be different during the periods evaluated relative to Existing Conditions.

Juveniles

Flows in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period. Flows under A3_LLT would be 9% to 27% lower than flows under Existing Conditions during November depending on water year type and would be up to 22% higher during January and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT in the remaining five months of the migration period would be similar to flows under Existing Conditions.

Adults

Flows in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be lower than flows under Existing Conditions during September depending on water year type, lower by 7% to 27% in November, and similar to flows under Existing Conditions in the remaining six months of the period.

Kelts

Flows in the Sacramento River upstream of Red Bluff were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during these two months would not differ between Existing Conditions and A3_LLT except for being higher by 13% in critical years in March and being 18% lower in wet years in April.

Overall in the Sacramento River, effects of Alternative 3 on water temperatures and mean monthly flow conditions during the applicable migration periods would not have biologically meaningful effects on migration.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Juveniles

Flows in Clear Creek during the October through May juvenile steelhead migration period under A3_LLT would be similar to or greater than flows under Existing Conditions except in critical years during February (6% lower), and in below normal years in March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Adults

Flows in Clear Creek during the September through March adult steelhead migration period under A3_LLT would generally be similar to or greater than flows under Existing Conditions except in critical years during September (37% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Kelts

Flows in Clear Creek during the March through April steelhead kelt downstream migration period under A3_LLT would be similar to or greater flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall in Clear Creek, Alternative 3 would have primarily negligible effects (<5%) on flows or would cause increases in mean monthly flow that would be beneficial for juvenile, adult, and kelt migration conditions.

Feather River

Water temperatures in the Feather River under Alternative 3 would be the same as those under Alternative 1A, which indicates that temperatures would not be different during the periods evaluated relative to Existing Conditions.

Juveniles

Flows in the Feather River at the confluence with the Sacramento River were examined during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than flows under Existing Conditions in all months and water years except during October, November, January and March in below normal years (6%,11%, 10%, and 12% lower, respectively), and during April and May in wet years (24% and 19% lower, respectively).

Adults

Flows in the Feather River at the confluence with the Sacramento River were examined during the September through March adult steelhead upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be up to 24% lower than flows under Existing Conditions during September, 6% lower than flows under Existing Conditions during October in below normal years, 11% lower than flows under Existing Conditions during November in below normal years, 10% lower than flows under Existing Conditions during January in below normal years and generally greater than flows under Existing Conditions in all other water years and months of the period.

Kelts

Flows in the Feather River at the confluence with the Sacramento River were examined during the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be greater than those under Existing Conditions in both months except for being 12% lower in below normal years during March and 24% lower in wet year during April.

Overall in the Feather River, effects of Alternative 3 on flow would not have biologically meaningful effects on juvenile, adult or kelt migration conditions above Thermalito Afterbay or at the confluence with the Sacramento River.

American River

Water temperatures in the American River under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-96, which indicates that temperatures would be higher during substantial portions of the juvenile and adult migration periods relative to Existing Conditions.

Juveniles

Flows in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be greater than flows under Existing Conditions in and October (up to 30% higher), generally higher in January, February, March and April except for dry and critical years in January, critical years in February and March, and above normal years in April. Flows would be lower than under Existing Conditions in November during all water year types (up to 35% lower), and in December under all water year types (up to21% lower) except for wet and below normal years. Flow in January would be greater than flows under Existing Conditions in wet, above normal, and below normal years and below Existing Conditions in dry and critical years.

Adults

Flows in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be greater than flows under Existing Conditions in and October (up to 30% higher), generally higher in January, February, March and April except for dry and critical years in January, critical years in February and March, and above normal years in April. Flows would be lower than under Existing Conditions in September and November during all water year types (up to 55% and 35% lower, respectively), and in December under all water year types (up to21% lower) except for wet and below normal years. Flow in January would be greater than flows under Existing Conditions in wet, above normal, and below normal years and below Existing Conditions in dry and critical years.

Kelts

Flows in the American River at the confluence with the Sacramento River were evaluated for the March and April kelt migration period. Flows under A3_LLT would generally be greater than flows under Existing Conditions except in critical years during March (12% lower) and in above normal years in April (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Overall in the American River, Alternative 3 would have significant impacts on juvenile and adult migration conditions through persistent and moderate to substantial flow reductions during drier water years. Alternative 3 would not affect kelt migration. Increases in mean monthly flow for some months and water year types would have beneficial impacts on steelhead for a portion of the migration period for juveniles and adults.

Stanislaus River

Flows in the Stanislaus River for Alternative 3 are substantially below those under Existing Conditions for juveniles, adults, or kelts (e.g., 36% lower in dry water years in February).

Water temperatures in the Stanislaus River under Alternative 3 would be the same as those under Alternative 1A, which indicates that temperatures would not be different during substantial portions of the periods evaluated relative to Existing Conditions.

San Joaquin River

Flows in the San Joaquin River for Alternative 3 are substantially below those under Existing Conditions for juveniles, adults or kelts (e.g., 16% lower in below normal years in March) except for similar flow conditions in November and December and somewhat higher flow conditions in some water years for January (up to 10% higher).

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River for Alternative 3 are substantially below those under Existing Conditions for juveniles, adults or kelts (e.g., 18% lower in dry years in May) except for somewhat higher flow conditions in some water years for January and February (up to 18% higher) and generally higher flows for all water years in December (up to 15% higher).

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Based on DPM results for Chinook salmon (see Impact AQUA-42), steelhead survival would not be expected to decrease more than 0.5%.

The proportion of Sacramento River water in the Delta under Alternative 3 would to be similar to Existing Conditions (<10% difference) during the entire adult steelhead upstream and kelt downstream migrations.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-96 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce the availability of suitable migration habitat and interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Relative to the CEQA baseline, Alternative 3 would degrade migration conditions in the American and Stanislaus rivers (based on persistent flow reductions and water temperature increases) and in the San Joaquin and Mokelumne rivers (based on persistent flow reductions). However, Alternative 3 would not have biologically meaningful impacts on juvenile, adult, or kelt migration in the Sacramento River, Clear Creek, or the Feather River. There would be no effects on through-Delta migration conditions because changes in juvenile survival and adult olfactory cues would be negligible.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration conditions for steelhead. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for steelhead under Alternative 1A (Impact AQUA-97 through AQUA-99) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

NEPA Effects: All of these effects have been determined to result in no adverse effects on steelhead for NEPA purposes for the reasons identified for Alternative 1A. Specifically for AQUA-98, the effects of contaminants on steelhead with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on steelhead are uncertain.

CEQA Conclusions: All of these effects would be considered less than significant for CEQA purposes for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for steelhead under Alternative 1A (Impact AQUA-100 through AQUA-108) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (CM12)

Impact AQUA-101: Effects of Invasive Aquatic Vegetation Management on Steelhead (CM13)

Impact AQUA-102: Effects of Dissolved Oxygen Level Management on Steelhead (CM14)

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (CM15)

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (CM16)

Impact AQUA-105: Effects of Illegal Harvest Reduction on Steelhead (CM17)

Impact AQUA-106: Effects of Conservation Hatcheries on Steelhead (CM18)

Impact AQUA-107: Effects of Urban Stormwater Treatment on Steelhead (CM19)

Impact AQUA-108: Effects of Removal/Relocation of Nonproject Diversions on Steelhead (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on steelhead for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusions: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on steelhead, for the reasons identified for Alternative 1A, and no mitigation is required.

Sacramento Splittail

Construction and Maintenance of CM1

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

The potential effects of construction of water conveyance facilities on Sacramento splittail under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-109) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-109, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-109 for Sacramento splittail, the impact of the construction of water conveyance facilities on Sacramento splittail would be less than significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only two intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-110) except that only two intakes would require maintenance under Alternative 3 rather than five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-110, the effect would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-110, the impact of the maintenance of water conveyance facilities on Sacramento splittail would be less than significant. No mitigation would be required.

Water Operations of CM1

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Water Exports from SWP/CVP South Delta Facilities

Under Alternative 3, total entrainment of juvenile splittail at the south Delta facilities (based on Yolo Bypass inundation) would be 569% greater compared to NAA (Table 11-3-38). The greatest increase in total entrainment would be in above normal (1,906% increase) and below normal (749% increase) water year types. However, this effect is related to the expected increase in overall juvenile splittail abundance resulting from additional floodplain habitat in wetter years. The average per capita rate of splittail entrainment across all years would be reduced 29% for juveniles (Table 11-3-39) and reduced 31% for adults (Table 11-3-40). This overall reduction in per capita salvage of splittail would be due to strict reductions in south Delta exports, especially during the winter and spring months. The relative impact of entrainment at the south Delta facilities on the splittail population would be reduced under Alternative 3 because the per capita entrainment risk would be lower compared to NAA.

Table 11-3-38. Juvenile Sacramento Splittail Entrainment Index[a] (Yolo Bypass Days of Inundation Method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	6,489,911 (676%)	6,303,252 (550%)
Above Normal	699,812 (1,529%)	708,417 (1,906%)
Below Normal	21,912 (641%)	22,344 (749%)
Dry	1,804 (63%)	2,149 (85%)
Critical	-339 (-22%)	112 (10%)
All Years	2,164,276 (693%)	2,106,566 (569%)

Shading indicates entrainment increased 10% or more.

a Estimated annual number of fish lost, based on normalized data, estimated from Yolo Bypass Inundation Method.

Table 11-3-39. Juvenile Sacramento Splittail Entrainment Index[a] (Per Capita Method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	-878,606 (-44%)	-554,287 (-33%)
Above Normal	7,377 (6%)	25,209 (22%)
Below Normal	4,763 (48%)	5,080 (53%)
Dry	-1,050 (-52%)	-559 (-37%)
Critical	-543 (-41%)	-285 (-27%)
All Years	-231,843 (-42%)	-130,296 (-29%)

Shading indicates entrainment increased 10% or more.

a Estimated annual number of fish lost, based on normalized data, estimated from delta inflow.

Table 11-3-40. Adult Sacramento Splittail Entrainment Index[a] (Salvage Density Method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet	-2,050 (-52%)	-2,185 (-53%)
Above Normal	-1,278 (-27%)	-1,294 (-27%)
Below Normal	-922 (-27%)	-658 (-21%)
Dry	-278 (-11%)	-113 (-5%)
Critical	-490 (-15%)	-267 (-9%)
All Years	-1,138 (-33%)	-1,060 (-31%)

Shading indicates entrainment increased 10% or more.

a Estimated annual number of fish lost, based on normalized data. Average (December–March).

Water Exports from SWP/CVP North Delta Intake Facilities

The effect would be similar in type to Alternative 1A (with five intakes), but the degree would be less because Alternative 3 has only two intakes. Therefore, the risk of impingement and predation at the north Delta intakes under Alternative 3 would be 40% of the risk relative to Alternative 1A (Impact AQUA-111).

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The effect of implementing dual conveyance for the NBA with an alternative Sacramento River intake would be the same as described under Alternative 1A (Impact AQUA-111). Reduced pumping from Barker Slough could reduce entrainment losses of larval splittail produced in the Yolo Bypass. There would be potential for increased predation and impingement risk associated with the alternative intake. Screens on the Barker Slough pumping plant currently exclude fish greater than 25 mm, and the alternate intake on the Sacramento River would be screened to exclude splittail greater than 10 mm in length.

Predation Associated with Entrainment

Splittail predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Per capita splittail entrainment and associated predation at the south Delta would decrease 29% under Alternative 3 compared to NAA.

Predation at the north Delta would increase due to the construction of the proposed water export facilities on the Sacramento River, as described for Alternative 1A (Impact AQUA-111). Potential predation at the north Delta would be partially offset by reduced predation loss at the SWP/CVP south Delta intakes and the increased production of juvenile splittail resulting from CM2 actions (Yolo Bypass Fisheries Enhancement). Further, the fishery agencies concluded that the predation was not a factor currently limiting splittail abundance. Thus this level of predation loss would not be expected to adversely affect the splittail population.

NEPA Effects: In conclusion, the effect of Alternative 3 on entrainment and predation loss would not be adverse and may provide a benefit, because the magnitude of potential entrainment and predation losses at the north Delta intakes would likely be more than offset by the substantial reduction in per capita south Delta entrainment losses and the increased production of juvenile splittail from *CM2 Yolo Bypass Fisheries Enhancement*.

CEQA Conclusion: Under Alternative 3, total juvenile entrainment (based on Yolo Bypass inundation) averaged across water years would be 533% greater compared to Existing Conditions. However, operational activities associated with reduced south Delta water exports would result in an overall decrease in the proportion of splittail population entrained for all water year types. Average per capita entrainment under Alternative 3 would be 22% decreased for juveniles and 33% reduced for adult splittail relative to Existing Conditions. Entrainment of splittail would be reduced at the NBA. The impact and conclusion for predation associated with entrainment would be the same as described above.

In conclusion, the impact on Sacramento splittail from entrainment and predation loss would be less than significant and may provide a benefit because the increase in predation loss at the north Delta under Alternative 3 would likely be more than offset by the substantial reduction in south Delta facilities entrainment and predation loss and the increased production of juvenile splittail from CM2, *Yolo Bypass Fisheries Enhancement*, actions. No mitigation would be required.

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

In general, Alternative 3 would have beneficial effects on splittail spawning habitat relative to NAA due to substantial increases in the quantity and quality of suitable spawning habitat in the Yolo Bypass. There would also be beneficial effects on channel margin and side-channel spawning habitats due to moderate increases in mean monthly flow in the Sacramento River and the Feather River.

Sacramento splittail spawn in floodplains and channel margins and in side-channel habitat upstream of the Delta, primarily in the Sacramento River and Feather River. Floodplain spawning overwhelmingly dominates production in wet years. During low-flow years when floodplains are not inundated, spawning in side channels and channel margins would be much more critical.

Floodplain Habitat

Effects of Alternative 3 on floodplain spawning habitat were evaluated for Yolo Bypass. Increased flows into Yolo Bypass may reduce flooding and flooded spawning habitat to some extent in the Sutter Bypass (the upstream counterpart to Yolo Bypass) but this effect was not quantified. Effects in Yolo Bypass were evaluated using a habitat suitability approach based on water depth (2 meter threshold) and inundation duration (minimum of 30 days). Effects of flow velocity were ignored because flow velocity was generally very low throughout the modeled area for most conditions, with generally 80 to 90% of the total available area having flow velocities of 0.5 foot per second or less (a reasonable critical velocity for early life stages of splittail) (Young and Cech 1996).

The proposed changes to the Fremont Weir would increase the frequency and duration of Yolo Bypass inundation events compared to NAA; the changes are attributable to the influence of the Fremont Weir notch at lower flows. For the drier type years (below normal, dry, and critical), Alternative 3 results in an increase in frequency of inundation events greater than 30 days compared to NAA. For wet and above normal year types, Alternative 3 generally results in a reduced frequency of shorter-duration events and an increased frequency of the longest-duration events (≥70 days) (Figure 11-3-4, Table 11-3-41). For below normal years, Alternative 3 would result in the occurrence of two inundation events ≥70 days, compared to no such events for NAA; and five more inundation events of 30-49 days and one more inundation event of 50-69 days, compared to NAA. In dry and critical years there would be one more inundation event of 30–49 days under Alternative 3, compared to NAA. For dry and critical years, project-related increases are for 30–49 day duration events only as there are no events of longer duration. These results indicate that overall project-related effects consist of an increase in occurrence of longer-duration inundation events that would be beneficial for splittail spawning by creating better spawning habitat conditions.

There would be increases in area of suitable splittail habitat in Yolo Bypass under A3_LLT ranging from 5 to 954 acres relative to NAA. Areas under A3_LLT would be 57%, 64%, and 285% greater than areas under NAA in wet, above normal, and below normal water years, respectively (Table 11-3-42). There would be increases in area under A3_LLT in dry and critical years relative to NAA, but they would be minimal (9 and 5 acres, respectively). These results indicate that there would be increases in inundated acreage in each water year type which would result in increased habitat and have a beneficial effect on splittail spawning.

A potential adverse effect of Alternative 3 that is not included in the modeling is reduced inundation of the Sutter Bypass as a result of increased flow diversion at the Fremont Weir. Potential effects on habitat and uncertainties in predicting the magnitude of such effects would be about the same as described for Alternative 1A. Conclusions are that Alternative 3 has the potential to reduce some of the habitat benefits of Yolo Bypass inundation on splittail production due to effects on Sutter Bypass inundation, but these effects have not been quantified.

Overall, these results that despite the potential for reductions in suitable spawning habitat in Sutter Bypass, the increased occurrence of longer-duration inundation events and increased inundation acreages in all water year types would have beneficial effects on splittail spawning habitat.

Table 11-3-41. Differences in Frequencies of Inundation Events (for 82-Year Simulations) of Different Durations on the Yolo Bypass under Different Scenarios and Water Year Types, February through June, from 15 2-D and Daily CALSIM II Modeling Runs

Number of Days of Continuous Inundation	Change in Number of Inundation Events for Each Scenario	
	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
30–49 Days		
Wet	-4	-2
Above Normal	0	0
Below Normal	5	5
Dry	1	1
Critical	1	1
50–69 Days		
Wet	-5	-5
Above Normal	-1	-1
Below Normal	1	1
Dry	0	0
Critical	0	0
≥70 Days		
Wet	6	5
Above Normal	3	3
Below Normal	2	2
Dry	0	0
Critical	0	0

Table 11-3-42. Increase in Splittail Weighted Habitat Area (Acres and Percent) in Yolo Bypass from Existing Biological Conditions to Alternative 3 by Water Year Type from 15 2-D and Daily CALSIM II Modeling Runs

Water Year Type	A3_LLT vs. EXISTING CONDITIONS	A3_LLT vs. NAA
Wet	1,093 (71%)	954 (57%)
Above Normal	746 (65%)	737 (64%)
Below Normal	357 (272%)	362 (285%)
Dry	9 (NA)	9 (NA)
Critical	5 (NA)	5 (NA)

NA = could not be calculated because the denominator was 0.

Channel Margin and Side-Channel Habitat

Splittail spawning and larval and juvenile rearing also occur in channel margin and side-channel habitat upstream of the Delta. These habitats are likely to be especially important during dry years, when flows are too low to inundate the floodplains (Sommer et al. 2007). Side-channel habitats are affected by changes in flow because greater flows cause more flooding, thereby increasing availability of such habitat, and because rapid reductions in flow dewater the habitats, potentially stranding splittail eggs and rearing larvae. Effects of the BDCP on flows in years with low-flows are expected to be most important to the splittail population because in years of high-flows, when most production comes from floodplain habitats, the upstream side-channel habitats contribute relatively little production.

Effects on channel margin and side-channel habitat were evaluated by comparing flow conditions for the Sacramento River at Wilkins Slough and the Feather River at the confluence with the Sacramento River for the time-frame February through June. These are the most important months for splittail spawning and larval rearing (Sommer pers. comm.), and juveniles likely emigrate from the side-channel habitats during May and June if conditions become unfavorable.

Differences between model scenarios for monthly average flows during February through June by water-year type were determined for the Sacramento River at Wilkins Slough and for the Feather River at the confluence (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For the Sacramento River at Wilkins Slough, flows during February through March under A3_LLT would be similar to flows under NAA. During April and June flows would be higher in most water years and in May they would be higher in all water years under NAA, resulting in a beneficial effect on rearing conditions. These results indicate that there would be some increases in flow (up to 24%) that would have beneficial effects on splittail rearing conditions in the Sacramento River.

Modeling indicated no differences in project-related effects on water temperature for Alternative 3 relative to Alternative 1A in any of the rivers analyzed for splittail effects. Modeling results for Alternative 1A show that Sacramento splittail spawning temperature tolerances would not be exceeded in the Sacramento River and would rarely be exceeded in the Feather River. Therefore, effects of Alternative 3 on water temperatures would not affect splittail spawning habitat conditions.

Stranding Potential

As indicated above, rapid reductions in flow can dewater channel margin and side-channel habitats, potentially stranding splittail eggs and rearing larvae. Due to a lack of quantitative tools and historical data to evaluate possible stranding effects, potential effects have been evaluated with a narrative summary. Effects for Alternative 3 would be as described for Alternative 1A, which concludes that Yolo Bypass improvements would be designed, in part, to further reduce the risk of stranding by allowing water to inundate certain areas of the bypass to maximize biological benefits, while keeping water away from other areas to reduce stranding in isolated ponds.

NEPA Effects: Collectively, these results indicate the effect on spawning habitat for Sacramento splittail would not be adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. Alternative 3 would result in increased spawning habitat in Yolo Bypass, would have negligible effects (<5% difference) or beneficial effects (based on increases in mean monthly flow to 32%) on channel margin and side-channel rearing habitats, and would have negligible effects on spawning conditions based on stranding potential (flow reductions) and changes in water temperature.

CEQA Conclusion: In general, Alternative 3 would have beneficial effects on splittail spawning habitat relative to the Existing Conditions based on substantial increases in the quantity and quality of suitable spawning habitat in the Yolo Bypass. There would also be beneficial impacts on channel margin and side-channel spawning habitat due to moderate increases in mean monthly flow in the Sacramento River and the Feather River.

Floodplain Habitat

Comparisons of Yolo Bypass inundation events with durations longer than 30 days under Alternative 3 relative to Existing Conditions (Table 11-3-41) indicate only small differences that would not likely have biologically meaningful effects on spawning conditions. In terms of acreage of suitable splittail spawning habitat in Yolo Bypass under Alternative 3 compared to Existing Conditions (Table 11-3-42), there would be substantial increases in acreages in all water year types, with increases of between 5 and 1,093 acres of suitable spawning habitat depending on water year type. Increased areas for wet, above normal, and below normal water years are predicted to be 71%, 65%, and 272%, respectively, for Alternative 3. Comparisons for dry and critical water years indicate project-related increases of 9 and 5 acres of suitable spawning habitat, respectively, compared to 0 acres for Existing Conditions. These results indicate that Alternative 3 would have beneficial effects on splittail habitat through increasing spawning habitats by up to 272%.

Channel Margin and Side-Channel Habitat

Modeled flows were in the Sacramento River at Wilkins Slough (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for February to June splittail spawning and early life stage rearing period (Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*). Results indicate that Alternative 3 would have negligible effects (<5%) during February and March, small to moderate increases in flow (to 16%) during April, larger increases during May and June (to 39%) and only one small reduction in flow (-13%) during May in wet years. These results indicate that effects of Alternative 3 on flows would generally have beneficial effects on splittail spawning and rearing conditions in the upper Sacramento River.

Flows in the Feather River at the confluence with the Sacramento River were evaluated during February through June. Flows during this period would show variable effects of A3_LLT compared to Existing Conditions depending on month and water year type, with primarily negligible effects (<5%) or increases in flow (to 27%) that would have beneficial effects on rearing conditions. There would be occurrences of small (-11%) to moderate (-24%) decreases in mean monthly flow under Alternative 3, including in drier water year types during March (-12% in below normal years) and most of June (-11% and -17% in dry and critical years) when effects of flow reductions would be more critical for rearing conditions. These results indicate that for the majority of the rearing period, Alternative 3 would result in increased flow in the Feather River that would have a positive effect on splittail rearing in channel margin and side-channel habitats. Flow reductions in drier water years would be infrequent and of relatively small magnitude and would not have biologically meaningful effects on splittail spawning success.

Modeling results indicate no differences in project-related effects on water temperature for Alternative 3 relative to Alternative 1A in any of the rivers analyzed for splittail effects. Modeling results for Alternative 1A show that Sacramento splittail spawning temperature tolerances would not be exceeded in the Sacramento River and rarely exceeded in the Feather River. Therefore, impacts on spawning habitat for Sacramento splittail would not be biologically meaningful.

Stranding Potential

As described in the NEPA effects section above, rapid reductions in flow can dewater channel margin and side-channel habitats, potentially stranding splittail eggs and rearing larvae. Due to a lack of quantitative tools and historical data to evaluate possible stranding effects, potential effects have been evaluated with a narrative summary. Effects for Alternative 3 would be as described for Alternative 1A, which concludes that Yolo Bypass improvements would be designed, in part, to further reduce the risk of stranding by allowing water to inundate certain areas of the bypass to maximize biological benefits, while keeping water away from other areas to reduce stranding in isolated ponds.

Summary of CEQA Conclusion

Collectively, these results indicate the impact on spawning habitat for Sacramento splittail would be less than significant because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. No mitigation would be necessary. Alternative 3 would result in increased spawning habitat in Yolo Bypass, and would have negligible effects on spawning conditions based on stranding potential (flow reductions) and changes in water temperature. Effects of Alternative 3 on mean monthly flows would consist of less-than-significant impacts (<5% difference), beneficial impacts based on increases in mean monthly flow to 27%, and infrequent small (-11%) to moderate (-24%) decreases in flow that would not have biologically meaningful impacts on channel margin and side-channel rearing habitats.

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

In general, Alternative 3 would have beneficial effects on splittail rearing habitat relative to NAA based on the beneficial effects on floodplain habitat in the Yolo Bypass and channel margin and side-channel habitats in the Sacramento River and the Feather River described in the previous impact discussion, Impact AQUA-112. Sacramento splittail rear in floodplain and main-channel environments; the analyses of splittail weighted habitat area in Yolo Bypass and effects of flow conditions on channel margin and side-channel habitats provided in the previous impact apply to rearing as well as spawning habitat for splittail.

NEPA Effects: Effects of Alternative 3 on flow would not have meaningful negative effects on the availability of channel margin and main-channel habitat, and would have beneficial effects from increases in mean monthly flow. Increased flows into Yolo Bypass may reduce flooding and flooded rearing habitat to some extent in the Sutter Bypass but would create habitat in the Yolo Bypass that would have a beneficial effect on rearing conditions.

CEQA Conclusion: In general, operations under Alternative 3 would have beneficial impacts on splittail rearing habitat relative to the Existing Conditions based on the beneficial impacts on floodplain habitat in the Yolo Bypass and channel margin and side-channel habitats in the Sacramento River and the Feather River described in Impact AQUA-112. Impacts on splittail rearing habitat are about the same as described for spawning habitat in Impact AQUA-112. As concluded above, the impact would be less than significant and no mitigation would be required. Effects of Alternative 3 on flow would not have meaningful negative impacts on the availability of channel margin and main-channel habitat, and would have beneficial impacts from increases in mean monthly flow. Increased flows into Yolo Bypass may reduce flooding and flooded rearing habitat to some extent in the Sutter Bypass but would create habitat in the Yolo Bypass that would have a beneficial impact on rearing conditions.

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

In general, effects of Alternative 3 on splittail migration conditions would be beneficial relative to NAA based on increases in mean monthly flow in the Sacramento River and the Feather River.

Effects of Alternative 3 on migration conditions for Sacramento splittail would be about the same as described above for channel margin and side-channel environments (Impact AQUA-112).

NEPA Effects: As concluded above, the effect is not adverse. Effects of Alternative 3 on flow would not have meaningful negative effects on the availability of channel margin and main-channel habitat, and would have beneficial effects on migration conditions from increases in mean monthly flow.

CEQA Conclusion: In general, the impact of Alternative 3 on splittail migration conditions would be beneficial relative to the Existing Conditions based on increases in mean monthly flow in the Sacramento River and the Feather River.

Effects of Alternative 3 on migration conditions for Sacramento splittail would be about the same as described above for channel margin and side-channel environments (Impact AQUA-112). As concluded above, the impact would be less than significant and no mitigation would be necessary. Effects of Alternative 3 on flow would not have meaningful negative impacts on the availability of channel margin and main-channel habitat, and would have beneficial impacts on migration conditions from increases in mean monthly flow.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for Sacramento splittail under Alternative 1A (Impact AQUA-115 through AQUA-117) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

NEPA Effects: All three of these effects have been determined to result in no adverse effects on Sacramento splittail. Specifically for AQUA-116, the effects of contaminants on Sacramento splittail with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on Sacramento splittail are uncertain.

CEQA Conclusion: These three impacts would be considered less than significant for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for Sacramento splittail under Alternative 1A (Impact AQUA-118 through AQUA-126) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (CM12)

Impact AQUA-119: Effects of Invasive Aquatic Vegetation Management on Sacramento Splittail (CM13)

Impact AQUA-120: Effects of Dissolved Oxygen Level Management on Sacramento Splittail (CM14)

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (CM15)

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (CM16)

Impact AQUA-123: Effects of Illegal Harvest Reduction on Sacramento Splittail (CM17)

Impact AQUA-124: Effects of Conservation Hatcheries on Sacramento Splittail (CM18)

Impact AQUA-125: Effects of Urban Stormwater Treatment on Sacramento Splittail (CM19)

Impact AQUA-126: Effects of Removal/Relocation of Nonproject Diversions on Sacramento Splittail (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on Sacramento splittail for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on Sacramento splittail, for the reasons identified for Alternative 1A, and no mitigation is required.

Green Sturgeon

Construction and Maintenance of CM1

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

The potential effects of construction of water conveyance facilities on green sturgeon under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-127) except that Alternative 3 includes two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-127, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for green sturgeon

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-127, the impact of the construction of water conveyance facilities on green sturgeon would be less than significant except for construction noise associated with pile driving which would only occur for two intakes rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce the noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-128) expect that only two intakes would need to be maintained under Alternative 3 rather than five as under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-128, the effect would not be adverse for green sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-128, the impact of the maintenance of water conveyance facilities on green sturgeon would be less than significant and no mitigation would be required.

Water Operations of CM1

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

NEPA Effects: Alternative 3 would result in an overall reduction in entrainment of green sturgeon across all water years compared to NAA (Table 11-3-43). Similar to Alternative 1A, entrainment reductions would be greater in wet and above normal water year types (40% decrease, 47 fish) than in below normal, dry, and critical years (19% decrease, 2–10 fish) compared to NAA. Alternative 3 would not have adverse effects on juvenile green sturgeon and may be beneficial due to the reduction in entrainment at the south Delta export facilities for all water year types compared to NAA (Table 11-3-43).

Table 11-3-43. Juvenile Green Sturgeon Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences (Absolute and Percentage) between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year Type[b]	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet and Above Normal	-44 (-39%)	-47 (-40%)
Below Normal, Dry, and Critical	-2 (-15%)	-10 (-19%)
All Years	-51 (-32%)	-56 (-34%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on non-normalized data.

[b] Sacramento Valley water year-types.

Predation Associated with Entrainment

Juvenile green sturgeon predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. The total reduction of juvenile green sturgeon entrainment, and hence predation loss, would change minimally between Alternative 3 and NAA (56 fish). The number of juvenile green sturgeon lost to predation at the south Delta facilities would change negligibly between Alternative 3 and NAA. The impact and conclusion for predation risk associated with NPB structures and the north Delta intakes would be the same as described for Alternative 1A (Impact AQUA-129). The effect on predation loss under Alternative 3 would not be adverse.

CEQA Conclusion: As described above, annual entrainment losses of juvenile green sturgeon across all years would decrease by about 51 fish, or 32% under Alternative 3 (A3_LLT) relative to Existing Conditions (Table 11-3-43). Impacts of water operations on entrainment of green sturgeon would be beneficial and no mitigation would be required.

The impact and conclusion for predation associated with entrainment would be the same as described immediately above. Since few juvenile green sturgeon are entrained at the south Delta, reductions in entrainment (32% reduction compared to Existing Conditions, representing 51 fish) under Alternative 3, would have little effect on entrainment-related predation loss. Overall, the impact would be less than significant, because there would be little change in predation loss under Alternative 3.

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

In general, Alternative 3 would reduce spawning and egg incubation habitat for green sturgeon relative to the NAA.

Mean monthly flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon. Lower flows can reduce the instream area available for spawning and egg incubation. Flows under A3_LLT would always be similar to or greater than flows under NAA, indicating there would be very few reductions in flows in the Sacramento River under Alternative 3 although flows can be lower or higher in individual months of individual years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows were examined in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June green sturgeon spawning and egg incubation period. Flows under A3_LLT would be similar to or greater than flows under NAA in both locations, except in critical years during June at the confluence. These results indicate that there would be very few reductions in flows in the Feather River under Alternative 3 independent of climate change (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures in the Sacramento and Feather rivers under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-130, which indicates that there would be no effect on temperatures during the period evaluated relative to NAA.

Flows in the San Joaquin River at Vernalis under Alternative 3 during March through June would not be different from flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

No water temperatures modeling was conducted in the San Joaquin River.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. Flows in the Sacramento, Feather, and San Joaquin Rivers and water temperatures in the Sacramento and Feather Rivers would be similar between Alternative 3 and NAA during the green sturgeon spawning and egg incubation period.

CEQA Conclusion: In general, Alternative 3 would reduce spawning and egg incubation habitat for green sturgeon relative to the Existing Conditions.

Mean monthly flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon. Flows under A3_LLT would generally be similar to or greater than those under Existing Conditions, except in wet years during May at Keswick and Red Bluff (18% and 14% lower, respectively), and in below normal years during March at Keswick (6% lower) and in dry and critical years during July at Keswick (6% and 11% lower, respectively)and Red Bluff (6% and 10% lower, respectively) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Also, flows can be lower or higher in individual months of individual years. These results indicate that there would be few reductions in flows in the Sacramento River under Alternative 3 relative to the Existing Conditions.

Flows were examined in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the March through July green sturgeon spawning and egg incubation period. At Thermalito Afterbay, flows under A3_LLT would generally be similar to or greater than those under Existing Conditions, except in below normal years during February and March and in wet years during May, in which flows under A3_LLT would be up to 33% lower than under Existing Conditions (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). At the confluence with the Sacramento River, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions, except in below normal years during March, in wet years during May, and in most water years during June, in which flows under A3_LLT would be up to 24% lower than under Existing Conditions. These results indicate that there would be few reductions in flows in the Feather River under Alternative 3 relative to the Existing Conditions.

Water temperatures in the Sacramento and Feather Rivers under Alternative 3 would be the same as those under Alternative 1A, Impact AQUA-130, which indicates that temperatures would be higher in both rivers during the periods evaluated relative to Existing Conditions.

Flows in the San Joaquin River at Vernalis under Alternative 3 would be up to 43% lower than flows under Existing Conditions during the March through June spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

No water temperature modeling was conducted for the San Joaquin River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-96 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce the availability of suitable migration habitat and interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Flows in the Sacramento and Feather Rivers during the green sturgeon spawning and egg incubation period would be similar between Existing Conditions and Alternative 3. However, water temperatures in both rivers would be greater under Alternative 3 relative to Existing Conditions. Temperature increases in these rivers could lead to reduced hatching success and egg mortality under Alternative 3. Further, Flows in the San Joaquin River would be substantially lower throughout the spawning and egg incubation period under Alternative 3, which could reduce habitat conditions and lead to dewatering of eggs.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning and egg incubation habitat for green sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

In general, Alternative 3 would not affect the quantity and quality of green sturgeon larval and juvenile rearing habitat relative to NAA.

Water temperature was used to determine the potential effects of Alternative 3 on green sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates. Water temperatures in the Sacramento River and Feather River for Alternative 3 are not different from those for Alternative 1A, which indicates that Alternative 3 would not affect temperatures relative to NAA in either river relative to NAA.

Water temperature modeling was not conducted in the San Joaquin River.

NEPA Effects: Collectively, these results indicate that this effect would not be adverse because it does not have the potential to substantially reduce the amount of suitable rearing habitat. Water temperature conditions in the Sacramento and Feather Rivers under Alternative 3 would not differ from those under the NEPA baseline during the green sturgeon juvenile rearing period.

CEQA Conclusion: In general, Alternative 3 would not affect the quantity and quality of green sturgeon larval and juvenile rearing habitat relative to Existing Conditions.

Water temperature was used to determine the potential effects of Alternative 3 on green sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates. Water temperatures in the Sacramento River and Feather River for Alternative 3 are not different from those for Alternative 1A discussed in Impact AQUA-131, which indicates that there would be increase in temperatures in both rivers relative to Existing Conditions.

Water temperature modeling was not conducted in the San Joaquin River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-96 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce the availability of suitable migration habitat and interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Water temperatures would be higher under Alternative 3 relative to Existing Conditions in the Sacramento and Feather Rivers during the green sturgeon juvenile rearing period.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for green sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

In general, Alternative 3 would reduce green sturgeon migration conditions relative to NAA.

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick Dam and Wilkins Slough and in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through June adult migration period (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River flows under A3_LLT would generally be similar to or greater than flows under NAA in all months except August, September, and November, during which flows would be up to 45% lower depending on location, month, and water year type.

Feather River flows under A3_LLT would generally be lower by up to 84% than those under NAA during July through September. Flows during other months under A3_LLT would generally be similar to or greater than flows under NAA with some exceptions.

Larval transport flows were also examined by utilizing the positive correlation between white sturgeon year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved green sturgeon larval transport that results in improved year class strength. Results for white sturgeon presented in Impact AQUA-150 below suggest that, using the positive correlation between Delta outflow and year class strength, green sturgeon year class strength would be lower under Alternative 3.

NEPA Effects: Collectively, these results indicate that the effect would be adverse because it has the potential to substantially interfere with the movement of green sturgeon. Reductions in flows in the Sacramento and Feather rivers during summer and fall months would affect the migratory abilities of larvae and juveniles by slowing or inhibiting downstream migration of larvae and juveniles.

This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. Even so, proposed mitigation (Mitigation Measure AQUA-132a through AQUA-132c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 3 would reduce green sturgeon migration conditions relative to the Existing Conditions.

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick Dam and Wilkins Slough and in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through July adult migration period (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions in all months except August, September, and November, during which flows would be up to 27% lower than under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. Flows under A3_LLT during other months would generally be similar to or greater than flows under Existing Conditions.

Flows in the Feather River under A3_LLT would generally be up to 54% lower than flows under Existing Conditions in June, July, August, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. Flows during other months under A3_LLT would generally be similar to or greater than flows under Existing Conditions.

For Delta outflow, the percent of months exceeding flow thresholds under A3_LLT would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (14% to 60% lower on a relative scale) (see Table 11-1A-70 below).

Summary of CEQA Conclusion

Collectively, these results indicate that the impact would be significant because it has the potential to substantially interfere with the movement of fish. The reduction in flows in the Sacramento and Feather Rivers would reduce the migration periods of larval, juvenile, and adult migration, which would substantially slow or inhibit their downstream migration. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-132a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Green Sturgeon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Although analysis conducted as part of the EIR/EIS determined that Alternative 3 would have significant and unavoidable adverse effects on migration, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on migration in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 3.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 3 operations only. Development of mitigation actions for the incremental impact on migration attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 3.

Mitigation Measure AQUA-132b: Conduct Additional Evaluation and Modeling of Impacts on Green Sturgeon Migration Conditions Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to migration under Alternative 3. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-132c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Green Sturgeon Migration Conditions Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on green sturgeon habitat, the BDCP proponents will consult with NMFS, USFWS, and CDFW to identify and implement any feasible operational means to minimize effects on migration. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-132a.

If feasible means are identified to reduce impacts on migration consistent with the overall operational framework of Alternative 3 without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on green sturgeon habitat is not feasible under Alternative 3 operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on green sturgeon would remain significant and unavoidable.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for green sturgeon under Alternative 1A (Impact AQUA-133 through AQUA-135) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

NEPA Effects: All three of these effects have been determined to result in no adverse effects on green sturgeon for the reasons identified for Alternative 1A. Specifically for AQUA-134, the effects of contaminants on green sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on green sturgeon are uncertain.

CEQA Conclusion: All three of these impacts would be considered less than significant for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for green sturgeon under Alternative 1A (Impact AQUA-136 through AQUA-144) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (CM12)

Impact AQUA-137: Effects of Invasive Aquatic Vegetation Management on Green Sturgeon (CM13)

Impact AQUA-138: Effects of Dissolved Oxygen Level Management on Green Sturgeon (CM14)

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (CM15)

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (CM16)

Impact AQUA-141: Effects of Illegal Harvest Reduction on Green Sturgeon (CM17)

Impact AQUA-142: Effects of Conservation Hatcheries on Green Sturgeon (CM18)

Impact AQUA-143: Effects of Urban Stormwater Treatment on Green Sturgeon (CM19)

Impact AQUA-144: Effects of Removal/Relocation of Nonproject Diversions on Green Sturgeon (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on green sturgeon for the reasons identified for Alternative 1A.

CEQA Conclusions: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on green sturgeon, for the reasons identified for Alternative 1A, and no mitigation is required.

White Sturgeon

Construction and Maintenance of CM1

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

The potential effects of construction of water conveyance facilities on white sturgeon under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-145) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-145, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for white sturgeon

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-145, the impact of the construction of water conveyance facilities on white sturgeon would be less than significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only two intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

> **Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise**
>
> Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.
>
> **Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise**
>
> Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-146) except that only two intakes would require maintenance under Alternative 3 rather than five as under

Alternative 1A. As concluded in Alternative 1A, Impact AQUA-146, the effect would not be adverse for white sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-146, the impact of the maintenance of water conveyance facilities on white sturgeon would be less than significant and no mitigation would be required.

Water Operations of CM1

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Alternative 3 is expected to reduce overall entrainment of juvenile white sturgeon at the south Delta export facilities, estimated as salvage density, by about 32% (105 fish) across all water year types as compared to NAA (Table 11-3-44). Similar to Alternative 1A, entrainment would be highest in wet and above normal water years. Under Alternative 3, entrainment in wet and above normal water years would be reduced 33% (96 fish), compared to NAA. Therefore, Alternative 3 would not have adverse effects on juvenile white sturgeon and may be beneficial.

Overall, the potential entrainment impacts of Alternative 3 on juvenile white sturgeon would be similar to those described for Alternative 1A for operating new SWP/CVP north Delta intakes, NPBs at the entrances to CCF and the DMC, and decommissioning agricultural diversions in ROAs. These actions have the potential to minimize or reduce entrainment, and may be beneficial to white sturgeon.

Table 11-3-44. Juvenile White Sturgeon Entrainment Index[a] at the SWP and CVP Salvage Facilities for Sacramento Valley Water Year-Types and Differences (Absolute and Percentage) between Model Scenarios for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year Types[b]	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wet and Above Normal	-74 (-28%)	-96 (-33%)
Below Normal, Dry, and Critical	-6 (-16%)	-9 (-22%)
All Years	-80 (-26%)	-105 (-32%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on non-normalized data.
[b] Sacramento Valley water year-types.

Predation Associated with Entrainment

Juvenile white sturgeon predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. The number of juvenile white sturgeon lost to predation at the south Delta facilities would change negligibly between Alternative 3 and NAA. The impact and conclusion for predation risk associated with NPB structures and the north Delta intakes would be the same as described for Alternative 1A (Impact AQUA-147).

NEPA Effects: Overall, the potential entrainment and predation impacts of Alternative 3 on juvenile white sturgeon would not be adverse, for the reasons described for Alternative 1A.

CEQA Conclusion: As described above, annual entrainment losses of juvenile white sturgeon associated with water exports from SWP/CVP south Delta facilities would result in an overall decrease in entrainment of 26% (80 fish) under Alternative 3 relative to Existing Conditions (Table 11-3-44). Impacts of water operations on entrainment of white sturgeon would be less than significant and may be beneficial. No mitigation would be required.

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

In general, Alternative 3 would not affect spawning and egg incubation habitat for white sturgeon relative to NAA.

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon. Flows at both locations under A3_LLT from February to May would be mostly similar to or greater than those under NAA, except in wet years during April (7% lower) at Verona (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These results indicate that there would be mostly small reductions in flows in the Sacramento River under Alternative 3.

Flows in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT would be similar to or greater than flows under NAA during February to May. Flows under A3_LLT at the confluence would always be similar to or greater than flows under NAA. These results indicate that there would be very few reductions in flows in the Feather River during the white sturgeon spawning and egg incubation period under Alternative 3.

Flows in the San Joaquin River under Alternative 3 would not be different from those under NAA throughout the February through May period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.Water temperatures in the Sacramento and Feather Rivers under Alternative 3 would not be different from those under Alternative 1A, Impact AQUA-148, which indicates that temperatures would not differ from those under NAA throughout the February through May period.

Water temperatures were not modeled in the San Joaquin River.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. Reductions in flows and increases in water temperatures under Alternative 3 are small and infrequent relative to NAA and, therefore, would not have a substantial effect on the species.

CEQA Conclusion: In general, Alternative 3 would not affect spawning and egg incubation habitat for white sturgeon relative to the Existing Conditions.

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). At Wilkins Slough, flows under A3_LLT would be similar to or greater than those under Existing Conditions, except in wet years during May (13% lower). At Verona, flows under A3_LLT from February to May would be generally similar to or greater than Existing Conditions, except for below normal and critical years during February (6% and 7% lower, respectively), below normal years during March (13% lower), wet and above normal years during April (8% and 7% lower, respectively), and wet years during May (19% lower). These results indicate that there would be mostly small reductions in flows in the Sacramento River under Alternative 3 relative to Existing Conditions.

Flows in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows at Thermalito Afterbay from February to May under A3_LLT would generally be similar to or greater than those under Existing Conditions, except in below normal years during February and March (22% and 33% lower, respectively) and in wet years during May (30% lower). Flows at the confluence with the Sacramento River under A3_LLT would generally be similar to or greater than flows under Existing Conditions, except in below normal years during March (12% lower) and wet years during May (24% lower). These results indicate that there would be few reductions in flows in the Feather River under Alternative 3 relative to Existing Conditions.

Flows in the San Joaquin River under Alternative 3 would be similar to flows under Existing Conditions during February and up to 43% lower during March through July.

Water temperatures in the Sacramento and Feather Rivers under Alternative 3 would be generally the same as those under Alternative 1A, Impact AQUA-148, which indicates that there would no effect on temperatures relative to Existing Conditions.

Temperatures were not modeled for the San Joaquin River.

Collectively, the results of the Impact AQUA-148 CEQA analysis indicate that the difference between the Existing Conditions and Alternative 3 could be significant because, under the Existing Conditions, the alternative could substantially reduce the availability of suitable spawning and egg incubation habitat, contrary to the NEPA conclusion set forth above. There would be substantial reductions in the majority of the white sturgeon spawning and egg incubation period in the San Joaquin River under Alternative 3 relative to Existing Conditions, which would reduce the quality and quantity of habitat available for spawning and egg incubation in the river. There would be no other flow- or temperature-related effects of Alternative 3 on white sturgeon spawning and egg incubation.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning and egg incubation habitat for white sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

In general, Alternative 3 would not affect the quantity and quality of white sturgeon larval and juvenile rearing habitat relative to NAA.

Water temperature was used to determine the potential effects of Alternative 3 on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Water temperatures in the Sacramento and Feather Rivers under Alternative 3 would not be different from those under Alternative 1A, Impact AQUA-149, which indicates that there would be no effect on temperatures in either river relative to Existing Conditions.

Water temperatures were not modeled for the San Joaquin River.

NEPA Effects: Collectively, these results indicate that this effect would not be adverse because it does not have the potential to substantially reduce the amount of suitable rearing habitat. Water temperature conditions in the Sacramento and Feather Rivers under Alternative 3 would not differ from those under the NEPA baseline during the white sturgeon juvenile rearing period.

CEQA Conclusion: In general, Alternative 3 would not affect the quantity and quality of white sturgeon larval and juvenile rearing habitat relative to Existing Conditions.

Water temperature was used to determine the potential impacts of Alternative 3 on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Water temperatures in the Sacramento and Feather rivers under Alternative 3 would not be different from those under Alternative 1A, which indicates that there would be no effect on temperatures in the Sacramento River relative to Existing Conditions, but temperatures would be higher than those under Existing Conditions during the majority of months in the Feather River.

Water temperatures were not modeled for the San Joaquin River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-149 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce the availability of suitable migration habitat and interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Water temperatures would be higher under Alternative 3 relative to Existing Conditions in Feather Rivers during the green sturgeon juvenile rearing period, but would be similar between Existing Conditions and Alternative 3 in the Sacramento River.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for green sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

In general, the effects of Alternative 3 on white sturgeon migration conditions relative to NAA are uncertain.

Analyses for white sturgeon focused on the Sacramento River (north Delta to RM 143—i.e., Wilkins Slough and Verona CALSIM nodes). Larval transport flows were represented by the average number of months per year that exceeded thresholds of 17,700 cfs (Wilkins Slough) and 31,000 cfs (Verona) (Table 11-3-45). Exceedances of the 17,700 cfs threshold for Wilkins Slough under A3_LLT were generally similar to those under NAA. The number of months per year above 31,000 cfs at Verona under A3_LLT would be up to 50% lower than under NAA. On an absolute scale, all of these changes would be negligible (up to 0.2 months).

Table 11-3-45. Difference and Percent Difference in Number of Months in Which Flow Rates Exceed 17,700 and 5,300 cfs in the Sacramento River at Wilkins Slough and 31,000 cfs at Verona

	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Wilkins Slough, 17,700 cfs[a]		
Wet	-0.04 (-2%)	0 (0%)
Above Normal	0.3 (18%)	0.1 (5%)
Below Normal	-0.1 (-25%)	0 (0%)
Dry	0 (0%)	0 (0%)
Critical	0 (0%)	0 (0%)
Wilkins Slough, 5,300 cfs[b]		
Wet	-0.1 (-2%)	0.1 (1%)
Above Normal	0 (0%)	0.3 (5%)
Below Normal	0.2 (4%)	0.5 (10%)
Dry	0.6 (11%)	0.3 (5%)
Critical	0.3 (10%)	0.3 (7%)
Verona, 31,000 cfs[a]		
Wet	-0.5 (-21%)	-0.2 (-9%)
Above Normal	-0.1 (-5%)	0.1 (6%)
Below Normal	-0.2 (-43%)	-0.1 (-33%)
Dry	-0.2 (-60%)	-0.1 (-50%)
Critical	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] Months analyzed: February through May.
[b] Months analyzed: November through May.

Larval transport flows were also examined by utilizing the positive correlation between year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved larval transport that results in improved year class strength. The percentage of months exceeding flow thresholds under A3_LLT would generally be lower than those under NAA (up to 50% lower) (Table 11-3-46). These results suggest that, using the positive correlation between Delta outflow and year class strength, year class strength would be lower under Alternative 3.

Table 11-3-46. Difference and Percent Difference in Percentage of Months in Which Average Delta Outflow is Predicted to Exceed 15,000, 20,000, and 25,000 Cubic Feet per Second in April and May of Wet and Above-Normal Water Years

Flow	Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
April			
15,000 cfs	Wet	-15 (-16%)	-15 (-16%)
	Above Normal	-25 (-27%)	-25 (-27%)
20,000 cfs	Wet	-12 (-14%)	-12 (-14%)
	Above Normal	-33 (-44%)	-25 (-38%)
25,000 cfs	Wet	-15 (-19%)	-12 (-15%)
	Above Normal	-17 (-29%)	-8 (-17%)
May			
15,000 cfs	Wet	-15 (-17%)	-8 (-10%)
	Above Normal	-33 (-40%)	-8 (-14%)
20,000 cfs	Wet	-35 (-41%)	-12 (-19%)
	Above Normal	-25 (-60%)	-17 (-50%)
25,000 cfs	Wet	-31 (-44%)	-19 (-33%)
	Above Normal	-17 (-50%)	-8 (-33%)
April/May Average			
15,000 cfs	Wet	-15 (-16%)	-8 (-9%)
	Above Normal	-33 (-33%)	-25 (-27%)
20,000 cfs	Wet	-23 (-26%)	-19 (-23%)
	Above Normal	-17 (-25%)	0 (0%)
25,000 cfs	Wet	-19 (-24%)	-8 (-11%)
	Above Normal	-25 (-50%)	-25 (-50%)

For juveniles, year-round migration flows at Verona would be up to 54% lower under A3_LLT relative to NAA during four of 12 months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For adults, the average number of months per year during the November through May adult migration period in which flows in the Sacramento River at Wilkins Slough exceed 5,300 cfs was determined (Table 11-3-45). The average number of months exceeding 5,300 cfs under A3_LLT would always be similar to greater than the number of months under NAA.

NEPA Effects: Upstream flows (above north Delta intakes) are similar between Alternative 3 and NAA (Table 11-3-45). However, due to the removal of water at the north Delta intakes, there are substantial differences in through-Delta flows between Alternative 3 and NAA (Table 11-5-46). Analysis of white sturgeon year-class strength (USFWS 1995) found a positive correlation between year class strength and Delta outflow during April and May. However, this conclusion was reached in the absence of north Delta intakes and the exact mechanism that causes this correlation is not known at this time. One hypothesis suggests that the correlation is caused by high flows in the upper river resulting in improved migration, spawning, and rearing conditions in the upper river. Another hypothesis suggests that the positive correlation is a result of higher flows through the Delta triggering more adult sturgeon to move up into the river to spawn. It is also possible that some combination of these factors are working together to produce the positive correlation between high flows and sturgeon year-class strength.

The scientific uncertainty regarding which mechanisms are responsible for the positive correlation between year class strength and river/Delta flow will be addressed through targeted research and monitoring to be conducted in the years leading up to the initiation of north Delta facilities operations. If these targeted investigations determine that the primary mechanisms behind the positive correlation between high flows and sturgeon year-class strength are related to upstream conditions, then Alternative 3 would be deemed Not Adverse due to the similarities in upstream flow conditions between Alternative 3 and NAA. However, if the targeted investigations lead to a conclusion that the primary mechanisms behind the positive correlation are related to in-Delta and through-Delta flow conditions, then Alternative 3 would be deemed adverse due to the magnitude of reductions in through-Delta flow conditions in Alternative 3 as compared to NAA.

CEQA Conclusion: In general, Alternative 3 would not affect white sturgeon migration conditions relative to Existing Conditions.

The number of months per year with exceedances above the 17,700 cfs threshold for Wilkins Slough under A3_LLT would generally be similar to or greater those under Existing Conditions, except in below normal years (25% lower) (Table 11-3-45). The number of months per year above 31,000 cfs at Verona under A3_LLT would be similar to or up to 60% lower than the number under Existing Conditions.

For Delta outflow, the percent of months exceeding flow thresholds under A3_LLT would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (14% to 60% lower on a relative sacle) (Table 11-3-46).

For juveniles, year-round migration flows at Verona would be up to 36% lower under A3_LLT relative to Existing Conditions in four of 12 months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under A3_LLT during other months are generally similar to or greater than flows under Existing Conditions.

For adult migration, the average number of months exceeding 5,300 cfs under A3_LLT would generally be similar to the number of months under Existing Conditions (Table 11-3-45).

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-150 CEQA analysis indicate that the difference between the Existing Conditions and Alternative 3 could be significant because, under the Existing Conditions, the alternative could substantially reduce the quality of suitable rearing habitat, contrary to the NEPA conclusion set forth above. The exceedance of flow thresholds in the Sacramento River and for Delta outflow would be lower under Alternative 3 than under the Existing Conditions, although there is high uncertainty that year class strength is due to Delta outflow or if both year class strength and Delta outflows are co-variable with another unknown factor. These reduced flows could have a substantial effect on the ability of sturgeon to migrate downstream, including delaying or slowing rates of successful migration downstream, and increasing the risk of mortality.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion of not adverse, and therefore would not in itself result in a significant impact on migration habitat of white sturgeon. Additionally, as described above in the NEPA Effects statement, further investigation is needed to better understand the association of Delta outflow to sturgeon recruitment, and if needed, adaptive management would be used to make adjustments to meet the biological goals and objectives. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for white sturgeon under Alternative 1A (Impact AQUA-151 through AQUA-153) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

NEPA Effects: As described in Alternative 1A, none of these impact mechanisms would be adverse to white sturgeon, and most would be at least slightly beneficial. Specifically for AQUA-152, the effects of contaminants on white sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on white sturgeon are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for white sturgeon under Alternative 1A (Impact AQUA-154 through AQUA-162) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (CM12)

Impact AQUA-155: Effects of Invasive Aquatic Vegetation Management on White Sturgeon (CM13)

Impact AQUA-156: Effects of Dissolved Oxygen Level Management on White Sturgeon (CM14)

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (CM15)

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (CM16)

Impact AQUA-159: Effects of Illegal Harvest Reduction on White Sturgeon (CM17)

Impact AQUA-160: Effects of Conservation Hatcheries on White Sturgeon (CM18)

Impact AQUA-161: Effects of Urban Stormwater Treatment on White Sturgeon (CM19)

Impact AQUA-162: Effects of Removal/Relocation of Nonproject Diversions on White Sturgeon (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on white sturgeon for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on white sturgeon, for the reasons identified for Alternative 1A, and no mitigation is required.

Pacific Lamprey

Construction and Maintenance of CM1

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

The potential effects of construction of water conveyance facilities on Pacific lamprey under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-163) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in

Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-163, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for Pacific lamprey

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-163, the impact of the construction of water conveyance facilities on Pacific lamprey would be less than significant except for construction noise associated with pile driving which would only occur for two intakes rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-164) except that only two intakes would be maintained under Alternative 3 rather than five as under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-164, the effect would not be adverse for Pacific lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-164, the impact of the maintenance of water conveyance facilities on Pacific lamprey would be less than significant and no mitigation would be required.

Water Operations of CM1

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

The potential entrainment impacts of Alternative 3 on Pacific lamprey would be similar but less than those described above for Alternative 1A for operating new SWP/CVP north Delta intakes (Impact AQUA-165), non-physical barriers at the entrances to Clifton Court Forebay and the Delta Mendota Canal (Impact AQUA-3), and decommissioning agricultural diversions in ROAs (Impact AQUA-3).

Under Alternative 3, average annual entrainment of Pacific lamprey at the south Delta export facilities, as estimated by salvage density, would be reduced by 25% (834 fish) (Table 11-3-47) across all water year types compared to NAA. Therefore, Alternative 3 would not have adverse effects on Pacific lamprey and may be beneficial because of the potential reduction of entrainment at Delta water export facilities.

Predation Associated with Entrainment

Lamprey predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Average pre-screen predation loss for fish entrained at the south Delta is 75% at Clifton Court Forebay and 15% at the CVP. Lamprey entrainment to the south Delta would be reduced by 25% compared to NAA and predation losses would be expected to be reduced at a similar proportion. The impact and conclusion for predation risk associated with NPB structures would be the same as described for Alternative 1A.

Predation at the north Delta would be increased due to the construction of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta is unknown because of the lack of knowledge about their distribution and population abundances in the Delta.

NEPA Effects: The overall effect of entrainment and predation on lamprey from Alternative 3 is considered not adverse, for the reason describe for Alternative 1A.

CEQA Conclusion: As described above, annual entrainment losses of Pacific lamprey would be decreased under Alternative 3 (A3_LLT) relative to Existing Conditions by 28% (939 fish).

Impacts of water operations on entrainment of Pacific lamprey are expected to be less than significant, and no mitigation would be required.

Table 11-3-47. Pacific Lamprey Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
All Years	-939 (-28%)	-834 (-25%)
	Shading indicates entrainment increased 10% or more.	

[a] Estimated annual number of fish lost, based on non-normalized data.

The impact and conclusion for predation associated with entrainment would be about the same as described above because the additional predation losses associated with the proposed north Delta intakes would be offset by the reduction in predation loss at the south Delta. The relative impact of predation loss on the lamprey population is unknown because there is little available knowledge on their distribution and abundance in the Delta. The impact would be less than significant. No mitigation would be required.

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

In general, Alternative 3 would reduce the quantity and quality of Pacific lamprey spawning habitat relative to NAA.

Flow-related effects on Pacific lamprey spawning habitat were evaluated by estimating effects of flow alterations on redd dewatering risk and effects of water temperature. Rapid reductions in flow can dewater redds leading to mortality. Dewatering risk was analyzed for the Sacramento River at Keswick, Sacramento River at Red Bluff, Trinity River downstream of Lewiston, Feather River at

Thermalito Afterbay, and American River at Nimbus Dam and at the confluence with the Sacramento River. Pacific lamprey spawn in these rivers between January and August. Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Water temperature results from the SRWQM and the Reclamation Temperature Model were used to assess the exceedances of water temperatures under all model scenarios in the upper Sacramento, Trinity, Feather, and American Rivers.

Flows in all rivers evaluated indicate negligible effects (<5%) or an increase in redd cohorts exposed to month-over-month flow reductions between January and August for Alternative 3 compared to NAA, indicates project-related increases would only occur in the Feather River, which would consist of a 40% increase in dewatering risk. (Table 11-3-48). Project-related effects in all other locations analyzed consist of negligible effects (<5%) that would not have biologically meaningful effects or decreases in dewatering risk (to -21% in the Sacramento River) that would have beneficial effects on spawning success.

Table 11-3-48. Differences between Model Scenarios in Dewatering Risk of Pacific Lamprey Redd Cohorts[a]

Location	Comparison[b]	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Sacramento River at Keswick	Difference	11	-11
	Percent Difference	20%	-14%
Sacramento River at Red Bluff	Difference	3	-15
	Percent Difference	6%	-21%
Trinity River downstream of Lewiston	Difference	1	1
	Percent Difference	1%	1%
Feather River at Thermalito Afterbay	Difference	1	43
	Percent Difference	1%	40%
American River at Nimbus Dam	Difference	33	-4
	Percent Difference	39%	-3%
American River at Sacramento River confluence	Difference	42	2
	Percent Difference	44%	3%

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%.

[b] Positive values indicate a higher value in Alternative 3 than under the baseline (EXISTING CONDITIONS or NAA).

For evaluation of effects of Alternative 3 on water temperatures, it was determined that the effects of Alternative 3 on water temperatures for the Sacramento River, Trinity River, and the American River would be similar to that for Alternative 1A. Results from Alternative 1A, Impact AQUA-166 indicate that egg exposure would be similar to NAA at most locations, although egg exposure would substantially increase in the Feather River below Thermalito Afterbay.

NEPA Effects: Collectively, these results indicate that the effect would be adverse because it has the potential to substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. There would be increases in egg cohorts (exposed to redd dewatering risk (43 cohorts or 40%) and temperatures greater than 71.6°F (84 cohorts or 91%) in the Feather River below Thermalito Afterbay. Increased redd dewatering risk and exposure risk to egg cohorts below Thermalito Afterbay would reduce spawning success there. This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect. Even so, proposed mitigation (Mitigation Measure AQUA-166a through AQUA-166c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 3 would reduce the quantity and quality of Pacific lamprey spawning habitat relative to the Existing Conditions.

Rapid reductions in flow can dewater redds leading to mortality. Predicted effects of Alternative 3 in the Sacramento River and American River are for increases in the number of redd cohorts predicted to experience a month-over-month change in flow of greater than 50% relative to Existing Conditions (Table 11-3-48). Changes would be most substantial for the American River, with increased risk of dewatering exposure to 33 cohorts or 39% at Nimbus Dam, and 42 cohorts or 44% at the confluence. Effects of Alternative 3 would be negligible (<5%) for the Trinity River and Feather River.

For evaluation of effects of Alternative 3 on water temperatures, it was determined that the effects of Alternative 3 on water temperatures for the Sacramento River, Trinity River, Feather River, and the American River would be similar to those described for Alternative 1A. Results from Alternative 1A, Impact AQUA-166 indicate that egg exposure would be greater than under Existing Conditions at the Sacramento, Feather, and American Rivers.

Summary of CEQA Conclusion

Collectively, these results indicate that the impact would be significant because it has the potential to substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. Effects of Alternative 3 on Pacific lamprey redd dewatering risk would be biologically meaningful in the Sacramento River (based on 20% increase in exposure risk) and the American River (based on a maximum of 44% increase in exposure risk) and would not have significant effects on dewatering risk in the Feather River and Trinity River. In addition, egg exposure to elevated temperatures would be greater than that under Existing Conditions at the Sacramento, Feather, and American Rivers.

This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not necessarily to a less-than-significant level.

Mitigation Measure AQUA-166a: Following Initial Operations of CM1, Conduct Additional Evaluation and Modeling of Impacts to Pacific Lamprey to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Although analysis conducted as part of the EIR/EIS determined that Alternative 3 would have significant and unavoidable adverse effects on spawning habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of CM1 and continuing through the life of the permit, the BDCP proponents will monitor effects on spawning habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 3.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 3 operations only. Development of mitigation actions for the incremental impact on spawning habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 3.

Mitigation Measure AQUA-166b: Conduct Additional Evaluation and Modeling of Impacts on Pacific Lamprey Spawning Habitat Following Initial Operations of CM1

Following commencement of initial operations of CM1 and continuing through the life of the permit, the BDCP proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to spawning habitat under Alternative 3. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program required by the BDCP (Chapter 3 of the BDCP, Section 3.6).

Mitigation Measure AQUA-166c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Pacific Lamprey Spawning Habitat Consistent with CM1

In order to determine the feasibility of reducing the effects of CM1 operations on Pacific lamprey habitat, the BDCP proponents will consult with NMFS, USFWS and CDFW to identify and implement any feasible operational means to minimize effects on spawning habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-166a.

If feasible means are identified to reduce impacts on spawning habitat consistent with the overall operational framework of Alternative 3 without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on Pacific lamprey habitat is not feasible under Alternative 3 operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on Pacific lamprey would remain significant and unavoidable.

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

In general, effects of Alternative 3 on flow would be negligible relative to NAA.

Flow-related impacts on Pacific lamprey rearing habitat were evaluated by estimating effects of flow alterations on ammocoete stranding risk and effects of water temperatures. Ammocoete stranding risk was analyzed for the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. The analysis of ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort was considered stranded if at least one month-over-month flow reduction was greater than the flow reduction at any time during the period.

Effects of Alternative 3 on Pacific lamprey ammocoete stranding were analyzed by calculating month-over-month flow reductions for the Sacramento River at Keswick for January through August (Table 11-3-49). Results indicate primarily no effect (0%) compared to NAA, with the exception of a small increase (7%) in 65% flow reductions that would not have biologically meaningful effects on stranding conditions and a small decrease (-9%) in 80% flow reduction exposures that would have a small, beneficial effect. These results indicate that Alternative 3 would not have biologically meaningful effects on Pacific lamprey ammocoete stranding conditions at Keswick.

Table 11-3-49. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

-80%	9	-9
-85%	4	0
-90%	NA	NA

NA = all values were 0.

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 3.

Results of comparisons for the Sacramento River at Red Bluff provide similar conclusions, with slightly more variability in results (Table 11-3-50). Results for Alternative 3 compared to NAA indicate no change (0%), negligible to small increases (to 5%) that would not have biologically meaningful effects on stranding conditions, and small decreases (to -9%) that would have a small, beneficial effect on stranding conditions. These results indicate that Alternative 3 would not have biologically meaningful effects on Pacific lamprey ammocoete stranding conditions at Red Bluff.

-90%	34	-1

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 3.

Comparisons for the Feather River indicate no difference (0%) or negligible project-related effects (<5%) for flow reductions up to 80%, and substantial decreases in cohorts exposed to 85% flow reductions (-42%) and 90% flow reductions (-28%) under Alternative 3, compared to NAA. This would have a beneficial effect on spawning success. (Table 11-3-52). These results indicate that Alternative 3 would not have biologically meaningful effects on Pacific lamprey ammocoete stranding conditions in the Feather River.

Table 11-3-52. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Feather River at Thermalito Afterbay

-90%	-64	-28

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 3.

Comparisons for the American River at Nimbus Dam (Table 11-3-53) indicate negligible effects (<5%) for most flow reduction categories, a small increase (8%) in cohorts exposed to 90% flow reductions, and small decreases (to -15%) in cohorts exposed to 70%, 80%, and 85% flow reductions for Alternative 3 compared to NAA. These results would have a beneficial effect on spawning success, and Alternative 3 would not have biologically meaningful effects on Pacific lamprey ammocoete stranding conditions in the American River at Nimbus Dam.

Table 11-3-53. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, American River at Nimbus Dam

-85%	332	-15
-90%	225	8

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 3.

Comparisons for the American River at the confluence with the Sacramento River (Table 11-3-54) (A3_LLT compared to NAA) indicates negligible effects (<5%) on cohort exposure for all flow reduction categories. These results indicate that Alternative 3 would not have biologically meaningful effects on Pacific lamprey ammocoete stranding conditions in the American River at the confluence with the Sacramento River.

Table 11-3-54. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, American River at the Confluence with the Sacramento River

	Percent Difference[a]

-55%	0	0
-60%	1	0
-65%	1	0
-70%	4	-4
-75%	41	3
-80%	198	1
-85%	250	0
-90%	339	5

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 3.

Because water temperatures under Alternative 3 would be similar to those under Alternative 1A, results of the analysis on ammocoete exposure to elevated temperatures for Alternative 3 would be similar to that for Alternative 1A. Results from Alternative 1A, Impact AQUA-167 indicate that there would be small to moderate increases and decreases in exposure relative to NAA that will balance out within rivers such that there would be no overall effect on Pacific lamprey ammocoetes.

NEPA Effects: Collectively these results indicate that effects would not be adverse because they would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. Alternative 3 would generally cause no effect (0%), negligible effects (<5%), isolated categories of flow reductions that would experience a small increase in cohort exposure but that would not have biologically meaningful adverse effects, or small decreases in stranding risk that would have beneficial effects. There would also be small, beneficial effects in the Sacramento River (decreased occurrence of month-over-month flow reductions to -12%) and more substantial beneficial effects in the Feather River (up to -15% in exposures to 70%, 80%, and 85% flow reductions) due to project-related effects of Alternative 3. There would be small to moderate increases and decreases in ammocoete exposure to elevated water temperatures relative to Existing Conditions that will balance out within rivers such that there would be no overall effect on Pacific lamprey ammocoetes.

CEQA Conclusion: In general, under Alternative 3 water operations, the quantity and quality of Pacific lamprey rearing habitat would not be affected relative to the CEQA baseline.

Comparisons of month-over-month flow reductions under Alternative 3 relative to Existing Conditions for the Sacramento River at Keswick indicate negligible changes (<5%) in occurrence of cohort exposure for all flow reduction categories with the exception of a small increase in exposure (9%) in the 80% flow reduction category (Table 11-3-49). These results indicate that effects of Alternative 3 on flow would not have biologically meaningful effects on Pacific lamprey ammocoete stranding risk in the Sacramento River at Keswick.

Comparisons of Alternative 3 to Existing Conditions for the Sacramento River at Red Bluff indicate negligible changes (<5%) in occurrence of cohort exposure for all flow reduction categories with the exception of small increases in exposure in the 60% (increase of 7%), 70% (increase of 9%), and 80% (increase of 5%) flow reduction categories, and a more substantial increase in the 90% flow reduction category (100% or from 56 to 112 cohorts exposed) (Table 11-3-49). These results indicate that effects of Alternative 3 on flow would cause increased risk of Pacific lamprey ammocoete stranding in the Sacramento River at Red Bluff but not to the extent that would be considered a biologically meaningful effect.

In the Trinity River, Alternative 3 would have no effect on cohort exposure for the lower flow reduction categories, and would cause moderate increases in cohort exposure (to 34%) for flow reductions from 75% to 90% (Table 11-3-51). The effects of Alternative 3 on flow reduction exposures are consistent for the higher flow reduction categories but of relatively small magnitude and therefore effects would not have biologically meaningful effects on rearing success.

In the Feather River, Alternative 3 would have no effect (0% difference) or negligible effects (<5%) on cohort exposure for the lower flow reduction categories, and would have a moderate increase in cohort exposure (24%) to flow reductions of 85% and a more substantial increase (64%) in exposures to flow reductions of 90% (Table 11-3-52). Based on the fact that moderate to substantial increases in cohort exposure would only occur for the two highest flow reduction categories, these results indicate that effects of Alternative 3 on flow would not have biologically meaningful effects on rearing success.

Comparisons for the American River at Nimbus Dam (Table 11-3-53) and at the confluence with the Sacramento River (Table 11-3-54) predict increased occurrence of cohort exposures under A3_LLT relative to Existing Conditions for 70% through 90% flow reduction events; predicted increases ranged from 27 to 332% for Nimbus Dam (increase from 56 to 252 cohorts exposed) and from 41 to 339% (increase from 56 to 246 cohorts exposed) for the confluence. These are substantial increases in cohort stranding exposure that would have negative effects on rearing success.

Because water temperatures under Alternative 3 would be similar to those under Alternative 1A, results of the analysis on ammocoete exposure to elevated temperatures for Alternative 3 would be similar to that for Alternative 1A. Results from Alternative 1A, Impact AQUA-167 indicate that there would be substantial increases in ammocoete exposure in all rivers relative to Existing Conditions.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-167 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of ammocoete mortality, contrary to the NEPA conclusion set forth above. Alternative 3 would have biologically meaningful effects in the American River at Nimbus Dam and at the confluence with the Sacramento River based on substantial increases in the number of cohorts exposed to stranding risk due to flow reductions in each of the higher flow reduction categories (increases ranging from 27 to 332% for Nimbus Dam and from 41 to 339% for the confluence). Alternative 3 would not affect ammocoete stranding risk in the Sacramento River, Trinity River, and the Feather River (based on negligible effects, reduced occurrence of flow reduction events, or moderate increases in risk, to 34%, and/or more substantial but isolated increases in risk, to 64%, that would not have biologically meaningful effects). There would be substantial increases in ammocoete exposure to increased temperatures in all rivers evaluated.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for Pacific lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

In general, effects of Alternative 3 on Pacific lamprey migration conditions would be negligible relative to NAA.

Macropthalmia

After 5–7 years Pacific lamprey ammocoetes migrate downstream and become macropthalmia once they reach the Delta. Migration generally is associated with large flow pulses in winter months (December through March) (U.S. Fish and Wildlife Service unpublished data) meaning alterations in flow have the potential to affect downstream migration conditions. The effects of Alternative 3 on seasonal migration flows for Pacific lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the migration pathways of Pacific lamprey during the likely outmigration period (December through May) were examined for the Sacramento River at Rio Vista and Red Bluff, the Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

Sacramento River

Effects of Alternative 3 on mean monthly flow rates for the Sacramento River at Rio Vista (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May compared to NAA would be primarily negligible effects (<5%) or decreases in flow to -15%, with small increases in flow during December in dry years (7%) and during May in dry years (8%). Meaningful (>5%) project-related reductions in flow would occur in drier water years (when effects on migration would be more critical) during January (-10% in critical years), March (below normal and dry years to -13%), and April (-6% in below normal years). These project-related decreases in flow are relatively infrequent during the migration period and of small magnitude and would not have biologically meaningful effects on macropthalmia migration success.

For the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), the difference in mean monthly flow rate for Alternative 3 compared to NAA for the December through May migration period indicates primarily negligible effects (<5%) or increases in flow to 15%, which would have a beneficial effect on migration conditions, and only a single occurrence of a small, project-related reduction in flow (-8%) during January in critical years. These results indicate that the effects of Alternative 3 on flow would not have biologically meaningful effects on outmigrating macropthalmia at this location.

Feather River

Comparisons for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate negligible project-related effects (<5%) or increases in flow to 42% which would have beneficial effects on migration conditions, with the exception of a single, project-related decreases in flow during January in critical years (-9%). Based on the predominance of negligible effects and/or increases in flow that would be beneficial for migration, this alternative would not have negative effects on macropthalmia migration in the Feather River at the confluence, compared to NAA.

American River

Comparisons for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December through May (A3_LLT compared to NAA) indicates project-related effects consist primarily of negligible effects (<5%), with small to moderate increases in flow (to 36%) during some months/water years that would be beneficial for migration, and with small decreases in flow (to -9%) predicted to occur during March in dry and critical years. These isolated, small decreases in flow would not have biologically meaningful effects on outmigrating macropthalmia in the American River. These results indicate that Alternative 3 would not have biologically meaningful effects on macropthalmia migration in the American River.

Overall, flow-related effects of Alternative 3 on outmigrating macropthalmia are not biologically meaningful in any of the rivers analyzed. Effects on flow would consist of negligible effects (<5%), small to moderate increases in flow that would have a beneficial effect on migration conditions, or infrequent and relatively small decreases in flow which would not have biologically meaningful effects on Pacific lamprey macropthalmia migration in the rivers analyzed.

Adults

Sacramento River

For the Sacramento River at Red Bluff for the time-frame January to June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), effects of Alternative 3 on mean monthly flow consist primarily of negligible effects (<5%) or infrequent, small increases in flow (to 13%) and a single occurrence of a small decrease in flow (-8%) during January in critical years. These results indicate that effects of Alternative 3 on flow would not have biologically meaningful effects on adult migration in the Sacramento River, relative to NAA.

Feather River

For the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) during January to June, mean monthly flows under Alternative 3 would be similar to (<5% difference) or greater than (to 32%) flows under NAA, for most months and water year types, with the exception of small decreases in flow during January in critical years (-9%) and during June in critical years (-8%). The predominance of increases in flow would have beneficial effects on migration conditions, and the few, small decreases would not have biologically meaningful effects on migration conditions. These results indicate that effects of Alternative 3 on flow would not have biologically meaningful effects on adult migration conditions in the Feather River, relative to NAA.

American River

Comparisons of mean monthly flow for the American River at the confluence with the Sacramento River for January to June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) (A3_LLT compared to NAA) indicates predominantly negligible effects (<5%) or increases in flow (to 36%) attributable to the project with the exception of small decreases in flow during March in dry (-7%) and critical (-9%) years. The predominance of increases in flow would have beneficial effects on migration conditions and the few, small decreases would not have biologically meaningful effects on migration conditions. These results indicate that effects of Alternative 3 on flow would not have biologically meaningful effects on adult migration conditions in the American River, relative to NAA.

Overall, these results indicate that project-related effects of Alternative 3 on mean monthly flows during the Pacific lamprey adult migration period would consist of negligible effects (<5%) or increases in flow (up to 36%) that would have beneficial effects on migration conditions, with a few isolated, small decreases that would not have biologically meaningful effects on migration conditions.

NEPA Effects: Collectively, these results indicate that the effect of Alternative 3 on Pacific lamprey macropthalmia and adult migration is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. There would be no biologically meaningful effects of Alternative 3 on flows in any river evaluated during the Pacific lamprey macropthalmia and adult migration periods.

CEQA Conclusion: In general, Alternative 3 would not affect the quantity and quality of Pacific lamprey migration habitat relative to the CEQA baseline.

Macropthalmia

Sacramento River

Comparisons of mean monthly flow rates in the Sacramento River at Rio Vista (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May for Alternative 3 relative to Existing Conditions indicate primarily negligible effects (<5%), or reductions in flow ranging from -5% to -36%. Effects in drier water year types when flow reductions would be most critical for migration conditions consist of negligible effects or small decreases (to -10%) that would not have biologically meaningful effects on migration conditions in all months during the migration period. These results indicate that Alternative 3 would not affect Pacific lamprey macropthalmia migration conditions in the Sacramento River at Rio Vista.

Comparisons for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate negligible (<5%) effects or increases in flow (to 19%) for Alternative 3 relative to Existing Conditions for all months and water years, which would have beneficial effects on migration conditions, with the exception of a small decrease in flow (-14%) during May in wet years when it would not negatively affect migration conditions. These results indicate that effects of Alternative 3 on flow would not have biologically meaningful effects on outmigrating macropthalmia in the Sacramento River at Red Bluff.

Feather River

Comparisons for the Feather River at the confluence (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate effects of Alternative 3 compared to Existing Conditions consist of negligible effects (<5%) or increases in flow (to 38%) that would have beneficial effects on migration conditions, with the exception of small decreases in flow during January in below normal years (-10%) and during March in below normal years (-12%), and a slightly larger reduction during May in wet years (-24%) when effects of flow reductions on migration conditions would be less critical. Flow reductions would be infrequent, of small magnitude, and of the greatest magnitude during wet years and therefore would not have biologically meaningful negative effects. These results indicate that the effects of Alternative 3 on flow would not have negative effects on outmigrating macropthalmia in the Feather River.

American River

Comparisons for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate variable results depending on the specific month and water year, with negligible effects (<5%) or decreases in flow (to -22%) during December, increases in wetter water years (to 28%) and decreases in drier water years (to -17%) during January through March, negligible effects (<5)% and small-scale increases or decreases (to -8%) during April, and reductions in flow (to -27%) during May in all but dry years (increase of 20%). Based on small to moderate reductions in flow (to -22%) in drier water years during most of the migration period (December through March and May), the effects of Alternative 3 on flow would affect conditions for outmigrating macropthalmia in the American River at the confluence.

Overall, flow-related effects of Alternative 3 on outmigrating macropthalmia are not biologically meaningful in the Sacramento River and Feather River (based on negligible effects on flow, increases in flow that would have beneficial effects, and isolated and/or small magnitude decreases in flow that would not have negative effects on migration conditions), but would cause negative effects on migration conditions in the American river (based on small to moderate flow reductions for most of the migration period).

Adults

Sacramento River

Comparisons of mean monthly flow for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) during the Pacific lamprey adult migration period from January through June indicate primarily negligible effects (<5%) or increases in flow (to 20%) that would have a beneficial effect on migration conditions, with the exception of a small decrease in mean monthly flow in May during wet years (-14%) when effects of flow reductions on migration conditions would be less critical. These results indicate that Alternative 3 would not have biologically meaningful effects on migration conditions in the Sacramento River at Red Bluff.

Feather River

Comparisons of mean monthly flow for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January to June indicate effects of Alternative 3 consist primarily of negligible effects (<5%) or increases in flow (to 27%) that would have beneficial effects on migration, with the exception of small decreases (to -12%) during January and March in below normal years that would not have biologically meaningful effects on migration conditions, a moderate reduction (-24%) during May in wet years when effects of flow reductions would be less critical for migration, and more prevalent reductions (to -20% in wet, dry and critical years) during June which is late in the migration period. Based on these results, effects of Alternative 3 on flow would not have biologically meaningful negative effects on adult migration conditions in the Feather River.

American River

Comparisons of mean monthly flow for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January to June indicate variable effects of Alternative 3 depending on the month and water year type, with negligible effects (<5%) or increases in flow (to 28%) in wetter water years and decreases (to -17%) in drier water years for January through March, negligible effects or small increases or decreases in flow (to 8%) during April, reductions in flow (to -27%) in all but dry years (increase of 20%) during May and decreases in wet (-28%) and critical years (-45%) in June with increases (to 33%) in above and below normal years. Small to moderate flow reductions would occur in drier years during most of the migration period, with the most substantial reductions occurring during January, May, and June (the onset and end of the migration period), Alternative 3 would affect adult migration conditions in the American River.

Overall, effects of Alternative 3 on adult Pacific lamprey migration conditions consist of negligible effects on flow (<5%), increases in flow that would be beneficial for migration conditions, and infrequent and/or small decreases in flow that would not have biologically meaningful negative effects in the rivers analyzed. There would be more substantial reductions in flow under Alternative 3 in the Feather River and the American River; however, based on the prevalence and magnitude of the effects, and the fact that the largest flow reductions would occur late in the migration period (June), it is concluded that effects of Alternative 3 on flow would not have biologically meaningful effects on migration conditions in these locations.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-168 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Alternative 3 would affect outmigrating macropthalmia and adult migration conditions in the American River (based on moderate flow reductions in drier years, to 22% for juvenile migration and to -45% for adult migration) during most months in the respective migration periods. Alternative 3 would not affect outmigrating macropthalmia or migrating adults in the Sacramento River and the Feather River (based on negligible effects on flow, increases in flow, to 38%, that would have beneficial effects, and decreases in flow in wet years, to -36%, or as isolated, -20%, and/or small magnitude, to -12%, decreases in flow in drier water years that would not have negative effects on migration conditions).

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on Pacific lamprey macropthalmia and adult migration habitat. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for Pacific lamprey under Alternative 1A (Impact AQUA-169 through AQUA-171) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

NEPA Effects: As described in Alternative 1A, none of these impact mechanisms would be adverse to Pacific lamprey, and most would be at least slightly beneficial.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for Pacific lamprey under Alternative 1A (Impact AQUA-172 through AQUA-180) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (CM12)

Impact AQUA-173: Effects of Invasive Aquatic Vegetation Management on Pacific Lamprey (CM13)

Impact AQUA-174: Effects of Dissolved Oxygen Level Management on Pacific Lamprey (CM14)

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (CM15)

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (CM16)

Impact AQUA-177: Effects of Illegal Harvest Reduction on Pacific Lamprey (CM17)

Impact AQUA-178: Effects of Conservation Hatcheries on Pacific Lamprey (CM18)

Impact AQUA-179: Effects of Urban Stormwater Treatment on Pacific Lamprey (CM19)

Impact AQUA-180: Effects of Removal/Relocation of Nonproject Diversions on Pacific Lamprey (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on Pacific lamprey for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusion: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on Pacific lamprey, for the reasons identified for Alternative 1A, and no mitigation is required.

River Lamprey

Construction and Maintenance of CM1

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

The potential effects of construction of water conveyance facilities on river lamprey under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-181) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in

Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-181, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for river lamprey

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-181, the impact of the construction of water conveyance facilities on river lamprey would be less than significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only two intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 3 would be similar to those described for Alternative 1A (see Impact AQUA-182) except that only two intakes would need to be maintained under Alternative 3 rather than five as under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-182, the impact would not be adverse for river lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-182, the impact of the maintenance of water conveyance facilities on river lamprey would be less than significant and no mitigation would be required.

Water Operations of CM1

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

The potential entrainment impacts of Alternative 3 on river lamprey would be proportionally similar to those described for Alternative 1A for operating new SWP/CVP north Delta intakes (Impact AQUA-183), non-physical barriers at the entrances to Clifton Court Forebay and the Delta Mendota Canal (Impact AQUA-183), and decommissioning agricultural diversions in ROAs (Impact AQUA-183). These actions would minimize or reduce potential entrainment.

NEPA Effects: Under Alternative 3, average annual entrainment of lamprey at the south Delta export facilities, as estimated by salvage density, would be reduced by 25% (834 fish) (Table 11-3-55) across all water year types compared to NAA. Therefore, Alternative 3 would not have adverse effects on lamprey.

Table 11-3-55. Lamprey Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities - for Alternative 3

	Absolute Difference (Percent Difference)	
Water Year Types	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
All Years	-939 (-28%)	-834 (-25%)
	Shading indicates entrainment increased 10% or more.	

a Estimated annual number of fish lost, based on non-normalized data.

CEQA Conclusion: As described above, annual entrainment losses of lamprey would be decreased under Alternative 3 (A3_LLT) relative to Existing Conditions by 28% (939 fish). Impacts of water operations on entrainment of river lamprey are considered less than significant, and no mitigation would be required.

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

In general, effects of Alternative 3 on river lamprey spawning conditions would be negligible relative to the NAA based.

Flow-related impacts on river lamprey spawning habitat were evaluated by estimating effects of flow alterations on redd dewatering risk as described for Pacific lamprey with appropriate time-frames for river lamprey incorporated into the analysis. Rapid reductions in flow can dewater redds leading to mortality. The same locations were analyzed as for Pacific lamprey: the Sacramento River at Keswick and Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and American River at Nimbus Dam and at the confluence with the Sacramento River. River lamprey spawn in these rivers between February and June so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage).

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, and substrate) of river lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, as described for Pacific lamprey, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, February to June.

Results for the Sacramento River indicate that there would be no biologically meaningful effects in any location evaluated (Table 11-3-56). In the Feather River, the effect is of small magnitude (9%) and would not have biologically meaningful effects on dewatering risk.

Table 11-3-56. Differences between Model Scenarios in Dewatering Risk of River Lamprey Redd Cohorts[a]

Location	Comparison[b]	EXISTING CONDITIONS vs. A3_LLT	NAA vs. A3_LLT
Sacramento River at Keswick	Difference	4	1
	Percent Difference	13%	3%
Sacramento River at Red Bluff	Difference	2	0
	Percent Difference	5 %	0%
Trinity River downstream of Lewiston	Difference	-4	-2
	Percent Difference	-6%	-3%
Feather River Below Thermalito Afterbay	Difference	-5	5
	Percent Difference	-7%	9%
American River at Nimbus	Difference	10	1
	Percent Difference	18%	2%
American River at Sacramento River confluence	Difference	16	-1
	Percent Difference	27%	-1%

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%.

[b] Positive values indicate a higher value in Alternative 3 than under the baseline (EXISTING CONDITIONS or NAA).

Because water temperatures under Alternative 3 would be similar to those under Alternative 1A, results of the analysis on river lamprey egg exposure to elevated temperatures for Alternative 3 would be similar to that for Alternative 1A. Results from Alternative 1A, Impact AQUA-184 indicate that egg exposure would be similar to NAA at most locations, although egg exposure would moderately increase in the Feather River below Thermalito Afterbay. Because this is isolated to a single location in the Feather River, it is not expected to cause a population level effect on river lamprey.

NEPA Effects: These results indicate that the effect is not adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. Effects of Alternative 3 on flow would have negligible effects (<5%) in all locations on redd dewatering risk and exposure to elevated temperatures, with the exception of a single increase in elevated water temperature exposure in one location, that would not have biologically meaningful effects on spawning success.

CEQA Conclusion: In general, effects of Alternative 3 on river lamprey spawning conditions would be negligible relative to the Existing Conditions.

Rapid reductions in flow can dewater redds leading to mortality. Flow-related impacts on river lamprey spawning habitat were evaluated by estimating effects of flow alterations on redd dewatering risk as described for Pacific lamprey with appropriate time-frames for river lamprey incorporated into the analysis, and evaluation of effects of Alternative 3 on water temperatures.

Conclusions for Alternative 1A are that effects of Alternative 3 on flow reductions during the river lamprey spawning period from February to June in the Sacramento River and American River consist of negligible effects (<5%) in the Sacramento River at Red Bluff, Trinity River, and Feather

River (Table 11-3-56). There would be increases in river lamprey redd cohort dewatering risk relative to Existing Conditions for the Sacramento River at Keswick (13%), and for the American River at Nimbus Dam (15%) and at the confluence (27%).

Because water temperatures under Alternative 3 would be similar to those under Alternative 1A, results of the analysis on egg exposure to elevated temperatures for Alternative 3 would be similar to that for Alternative 1A. Results from Alternative 1A, Impact AQUA-184 indicate that egg exposure would be greater than under Existing Conditions at the Sacramento, Feather, American, and Stanislaus Rivers.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-184 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially, reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above. River lamprey egg exposure to elevated water temperatures would be greater than under Existing Conditions at the Sacramento, Feather, American, and Stanislaus Rivers. However, there would be negligible effects (<5%) on redd dewatering in the Sacramento River at Red Bluff, the Trinity River, and the Feather River; the increased exposure of river lamprey redd cohorts to dewatering from the project predicted for the Sacramento River at Keswick and the American River consist of small (13%, 15%) to moderate (27%) increased risks of dewatering that would not have biologically meaningful negative effects.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning and egg incubation habitat for river lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

In general, effects of Alternative 3 on river lamprey rearing conditions would be negligible relative to the NAA,.

Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Flow-related effects on river lamprey rearing habitat were evaluated by estimating effects of flow alterations on ammocoete exposure, or stranding risk, as described for Pacific lamprey. Effects of Alternative 3 on flow were evaluated in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River. As for Pacific lamprey, the analysis of river lamprey ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (February through June) and spend 5 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than the flow reduction at any time during the period.

For evaluation of ammocoete stranding risk, comparisons of Alternative 3 to NAA for the Sacramento River at Keswick (Table 11-3-57) indicated either no effect (0%), negligible effects (<5% difference), or a small increase (11%) or decrease (-7%) in cohort exposure due to flow reductions attributable to the project. These results indicate that the project-related effects of Alternative 3 on flow reductions consist of negligible or small effects on ammocoete exposure to flow reductions and would not cause biologically meaningful effects in the Sacramento River at Keswick.

Note: Negative values indicate reduced cohort exposure, a benefit of Alternative 3.
NA = could not be calculated because the denominator was 0.

Results of comparisons for the Sacramento River at Red Bluff (Table 11-3-58) indicate no change (0%) or negligible effects (<5%) attributable to the project with the exception of a small increase (5%) in exposure to 60% flow reductions, which would not have biologically meaningful negative effects, and a decrease (-14%) in exposure to 75% flow reductions, which would have a small beneficial effect. These results indicate that the effects of Alternative 3 on flow reductions would not have biologically meaningful effects on river lamprey ammocoete stranding in the Sacramento River at Red Bluff, relative to NAA.

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 3.

Comparisons for the Trinity River negligible effects (<5%) or reductions in exposures (-5%) in all flow categories attributable to the project, under Alternative 3 relative to NAA (Table 11-3-59). These results indicate that project-related effects of Alternative 3 on flow would not have biologically meaningful effects on river lamprey ammocoete stranding in the Trinity River.

Comparisons for the Feather River (A3_LLT compared to NAA) indicate negligible effects (<5%) or reductions in exposures (to -32%) in all flow categories attributable to the project, which would have beneficial effects on ammocoete rearing success (Table 11-3-60). These results indicate that project-related effects of Alternative 3 on flow would not have biologically meaningful negative effects on river lamprey ammocoete stranding in the Feather River, relative to NAA.

Comparisons for the American River at Nimbus Dam(A3_LLT compared to NAA) (Table 11-3-61) and at the confluence with the Sacramento River (Table 11-3-62) indicate no effect (0%), negligible effects (<5%), or small increases or decreases (to 12%) that would not have biologically meaningful effects on spawning success. These results indicate that project-related effects of Alternative 3 on flow would not have biologically meaningful negative effects on river lamprey ammocoete stranding in the American River, relative to NAA.

-85%	330	0
-90%	396	7

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 3.

Because water temperatures under Alternative 3 would be similar to those under Alternative 1A, results of the analysis on ammocoete exposure to elevated temperatures for Alternative 3 would be similar to that for Alternative 1A. Results from Alternative 1A, Impact AQUA-185 indicate that there would be small to moderate increases and decreases in exposure relative to NAA that will balance out within rivers such that there would be no overall effect on river lamprey ammocoetes.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. Effects of Alternative 3 on ammocoete rearing in all locations analyzed would consist of negligible effects on flow reductions (<5% difference), small increases in occurrence of one or more flow reduction categories (to 12%) that would not have biologically meaningful effects, and small to substantial reductions (7% to 32% lower) in occurrence of flow reductions that would have beneficial effects on rearing success. Decreased occurrence of flow reduction events (i.e., a beneficial effect) would be most consistent and of the greatest magnitude in the Feather River, with reductions up to 32% for all flow reduction categories. In addition, there would be small to moderate increases and decreases in ammocoete exposure to elevated water temperatures that will balance out within rivers such that there would be no overall effect on river lamprey ammocoetes.

CEQA Conclusion: In general, under Alternative 3 water operations, the quantity and quality of spawning and egg incubation habitat for river lamprey rearing habitat would not be affected relative to the CEQA baseline.

Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Flow-related effects on river lamprey rearing habitat were evaluated by estimating effects of flow alterations on ammocoete exposure, or stranding risk, as described for Pacific lamprey, and effects of Alternative 3 on water temperature.

For evaluation of ammocoete stranding risk, comparisons of Alternative 3 to Existing Conditions for the Sacramento River at Keswick indicate negligible effects (<5%) on the number of ammocoete cohorts exposed to flow reductions for all flow reduction categories (Table 11-3-57) with the exception of a small increase (12%) in month-over-month flow reductions of 65% and a 44%

increase in reductions of 85%. Comparisons for the Sacramento River at Red Bluff indicate slightly more variable results with negligible effects (<5%) for all flow reduction categories except for small increases (5% to 12%) in the 55%, 60%, and 70% flow reduction categories, and a more substantial increase (100%, or from 25 to 50 cohorts) in the 85% flow reduction category (Table 11-3-58). While there would be a fairly substantial increase in the number of cohorts exposed to the 85% reduction category, effects would be negligible or small in all other flow reduction categories and therefore conclusions are that effects of Alternative 3 on flow reductions would not have biologically meaningful effects on river lamprey ammocoete stranding in the Sacramento River.

Comparisons for the Trinity River indicated no effect (0%) for flow reduction categories from 50% to 70%, and increases ranging from 24% to 47% for the higher flow reduction categories (Table 11-3-59). These consistent and more substantial increases in ammocoete cohort exposures to larger flow reductions would have negative effects on ammocoete rearing success through meaningful increases in risk of stranding.

Comparisons for the Feather River indicated no effect or reductions in frequency of occurrence for all flow reduction categories with the exception of a small increase in cohort exposure (5%) to 85% flow reductions (Table 11-3-60). These results indicate that the effects of Alternative 3 on flow would not have biologically meaningful effects on river lamprey ammocoete stranding in the Feather River.

Comparisons for the American River at Nimbus Dam (Table 11-3-61) and at the confluence with the Sacramento River (Table 11-3-62) indicate increased ammocoete cohort exposures to flow reductions between 70 and 90% for Alternative 3 compared to Existing Conditions; meaningful (>5%) predicted increases are from 117 to 420% (increase in cohorts exposed from 25 to 130) for Nimbus Dam and from 15 to 396% (increase in cohorts exposed from 25 to 124) for the confluence. These consistent and substantial increases in ammocoete cohorts exposed to flow reductions would have negative effects on ammocoete rearing success through increased risk of stranding in the American River.

Because water temperatures under Alternative 3 would be similar to those under Alternative 1A, results of the analysis on ammocoete exposure to elevated temperatures for Alternative 3 would be similar to that for Alternative 1A. Results from Alternative 1A, Impact AQUA-185 indicate that there would be moderate to large increases in ammocoete exposure under Alternative 1A relative to Existing Conditions in all rivers evaluated that would substantially reduce rearing habitat conditions.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-185 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of ammocoete mortality, contrary to the NEPA conclusion set forth above. Alternative 3 would have substantial effects on ammocoete cohort stranding in the Trinity River (increases to 47% for the larger flow reduction categories) and American River (increases to 420% for the larger flow reduction categories), but would not have effects in the Sacramento River and the Feather River (based on negligible effects, <5%, small increases, to 12%, in some flow reduction categories, or larger, isolated increases, to 100%, in a single flow reduction category). In addition, there would be moderate to large increases in ammocoete exposure in all rivers evaluated that would substantially reduce rearing habitat conditions for river lamprey.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for river lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

In general, effects of Alternative 3 on river lamprey migration conditions would be negligible relative to the NAA.

Macropthalmia

After 3 to 5 years river lamprey ammocoetes migrate downstream and become macropthalmia once they reach the Delta. River lamprey migration generally occurs September through November (U.S. Fish and Wildlife Service unpublished data). The effects of water operations on seasonal migration flows for river lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the likely migration pathways of river lamprey during the likely migration period (September through November) were examined to predict how Alternative 3 may affect migration flows for outmigrating macropthalmia.

Analyses were conducted for the Sacramento River at Red Bluff, Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

Sacramento River

Comparisons for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for September through November (A3_LLT compared to NAA) indicates negligible effects (<5%) or project-related decreases (to -43%) in wetter water years during September and a moderate increase (17%) in critical years, more substantial increases to 33% during October in all water years, and decreases to -29% during November in all water years. The more substantial decreases in flow during September would occur in wetter water years when effects on migration would be less critical. Increases in mean monthly flow during October would have a beneficial effect on migration, and decreases during drier years (when effects would be more critical for migration) during November are relatively small (-23% in below normal years, -13% in dry years, and -8% in critical years). These results indicate that while flow reductions would occur, flow reductions would not be consistent or substantial enough throughout the migration period to have biologically meaningful effects on outmigrating macropthalmia.

Feather River

Comparisons for the Feather River at the confluence with the Sacramento River for September through November indicate decreases in mean monthly flows (to -68%) during September in all but critical years (increase of 9%), primarily increased flows during October (to 23%), and small decreases during November in wetter water years (to -11%) and a small increase (6%) or negligible effect (<5%) in drier years. Isolating the effects of the project from the effects of climate change (A3_LLT compared to NAA) indicates project-related effects would cause decreases in mean monthly flow during September in wetter years (to -53%) when effects on migration would be less critical, and increases (to 19%) in drier years which would have a beneficial effect on migration; primarily increases during October (to 56%) which would have beneficial effects on migration conditions, and negligible effects (<5%) or small increases or decreases during November (to 13%) which would not have biologically meaningful effects on migration conditions. These results indicate that effects of Alternative 3 on flow would not have biologically meaningful effects on river lamprey macropthalmia migration in the Feather River.

American River

Comparisons for the American River at the confluence with the Sacramento River for September through November indicate substantial reductions in flows during September in all water years (-31 to -58%), and during November in all water years (-13% to -39%). Flow during October would increase in all water years (18% to 40%). Isolating the effects of the project from the effects of climate change (A3_LLT compared to NAA) indicates a slightly smaller project-related contribution to decreased flows during September in wetter water years (to -50%) and a negligible effect (<5%) and small increase (6%) in drier water years when flow effects would be more critical for migration, increases in mean monthly flows during October in all water years (to 33%) which would have beneficial effects on migration, and negligible project-related changes during November except for relatively small decrease in mean monthly flow (-15%) in above normal water years. These results indicate that project-related effects of Alternative 3 on flows would not have biologically meaningful effects on river lamprey macropthalmia migration in the American River.

Overall, despite some variation in results by location, month, and water year type, these results indicate that Alternative 3 would not have biologically meaningful effects on river lamprey macropthalmia migration.

Adults

Effects of Alternative 3 on flow during the adult migration period, September through November, would be the same as described for the macropthalmia migration period, September through November, above.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. Effects of Alternative 3 on flow would generally consist of negligible effects (<5% difference), increases in mean monthly flow, to 56%, that would have beneficial effects on migration conditions, small to moderate decreases, to -29%, in drier years that would not occur with sufficient frequency to have biologically meaningful effects, and more substantial decreases in flow, to -53%, that would occur in wetter years when flow reductions would not have negative effects on migration conditions due to higher flow conditions.

CEQA Conclusion: In general, under Alternative 3 water operations, the quantity and quality of river lamprey migration habitat would not be affected relative to the CEQA baseline.

Macropthalmia

Sacramento River

Comparisons for the Sacramento River at Red Bluff for September through November indicate variable effects of Alternative 3 during September, with negligible effects (<5%) or a small increase in flow (9%, above normal years), with the exception of moderate flow reductions in wet years (-24%) and dry years (-20%). Effects during October would consist of increases in mean monthly flow for all water year types (14 to 30%) that would have a beneficial effect on migration conditions. Effects during November would consist of relatively small to moderate reductions in mean monthly flow (-5% to -21%) in all water years, with the maximum flow reduction in a drier water year type of -15% (dry years). Flow reductions during September (-20%) and November (-15%) in dry years, and smaller reductions during November in below normal (-13%) and critical years (-10%), would have incremental effects on migration conditions. However, these effects would be offset by more substantial increases in October. Overall effects of Alternative 3 on flows would not have biologically meaningful effects on river lamprey macropthalmia migration conditions in the Sacramento River.

Feather River

Comparisons for the Feather River at the confluence with the Sacramento River for September through November indicate variable results by month and water year type, with primarily decreases (to -24%) during September with the exception of an increase (14%) in critical years, primarily increases in mean monthly flow during October (to 40%), and negligible effects (<5%) or small-scale increases (6%) or decreases (to -13%) in flow that would not be of a magnitude to cause biologically meaningful effects. While decreases for some of the drier water years during September and below normal years during November would contribute incrementally to migration conditions, overall effects of Alternative 3 on flows would not have biologically meaningful negative effects on river lamprey macropthalmia migration conditions in the Feather River.

American River

Comparisons for the American River at the confluence with the Sacramento River for September through November indicate reductions in flow during September and November in all water year types, ranging from -15 to -55%, and increases in mean monthly flow during October for all water years ranging from 9% to 30%. The increases in mean monthly flow during October would have a beneficial effect on migration conditions, but the predominance of moderate to substantial decreased flows under Alternative 3 during September and November in all water years (with decreases during drier water years ranging from -15% to -55%) would have negative effects on river lamprey macropthalmia migration conditions in the American River.

Overall, these results indicate that effects of Alternative 3 on flow from September through November would not have biologically meaningful effects on river lamprey macropthalmia migration in the Sacramento River and the Feather River, but would have negative effects in the American River.

Adults

Effects of Alternative 3 on flow during the adult migration period, September through November, would be the same as described for the macropthalmia migration period, September through November, above.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-186 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 3 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Effects of Alternative 3 on flow would be substantial for river lamprey macropthalmia and adult migration conditions in the American River based on substantial flow reductions for all water year types, including in drier years (to -55%), during two out of three months of the migration period. There would be no negative effects of Alternative 3 on flow in the Sacramento River or Feather River based on negligible effects (<5% difference), increases in mean monthly flow (to 40%) that would have beneficial effects on migration, moderate decreases (to -24%) in wetter years when effects on migration would not be as critical, and infrequent, small to moderate decreases in drier years (to -20%) that would not have biologically meaningful effects.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 3. This indicates that the differences between Existing Conditions and Alternative 3 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration conditions for river lamprey. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 3 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for river lamprey under Alternative 1A (Impact AQUA-187 through AQUA-189) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

NEPA Effects: All three of these effects have been determined to result in no adverse effects on river lamprey for the reasons identified for Alternative 1A.

CEQA Conclusion: All three of these impacts would be considered less than significant for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 3 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 3 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for river lamprey under Alternative 1A (Impact AQUA-190 through AQUA-198) also appropriately characterize effects under Alternative 3.

The following impacts are those presented under Alternative 1A that are identical for Alternative 3.

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (CM12)

Impact AQUA-191: Effects of Invasive Aquatic Vegetation Management on River Lamprey (CM13)

Impact AQUA-192: Effects of Dissolved Oxygen Level Management on River Lamprey (CM14)

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (CM15)

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (CM16)

Impact AQUA-195: Effects of Illegal Harvest Reduction on River Lamprey (CM17)

Impact AQUA-196: Effects of Conservation Hatcheries on River Lamprey (CM18)

Impact AQUA-197: Effects of Urban Stormwater Treatment on River Lamprey (CM19)

Impact AQUA-198: Effects of Removal/Relocation of Nonproject Diversions on River Lamprey (CM21)

NEPA Effects: The nine impact mechanisms have been determined to range from no effect, to no adverse effect, or beneficial effects on river lamprey for NEPA purposes, for the reasons identified for Alternative 1A.

CEQA Conclusions: The nine impact mechanisms would be considered to range from no impact, to less than significant, or beneficial on river lamprey, for the reasons identified for Alternative 1A, and no mitigation is required.

Non-Covered Aquatic Species of Primary Management Concern

Construction and Maintenance of CM1

The effects of construction and maintenance of CM1 under Alternative 3 would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

Refer to Impact AQUA-1 under delta smelt for a discussion of the effects of construction of water conveyance facilities on non-covered species of primary management concern. The potential effects of the construction of water conveyance facilities under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-1) except that Alternative 3 would include two intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 4,450 lineal feet of existing shoreline habitat into intake facility structures and would require about 10.2 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. The effects related to temporary increases in turbidity, accidental spills, underwater noise, in-water work activities, and disturbance of contaminated sediments would be similar to Alternative 1A and the same environmental commitments and mitigation measures (described under Impact AQUA-1 for delta smelt and in Appendix 3B, *Environmental Commitments*) would be available to avoid and minimize potential effects. Additionally, California bay shrimp would not be affected because they do not occur in the vicinity and Sacramento-San Joaquin roach and hardhead are unlikely to be affected because their primary distributions are upstream.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-199, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for non-covered aquatic species of primary management concern.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-1, the impact of the construction of the water conveyance facilities on non-covered aquatic species of primary management concern would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only two intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

Refer to Impact AQUA-2 under delta smelt for a discussion of the effects of maintenance of water conveyance facilities on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude, and range of impact mechanisms that are relevant to the aquatic environment and aquatic species.

NEPA Effects: The potential effects of the construction of water conveyance facilities under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-200). For a detailed discussion, please see Alternative 1A, Impact AQUA-200. California bay shrimp would not be affected because they do not occur in the vicinity and Sacramento-San Joaquin roach and hardhead are unlikely to be affected because their primary distributions are upstream. Consequently, the effects would not be adverse.

CEQA Conclusion: As described above, these impacts would be less than significant.

Water Operations of CM1

The effects of water operations of CM1 under Alternative 3 include a detailed analysis of the following species:

- Striped Bass
- American Shad
- Threadfin Shad
- Largemouth Bass
- Sacramento tule perch
- Sacramento-San Joaquin roach—California species of special concern
- Hardhead—California species of special concern
- California bay shrimp

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-201 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

Striped bass eggs and larvae would be vulnerable to entrainment at the proposed north SWP/CVP Delta diversions and the alternate NBA intake as these life stages are passively transported downstream to the north Delta. State of the art fish screens on these north Delta intakes though would exclude juvenile and adult striped bass.

Entrainment losses under Alternative 3 to the SWP/CVP south Delta intakes would be expected to decrease compared to NAA since exports from the south Delta facilities would be substantially reduced in the summer. This result is based on the assumption that striped bass entrainment is proportional to south Delta exports.

Agricultural diversions are potential sources of entrainment for small fish such as larval and juvenile striped bass (Nobriga et al. 2004). Reduction or consolidation of diversions from the ROAs (approximately 4–12% of diversions) would not increase entrainment and may provide a minor benefit. Also, restoration activities as part of the conservation measures should increase the amount of habitat for young striped bass (e.g. inshore rearing habitat), and increase their food supply. The expectation is that these habitat changes would result in at least a minor improvement in production of juvenile striped bass.

NEPA Effects: Variations in striped bass survival rates during the first few months of life are moderated by a population bottleneck between YOY striped bass and three-year-old individuals (Kimmerer et al. 2000). Therefore it would be expected that reductions in entrainment of juveniles and adults at the south Delta intakes would have a greater population impact than increases in entrainment of striped bass larvae and eggs at the proposed SWP/CVP north Delta intakes and the NBA intake. Furthermore, decommissioning of agricultural diversions may also reduce entrainment of striped bass. Overall, the effect on striped bass entrainment would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of striped bass would be the same as described immediately above. The changes in entrainment under Alternative 3 would not substantially reduce the striped bass population when other conservation measures are taken into account. The impact would be less than significant and no mitigation would be required.

American Shad

American shad eggs and larvae would be vulnerable to entrainment at the proposed north SWP/CVP Delta diversions and the alternate NBA intake as these life stages are passively transported downstream to the north Delta. State of the art fish screens on these north Delta intakes though would exclude juvenile and adult American shad.

NEPA Effects: American shad entrainment losses under Alternative 3 would decrease compared to NAA due to reduced south Delta exports in the summer. Reduced south Delta entrainment would also be expected to reduce predation loss associated with these facilities, especially within Clifton Court Forebay. Reduction or consolidation of agricultural diversions in ROAs would not increase entrainment. Overall, the effect on American shad would not be adverse, and would be slightly beneficial.

CEQA Conclusion: The impact of water operations on entrainment of American shad would be the same as described immediately above. The changes in entrainment under Alternative 3 would not substantially reduce the American shad population. The impact would be less than significant and no mitigation would be required.

Threadfin Shad

The effect of water operations on entrainment of threadfin shad would be the same as discussed for Alternative 1A, Impact AQUA-201. Entrainment at the south Delta would be reduced due to overall lower exports from south Delta facilities; there would also be a concomitant reduction in predation loss especially within Clifton Court Forebay. There would be entrainment of threadfin shad eggs and larvae at the north Delta intakes. Decommissioning agricultural diversions in Delta ROAs would decrease or have no impact on threadfin shad entrainment.

NEPA Effects: Overall, threadfin shad entrainment would be reduced because they are most abundant in the southwestern portion of the Delta and would benefit from reduced south Delta exports. The effect would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of threadfin shad would be the same as described immediately above. The changes in entrainment under Alternative 3 would not substantially reduce the threadfin shad population. The impact would be less than significant and no mitigation would be required.

Largemouth Bass

NEPA Effects: Since largemouth bass are predominantly found in the south and central portions of the Delta, largemouth bass would be most vulnerable to entrainment at south Delta facilities. Entrainment to the south Delta would be reduced because of reductions in south Delta exports in the summer. As discussed for Alternative 1A, Impact AQUA-201, few larval largemouth bass would be vulnerable to entrainment to north Delta and alternative NBA intakes since they are not expected to readily occur there. Decommissioning agricultural diversions could reduce entrainment of largemouth bass since they hold in shallow water habitats where most agricultural diversions are sited. Overall entrainment would be reduced under Alternative 3 and there could be a small benefit to the species.

CEQA Conclusion: The impact of water operation on largemouth bass would be as described immediately above. The changes in entrainment under Alternative 3 could benefit the largemouth bass population. The impact would be less than significant and no mitigation would be required.

Sacramento Tule Perch

NEPA Effects: The effects and conclusion for this impact would be similar to Alternative 1A, Impact AQUA-201. Entrainment of Sacramento tule perch to the SWP/CVP south Delta facilities would decrease because south Delta exports would be less compared to NAA (NAA). Entrainment-related predation loss would also be reduced. Because Sacramento tule perch are viviparous, newly born Sacramento tule perch would be large enough to be effectively screened at the proposed north Delta facilities. Reduction or consolidation of the agricultural diversions would decrease entrainment of Sacramento tule perch into these agricultural intakes. Overall the reduction in entrainment of Sacramento tule perch under Alternative 3 would not be adverse, and may provide a benefit for the species.

CEQA Conclusion: The impact of water operations on entrainment of Sacramento tule perch would be the same as described immediately above. The changes in entrainment under Alternative 3 would not substantially reduce the Sacramento tule perch population. The impact would be less than significant and no mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: The effect of water operations on entrainment of Sacramento-San Joaquin roach under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-201). As described for Alternative 1A, Impact AQUA-201, the effects would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of Sacramento-San Joaquin roach would be the same as described immediately above. The impacts would be less than significant.

Hardhead

NEPA Effects: The effect of water operations on entrainment of hardhead under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-3). That discussion under delta smelt addresses the type, magnitude, and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. As described for Alternative 1A, Impact AQUA-3 the effects would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of hardhead would be the same as described immediately above. The impacts would be less than significant.

California Bay Shrimp

NEPA Effects: The effect of water operations on entrainment of California bay shrimp under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-3). That discussion under delta smelt addresses the type, magnitude, and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. California bay shrimp do not occur in the vicinity of the intakes and there would be no effect.

CEQA Conclusion: The impact of water operations on entrainment of California bay shrimp would be the same as described immediately above. There would be no impact.

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-202 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

In general, Alternative 3 would slightly improve the quality and quantity of upstream habitat conditions for striped bass relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to or greater than flows under NAA during April through June except in wet years during May compared to NAA (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA during April through June except in above normal years during April (11% lower)(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be substantially greater by up to 162% than flows under NAA during April through June, regardless of water year (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would be similar to or greater than flows under NAA, regardless of water year type.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period. Further, water temperatures were not modeled in Clear Creek or the San Joaquin River.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 3 would not cause a substantial reduction in striped bass spawning, incubation, or initial rearing habitat. Flows in all rivers examined during the April through June spawning, incubation, and initial rearing period under Alternative 3 would generally be similar to flows under NAA. In the Feather River, flows under Alternative 3 would be greater than flows under NAA, indicating that the alternative would provide flow-related improvements to upstream habitat for striped bass. There would be no temperature-related effects of Alternative 3 on upstream striped bass habitat.

CEQA Conclusion: In general, Alternative 3 would slightly improve the quality and quantity of upstream habitat conditions for striped bass relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under Existing Conditions during April and generally greater than flows under Existing

Conditions during May and June, except in wet years during May (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to flows under Existing Conditions during April through June, except in critical water years, in which flows would be 6% to 14% greater under A3_LLT depending on month (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be substantially greater by up to 149% than flows under Existing Conditions during April through June, except in wet years during May (30% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal years during April (6% lower) and wet and critical years during June (26% and 39% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during May would generally up to 25% than under Existing Conditions.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

Collectively, these results indicate that the impact would be less than significant because Alternative 3 would result in a cumulative improvement of spawning, incubation, and initial rearing habitat. Therefore, no mitigation is necessary. Flows in all rivers examined during the April through June spawning, incubation, and initial rearing habitat of striped bass. Flows in all rivers except the San Joaquin and Stanislaus rivers during the April through June spawning, incubation, or initial rearing period under Alternative 3 would generally be similar to or greater than flows under the Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 3 relative to the Existing Conditions, although this effect would not be biologically meaningful to striped bass. There would be no temperature-related effects of Alternative 3 on upstream striped bass habitat.

American Shad

In general, Alternative 3 would slightly improve the quality and quantity of upstream habitat conditions for American shad relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to or greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA during April through June except in above normal years during April (11% lower)(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be substantially greater by up to 162% than flows under NAA during April through June, regardless of water year (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would be similar to or greater than flows under NAA, regardless of water year type.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period. Further, water temperatures were not modeled in Clear Creek or the San Joaquin River.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 3 would not cause a substantial reduction in American shad spawning or adult migration. Flows in all rivers examined during the April through June adult migration and spawning period under Alternative 3 would nearly always be similar to flows would generally be similar to flows under the NAA. In the Feather River, flows under Alternative 3 would be greater than flows under the NAA, indicating that the alternative would provide flow-related improvements to upstream habitat for American shad. There would be no temperature-related effects of Alternative 3 on upstream American shad habitat.

CEQA Conclusion: In general, Alternative 3 would slightly improve the quality and quantity of upstream habitat conditions for American shad relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under Existing Conditions during April and generally greater than flows under Existing Conditions during May and June, except in wet years during May (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to flows under Existing Conditions during April through June, except in critical water years, in which flows would be 6% to 14% greater under A3_LLT depending on month (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be substantially greater by up to 149% than flows under Existing Conditions during April through June, except in wet years during May (30% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal years during April (6% lower) and wet and critical years during June (26% and 39% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during May would generally up to 25% than under Existing Conditions.

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

Collectively, these results indicate that the impact would be less than significant because Alternative 3 would not cause a substantial reduction in American shad adult migration and spawning habitat, and no mitigation would be required. Flows in all rivers examined during the April through June adult migration and spawning period under Alternative 3 would nearly always be similar to or greater than flows under the Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 3 relative to the Existing Conditions, although this effect would not be biologically meaningful to American shad. There would be no temperature-related effects of Alternative 3 on upstream American shad habitat.

Threadfin Shad

In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during April through August threadfin shad spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under NAA during April, June, and July, greater by up to 15% during May, and lower by up to 18% during August (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would be similar to flows under NAA, except in above normal years during April (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would nearly always be similar to or greater than flows under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be greater during April through June (up to 72% greater) and lower (by up to 44%) than flows under NAA during July and August (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under NAA during April, greater by up to 31% during May and June, and lower by up to 30% during July and August (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 3 would not cause a substantial reduction in spawning habitat. Flows in all rivers examined during the April through August spawning period under Alternative 3 would generally be similar to or greater than flows under the NAA, except during summer months in the Sacramento, Feather, and American rivers. Lower flows during these months these rivers are not of sufficient magnitude or frequency to have a biologically meaningful effect on threadfin shad. The percentage of months below the spawning temperature threshold would be similar in all rivers between Alternative 3 and the NAA.

CEQA Conclusion: In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during April through August spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under Existing Conditions during April and July, greater by up to 20% during May and June, and lower by up to 24% during August (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to flows under Existing Conditions throughout the period, except during June, when flows would be up to 28% greater than flows under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would nearly always be similar to or greater than flows under Existing Conditions throughout the period, except in critical years during August (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally greater during April through June (up to 149% greater), and lower during July and August (up to 51% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under Existing Conditions during April and June and lower by up to 52% during May, July, and August (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

Collectively, these results indicate that the impact would be less than significant because Alternative 3 would not cause a substantial reduction in habitat, and no mitigation is necessary. Flows in all rivers examined during the April through August spawning period under Alternative 3 would generally be similar to or greater than flows under the Existing Conditions, except during summer months in the Sacramento, Feather, and American rivers. Lower flows during these months in these rivers would not be of sufficient magnitude or frequency to cause a biologically meaningful effect on threadfin shad. The percentage of months outside all temperature thresholds are generally lower under Alternative 3 than under the Existing Conditions, indicating that there would be a net temperature benefit of Alternative 3 to threadfin shad.

Largemouth Bass

In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for largemouth bass relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA during March through June except in above normal water years during April (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under NAA during March through June except in below normal years during March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would be substantially greater (up to 162% greater) than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would be similar to flows under NAA except in March dry and critical years (7% and 8%, respectively). Flows during May and June under A3_LLT would generally be up to 31% greater than flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 3 would not cause a substantial reduction spawning habitat. Flows in all rivers examined during the year under Alternative 3 are generally similar to or greater than flows under NAA in most months. Flows from July through September are generally lower in the Feather River high flow channel and in the American River below Nimbus Dam, although these reductions would not be biologically meaningful to the largemouth bass population. The percentage of months outside all temperature thresholds examined in the Feather River under Alternative 3 are generally similar to or lower than under NAA.

CEQA Conclusion: In general, Alternative 3 would reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in wet years during May (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March and critical years during May (6% lower in both) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would be similar to or greater than flows under Existing Conditions during March through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be substantially greater (up to 149% greater) than flows under Existing Conditions during March through June, except in below normal years during March (33% lower) and in wet years during May (30% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during March, April, and June with some exceptions (up to 39% lower). Flows under A3_LLT in May would generally be up to 25% lower than those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

Collectively, these results indicate that the impact would be less than significant because Alternative 3 would not cause a substantial reduction in largemouth bass habitat. No mitigation is necessary.

Sacramento Tule Perch

In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round Sacramento tule perch presence. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT generally be similar to flows under NAA during January through April, June, July, and December, greater by up to 33% during May and October, and lower by up to 43% during August, September, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the period with some exceptions (up to 11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the year, with some exceptions (up to 37% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be greater during April through June and October through November (up to 72% greater) and lower (up to 84%) than flows under NAA during July through September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under NAA during January through April and November through December, greater by up to 31% during May, June and October, and lower by up to 47% during July through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months exceeding water temperature thresholds of 72°F and 75°F for the year-round occurrence of all life stages of Sacramento tule perch was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quantity and quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 3 would not cause a substantial reduction in upstream habitat for Sacramento tule perch. Flows under Alternative 3 in all rivers examined throughout the year are generally similar to or greater than flows under NAA, except during summer months in the Feather and American rivers. These reductions in flows, however, would not cause an overall biologically meaningful effect on Sacramento tule perch. The percentages of months outside all temperature thresholds are generally lower under Alternative 3 than under NAA.

CEQA Conclusion: In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round Sacramento tule perch presence. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under Existing Conditions during January, March, April, July, September, and December, greater by up to 30% during February, May, June, and October, and lower by up to 24% during August and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to flows under Existing Conditions during March through May and July through September, greater by up to 61% during January, February, and June, and lower by up to 25% during October and December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August and September (17% and 38%, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be similar to flows under Existing Conditions during February and November, greater during January, March through June, October, and December (up to 149% greater), and lower during July through September (up to 51% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under Existing Conditions during January, April, and June, greater by up to 29% during February, March, and October, and lower by up to 52% during May, July through September, November, and December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the year relative to Existing Conditions.

Water Temperature

The percentage of months exceeding water temperatures of 72°F and 75°F for the year-round occurrence of all life stages of Sacramento tule perch was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A.

Collectively, these results indicate that the impact would not be significant because Alternative 3 would not cause a substantial reduction in upstream habitat for Sacramento tule perch. No mitigation is necessary. Flows would be lower during half of the year in the American River. However, given that flow reductions in other rivers, including the San Joaquin and Stanislaus rivers, would be minimal, flow reductions in the American River would not cause biologically meaningful effects to Sacramento tule perch habitat. The percentages of months outside all temperature thresholds are generally lower under Alternative 3 than under the Existing Conditions.

Sacramento-San Joaquin Roach – California Species of Special Concern

In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA during March through June except in above normal water years during April (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under NAA during March through June except in below normal years during March (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would be similar to flows under NAA except in March dry and critical years (7% and 8%, respectively). Flows during May and June under A3_LLT would generally be up to 31% greater than flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A.

NEPA Effects: As described for Alternative 1A, Alternative 3 would not adversely effect on the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the NAA

CEQA Conclusion: In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in wet years during May (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March and critical years during May (6% lower in both) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would be similar to or greater than flows under Existing Conditions during March through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be substantially greater (up to 149% greater) than flows under Existing Conditions during March through June, except in below normal years during March (33% lower) and in wet years during May (30% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions during March, April, and June with some exceptions (up to 39% lower). Flows under A3_LLT in May would generally be up to 25% lower than those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

Hardhead – California Species of Special Concern

In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for hardhead relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would always to be similar to flows under NAA throughout the period regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be substantially greater (up to 162% greater) than flows under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would be similar to or greater than flows under NAA in April and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

NEPA Effects: In general, Alternative 3 would not adversely affect the quality and quantity of upstream habitat conditions for hardhead relative to the NAA.

CEQA Conclusion: In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions throughout the period, except in wet years during May (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions throughout the period, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would be similar to or greater than flows under Existing Conditions throughout the period regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be substantially greater by up to 149% than flows under Existing Conditions throughout the period, except in wet years during May (30% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would be similar to or greater than flows under Existing Conditions during April, except in above normal years (6% lower). Flows under A3_LLT would generally be lower than flows under Existing Conditions, by up to 25%, during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A.

California Bay Shrimp

NEPA Effects: The effect of water operations on spawning habitat of California bay shrimp under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-4). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. As described for Alternative 1A, Impact AQUA-4, the effects would not be adverse.

CEQA Conclusion: The impact of water operations on spawning habitat of California bay shrimp would be the same as described immediately above. The impacts would be less than significant.

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-203 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

NEPA Effects: The discussion under Alternative 3, Impact AQUA-202 for striped bass also addresses the embryo and initial rearing period. That analysis indicates that there are no adverse effects on striped bass rearing during that period. Other effects of water operations on rearing habitat for striped bass under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203). As described for Alternative 1A, Impact AQUA-203, the effects would not be adverse.

CEQA Conclusion: As described above the impacts on striped bass rearing habitat would be less than significant.

American Shad

NEPA Effects: The effects of water operations on rearing habitat for striped bass under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203). As described for Alternative 1A, Impact AQUA-203, the effects would not be adverse.

CEQA Conclusion: As described above the impacts on American shad rearing habitat would be less than significant.

Threadfin Shad

NEPA Effects: The effects of water operations on rearing habitat for threadfin shad under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203). As described for Alternative 1A, Impact AQUA-203, the effects would not be adverse.

CEQA Conclusion: As described above the impacts on threadfin shad rearing habitat would be less than significant.

Largemouth Bass

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under NAA during April, June, and July, greater by up to 33% during May and October, and lower by up to 43% during August, September, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to flows under NAA throughout the period, except in critical years during October (6% lower) and wet years during November (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, April through November flows under A3_LLT would generally be similar to or greater than flows under NAA, with some exceptions (up to 37% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be lower (up to 84%) than flows under NAA during July through September and greater during April through June and October through November (up to 72% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under NAA during April and November, greater by up to 31% during May, June, and October, and lower by up to 47% during July through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round adult largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under NAA during January through April, June, July, and December, greater by up to 33% during May and October, and lower by up to 43% during August, September, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the period with some exceptions (up to 11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the year, with some exceptions (up to 37% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be greater during April through June and October through November (up to 72% greater) and lower (up to 84%) than flows under NAA during July through September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under NAA during January through April and November through December, greater by up to 31% during May, June and October, and lower by up to 47% during July through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the year-round period.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 3 would not cause a substantial reduction in juvenile or adult rearing habitat. Flows in all rivers examined during the year under Alternative 3 are generally similar to or greater than flows under NAA in most months. Flows from July through September are generally lower in the Feather River high flow channel and in the American River below Nimbus Dam, although these reductions would not be biologically meaningful to the largemouth bass population. The percentage of months outside all temperature thresholds examined in the Feather River under Alternative 3 are generally similar to or lower than under NAA.

CEQA Conclusion: In general, Alternative 3 would reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to the Existing Conditions.

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under Existing Conditions during April and July, greater by up to 30% during May, June, and October, and lower by up to 24% during August, September, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to flows under Existing Conditions during April, May, and July through September, greater by up to 28% during June, and lower by up to 25% during October and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions throughout the April through November period, except in critical years during August and September (17% to 38% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be similar to flows under Existing Conditions during November, lower during July through September (up to 51% lower), and greater during April through June and October (up to 149% greater) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under Existing Conditions during April and June, greater by up to 29% during October, and lower by up to 52% during May, July through September, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round adult largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under Existing Conditions during January, March, April, July, September, and December, greater by up to 30% during February, May, June, and October, and lower by up to 24% during August and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to flows under Existing Conditions during March through May and July through September, greater by up to 61% during January, February, and June, and lower by up to 25% during October and December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August and September (17% and 38%, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be similar to flows under Existing Conditions during February and November, greater during January, March through June, October, and December (up to 149% greater), and lower during July through September (up to 51% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under Existing Conditions during January, April, and June, greater by up to 29% during February, March, and October, and lower by up to 52% during May, July through September, November, and December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

Collectively, these results indicate that the impact would not be significant because Alternative 3 would not cause a substantial reduction in largemouth bass habitat. No mitigation is necessary. Flows would be lower during half of the year-round adult rearing period in the American River. However, given that flow reductions in other rivers, including the San Joaquin and Stanislaus rivers, would be minimal, flow reductions in the American River would not cause biologically meaningful effects to largemouth bass habitat. The percentages of months outside all temperature thresholds are generally lower under Alternative 3 than under the Existing Conditions.

Sacramento Tule Perch

NEPA Effects: The effects of water operations on rearing habitat for Sacramento tule perch under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-5). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. As described for Alternative 1A, Impact AQUA-5, the effects would not be adverse.

CEQA Conclusion: As described above the impacts on Sacramento tule perch rearing habitat would be less than significant.

Sacramento-San Joaquin Roach

In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach rearing period. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under NAA during January through April, June, July, and December, greater by up to 33% during May and October, and lower by up to 43% during August, September, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the period with some exceptions (up to 11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the year, with some exceptions (up to 37% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be greater during April through June and October through November (up to 72% greater) and lower (by up to 84%) than flows under NAA during July through September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under NAA during January through April and November through December, greater by up to 31% during May, June and October, and lower by up to 47% during July through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 3 would not cause a substantial reduction in rearing habitat. Flows under Alternative 3 in all rivers examined throughout the year are generally similar to or greater than flows under NAA, except during summer months in the Feather and American rivers, although these reductions would not be biologically meaningful to the roach population. The percentage of months outside temperature thresholds is generally similar to or lower under Alternative 3 than under NAA.

CEQA Conclusion: In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach rearing period. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under Existing Conditions during January, March, April, July, September, and December, greater by up to 30% during February, May, June, and October, and lower by up to 24% during August and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to flows under Existing Conditions during March through May and July through September, greater by up to 61% during January, February, and June, and lower by up to 25% during October and December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August and September (17% and 38%, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be similar to flows under Existing Conditions during February and November, greater during January, March through June, October, and December (up to 149% greater), and lower during July through September (up to 51% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under Existing Conditions during January, April, and June, greater by up to 29% during February, March, and October, and lower by up to 52% during May, July through September, November, and December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

Collectively, these results indicate that the impact would not be significant because Alternative 3 would not cause a substantial reduction in Sacramento-San Joaquin roach habitat. No mitigation is necessary. Flows would be lower during half of the year-round adult rearing period in the American River. However, given that flow reductions in other rivers, including the San Joaquin and Stanislaus rivers, would be minimal, flow reductions in the American River would not cause biologically meaningful effects to roach habitat. The percentages of months outside all temperature thresholds are generally lower under Alternative 3 than under the Existing Conditions.

Hardhead

In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for hardhead relative to NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult rearing.

In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under NAA during January through April, June, July, and December, greater by up to 33% during May and October, and lower by up to 43% during August, September, and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the period with some exceptions (up to 11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under NAA throughout the year, with some exceptions (up to 37% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be greater during April through June and October through November (up to 72% greater) and lower (up to 84%) than flows under NAA during July through September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under NAA during January through April and November through December, greater by up to 31% during May, June and October, and lower by up to 47% during July through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 65°F to 82.4°F suitable water temperature range for year-round juvenile and adult hardhead rearing was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 3 would not cause a substantial reduction in rearing habitat. Flows under Alternative 3 in all rivers examined throughout the year are generally similar to or greater than flows under NAA, except during summer months in the Feather and American rivers. These reductions in flows, however, would not cause an overall biologically meaningful effect on hardhead. The percentages of months outside all temperature thresholds are generally lower under Alternative 3 than under NAA.

CEQA Conclusion: In general, Alternative 3 would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult rearing. In the Sacramento River upstream of Red Bluff, flows under A3_LLT would generally be similar to flows under Existing Conditions during January, March, April, July, September, and December, greater by up to 30% during February, May, June, and October, and lower by up to 24% during August and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).*

In the Trinity River below Lewiston Reservoir, flows under A3_LLT would generally be similar to flows under Existing Conditions during March through May and July through September, greater by up to 61% during January, February, and June, and lower by up to 25% during October and December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under A3_LLT would generally be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during August and September (17% and 38%, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under A3_LLT would generally be similar to flows under Existing Conditions during February and November, greater during January, March through June, October, and December (up to 149% greater), and lower during July through September (up to 51% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under A3_LLT would generally be similar to flows under Existing Conditions during January, April, and June, greater by up to 29% during February, March, and October, and lower by up to 52% during May, July through September, November, and December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under Alternative 3 would be about the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months in which year-round in-stream temperatures would be outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead rearing was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, Feather, American, and Stanislaus rivers under Alternative 3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

Collectively, these results indicate that the impact would be significant because Alternative 3 would cause a substantial reduction in hardhead habitat. No mitigation is necessary. Flows would be lower during half of the year-round juvenile and adult rearing period in the American River. However, given that flow reductions in other rivers, including the San Joaquin and Stanislaus rivers, would be minimal, flow reductions in the American River would not cause biologically meaningful effects to hardhead habitat. The percentages of months outside both temperature thresholds are generally lower under Alternative 3 than under the Existing Conditions.

California Bay Shrimp

NEPA Effects: The effect of water operations on rearing habitat of California bay shrimp under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-5). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. As described for Alternative 1A, Impact AQUA-5, the effects would not be adverse.

CEQA Conclusion: As described above the impacts on California bay shrimp rearing habitat would be less than significant.

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-204 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

NEPA Effects: Monthly flows in the Sacramento River downstream of the north Delta intakes would decrease (7–13% for NAA) under Alternative 3 during the adult striped bass migration. Sacramento River flows are highly variable interannually, and striped bass are still able to migrate upstream the Sacramento River during lower flow years. Overall, the effect of reduced Sacramento flows under Alternative 3 would not be adverse for striped bass.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because the changes in flow (15–21% lower compared to Existing Conditions) would not interfere substantially with movement of pre-spawning adult striped bass through the Delta. No mitigation would be required.

American Shad

NEPA Effects: Flows in the Sacramento River below the north Delta diversion facilities would be lower than NAA during March-May. Monthly flows on average would be 7–16% less than NAA when climate change effects are accounted for. Flows from the San Joaquin River at Vernalis would be unchanged. Sacramento River flows are highly variable interannually, and American shad are still able to migrate upstream the Sacramento River during lower flow years. Overall, the impact to American shad migration habitat conditions would not be adverse under Alternative 3.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because the changes in flow (15–21% lower compared to Existing Conditions) would not interfere substantially with movement of American shad from the Delta to upstream spawning habitat. No mitigation would be required.

Threadfin Shad

NEPA Effects: Threadfin shad are semi-anadromous, moving between freshwater and brackish water habitats. Threadfin shad found in the Delta to not actively migrate upstream to spawn. Therefore there is no effect on migration habitat conditions.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because flow changes in the Delta under Alternative 3 would not alter movement patterns for threadfin shad and no mitigation would be required.

Largemouth Bass

NEPA Effects: Largemouth bass are non-migratory fish within the Delta. Therefore they do not use the Delta as migration habitat corridor. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes under Alternative 3 would not affect largemouth movements within the Delta. No mitigation would be required.

Sacramento Tule Perch

NEPA Effects: Similar with largemouth bass, Sacramento tule perch are a non-migratory species and do not use the Delta as a migration corridor as they are a resident Delta species. There would be no effect.

CEQA Conclusion: As described immediately above, flow movements would not affect Sacramento tule perch movements within the Delta. No mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: For Sacramento-San Joaquin roach the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 3, Impact AQUA-202 for spawning. As described for Alternative 3, Impact AQUA-202, the overall change in flows under Alternative 3 would slightly improve the upstream conditions relative to NAA. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for Sacramento-San Joaquin roach would not be significant and no mitigation is required.

Hardhead

NEPA Effects: For hardhead the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 3, Impact AQUA-202 for spawning. As described for Alternative 3, Impact AQUA-202, the overall change in flows under Alternative 3 would slightly improve the upstream conditions relative to NAA. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for hardhead would not be significant and no mitigation is required.

California Bay Shrimp

NEPA Effects: The effect of water operations on migration conditions of California bay shrimp under Alternative 3 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-6). That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. As described for Alternative 1A, Impact AQUA-6, the effects of Alternative 3 would not be adverse.

CEQA Conclusion: As described above the impacts on California bay shrimp migration conditions would be less than significant.

Restoration Measures (CM2, CM4–CM7, and CM10)

The effects of restoration measures under Alternative 3 would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Refer to Impact AQUA-7 under delta smelt for a discussion of the effects of construction of restoration measures on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species.

NEPA Effects: The potential effects of the construction of restoration measures under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-7). As described for Alternative 1A, Impact AQUA-7, the effects of Alternative 3 would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of the construction of restoration measures would be less than significant.

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-8 under delta smelt a discussion of the effects of contaminants associated with restoration measures on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of contaminants associated with restoration measures under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-8). As described for Alternative 1A, Impact AQUA-8, the effects of Alternative 3 would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of contaminants associated with restoration measures would be less than significant.

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

Refer to Impact AQUA-9 under delta smelt a discussion of the effects of restored habitat conditions on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. Although there are minor differences the effects are similar.

NEPA Effects: The potential effects of restored habitat conditions under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-8). For a detailed discussion, please see Alternative 1A, Impact AQUA-8. In addition, see Alternative 1A, Impact AQUA-207 for a discussion of the different effects on non-covered species of primary management concern. As described for Alternative 1A, the effects of Alternative 3 would range from slightly beneficial to beneficial.

CEQA Conclusion: As described immediately above, the impacts of restored habitat conditions would range from slightly beneficial to beneficial.

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (CM12)

NEPA Effects: Refer to Impact AQUA-10 under delta smelt for a discussion of the effects of methylmercury management on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of methylmercury management under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-10). As described for Alternative 1A, Impact AQUA-10, the effects of Alternative 3 would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of methylmercury management would be less than significant.

Impact AQUA-209: Effects of Invasive Aquatic Vegetation Management on Non-Covered Aquatic Species of Primary Management Concern (CM13)

Refer to Impact AQUA-11 under delta smelt a discussion of the effects of invasive aquatic vegetation management on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of invasive aquatic vegetation management under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-11) except for predatory species (striped bass and largemouth bass) and Sacramento tule perch. Invasive aquatic vegetation provides hiding habitat for predatory fish which improves their hunting success. Sacramento tule perch also use the cover of aquatic plants in the Sacramento and San Joaquin rivers and in Suisun marsh. Consequently, reducing the amount of invasive aquatic habitat will negatively affect these predatory species and Sacramento tule perch. However, this control will not substantially reduce the ability of the predatory species to hunt and there will still be many other habitats in which the predatory species can successfully hunt and in which Sacramento tule perch will thrive.

NEPA Effects: As described above, the effect on non-covered aquatic species will not be adverse. Control of invasive aquatic vegetation would not occur within California bay shrimp habitat and there would be no effect on them.

CEQA Conclusion: Refer to Impact AQUA-11 under delta smelt a discussion of the effects of invasive aquatic vegetation management on non-covered species of primary management concern. There are minor differences and the effects are similar except for predatory species (striped bass and largemouth bass) and Sacramento tule perch. Invasive aquatic vegetation provides hiding habitat for predatory fish which improves their hunting success. Control of invasive aquatic vegetation would not occur within California bay shrimp habitat and there would be no effect on them. Sacramento tule perch use the cover of aquatic plants in the Sacramento and San Joaquin rivers and in Suisun marsh. Consequently, reducing the amount of invasive aquatic habitat will negatively affect the predatory species and Sacramento tule perch. However, this control will not substantially reduce the ability of the predatory species to hunt and there will still be many other habitats in which the predatory species can successfully hunt and in which Sacramento tule perch will thrive. Therefore the impact on them will not be significant and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

The effects of restoration measures under Alternative 3 would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-210: Effects of Dissolved Oxygen Level Management on Non-Covered Aquatic Species of Primary Management Concern (CM14)

NEPA Effects: Refer to Impact AQUA-12 under delta smelt for a discussion of the effects of dissolved oxygen management on non-covered species of primary management concern. The potential effects of dissolved oxygen management under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-12). For a detailed discussion, please see Alternative 1A, Impact AQUA-12. California bay shrimp do not occur in this habitat and there would be no effect on them. As described immediately above, the impacts of oxygen level management would be beneficial.

CEQA Conclusion: As described immediately above, the impacts of oxygen level management would be beneficial.

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (CM15)

NEPA Effects: Refer to Alternative 1A, Impact AQUA-13 under delta smelt a discussion of the effects of predatory fish (striped bass and largemouth bass) and predator management on non-predatory fish. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The purpose of predatory fish management is to reduce the numbers of predatory fish and to reduce their hunting success. This management will have negative effects on predatory fish. However, the numbers of predatory fish are high and the extent of the habitats in which they hunt is extensive. As described for Alternative 1A, the effects of this management will not be adverse. California bay shrimp do not occur in these habitats and there would be no effect on them.

Therefore the effects of this management will not be adverse. California bay shrimp do not occur in these habitats and there would be no effect on them.

CEQA Conclusion: Refer to Alternative 1A, Impact AQUA-13 under delta smelt a discussion of the effects of predatory fish and predator management on non-predatory fish. The purpose of predatory fish management is to reduce the numbers of predatory fish and to reduce their hunting success. This management will have negative effects on predatory fish. However, the numbers of predatory fish are high and the extent of the habitats in which they hunt is extensive. Therefore the effects of this management will not be significant. No mitigation is required. California bay shrimp do not occur in these habitats and there would be no effect on them.

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (CM16)

Refer to Impact AQUA-14 under delta smelt for a discussion of the effects of nonphysical fish barriers on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species.

NEPA Effects: The potential effects of nonphysical fish barriers under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-14). For a detailed discussion, please see Alternative 1A, Impact AQUA-14. The effects would be similar except for Sacramento-San Joaquin roach and hardhead which are unlikely to be present in their vicinity. California bay shrimp do not occur in these habitats and there would be no effect on them. As described for Alternative 1A, the effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of nonphysical fish barriers would be less than significant.

Impact AQUA-213: Effects of Illegal Harvest Reduction on Non-Covered Aquatic Species of Primary Management Concern (CM17)

Refer to Impact AQUA-15 under delta smelt for a discussion of the effects of illegal harvest reduction on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species.

NEPA Effects: The potential effects of illegal harvest reduction under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-15). California bay shrimp do not occur in these habitats and there would be no effect on them. As described for Alternative 1A, the effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of illegal harvest reduction would be less than significant.

Impact AQUA-214: Effects of Conservation Hatcheries on Non-Covered Aquatic Species of Primary Management Concern (CM18)

NEPA Effects: Refer to Impact AQUA-16 under delta smelt for a discussion of the effects of conservation hatcheries on non-covered species of primary management concern. The potential effects of conservation hatcheries under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-16). As described for Alternative 1A, there would be no effect.

CEQA Conclusion: As described immediately above, conservation hatcheries would have not impact.

Impact AQUA-215: Effects of Urban Stormwater Treatment on Non-Covered Aquatic Species of Primary Management Concern (CM19)

NEPA Effects: Refer to Impact AQUA-17 under delta smelt for a discussion of the effects of stormwater treatment on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of stormwater treatment under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-17). As described for Alternative 1A, these effects would be beneficial.

CEQA Conclusion: As described immediately above, the impacts of stormwater management would be beneficial.

Impact AQUA-216: Effects of Removal/Relocation of Nonproject Diversions on Non-Covered Aquatic Species of Primary Management Concern (CM21)

Refer to Impact AQUA-18 under delta smelt for a discussion of the effects of removal/relocation of nonproject diversions on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species.

NEPA Effects: The potential effects of removal/relocation of nonproject diversions under Alternative 3 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-18). For a detailed discussion, please see Alternative 1A, Impact AQUA-18. The effects would be similar except for Sacramento-San Joaquin roach, hardhead and Sacramento perch which are unlikely to be present near these diversions. California bay shrimp do not occur in these habitats and there would be no effect on them. As described for Alternative 1A, the effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of removal/relocation of nonproject diversions would be less than significant.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: Similar to the description for Alternative 1A, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 3 would not be substantially reduced when compared to NAA.

CEQA Conclusion: Similar to the description for Alternative 1A, Alternative 3 would reduce the quantity of coldwater fish habitat in the CVP and SWP as shown in Table 11-1A-102. There would be a greater than 5% increase (5 years) for several of the reservoirs, which could result in a significant impact. These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. As a result, the CEQA conclusion regarding Alternative 3, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on coldwater habitat in upstream reservoirs. This impact is found to be less than significant and no mitigation is required.

11.3.4.9 Alternative 4—Dual Conveyance with Modified Pipeline/Tunnel and Intakes 2, 3, and 5 (9,000 cfs; Operational Scenario H)

Alternative 4 would result in the same potential construction impact mechanisms as Alternative 1A; however, there would be two fewer intakes under Alternative 4. Consequently, the intensity and extent of impacts related to the construction of the intakes would be less under Alternative 4 than under Alternative 1A. As a result of having fewer intakes, however, Alternative 4 will also include an expanded Clifton Court Forebay with a new embankment dividing the forebay into a north cell and a south cell along with additional connections and control structures to the Banks and Jones pumping plants. These actions will result in additional construction impacts for Alternative 4 compared to Alternative 1A.

Alternative 4 has a lower maximum diversion capacity (up to 9,000 cfs) from the north Delta area than Alternative 1A (up to 15,000 cfs).

The temporary construction footprint of the three intakes would occupy about 16.21 acres of in-water habitat, while the total permanent in-water footprint would be approximately 12.3 acres (9.5 acres smaller under Alternative 4 than under Alternative 1A). The total length of permanent intakes and the associated bank protection would be approximately 6,360 feet (5,540 feet less than Alternative 1A) (see Table 11-5). Under Alternative 4 there would be five barge locations rather than six under Alternative 1A. One of the five barge landings under Alternative 4 would be in the same location as Alternative 1A while the four would be in different locations. The analysis assumes all of these would operate the same as the landings under Alternative 1A. The effects of the landing construction and operation, including the cargo handling system, are assumed to be the same under Alternative 4 as under Alternative 1A although some barge activities would take place on levees using a barge ramp in conjunction with a crane/excavator barge or a crane or excavator placed on or near the levee. Therefore, all impacts related to construction of the conveyance tunnel and pipelines, and the barge unloading facilities, are considered to be the same. The Sacramento River channel and bank would be affected by construction of the three north Delta intake facilities (Intakes 2, 3, and 5) between RM 44 (south of Freeport) and approximately RM 39 (at the town of Courtland). The locations, dimensions, and construction footprints of the intakes considered in Alternative 4 are provided in Table 11-5.

The number of barge trips required under Alternative 4 would be similar to the estimated 3,000 barge trips under Alternative 1A; although only three intake facilities would be constructed under Alternative 4 compared to five intakes under Alternative 1A additional trips would be required for Clifton Court Forebay construction. Other aspects of in-water construction would be similar under Alternative 4 as described for Alternative 1A, except as they relate to the reduced number of intakes constructed and construction at Clifton Court Forebay under Alternative 4.

New water conveyance facilities of Alternative 4 that would affect the aquatic environment include creating a north and south cell in Clifton Court Forebay by constructing an embankment to separate them, increasing the forebay by 690 acres (to 2,950 acres total) by expanding the south cell to the southeast, and excavating the existing Clifton Court Forebay to expand the storage (Table 3-11). Additionally, three culvert siphons would be constructed under Alternative 4. One would serve as a transition between Tunnel 2 and the expanded Clifton Court Forebay under Italian Slough, one would connect the north cell of the expanded Clifton Court Forebay to a new approach canal to the Banks and Jones Pumping Plants under the south cell of the Forebay, and one would connect the new approach canal to the existing approach canal to Banks Pumping Plant under Byron Highway. Construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas.

Alternative 4 also includes different water conveyance operational criteria (Operational Scenario H) than Alternative 1A (Operational Scenario A), resulting in different patterns of water withdrawals from the north Delta, and potentially different effects on water quality and aquatic habitat conditions in the Plan Area. As fully described in Chapter 3, *Description of Alternatives,* Alternative 4 operations incorporate a decision tree process that results in four potential operational sub-scenarios, depending on the outcome of the decision tree process for spring outflow and Fall X2 operations. The decision tree process will specifically test the need for Fall X2 for delta smelt and spring outflow for longfin smelt as described in Chapter 3, *Description of Alternatives*. The four potential operational outcomes of the decision tree are as follows:

- Scenario H1 – Does not include enhanced spring outflow or Fall X2 requirements.
- Scenario H2 – includes enhanced spring outflow, but not Fall X2 requirements. This scenario lies within the range of the other scenarios.
- Scenario H3 – Does not include enhanced spring outflow, but includes Fall X2 requirements (similar to Alternative 2A). This scenario lies within the range of the H1 and H4 scenarios.
- Scenario H4 – Includes both enhanced spring outflow requirements, and Fall X2 requirements.

Based on a comparison of the flow effects of H1 and H4, it is concluded that they represent the bookends for operational effects of Alternative 4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis, Section11C.4.3*. As such, H1 and H4, along with Scenario H3, which includes Fall X2 but not enhanced spring outflow, are used as the primary point of comparison for purposes of evaluating the effects of Alternative 4 because together they represent the end and middle points of potential effects. The decision tree will be used to determine the actual operational scenario for Alternative 4 prior to CM1 operations in order to achieve results that are not adverse and are less than significant. The operations impact analysis compares late long-term (LLT) Alternative 4 results for Existing Conditions (CEQA) or no action (NEPA) with the range of outcomes from the operational sub-scenarios (H1–H4), and concludes with a single impact statement for each issue.

Delta Smelt

Construction and Maintenance of CM1

The construction and maintenance activities would occur entirely within designated critical habitat. Small numbers of delta smelt eggs, larvae, and adults could be present in the north Delta in June during a portion of the in-water construction period for the intake facilities. Small numbers could also be present in June or July during construction of the barge landings in the east Delta and south Delta and during construction at Clifton Court Forebay (see Table 11-4).

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of construction of the water conveyance facilities on delta smelt or critical habitat would be similar to those described for Alternative 1A (Impact AQUA-1) except that Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less.

Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan,* would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects. As concluded for Alternative 1A, Impact AQUA-1, the effect would not be adverse for delta smelt.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-1, the impact of the construction of the water conveyance facilities on delta smelt or critical habitat would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A (see Impact AQUA-2) except that only three intakes would need to be maintained under Alternative 4 rather than five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-2, the impact would not be adverse for delta smelt or their designated critical habitat.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-2 for delta smelt, the impact of the maintenance of water conveyance facilities on delta smelt or critical habitat would not be significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Water Exports from SWP/CVP South Delta Facilities

Alternative 4 would result in lower overall entrainment of delta smelt than the NAA. The predicted entrainment of larval/juvenile delta smelt at the south Delta export facilities was generally lowest under Scenario H4 operations, and highest under the NAA and H3/H1 scenarios (Figure 11-4-1). Each of the Alternative 4 subscenarios would result in lower entrainment of delta smelt in wet and above-normal water years; however, only H4 provided for lower predicted entrainment in below-normal and dry water years, and all of the subscenarios had similar entrainment to the NAA in critical water years.

The predicted entrainment of adult delta smelt was generally lower than the NAA under Alternative 4 operations (Figure 11-4-2). This pattern was most pronounced and most similar among subscenarios in wet and above-normal water years in which predicted entrainment was lowered by about one-third and one-quarter respectively. The predictions of adult delta smelt entrainment were lower than, but increasingly similar to, the NAA as modeled hydrology got drier (below-normal, dry, critical). Estimated entrainment under Scenario H3 would be 0.015 less (20% lower in relative terms) for adults and 0.019 less (9% lower in relative terms) for the combined juvenile and adult population compared to NAA (Table 11-4-1). These differences represent 2% or less of the population.

Entrainment losses of delta smelt at the SWP/CVP south Delta facilities are related to OMR flows. All of the Alternative 4 subscenarios include the same south Delta operational criteria, but the differences in spring and fall outflow result in minor differences in actual operations, and resultant minor differences in entrainment effects on delta smelt (Figures 11-4-1 and 11-4-2). Scenario H3 does not include enhanced spring outflow, although it includes stricter south Delta operational criteria relative to OMR flows as compared to the NAA. Because delta smelt entrainment occurs primarily in the winter and spring, Scenario H3 represents greatest potential effects of delta smelt entrainment based on methods that correlate spring OMR flows and delta smelt entrainment.

Table 11-4-1. Proportional Entrainment Index of Delta Smelt at SWP/CVP South Delta Facilities for Alternative 4 (Scenario H3)

Water Year	Proportional Entrainment[a] Difference in Proportions (Relative Change in Proportions)	
	EXISTING CONDITIONS vs. A4	NAA vs. A4
Total Population		
Wet	-0.017 (-16%)	-0.043 (-32%)
Above Normal	-0.010 (-6%)	-0.038 (-20%)
Below Normal	0.024 (11%)	-0.006 (-2%)
Dry	0.015 (6%)	-0.004 (-1%)
Critical	0.009 (3%)	0.010 (3%)
All Years	0.002 (1%)	-0.019 (-9%)
Juvenile Delta Smelt (March–June)		
Wet	0.011 (28%)	-0.016 (-24%)
Above Normal	0.011 (14%)	-0.018 (-16%)
Below Normal	0.034 (25%)	0.003 (1%)
Dry	0.024 (13%)	0.004 (2%)
Critical	0.015 (6%)	0.011 (4%)
All Years	0.018 (15%)	-0.005 (-3%)
Adult Delta Smelt[b] (December–March)		
Wet	-0.028 (-40%)	-0.027 (-39%)
Above Normal	-0.021 (-26%)	-0.020 (-25%)
Below Normal	-0.010 (-13%)	-0.008 (-10%)
Dry	-0.009 (-11%)	-0.008 (-10%)
Critical	-0.006 (-9%)	-0.001 (-2%)
All Years	-0.017 (-22%)	-0.015 (-20%)

Shading indicates >5% or more increased entrainment.

Note: Negative values indicate lower entrainment loss under Alternative 4 than under existing biological conditions.

[a] Proportional entrainment index calculated in accordance with USFWS BiOp (U.S. Fish and Wildlife Service 2008a).

[b] Adult proportional entrainment adjusted according to Kimmerer (2011).

Water Exports from SWP/CVP North Delta Intake Facilities

The impact would be similar in manner to Impact AQUA-3 in Alternative 1A for north Delta intakes, but possibly lower because Alternative 4 has fewer intakes. Potential entrainment and impingement risks at the proposed north Delta facilities would be limited since delta smelt rarely occur in the vicinity of the proposed intake sites (Swanson et al. 2005, 2010; White et al. 2007). The intakes would be screened to exclude fish larger than approximately 15 mm.

Water Exports with a Dual Conveyance for the SWP North Bay Aqueduct

Particle tracking modeling simulated delta smelt larval entrainment at the North Bay Aqueduct. A total of 38 runs were analyzed under Scenario H3, with each hydroperiod matched to a 20-mm larval delta smelt starting distribution on the basis of Delta outflow. Particle entrainment at the NBA was low, averaging 1.4% under Scenario H3 compared to 1.9% under NAA, or 25% lower in relative terms (Table 11-4-2).

Table 11-4-2. Average Percentage (and Difference) of Particles Representing Larval Delta Smelt Entrained by the North Bay Aqueduct under Alternative 4 (Scenario H3) and Baseline Scenarios

Average Percent Particles Entrained at NBA			Difference (and Relative Difference)	
EXISTING CONDITIONS	NAA	A4_LLT	A4_LLT vs. EXISTING CONDITIONS	A4_LLT vs. NAA
1.9	1.9	1.4	-0.52 (-27%)	-0.46 (-25%)

Note: 60-day DSM2-PTM simulation. Negative difference indicates lower entrainment under the alternative compared to the baseline scenario

Predation Associated with Entrainment

Under Alternative 4, pre-screen predation losses at the south Delta facilities would be reduced commensurate with the reductions in entrainment described above. Predation loss at the north Delta intakes may occur but would be limited because few delta smelt are anticipated to occur that far upstream.

NEPA Effects: Delta smelt entrainment under Alternative 4 would not be adverse relative to the NAA; model predictions indicate that notable reductions in entrainment would occur. Thus, Alternative 4 is likely to benefit delta smelt due to lower average entrainment and associated predation losses at the south Delta export facilities coupled with expectations of minimal entrainment risk at the north Delta facilities and NBA intakes.

CEQA Conclusion: As described above (Table 11-4-1), under Scenario H3 entrainment at the south Delta SWP/CVP water export facilities averaged across all years would be 0.017 less (a 22% relative decrease) for adult delta smelt, and 0.018 more (a 15% relative increase) for juvenile delta smelt compared to Existing Conditions. However, the percentage of the larval/juvenile population affected would be small (<2%). It is worth considering how this result differs from the NEPA conclusion set forth above. Under the CEQA analysis, Alternative 4 could substantially increase larval/juvenile proportional entrainment when compared to Existing Conditions. However, as described under Alternative 1A (Impact AQUA-3), this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. Note that the analysis for larvae and juveniles includes both OMR flows and X2 as predictors of proportional entrainment; primarily because of sea level rise assumptions, X2 would be further upstream in the ELT and LLT even with similar water operations, so that the comparison of Alternative 4 in the ELT and LLT to Existing Conditions is confounded. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment.

Therefore, the analysis of larval/juvenile delta smelt entrainment at the south Delta SWP/CVP water export facilities is better informed by the results from the NEPA analysis presented above, which accounts for sea level rise by considering the NAA in the LLT. When compared to NAA and informed by the NEPA analysis, above, larval-juvenile delta smelt entrainment is generally similar to conditions without BDCP (entrainment is reduced by 3%). Proportional entrainment under Scenario H1 would be similar to H3, and would be lower under Scenario H4. Entrainment under Scenario H1 would be similar to Scenario H3 and lower than Existing Conditions while conditions under Scenario H4 would further reduce entrainment relative to Scenario H3. Scenarios H1 and H4 represent the full range of conditions expected under the four potential outcomes for Alternative 4, and therefore entrainment is expected to be reduced under Alternative 4. Pre-screen delta smelt predation losses at the south Delta facilities would be no greater and may be lower compared to Existing Conditions due to lower overall entrainment. Predation losses at the north Delta intakes would be minimal because delta smelt rarely occur in that vicinity. Overall, the impact would be less than significant because overall entrainment of delta smelt would be reduced compared to Existing Conditions and only a small proportion of the delta smelt population would be affected. No mitigation would be required.

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

NEPA Effects: The effects of operations under Alternative 4 on abiotic spawning habitat would be similar as those described for Alternative 1A (Impact AQUA-4). Flows affect the amount of spawning habitat available to delta smelt (Hobbs et al. 2005; 2007), although spawning habitat is not known to be limited. Alternative 4 would reduce the flows downstream of the north Delta intakes, with the reduction being greatest for H1 and H3 (which do not include enhanced spring outflow) and lowest for H2 and H4 (which include enhanced spring outflow). However, flow reductions below the north Delta intakes are not expected to substantially reduce available spawning habitat under any of the operating scenarios for Alternative 4 because implementation of *CM4 Tidal Natural Communities Restoration* is expected to more than offset any loss of spawning habitat caused by reduced flows below the north Delta intakes. This is indicated by the results presented in Appendix 5E of the BDCP Effects Analysis (section 5E.4.2.4.4), wherein the habitat suitability index for delta smelt eggs/larvae in each subregion of the Plan Area is appreciably greater under the BDCP than under Existing Conditions. Therefore, there will be no adverse effect on delta smelt spawning.

CEQA Conclusion: As described above, operations under Alternative 4 would not reduce abiotic spawning habitat availability or change water temperatures for spawning delta smelt under any of the proposed flow scenarios. Consequently, the impact would be less than significant, and no mitigation is required.

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

Larval and juvenile delta smelt generally rear throughout the west Delta, Suisun Bay, Suisun Marsh, and in Cache Slough. Other areas in the Delta may also be used for rearing. The extent of abiotic habitat for delta smelt in the fall (September–December, the older juvenile rearing and maturation period) as a function of changes in flows was assessed using a technique based on the method of Feyrer and coauthors (2011) (as detailed in *BDCP Effects Analysis –Appendix 5.C, Flow, Section 5C.5.4.5.1 Delta Smelt Fall Abiotic Habitat Index hereby incorporated by reference*. *BDCP Effects Analysis –Appendix 5.E Habitat Restoration* presents additional analyses of effects on delta smelt related to juvenile habitat).

Feyrer and coauthors (2011) demonstrated that X2 in the fall correlates nonlinearly with an index of delta smelt abiotic habitat in the West Delta, Suisun Bay, and Suisun Marsh subregions, as well as smaller portions of the Cache Slough, South Delta, and North Delta subregions (see Figure 3 of Feyrer et al. 2011). Investigations in recent years have indicated that delta smelt occur year-round in the Cache Slough subregion, including Cache Slough, Liberty Island, and the Sacramento Deep Water Ship Channel (Baxter et al. 2010; Sommer et al. 2011). Whether the same individuals are residing in these areas for their full life cycles or different individuals are moving between upstream and downstream habitats is not known (Sommer et al. 2011). The delta smelt fall abiotic habitat index is the surface area of water in the west Delta, Suisun Bay, and Suisun Marsh (as well as smaller portions of the Cache Slough, South Delta, and North Delta subregions) weighted by the probability of presence of delta smelt based on water clarity (Secchi depth) and salinity (specific conductance) in the water. Feyrer and coauthors' (2011) method found these two variables to be significant predictors of delta smelt presence in the fall. They also concluded that water temperature was not a predictor of delta smelt presence in the fall, although it has been shown to be important during summer months (Nobriga et al. 2008).

Investigations in recent years have indicated that delta smelt occur year-round in the Cache Slough subregion, including Cache Slough, Liberty Island, and the Sacramento Deep Water Ship Channel (Baxter et al. 2010; Sommer et al. 2011). The degree of individual movement between upstream and downstream habitats has not been confirmed (Sommer et al. 2011), although emerging evidence suggests that a substantial fraction of the fish occurring in the upstream areas are residing there throughout the year (Hobbs in prep.).

Disagreements regarding the relationship between Fall X2 and delta smelt abundance prompted the development of the Fall X2 decision tree, which will use information generated by adaptive management processes under BDCP to inform operational rules for CM1 in the fall months.

The intent of the Fall X2 decision tree is to benefit delta smelt rearing habitat through some combination of outflow and physical habitat restoration. The decision tree branches represent several modeled possibilities for how operations and habitat restoration could combine to provide habitat benefits for this species. Scenarios H1 and H4 bracket a range of fall outflow operations that, based on current understanding, might be required. Scenarios H3 and H4 include Fall X2 per the 2008 Delta Smelt BiOp while Scenarios H1 and H2 do not. These differences drive the results presented below. Habitat restoration (CM4), particularly in the Suisun Marsh, West Delta, and Cache Slough ROAs is intended to improve rearing habitat suitability per unit of flow (see Results below), particularly by supplementing food production.

Analysis of larval and juvenile delta smelt habitat suitability in the restoration opportunity areas (ROAs) demonstrated that *CM4 Tidal Natural Communities Restoration* has the potential to result in considerably more suitable delta smelt habitat than currently exists.

Under Scenarios H3 and H4 operations (which include Fall X2), if it is assumed that habitat restoration will provide similar environmental conditions and occupancy to adjacent existing tidal areas, the abiotic habitat index would be 28-30% greater compared to NAA (Table 11-4-3). The greatest increase (34–38% higher compared to NAA) could occur in below normal and dry years. These estimates are based on an assumption that 100% of the newly restored habitat in Suisun Marsh, West Delta, and Cache Slough ROAs would be utilized by rearing delta smelt, and that food production benefits of the new habitat would be high. With fully effective BDCP habitat restoration actions, the abiotic habitat index under Scenario H1 would be similar (3% lower) than under the NAA, and with ineffective restoration, H1 would result in a 21% reduction in fall abiotic habitat compared to NAA.

NEPA Effects: The BDCP includes both water operations and habitat restoration components that are expected to provide habitat benefits to delta smelt. As described above, the contribution of operations to delta smelt habitat can be estimated on the basis of Delta outflow. The benefits of restored habitat for this species will depend on the success of restoration in creating physical habitat for smelt and in fostering ecological conditions that favor good feeding conditions and production of food upon which smelt can feed. The magnitude of restored habitat benefits is uncertain. As such, restoration success will have to be assessed empirically during the term of the BDCP permit. In the absence of restored habitat, or in the event BDCP habitat restoration does not produce the desired benefits, the average fall abiotic habitat index across all years would be similar to NAA in the Scenarios that include augmented fall outflow (2% greater under Scenario H3 and 3% greater under Scenario H4) (Figure 11-4-4, Table 11-4-3). Under Scenarios H1 and H2, which do not include Fall X2, the abiotic habitat index would be 21% (H1) and XX% (H2) lower than NAA. If BDCP habitat restoration produces large benefits for delta smelt, then the extent of suitable abiotic habitat and other habitat measures would be correspondingly higher in all scenarios, and the net benefits might exceed the NAA in the low outflow scenario.

Through the term of the permit, BDCP water operations will be subject to adjustment via adaptive management, beginning with the decision tree process in the years prior to CM1 operations. Recognizing the uncertainties of habitat restoration and disagreement regarding the importance of fall outflow augmentation to delta smelt, the Decision Tree phase of adaptive management is designed to allow for further evaluation of the need for fall outflow, concurrent with early evaluation of the level of benefits of BDCP habitat restoration for delta smelt. The decision tree process will inform a decision made at the time CM1 operations begin regarding the parameters of water operations. That decision will, on the basis of what has been learned about the effects of outflow and habitat restoration, identify CM1 operations that are expected to meet the delta smelt population growth and abundance objectives. Those operations will ensure the impacts of water operations on rearing habitat for delta smelt are not adverse and support a contribution to recovery of this species. Following this decision, the Adaptive Management Program will continue to evaluate the effects of water operations and habitat restoration on the delta smelt population, including making adjustments as appropriate to improve water supply reliability.

CEQA Conclusion: Without habitat restoration, the average fall abiotic habitat index for Alternative 4 would be greater than Existing Conditions for Scenario H3 (25% greater) and Scenario H4 (26% greater), and reduced 4% for Scenario H1 (Table 11-4-3). However, with habitat restoration under Alternative 4 (Scenarios H1–H4) the average fall abiotic habitat index would increase 21% under Scenario H1 and increase 57-59% under Scenarios H3 and H4 (Table 11-4-3, Figure 11-4-3).

Note that the CEQA analysis predicts a greater increase in the abiotic habitat index relative to baseline than the NEPA analysis. It is unclear whether this increase compared to Existing Conditions is a function of project operations under the alternative, or attributable to differences in modeling assumptions (Existing Conditions does not include Fall X2). The NEPA analysis is a better approach for isolating the effect of the alternative from the effects of sea level rise, climate change, future water demands, and implementation of required actions such as the Fall X2 requirement.

When compared to the NAA and informed by the NEPA analysis, the average delta smelt abiotic habitat index under Alternative 4 without restoration would be 21% lower under Scenario H1 and similar to baseline with Fall X2 under Scenarios H3 and H4. With restoration, the average abiotic index would be 3% lower under Scenario H1 and 28-30% greater under Scenarios H3 and H4 compared to NAA.

Overall, there would be a beneficial impact on the species compared to existing conditions without Fall X2, primarily from implementation of the restoration. The benefits of restored habitat for this species will depend on the success of restoration in creating physical habitat for smelt and in fostering ecological conditions that favor good feeding conditions and production of food upon which smelt can feed. The magnitude of restored habitat benefits is uncertain. As described above in the NEPA analysis, BDCP water operations will be subject to adjustment via adaptive management, in order to ensure the impacts of water operations on rearing habitat for delta smelt are not significant and to support a contribution to recovery of this species. The Adaptive Management Program with the decision tree process will evaluate the effects of water operations and habitat restoration on the delta smelt population, including adjustments as appropriate to improve water supply reliability.

Therefore, since Alternative 4 would benefit rearing delta smelt because the abiotic habitat index under all the flow scenarios would be greater than Existing Conditions, the impact is less than significant. No mitigation would be required.

Table 11-4-3. Differences in Delta Smelt Fall Abiotic Index (hectares) between Alternative 4 (Scenarios H3, H1, and H4) and Existing Biological Conditions Scenarios, with and without Habitat Restoration, Averaged by Prior Water Year Type

	EXISTING CONDITIONS vs. A4			NAA vs. A4		
Water Years	H3	H1	H4	H3	H1	H4
Without Restoration						
All	1,002 (25%)	-140 (-3.5%)	1,034 (26.0%)	116 (2%)	-1,022 (-21%)	153 (3%)
Wet	2,183 (46%)	-657 (-14.0%)	2,192 (46.6%)	-13 (0%)	-2,853 (-41%)	-4 (0%)
Above Normal	1,718 (45%)	13 (0.3%)	1,739 (45.5%)	50 (1%)	-1,655 (-30%)	72 (1%)
Below Normal	-5 (0%)	32 (0.8%)	156 (3.8%)	233 (6%)	180 (5%)	303 (8%)
Dry	222 (6%)	267 (7.5%)	282 (7.9%)	313 (9%)	358 (10%)	373 (11%)
Critical	24 (1%)	27 (0.9%)	33 (1.1%)	23 (1%)	26 (1%)	33 (1%)
With Restoration						
All	2,335 (59%)	821 (20.6%)	2,289 (57.5%)	1,449 (30%)	-155 (-3%)	1,453 (28%)
Wet	4,073 (87%)	339 (7.2%)	3,909 (83.1%)	1,876 (27%)	-1,857 (-27%)	1,712 (25%)
Above Normal	3,228 (84%)	1,057 (27.6%)	3,250 (85.0%)	1,560 (28%)	-610 (-11%)	1,583 (29%)
Below Normal	1,222 (30%)	1,152 (27.8%)	1,305 (31.5%)	1,370 (34%)	1,300 (33%)	1,453 (36%)
Dry	1,216 (34%)	1,243 (34.9%)	1,268 (35.6%)	1,308 (38%)	1,334 (38%)	1,359 (39%)
Critical	729 (24%)	630 (21.1%)	575 (19.3%)	728 (24%)	630 (21%)	575 (19%)

Note: Negative values indicate lower habitat indices under alternative scenarios. Water year 1922 was omitted because water year classification for prior year was not available.

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

From December to March, many mature delta smelt migrate upstream from brackish rearing areas in and around Suisun Bay and the confluence of the Sacramento and San Joaquin Rivers (U.S. Fish and Wildlife Service 2008a; Sommer et al. 2011). The initiation of migration is associated with pulses of freshwater inflow, which are turbid, cool, and less saline (Grimaldo et al. 2009). Changes in flow under Alternative 4 could change turbidity, but is not expected to result in changes in water temperatures or pulses of local rainwater into the Delta. As described above in Impact AQUA-4, in-Delta water temperatures would not change in response to Alternative 4 flows. The modeling results indicate no biologically meaningful changes in water temperature within the Delta under Alternative 4 and no substantial changes in the number of stressful or lethal condition days for juveniles.

Turbid water is an important habitat characteristic for delta smelt (Nobriga et al. 2008; Feyrer et al. 2011), and has been correlated to long-term changes in delta smelt abundance or survival either by itself or in combination with other factors (Thomson et al. 2010; Miller et al. 2012). Therefore, it is assumed that turbidity is an attribute of critical importance to delta smelt larvae, juveniles, and adults. Operation of the north Delta intakes (*CM1 Water Facilities and Operation*) is estimated to result in around 8 to 9% less sediment entering the Plan Area from the Sacramento River, the main source of sediment for the Delta and downstream subregions. In addition, sediment could be accreted (captured) in the ROAs (*CM4 Tidal Natural Communities Restoration*). Notching the Fremont Weir (*CM2 Yolo Bypass Fisheries Enhancements)* will also direct more Sacramento River water and sediment into the Bypass. These actions could limit sediment supply to areas currently important to delta smelt, such as Suisun Bay, which would result in less seasonal deposition of sediment that could be resuspended by wind-wave action to make/keep the overlying water column turbid. Therefore, there is a potential for a slight increase in water clarity, and a corresponding reduction in habitat quality for delta smelt. However, Alternative 4 is not expected to affect suspended sediment concentration during the first flush of precipitation that cues delta smelt migration. As such, turbidity cues associated with adult delta smelt migration should not change. With regard to suspended sediment concentrations at other times of the year, any effect will be minimized through the reintroduction of sediment collected at the north Delta intakes into tidal natural communities restoration projects (CM4), consistent with the Environmental Commitment addressing Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material.

NEPA Effects: Alternative 4 may decrease sediment supply to the estuary by 8 to 9 percent, with the potential for decreased habitat suitability for delta smelt in some locations.

CEQA Conclusion: As described above, operations for all flow operating scenarios under Alternative 4 would not substantially alter the turbidity cues associated with winter flush events that may initiate migration, nor would there be appreciable changes in water temperatures. Consequently, the impact on adult delta smelt migration conditions would be less than significant, and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same restoration measures as Alternative 1A. Because no substantial differences in impacts of tidal habitat restoration on delta smelt are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the effects of restoration measures described for delta smelt under Alternative 1A (Impacts AQUA-7 through AQUA-9) also appropriately disclose the anticipated effects of habitat restoration in Alternative 4.

The following impacts are those presented under Alternative 1A that are anticipated to be identical for Alternative 4.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on delta smelt are the same for Alternative 4, as those described under Alternative 1A (Impacts AQUA 7-through AQUA-9). Despite the anticipated improvements in habitat and habitat functions in the Delta from tidal habitat restoration activities, habitat quality for delta smelt is expected to decline by the LLT primarily because of climate change (Cloern et al. 2011; Brown et al. 2013). However, it is concluded that overall, the effect of landscape restoration activities in Alternative 4 relative to NAA is expected to provide a net benefit for delta smelt, which spend their entire lives in the Plan Area. The ultimate performance of habitat restoration is expected to interact with river and Delta outflows such that the benefits of habitat restoration would be greatest in H4 and lowest in H1. Specifically for AQUA-8, the effects of contaminants on delta smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on delta smelt are uncertain.

CEQA Conclusion: All three of the impact mechanisms listed above would be beneficial or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for delta smelt under Alternative 1A (Impacts AQUA-10 through AQUA-18) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (CM12)

Impact AQUA-11: Effects of Invasive Aquatic Vegetation Management on Delta Smelt (CM13)

Impact AQUA-12: Effects of Dissolved Oxygen Level Management on Delta Smelt (CM14)

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (CM15)

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (CM16)

Impact AQUA-15: Effects of Illegal Harvest Reduction on Delta Smelt (CM17)

Impact AQUA-16: Effects of Conservation Hatcheries on Delta Smelt (CM18)

Impact AQUA-17: Effects of Urban Stormwater Treatment on Delta Smelt (CM19)

Impact AQUA-18: Effects of Removal/Relocation of Nonproject Diversions on Delta Smelt (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on delta smelt are the same as those described under Alternative 1A (Impacts AQUA-10 through AQUA-18). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

Longfin Smelt

Construction and Maintenance of CM1

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

The potential effects of construction of the water conveyance facilities on longfin smelt would be similar to those described for Alternative 1A (Impact AQUA-19) except that Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging). Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less.

Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-19, the effect would not be adverse for longfin smelt.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-19, the impact of the construction of water conveyance facilities on longfin smelt would not be significant except for construction noise associated with pile driving. Potential pile driving impacts under Alternative 4 would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

NEPA Effects: The potential effects of water conveyance facilities maintenance under Alternative 4 would be the similar to those described for Alternative 1A, Impact AQUA-20, except that only three intakes would need to be maintained under Alternative 4 instead of the five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-20, the impact would not be adverse for longfin smelt.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-20, the impact of the maintenance of water conveyance facilities on longfin smelt would not be significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Water Exports from SWP/CVP South Delta Facilities

For larval longfin smelt, entrainment risk was simulated using particle tracking modeling for wetter and drier starting distributions. Average particle entrainment by the south Delta facilities was 1.0–1.3% under Scenario H3, which does not include enhanced spring outflow, compared to 1.4–1.8% under NAA. Larval entrainment under Scenario H1 would be similar to Scenario H3 because of similar spring outflow and south Delta operations. Under Scenarios H2 and H4 for Alternative 4, which include enhanced spring outflow, larval longfin smelt entrainment would be lower than NAA because of the enhanced spring outflow criteria that results in a further reduction in south Delta exports.

Table 11-4-4. Percentage of Particles (and Difference) Representing Longfin Smelt Larvae Entrained by the South Delta Facilities under Alternative 4 (Scenario H3) and Baseline Scenarios

	Percent Particles Entrained			Difference (and Relative Difference)	
Starting Distribution	EXISTING CONDITIONS	NAA	A4_LLT	A4_LLT vs. EXISTING CONDITIONS	A4_LLT vs. NAA
Wetter	1.7	1.4	1.0	-0.69 (-41%)	-0.45 (-31%)
Drier	2.1	1.8	1.3	-0.83 (-39%)	-0.50 (-28%)

Note: 60-day DSM2-PTM simulation of wetter and drier starting distributions. Negative values indicate lower entrainment under the alternative compared to the baseline scenario.

For juveniles and adults, entrainment at the south Delta facilities (entrainment index based on the salvage-density method, averaged across all water year types) under the Scenario H3 would be 42% lower for juveniles and 52% lower for adults compared to baseline conditions (Table 11-4-5). Scenarios H2 and H4 would result in even greater reductions in entrainment, due to higher spring outflows and the associated reduction in south Delta exports. Under all Alternative 4 scenarios, the predicted adult and juvenile entrainment decreases in all five water year types. Estimated entrainment under Scenario H1 would be similar to Scenario H3.

Table 11-4-5. Longfin Smelt Entrainment Index at the SWP and CVP Salvage Facilities—Differences (Absolute and Percentage) between Model Scenarios for Alternative 4 (Scenario H3)

		Absolute Difference (Percent Difference)	
Life Stage	Water Year Types	EXISTING CONDITIONS vs. A4 (H3)	NAA vs. A4 (H3)
Juvenile (March–June)	Wet	-34,213 (-54%)	-39,655 (-57%)
	Above Normal	-1,054 (-23%)	-1,343 (-28%)
	Below Normal	-571 (-19%)	-779 (-24%)
	Dry	-65,111 (-12%)	-123,418 (-21%)
	Critical	-199,486 (-35%)	-125,616 (-25%)
	All Years	-97,872 (-37%)	-122,883 (-42%)
Adult (December–March)	Wet	-67 (-52%)	-71 (-53%)
	Above Normal	-302 (-46%)	-342 (-50%)
	Below Normal	-728 (-38%)	-650 (-35%)
	Dry	-364 (-30%)	-299 (-26%)
	Critical	-7,981 (-33%)	-5,847 (-26%)
	All Years	-1,885 (-52%)	-1,849 (-52%)

Water Exports from SWP/CVP North Delta Intake Facilities

As described under Alternative 1A for Impact AQUA-22, longfin smelt are not known to spawn in the reach of the Sacramento River where the north Delta diversions will be built. Therefore, entrainment of longfin smelt at the proposed north Delta intakes would be extremely low because this species is only expected to occur occasionally in very low numbers this far upstream on the Sacramento River.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

Particle tracking modeling was used to simulate larval longfin smelt entrainment to the NBA under Scenario H3. In general, average percent particle entrainment at the NBA under both NAA and Scenario H3 was about 0.1% for the wetter starting distribution, and was just under 0.2% for Alternative 4 and 0.14% for NAA under the drier starting distribution (Table 11-4-6). Entrainment of larval longfin smelt under Alternative 4 for all scenarios is expected to be low and similar to NAA. Note that the PTM modeling results do not account for the provision of an alternative NBA intake on the Sacramento River upstream of longfin smelt likely areas of occurrence, which potentially would reduce the number of longfin smelt larvae that otherwise would be entrained at the Barker Slough intake to the NBA.

Table 11-4-6. Percentage of Particles (and Difference) Representing Longfin Smelt Larvae Entrained by the North Bay Aqueduct under Alternative 4 (Scenario H3) and Baseline Scenarios

Starting Distribution	Percent Particles Entrained: EXISTING CONDITIONS	NAA	A4_LLT	Difference (and Relative Difference): A4_LLT vs. EXISTING CONDITIONS	A4_LLT vs. NAA
Wetter	0.10	0.09	0.10	0.00 (-3%)	0.01 (10%)
Drier	0.18	0.14	0.19	0.01 (7%)	0.04 (31%)

Note: Values reported are averages of 60-day DSM2-PTM simulation of wetter and drier starting distributions, based on 27 simulated months. Negative values indicate lower entrainment under the alternative compared to the baseline scenario.

Predation Associated with Entrainment

Pre-screen predation losses of longfin smelt at the SWP/CVP south Delta water export facilities are believed to be high and proportional to entrainment. It is assumed that pre-screen predation losses of longfin smelt would be similar to delta smelt based on their similar size, shape, and pelagic nature. Predation losses of both juvenile and adult longfin smelt under Alternative 4 would be no greater than baseline and may be lower, given the much lower entrainment losses at the south Delta facilities (37–42% lower for juveniles and 52–53% lower for adults) compared to NAA (Table 11-4-5). Predation loss at the proposed north Delta intakes would be unlikely because longfin smelt do not generally occur that far upstream on the Sacramento River. Under the range of flow operating scenarios under Alternative 4, entrainment-related predation loss would be reduced relative to NAA, with the greatest decreases in entrainment occurring under Scenario H4.

NEPA Effects: To summarize, predation of juvenile and adult longfin smelt, as a function of entrainment at the SWP/CVP south Delta facilities, would be reduced substantially under all flow operating scenario for Alternative 4 compared to NAA across all water years (Table 11-4-5). Predation loss of longfin smelt at the proposed north Delta intakes would be unlikely since longfin smelt are not expected to occur in that area of the Sacramento River. Longfin smelt entrainment to the NBA, and associated predation, would be unchanged compared to NAA. The predation risk associated with the NPB structures would be low, the same as described for Alternative 1A. In conclusion, Alternative 4 would not have an adverse effect on entrainment-related predation and would likely provide a benefit to the species because of substantial reductions in juvenile and adult entrainment at the south Delta facilities.
