CEQA Conclusion: Entrainment of all life stages of longfin smelt at the south Delta facilities would be reduced under Alternative 4 compared to Existing Conditions. Particle entrainment, representing larval longfin smelt, was lower under Alternative 4 for both drier and wetter starting distributions (refer to *BDCP Appendix 5.B* for further details). Entrainment loss would be substantially lower for both juvenile (37% less) and adult longfin smelt (52% less) (Table 11-4-5). Entrainment to the north Delta intakes would be unlikely because longfin smelt are not expected to occur in the vicinity of the intakes. Larval entrainment to the NBA, as indicated by particle tracking, would be minimal under both wetter (0.1%) and drier (0.2%) starting distributions, and at levels similar to the Existing Conditions. In conclusion, Alternative 4 would provide a benefit to the species because of the substantial reductions in south Delta entrainment, and therefore no mitigation would be required.

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

Adult longfin smelt inhabit primarily brackish water and marine areas in San Pablo and San Francisco Bays and nearshore coastal marine waters. Prespawning adult longfin smelt use the Delta for staging and spawning. The planktonic larvae are transported downstream after hatching; within the Plan Area, the early juvenile life stages rear in the low-salinity areas of the West Delta and Suisun Bay subregions. Juvenile and adult longfin smelt occupying the Plan Area during fall through spring migrate westward into San Francisco Bay during the summer.

Longfin smelt spawn in the late winter and early spring months when water temperatures in the lower rivers and Delta are seasonally cool. Longfin smelt spawn adhesive eggs that are thought to be deposited on sand and gravel and possibly other hard substrates. Spawning occurs in the lower reaches of the Sacramento River in the vicinity of Cache Slough and Rio Vista, although some spawning occurs in the lower San Joaquin River based on presence of early larval and adult longfin smelt in CDFW larval trawl samples (California Department of Fish and Game 2009b). Spawning also occurs in Suisun Marsh and the Napa River.

Immediately after hatching from the incubating eggs, longfin smelt larvae are planktonic and drift passively with water flows; older larvae use a variety of behaviors to help retain themselves in favorable habitats (Bennett et al. 2002). Larvae are typically present in the Delta during the late winter and early spring months. Juvenile longfin smelt rear in the spring (approximately March to June) in the Suisun Bay and the West Delta subregions before migrating downstream of the Plan Area into San Pablo and San Francisco Bays and nearshore coastal marine waters, where they continue to rear for a year or more. Larval and early juvenile longfin smelt could be affected by covered activities when they are present in the Plan Area during the winter and spring months.

Longfin smelt rear in the Plan Area principally during spring and the abundance of longfin smelt in the Fall Midwater Trawl (FMWT) has been correlated to outflow (expressed as the location of X2) in the preceding winter and spring months (January–June), when spawning and rearing are occurring (Kimmerer 2002a; Kimmerer et al. 2009; Rosenfield and Baxter 2007; Mac Nally et al. 2010; Thomson et al. 2010). Based on Kimmerer et al. (2009), reduced outflow in January through June, compared to the NAA, has the potential to reduce longfin smelt abundance. The X2–longfin smelt abundance relationship provided by Kimmerer et al. (2009) was used to evaluate the effects of the alternatives on longfin smelt, following the historical observation that lower X2 (farther downstream) would contribute to increased recruitment. Relationships between December through May X2 position and log longfin smelt abundance developed by Kimmerer et al. (2009) were used to determine how the changes in winter-spring X2 position described above might influence longfin smelt abundance the following fall.

Table 11-4-7. Differences in Mean Monthly Delta Outflow (cfs) between NAA and Alternative 4 Scenarios H1, H2, H3, and H4, by Water Year Type, for Winter-Spring (December–June)

Month	Water-Year Type	NAA vs. H1	NAA vs. H2	NAA vs. H3	NAA vs. H4

Ultimately, initial Alternative 4 water operations will be determined through the BDCP decision tree process to determine the necessary spring Delta outflow. Under Scenarios H1 and H3, which do not include enhanced spring outflow, modeled average Delta spring outflow is often lower than the NAA. The spring outflows in H2 and H4, which include the enhanced spring outflow, were greater than NAA in a number of years, as illustrated by differences in water-year-type average Delta outflow (See Table 11-4-7 above). As such, based on Kimmerer et al. 2009, the longfin smelt abundance for H1 and H3 ranged from a reduction of 32 to 37% compared to Existing Conditions, to a reduction of 3% to an increase of 3% compared to the NAA. For H2 and H4, which include enhanced spring outflow and climate change effects, the predicted longfin smelt abundance ranged from a reduction of 26% to 30% compared to Existing Conditions to an increase of 12% to 16% when compared to the NAA, based on the X2-abundance equation in Kimmerer et al. (2009).

NEPA Effects: Through the term of the permit, BDCP water operations will be subject to adjustment via adaptive management, beginning with the decision tree process in the years prior to CM1 operations. Recognizing the uncertainties of habitat restoration and disagreement regarding the magnitudes of spring outflow augmentation necessary to support the conservation of longfin smelt, the Decision Tree phase of adaptive management is designed to allow for further evaluation of this, and other species' spring outflow needs, concurrent with early evaluation of the level of benefits of BDCP habitat restoration for longfin smelt. The decision tree process will inform a decision made at the time CM1 operations begin regarding the parameters of water operations. That decision will, on the basis of what has been learned about the effects of outflow and habitat restoration, identify CM1 operations that are expected to meet the longfin smelt population growth objective. Those operations will ensure the impacts of water operations on rearing habitat for longfin smelt are not adverse and support a contribution to recovery of this species. Following this decision, the Adaptive Management Program will continue to evaluate the effects of water operations and habitat restoration on the longfin smelt population, including making adjustments as appropriate to improve water supply reliability.

Table 11-4-8. Estimated Differences Between Alternative 4 (Scenario H3) and Baseline for Longfin Smelt Relative Abundance in the Fall Midwater Trawl or Bay Otter Trawl Based on the X2-Relative Abundance Regression of Kimmerer et al. (2009)

	Shading indicates relative abundance under Alt4 decrease of 10% or greater.			

CEQA Conclusion: Under Alternative 4, average Delta outflow would be slightly greater than under Existing Conditions during January and February (Table 11-4-9). Under Scenarios H1 and H3, monthly Delta outflow is reduced in March to June compared to Existing Conditions, with variation among water year types. Under Scenarios H2 and H4, average Delta outflows would be similar to Existing Conditions from January to April, but on average 12% lower in May and 17% lower in June.

Table 11-4-9. Differences in Mean Monthly Delta Outflow (cfs) between Existing Conditions and Alternative 4 Scenarios H1, H2, H3, and H4, by Water Year Type, for Winter-Spring (December–June)

Average relative abundance of longfin smelt, as estimated by the Kimmerer et al. 2009 method, is 32% to 38% lower under Scenarios H1 and H3 compared to Existing Conditions (Table 11-4-8). For H2 and H4, which include enhanced spring outflow, the longfin smelt abundance is 26% to 31% lower compared to Existing Conditions, based on Kimmerer et al. 2009.

Contrary to the NEPA conclusion set forth above, these results indicate that the difference between Existing Conditions and Alternative 4 could be significant because the alternative could substantially reduce relative abundance based on Kimmerer 2009. However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed above (Section 11.3.3), because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA) models anticipated future conditions that would occur in 2060 (LLT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the NEPA analysis, which compares results between the alternative and NAA, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA and informed by the NEPA analysis, above, the average longfin smelt abundance, based on Kimmerer et al. (2009), increased 1% to 5% for H1 and H3, and increased 12% to 16% for H2 and H4, which include enhanced spring outflow (Table 11-4-8). These results represent the increment of change attributable to the alternative, demonstrating the similarities in modeled longfin smelt recruitment under Alternative 4 and the NAA, and addressing the limitations of the comparison the CEQA baseline (Existing Conditions). Furthermore, the decision tree process, which is part of the Adaptive Management and Monitoring Program, is designed to allow for an evaluation of the needed volume of spring outflow and to inform a decision regarding starting operations. This will help the BDCP to meet the longfin smelt population growth and abundance objectives, and will ensure the impacts of water operations on spawning, egg incubation and rearing habitat for longfin smelt are less than significant. After initial starting operations, the Adaptive Management Program will continue to evaluate water operations and make adjustments as necessary to protect longfin smelt abundances and ensure the impacts of water operations on spawning, egg incubation and rearing habitat for longfin smelt are less than significant. Therefore, this impact is found to be less than significant and no mitigation is required. In addition, CM4 could also improve the quality of spawning and rearing habitat for longfin smelt, by increasing suitable habitat area and food production in the Delta, although there is some uncertainty of the outcome related to habitat restoration.

Impact AQUA-23: Effects of Water Operations on Rearing Habitat for Longfin Smelt

The analysis, NEPA Effects and CEQA Conclusion for effects of water operations on rearing habitat for longfin smelt is included in Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt.

Impact AQUA-24: Effects of Water Operations on Migration Conditions for Longfin Smelt

The analysis, NEPA Effects and CEQA Conclusion for effects of water operations on migration conditions for longfin smelt is included in Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same restoration measures as Alternative 1A. Because no substantial differences in restoration-related effects on fish are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the effects of restoration measures on longfin smelt described under Alternative 1A (Impacts AQUA-25 through AQUA-27) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on longfin smelt are the same, as those described under Alternative 1A (Impacts AQUA-25 through AQUA-27). The effects would not be adverse, and would generally be beneficial. Specifically for AQUA-26, the effects of contaminants on longfin smelt with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on longfin smelt are uncertain.

CEQA Conclusion: All three of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related effects on fish are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the effects of other conservation measures on longfin smelt described under Alternative 1A (Impacts AQUA-28 through AQUA-36) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (CM12)

Impact AQUA-29: Effects of Invasive Aquatic Vegetation Management on Longfin Smelt (CM13)

Impact AQUA-30: Effects of Dissolved Oxygen Level Management on Longfin Smelt (CM14)

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (CM15)

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (CM16)

Impact AQUA-33: Effects of Illegal Harvest Reduction on Longfin Smelt (CM17)

Impact AQUA-34: Effects of Conservation Hatcheries on Longfin Smelt (CM18)

Impact AQUA-35: Effects of Urban Stormwater Treatment on Longfin Smelt (CM19)

Impact AQUA-36: Effects of Removal/Relocation of Nonproject Diversions on Longfin Smelt (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on longfin smelt are the same as those described under Alternative 1A (Impacts AQUA-28 through AQUA-36). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

Winter-Run Chinook Salmon

Construction and Maintenance of CM1

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

The potential effects of construction of the water conveyance facilities on winter-run Chinook salmon would be the same as those described for Alternative 1A (Impact AQUA-37) except that Alternative 4 would include three intakes instead of five, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less. Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-37, the effect would not be adverse for Chinook salmon.

CEQA Conclusion: As described in Alternative 1A (Impact AQUA-37) the impact of construction of the water conveyance facilities on Chinook salmon would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A (Impact AQUA-38) except that only three intakes would need to be maintained under Alternative 4 rather than five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-38, the impact would not be adverse for winter-run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-38, the impact of the maintenance of water conveyance facilities on Chinook salmon would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

The proportion of juvenile winter-run Chinook salmon subject to entrainment is low under Existing Conditions and NAA (annual index of abundance average 1.4%) and Alternative 4 would further reduce entrainment of juvenile winter-run Chinook salmon at the south Delta facilities. For example, Scenario H3 would reduce the proportion of juvenile winter-run Chinook entrained in the south Delta (average of 0.6%). As such, average entrainment under Scenario H3 would be reduced by 52% (~3,500 fish: Table 11-4-10) across all water years compared to NAA. Entrainment would be substantially reduced in wet and above normal water year types (60–70% less than NAA) and would be moderately reduced in below normal, dry, and critical water year types (18–33% less than NAA).

Scenarios H2 and H4 is expected to further reduce entrainment of winter-run salmon because south Delta exports during the spring would be less relative to the Scenario H3. Entrainment losses under Scenario H1 are expected to be similar to Scenario H3.

Table 11-4-10. Juvenile Winter-Run Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 4 (Scenario H3)

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-7,816 (-69%)	-8,237 (-70%)
Above Normal	-3,919 (-59%)	-4,043 (-60%)
Below Normal	-2,666 (-37%)	-2,241 (-33%)
Dry	-1,116 (-29%)	-809 (-23%)
Critical	-343 (-27%)	-205 (-18%)
All Years	-3,584 (-53%)	-3,524 (-52%)

Note: Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

The effect of Alternative 4 on entrainment and impingement at the north Delta intakes would be the same as described for Alternative 1A (Impact AQUA-39), but the degree would be less because Alternative 4 would have fewer intakes. State-of-the-art fish screens operated with an adaptive management plan would be expected to eliminate entrainment risk for juvenile winter-run Chinook salmon.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The effect would be the same as described for Alternative 1A (Impact AQUA-39). Entrainment and impingement effects would be minimal because intakes on the Sacramento River would have state-of-the-art screens installed.

Predation Associated with Entrainment

Entrainment-related predation loss of winter-run Chinook salmon at the south Delta facilities under this alternative would be no greater than loss under NAA and may be lower than loss under NAA due to a decrease in entrainment loss. Entrainment-related predation losses at the south Delta under Scenario H1 are expected to be similar to Scenario H3, and decreased further under Scenarios H2 and H4 as spring outflow is increased and south Delta exports are decreased.

Predation at the north Delta would be increased due to the installation of the proposed SWP/CVP North Delta intake facilities on the Sacramento River. Bioenergetics modeling with a median predator density predicts increased predation loss of about 4,300 juveniles, or 0.16% of the winter-run Chinook salmon juvenile index of abundance under Alternative 4 (Table 11-4-11).

Table 11-4-11. Winter-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion (NDD) Intakes (Three Intakes for Alternative 4)

Striped Bass at NDD (Three Intakes)			Winter-Run Chinook Consumed	
Density Assumption	Bass per 1,000 Feet of Intake	Total Number of Bass	Number	Percentage of Annual Juvenile Production
Low	18	86	648	0.02%
Median	119	571	4,283	0.16%
High	219	1,051	7,881	0.30%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (Appendix 5F Biological Stressors).

NEPA Effects: In conclusion, Alternative 4 would reduce overall entrainment losses of juvenile winter-run Chinook salmon relative to NAA. This effect would not be adverse and would provide a benefit to the species because of the reductions in entrainment loss and mortality.

CEQA Conclusion: As described above, entrainment losses of juvenile winter-run Chinook salmon at the south Delta facilities would decrease under Alternative 4 compared to Existing Conditions (Table 11-4-10). Overall, impacts of water operations on entrainment of juvenile Chinook salmon (winter-run ESU) would be less than significant and may be beneficial. No mitigation would be required.

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

In general, the effects of Alternative 4 on spawning and egg incubation habitat for winter-run Chinook salmon relative to the NAA are uncertain.

H3/ESO

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam were examined during the May through September winter-run spawning period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation. Flows under H3 would generally be greater (by up to 20%) than flows under NAA during May and June and similar during July through September. Based on these flow results, it is expected that H3 would generally provide flow-related benefits to winter-run Chinook salmon spawning and egg incubation habitat in earlier months and no effects in later months.

Shasta Reservoir storage volume at the end of May influences flow rates below the dam during the May through September winter-run spawning and egg incubation period. May Shasta storage under H3 would be similar (<5% difference) to storage under NAA for all water year types (Table 11-4-12).

Table 11-4-12. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Alternative 4 (Scenario H3)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-59 (-1%)	-25 (-1%)
Above Normal	-156 (-3%)	-70 (-2%)
Below Normal	-330 (-8%)	-132 (-3%)
Dry	-550 (-15%)	-106 (-3%)
Critical	-622 (-25%)	-38 (-2%)

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H3in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-15. There would be no difference in levels of concern between NAA and H3.

Table 11-4-13. Maximum Water Temperature Criteria for Covered Salmonids and Sturgeon Provided by NMFS and Used in the BDCP Effects Analysis

Location	Period	Maximum Water Temperature (°F)	Purpose
Upper Sacramento River			
Bend Bridge	May–Sep	56	Winter- and spring-run spawning and egg incubation
		63	Green sturgeon spawning and egg incubation
Red Bluff	Oct–Apr	56	Spring-, fall-, and late fall–run spawning and egg incubation
Hamilton City	Mar–Jun	61 (optimal), 68 (lethal)	White sturgeon spawning and egg incubation
Feather River			
Robinson Riffle (RM 61.6)	Sep–Apr	56	Spring-run and steelhead spawning and incubation
	May–Aug	63	Spring-run and steelhead rearing
Gridley Bridge	Oct–Apr	56	Fall- and late fall–run spawning and steelhead rearing
	May–Sep	64	Green sturgeon spawning, incubation, and rearing
American River			
Watt Avenue Bridge	May–Oct	65	Juvenile steelhead rearing

Table 11-4-14. Number of Days per Month Required to Trigger Each Level of Concern for Water Temperature Exceedances in the Sacramento River for Covered Salmonids and Sturgeon Provided by NMFS and Used in the BDCP Effects Analysis

Exceedance above Water Temperature Threshold (°F)	Level of Concern			
	None	Yellow	Orange	Red
1	0–9 days	10–14 days	15–19 days	≥20 days
2	0–4 days	5–9 days	10–14 days	≥15 days
3	0 days	1–4 days	5–9 days	≥10 days

Table 11-4-15. Differences between Baseline and H3 Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. H3	NAA vs. H3
Red	31 (61%)	0 (0%)
Orange	-17 (-100%)	0 (NA)
Yellow	-11 (-100%)	0 (NA)
None	-3 (-100%)	0 (NA)

Note: For definitions of levels of concern, see Table 11-4-14.
NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4-16). Total degree-days under H3 would be up to 11% lower than under NAA during May and June and up to 11% higher during July through September.

Table 11-4-16. Differences between Baseline and H3 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
May	Wet	1,065 (282%)	-137 (-9%)
	Above Normal	228 (107%)	-127 (-22%)
	Below Normal	434 (198%)	-29 (-4%)
	Dry	246 (132%)	-168 (-28%)
	Critical	454 (205%)	44 (7%)
	All	2,427 (200%)	-417 (-10%)
June	Wet	500 (130%)	-211 (-19%)
	Above Normal	66 (45%)	-163 (-43%)
	Below Normal	276 (199%)	-76 (-15%)
	Dry	514 (273%)	-20 (-3%)
	Critical	623 (155%)	73 (8%)
	All	1,979 (157%)	-397 (-11%)
July	Wet	653 (126%)	47 (4%)
	Above Normal	347 (428%)	77 (22%)
	Below Normal	591 (402%)	135 (22%)
	Dry	1,313 (466%)	385 (32%)
	Critical	1,776 (216%)	-10 (-0.4%)
	All	4,680 (253%)	634 (11%)
August	Wet	2,091 (300%)	128 (5%)
	Above Normal	830 (203%)	171 (16%)
	Below Normal	1,246 (470%)	211 (16%)
	Dry	2,063 (308%)	453 (20%)
	Critical	2,732 (184%)	113 (3%)
	All	8,962 (254%)	1,076 (9%)
September	Wet	806 (109%)	97 (7%)
	Above Normal	586 (82%)	186 (17%)
	Below Normal	1,570 (210%)	424 (22%)
	Dry	2,425 (190%)	-171 (-4%)
	Critical	1,938 (93%)	47 (1%)
	All	7,325 (132%)	583 (5%)

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under H3 would be lower or similar to mortality under NAA except in below normal and dry water years (76% and 11% greater, respectively), although the absolute increase in these water years would be only 1% (Table 11-4-17). Therefore, the increase in mortality from NAA to H3, although relatively large, would be negligible at an absolute scale to the winter-run population.

Table 11-4-17. Difference and Percent Difference in Percent Mortality of Winter-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	1 (262%)	-0.1 (-4%)
Above Normal	2 (340%)	-0.1 (-3%)
Below Normal	2 (228%)	1 (76%)
Dry	7 (436%)	1 (11%)
Critical	42 (156%)	-2 (-3%)
All	9 (185%)	0.1 (1%)

SacEFT predicts that there would be a 28% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under H3 relative to NAA (Table 11-4-18). On an absolute scale, this reduction would be small (9% lower). SacEFT predicts that the percentage of years with good (lower) redd scour risk, good (lower) redd dewatering risk, and good egg incubation conditions under H3 would be similar to the percentage of years under NAA. These results indicate that there would be a small negative effect of H3 on spawning habitat, but no effects on other modeled parameters.

The biological significance of a reduction in available suitable spawning habitat varies at the population level in response to a number of factors, including adult escapement. For those years when adult escapement is less than the carrying capacity of the spawning habitat, a reduction in area would have little or no population level effect. In years when escapement exceeds carrying capacity of the reduced habitat, competition among spawners for space (e.g., increased redd superimposition) would increase, resulting in reduced reproductive success. The reduction in the frequency of years in which spawning habitat availability is considered to be good by SacEFT could result in reduced reproductive success and abundance of winter-run Chinook salmon if the number of spawners is limited by spawning habitat quantity.

Table 11-4-18. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Winter-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3	NAA vs. H3
Spawning WUA	-35 (-60%)	-9 (-28%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-25 (-26%)	-2 (-3%)
Redd Dewatering Risk	3 (12%)	-1 (-3%)
Juvenile Rearing WUA	-24 (-48%)	1 (4%)
Juvenile Stranding Risk	0 (0%)	-11 (-35%)
WUA = Weighted Usable Area.		

H1/LOS

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H1 between May and September would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).* Further, May storage in Shasta Reservoir under H1 would be similar to storage under H3 (Table 11-4-19).

Table 11-4-19. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Shasta Reservoir for H1, H3, and H4 Scenarios

Water Year	H3 vs. H1	H3 vs. H4
Wet	-1 (-0.02%)	15 (0.4%)
Above Normal	7 (0.2%)	17 (0.4%)
Below Normal	34 (0.9%)	149 (3.9%)
Dry	115 (3.6%)	117 (3.6%)
Critical	32 (1.8%)	148 (8.1%)

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern”, as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-20. There would be no difference in levels of concern between NAA and H1.

Table 11-4-20. Differences between Baseline Scenarios and H1 and H4 Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
Red	31 (61%)	0 (0%)	30 (59%)	-1 (-1%)
Orange	-17 (-100%)	0 (NA)	-16 (-94%)	1 (NA)
Yellow	-11 (-100%)	0 (NA)	-11 (-100%)	0 (NA)
None	-3 (-100%)	0 (NA)	-3 (-100%)	0 (NA)

Note: For definitions of levels of concern, see Table 11-4-14.
NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4-21). Total degree-days under H1 would be up to 11% to 12% lower than under NAA during May and June and 8% to 16% higher during July through September.

Table 11-4-21. Differences between Baseline Scenarios and H1 and H4 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
May	Wet	1,050 (279%)	-152 (-10%)	1,109 (294%)	-93 (-6%)
	Above Normal	273 (128%)	-82 (-14%)	290 (136%)	-65 (-11%)

H4/HOS

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H4 between May and September would generally be similar to flows under H3, except during May and June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).* During May and June, flows would be up to 13% lower under H4 than under H3, although these reductions are too low of magnitude to have a biologically meaningful effect on winter-run Chinook salmon spawning and egg incubation habitat. Further, May storage in Shasta Reservoir under H4 would be similar to storage under H3 (Table 11-4-19).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H4 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-20. There would be no difference in levels of concern between NAA and H4.

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4-21). Total degree-days under H4 would be up to 5% lower than under NAA during August and similar during other months.

NEPA Effects: Alternative 4 does not propose any changes in Shasta Reservoir operating criteria, and CALSIM results show that Reclamation could operate Shasta in such a manner that it does not affect upstream storage or flows substantially as compared to the NAA. Available analytical tools show conflicting results regarding the temperature effects of relatively small changes in predicted summer and fall flows. Several models (CALSIM, SRWQM, and Reclamation Egg Mortality Model) generally show no change in upstream conditions as a result of Alternative 4. However, one model, SacEFT, shows adverse effects under some conditions. After extensive investigation of these results, they appear to be a function of high model sensitivity to relatively small changes in estimated upstream conditions, which may or may not accurately predict adverse effects. Temperature and end of September storage criteria from the NMFS (2009a) BiOp for Shasta reservoir are maintained, in order to minimize adverse effects to spawning and incubating salmonids including winter-run-run Chinook salmon. However, the new NDD structures allow for spring time deliveries of water south of the Delta that are currently constrained under the NAA. For this reason, additional spring storage criteria may be necessary to ensure Shasta operations similar to what was modeled. These discussions will occur in the Section 7 consultation with Reclamation on Shasta and system-wide operations, which is outside the scope of BDCP. In conclusion, Alternative 4 modeling results support a finding that effects are uncertain. Alternative 4 does not propose any changes to Shasta operating criteria, but modeled results are mixed and operations that match the CALSIM modeling are not assured. Model results will be submitted to independent peer review to confirm that adverse effects are not reasonably anticipated to occur.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of spawning and egg incubation habitat for winter-run Chinook salmon would not change relative to Existing Conditions.

H3/ESO

CALSIM flows in the Sacramento River between Keswick and upstream of Red Bluff were examined during the May through September winter-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows at Keswick under H3 combined with climate change, during May and June would generally be up to 22% greater than flows under Existing Conditions, lower by up to 29% during August and September, and similar during July with some exceptions. Flows upstream of Red Bluff under H3 during May and June would generally be up to 20% greater than flows under Existing Conditions, up to 26% lower during August, and similar during July and September, with some exceptions.

Shasta Reservoir storage volume at the end of May under H3 combined with climate change, would be similar to storage under Existing Conditions in wet and above normal water years and 8% to 25% lower in below normal, dry, and critical water years (Table 11-4-12). This indicates that there would be a small to moderate effect of H3 on flows during the spawning and egg incubation period in drier water years.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 during May and June. Mean monthly water temperature would be up to 14% higher under H3 in July through September depending on month, water year type, and location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern”, as defined in Table 11-4-14. The number of years classified as “red” would increase by 61% under H3 relative to Existing Conditions (Table 11-4-15).

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4-16). Total degree-days under H3 would be 132% to 273% higher than that under Existing Conditions depending on month throughout the period.

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under H3 would be 156% to 436% greater (relative scale) than mortality under Existing Conditions depending on water year type (Table 11-4-17). However, only in dry (7% higher) and critical (42% higher) years would the increase be >5% of the winter-run population on an absolute scale and, therefore, be biologically meaningful. Overall, these results indicate that H3, in combination with climate change effects, would cause increased winter-run Chinook salmon mortality in the Sacramento River in drier years.

SacEFT predicts that there would be a 60% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under H3 relative to Existing Conditions (Table 11-4-18) as a result of the combined effects of climate change and Alternative 4. SacEFT predicts that the percentage of years with good (lower) redd scour risk under H3 and climate change would be similar to the percentage of years under Existing Conditions. SacEFT predicts that the percentage of years with good egg incubation conditions under H3 and climate change would be 26% lower than under Existing Conditions. SacEFT predicts that the percentage of years with good (lower) redd dewatering risk under H3 and climate change would be 12% greater than the percentage of years under Existing Conditions. These results indicate that Alternative 4, in combination with climate change effects which are the primary driver for these changes, would cause a large reduction in spawning WUA and egg incubation conditions.

H1/LOS

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H1 between May and September would generally be similar to flows under H3 (Appendix 11C, CALSIM II Model

Results utilized in the Fish Analysis). Also, May storage in Shasta Reservoir under H1 would be similar to storage under H3 (Table 11-4-19).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be up to 13% higher under H1 in July through September depending on month, water year type, and location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-20. There would be a 61% increase in the number of years with a red level of concern under H1 relative to Existing Conditions.

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4-21). Total degree-days under H1 would be 153% to 252% higher than under Existing Conditions depending on month.

H4/HOS

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H4 between May and September would generally be similar to flows under H3, except during May and June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).* During these months, flows would be up to 13% lower under H4 than under H3, although these reductions are too low of magnitude to have a biologically meaningful effect on winter-run Chinook salmon spawning and egg incubation habitat. Additionally, May storage in Shasta Reservoir under H4 would be similar to storage under H3 in all water years except critical, in which storage under H4 would be 8% greater than storage under H3 (Table 11-4-19). Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be up to 12% higher under H4 in July through September depending on month, water year type, and location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H4 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-20. There would be a 59% increase in the number of years with a red level of concern under H4 relative to Existing Conditions.

Total degree-days exceeding 56°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4-21). Total degree-days under H4 would be 112% to 220% higher than under Existing Conditions depending on month.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-40 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, when compared to the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above, which is directly related to the inclusion of climate change effects in Alternative 4.

Egg mortality (according to the Reclamation egg mortality model) in drier water years, during which winter-run Chinook salmon would already be stressed due to reduced flows and increased temperatures, would be up to 42% greater under Alternative 4, including climate change, compared to the CEQA baseline (Table 11-4-17). Egg incubation conditions according to the SacEFT model are predicted to be 26% lower under H3, including climate change, than under the CEQA baseline. Further, the extent of spawning habitat predicted by SacEFT would be 60% lower underH3, including climate change, compared to the CEQA baseline (Table 11-4-18), which represents a substantial reduction in spawning habitat and, therefore, in adult spawner and redd carrying capacity. Exceedances above NMFS temperature thresholds would be substantially greater under Alternative 4 relative to the CEQA baseline. Conditions under H4 would generally be similar under H1 and H4 to those under H3, although May storage and flows would be slightly higher under H4 and temperatures would be lower under H1 during spring but higher during fall.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow and reservoir storage outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between future conditions without the alternative (NAA) and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for winter-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

In general, Alternative 4 would not adversely affect rearing habitat for fry and juvenile winter-run Chinook salmon relative to the NAA.

H3/ESO

Sacramento River flows upstream of Red Bluff were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can lead to reduced extent and quality of fry and juvenile rearing habitat. Flows under H3 during August through October and December would generally be similar to flows under NAA with few exceptions. Flows during November under H3 would generally be5% to 18% lower than flows under NAA. This reduction in flow during 1 of 5 months of the rearing period is not expected to have a biologically meaningful effect on rearing juvenile winter-run Chinook salmon due to limited duration and magnitude.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under H3 would not different from the percentage of years under NAA (Table 11-4-18). In addition, the percentage of years with good (low) juvenile stranding risk under H3 is predicted to be 35% lower than under NAA. On an absolute scale, the reduction in juvenile stranding risk would be small (11%) and would not have a biologically meaningful effect on winter-run Chinook salmon. These results indicate that neither the quantity nor quality of juvenile rearing habitat in the Sacramento River would differ between NAA and H3.

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under H3 would be 5% higher than under NAA. These results are somewhat inconsistent with SacEFT results, which indicate that juvenile stranding risk would increase under H3 (Table 11-4-18). However, the increase in juvenile stranding risk predicted by SacEFT is small on an absolute scale (11% lower) and would not affect winter-run Chinook salmon at a population scale, which is more consistent with SALMOD results. Both SacEFT and SALMOD are considered to be reliable models for winter-run Chinook salmon in the Sacramento River. SALMOD has been used for decades for assessing changes in flows associated with SWP and CVP. Therefore, results of both models were used to draw conclusions about winter-run Chinook salmon rearing conditions.

H1/LOS

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H1 between August and December would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), with exceptions during some months and water year types. However, these reductions would be too infrequent or of too low of magnitude to have biologically meaningful effects on winter-run Chinook salmon.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

H4/HOS

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H4 between August and December would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

NEPA Effects: Collectively, these results indicate that the effect of Alternative 4 is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat or substantially interfere with winter-run Chinook salmon rearing. Differences in flows and temperatures are generally small and inconsistent among months and water year types. SALMOD and SacEFT predicted contradicting results regarding habitat-related mortality although the magnitude of effect predicted by both models would not be biologically meaningful. There would be no differences between scenarios.

CEQA Conclusion: In general, Alternative 4 would not reduce the quantity and quality of fry and juvenile rearing habitat for winter-run Chinook salmon relative to Existing Conditions.

H3/ESO

Sacramento River flows upstream of Red Bluff were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* Lower flows can lead to reduced extent and quality of fry and juvenile rearing habitat. Flows under H3 during August and November would generally be lower by up to 26% than flows under Existing Conditions and similar to flows under Existing Conditions during September, October, and December.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be higher (by up to 14%, but generally less than 8%) under H3 in August through October depending on month, water year type, and location. There would be no differences (<5%) between Existing Conditions and H3 in mean monthly water temperature during July, November, and December at either location.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under H3, combined with climate change, would be 48% lower than under Existing Conditions (Table 11-4-18). The percentage of years with good (low) juvenile stranding risk under H3 is predicted to be identical to the percentage under Existing Conditions. This indicates that the amount of juvenile rearing habitat in the Sacramento River would be lower under H3 relative to Existing Conditions, but juvenile stranding risk would be similar between scenarios

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under H3 would be 6% higher than under Existing Conditions. These results are inconsistent with SacEFT results, which indicate that juvenile rearing WUA would be substantially reduced by H3 (Table 11-4-18). Both

SacEFT and SALMOD are considered to be reliable models for winter-run Chinook salmon in the Sacramento River. SALMOD has been used for decades for assessing changes in flows associated with SWP and CVP. Therefore, results of both models were used to draw conclusions about winter-run Chinook salmon rearing conditions.

H1/LOS

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H1 between August and December would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis),* with exceptions during some months and water year types. However, these reductions would be too infrequent or of too low of magnitude to have biologically meaningful effects on winter-run Chinook salmon.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be higher (by up to 13%, but generally less than 8%) under H1 in August through October depending on month, water year type, and location. There would be no differences (<5%) between Existing Conditions and H1 in mean monthly water temperature during July, November, and December at either location.

H4/HOS

Flows in the Sacramento River between Keswick and Red Bluff Diversion Dam under H4 between August and December would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be higher (by up to 12%, but generally less than 8%) under H4 in August through October depending on month, water year type, and location. There would be no differences (<5%) between Existing Conditions and H4 in mean monthly water temperature during July, November, and December at either location.

Summary of CEQA Conclusion

These results indicate that the impact would be less than significant because it does not have the potential to substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish, and no mitigation is necessary. Flows are generally comparable between Alternative 4 and Existing Conditions and there would be small increases under the alternative in water temperatures during some of the period of presence. SALMOD and SacEFT predicted contradicting results regarding habitat-related mortality. Overall, the impact would be less than significant. There would be no differences between scenarios.

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

In general, the effects of Alternative 4 on winter-run Chinook salmon migration conditions relative to the NAA are uncertain.

Upstream of the Delta

H3/ESO

Flows in the Sacramento River upstream of Red Bluff were examined for the July through November juvenile emigration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). A reduction in flow may reduce the ability of juvenile winter-run to migrate effectively through the Sacramento River. Flows under H3 would be 5% to 18% lower than under NAA during November and generally similar to NAA during the rest of the juvenile winter-run Chinook salmon migration period (July through October).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

Flows in the Sacramento River upstream of Red Bluff during the adult winter-run Chinook salmon upstream migration period (December through August) under H3 would generally be similar to those under NAA, except during May and June in which flows would be up to 12% greater than flows under NAA.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

H1/LOS

Flows in the Sacramento River upstream of Red Bluff during the July through November juvenile emigration period under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) except in wetter water year types during September and November. Reductions during November would be too low of magnitude (3% to 12% lower) to have biologically meaningful effects on emigrating juveniles. Flow reductions during both months would occur only during wetter water years when flow reductions are less critical to emigrating juveniles and, therefore, would not cause biologically meaningful effects.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

Flows in the Sacramento River upstream of Red Bluff during the adult winter-run Chinook salmon upstream migration period (December through August) would generally be similar to or greater than flows under H3.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in* *the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

H4/HOS

Flows in the Sacramento River upstream of Red Bluff during the July through November juvenile emigration period under H4 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

Flows in the Sacramento River upstream of Red Bluff during the adult winter-run Chinook salmon upstream migration period (December through August) would generally be similar to flows under H3, except during June in which flows would be up to 12% lower under H4 and during August, in which flows would be up to 13% greater under H4. These flow reductions and increases would not be of sufficient frequency or magnitude to cause biologically meaningful effects on migrating adults.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

Through-Delta

H3/ESO

Juveniles

Plan Area flows have considerable importance for downstream migrating juvenile salmonids and would be affected by the north Delta diversions, as discussed above for winter-run Chinook above (Impact AQUA-42 for Alternative 1A). Average monthly flows Sacramento River flows below the NDD under H3 for juvenile winter-run migrants (November through May) would be reduced 11% to 23% compared to NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Note that *CM1 Water Facilities and Operation* includes bypass flow criteria that will be managed in real time to minimize adverse effects of diversions at the north Delta intakes on downstream-migrating salmonids.

Potential predation effects at the north Delta intakes could occur if predatory fish aggregated along the screens as has been observed at other long screens in the Central Valley (Vogel 2008). Baseline levels of predation are uncertain, however. Analysis by a bioenergetics model (Appendix 5.F, *Biological Stressors on Covered Fish,* Section 5.F.3.2.1) suggests that considerably less than 0.3% of winter-run juveniles could be preyed upon (Table 11-4-22). Using another scenario of predation that assumes a 5% loss per intake (based on GCID losses, Vogel 2008) would yield a cumulative loss of about 12% of the annual production that reaches the north Delta. The three intake structures would also permanently displace approximately 13.7 acres of in-water habitat and 7,450 linear feet of shoreline along the migration route. However, there are appreciable uncertainties in these analyses, including unknown baseline levels of predation, uncertainty in the bioenergetics model parameters, and the comparability of the GCID intakes for estimating loss rates. This is discussed in detail in Alternative 1A.

Table 11-4-22. Winter-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion Intakes (Three Intakes for Alternative 4)

Striped Bass at NDD (Three Intakes)			Winter-Run Chinook Consumed	
Density Assumption	Bass per 1,000 Feet of Intake	Total Number of Bass	Number	Percentage of Annual Juvenile Production
Low	18	86	648	0.02%
Median	119	571	4,283	0.16%
High	219	1,051	7,881	0.30%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (Appendix 5F Biological Stressors).

Through-Delta survival by juvenile winter-run Chinook salmon, as estimated by the Delta Passage Model under Scenario H3, averaged 33.2% across all years, 26% in drier years up to 45.3% in wetter years (for further details, refer to *BDCP Appendix 5.C, Section 5C.5.3.1.3.1*). Average juvenile survival under H3 was similar or slightly lower than NAA (1% less, a 3% relative decrease) (Table 11-4-23).

Table 11-4-23. Through-Delta Survival (%) of Emigrating Juvenile Winter-Run Chinook Salmon under Alternative 4 (Scenarios H3, H1, and H4)

Water Year Type	Average Percentage Survival					Difference in Percentage Survival (Relative Difference)					
	SCENARIO					EXISTING CONDITIONS vs. Alt 4 Scenario			NAA vs. Alt 4 Scenario		
	EXISTING CONDITIONS	NAA	H3	H1	H4	H3	H1	H4	H3	H1	H4
Wetter Years	46.3	46.1	45.3	45.2	46.0	-1.1 (-2%)	-1.1 (-2%)	-0.3 (-1%)	-0.8 (-2%)	-0.9 (-2%)	-0.1 (0%)
Drier Years	28.0	27.1	26.0	26.1	25.7	-2.0 (-7%)	-1.9 (-7%)	-2.3 (-8%)	-1.1 (-4%)	-1.0 (-4%)	-1.4 (-5%)
All Years	34.9	34.2	33.2	33.3	33.3	-1.6 (-5%)	-1.6 (-5%)	-1.6 (-5%)	-1.0 (-3%)	-0.9 (-3%)	-0.9 (-3%)

Note: Average Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and Above Normal Water Years (6 years).
Drier = Below Normal, Dry and Critical Water Years (10 years).
H3 = ESO operations, H1 = Low Outflow, H4 = High Outflow.

Adults

Adult salmonids migrating through the delta use flow and olfactory cues for navigation to their natal streams (Marston et al. 2012), as discussed above for winter-run Chinook (Impact AQUA-42 for Alternative 1A). The importance of flow changes to currently affect these cues is rated as low but with low certainty. Attraction flows and olfactory cues in the west Delta would be altered because of shifts in exports from the south Delta to the north Delta. Flows in the Sacramento River downstream of the north Delta intake diversions would be reduced, with concomitant proportional increases in

San Joaquin River flow, with differences between water-year types because of differences in the relative proportion of water being exported from the north Delta and south Delta facilities (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

These changes would slightly decrease the Sacramento River olfactory cues used by migrating adults. Fingerprint analyses determined that attraction flow, as estimated by the percentage of Sacramento River water at Collinsville, declined from NAA to Scenario H3 operations by up to 4% during the peak migration period for winter-run adults (December through February) (Table 11-4-24). The flow changes under Scenario H3 would slightly decrease the olfactory cues for migrating adult salmon in the Sacramento River (by 9% or less compared to NAA). Nevertheless, the Sacramento River would still represent a substantial proportion of Delta outflows. Under Scenario H4, the difference would be less due to increased spring outflows in March, April, and May. Scenario H1 results would be similar to Scenario H3. Overall, the reductions in olfactory cues resulting from all scenarios would be less than the magnitude of change in dilution (20% or more) reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect adult Chinook salmon migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 for Alternative 1A.

Table 11-4-24. Percentage (%) of Water at Collinsville that Originated in the Sacramento River during the Adult Winter-Run Chinook Salmon Migration Period for Alternative 4 (Scenario H3)

Month	EXISTING CONDITIONS	NAA	H3	EXISTING CONDITIONS vs. H3	NAA vs. H3
December	67	66	66	-1	0
January	76	75	73	-3	-2
February	75	72	68	-7	-4
March	78	76	68	-10	-8
April	77	75	66	-11	-9
May	69	65	59	-10	-6
June	64	62	58	-6	-4
July	64	65	56	-8	-9
	Shading indicates 10% or greater difference.				

H1/LOS

Juveniles

Plan Area flows have considerable importance for downstream migrating juvenile salmonids and would be affected by the north Delta diversions, as discussed above for winter-run Chinook above (Impact AQUA-42 for Alternative 1A). Under H1, Sacramento River flows below the NDD during the juvenile winter-run migration period (November-May) would be reduced compared to NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Note that *CM1 Water Facilities and Operation* includes bypass flow criteria that will be managed in real time to minimize adverse effects of diversions at the north Delta intakes on downstream-migrating salmonids.

Through-Delta survival by juvenile winter-run Chinook salmon under Scenario H1 averaged 33.3% across all years, 26.1% in drier years up to 45.2% in wetter years (for further details, refer to *BDCP*

Appendix 5.C, Section 5C.5.3.1.3.1). Average survival under Scenario H1 was generally similar to NAA (Table 11-4-23).

Overall, the similarity in through-Delta survival these scenarios is explained by the relatively low overlap of the winter-run Delta entry distribution with the spring period that has differing outflows for the Alternative 4 operations scenarios. In addition, the DPM has less representation of intermediate-outflow years where the differences among the Alternative 4 operations scenarios are more pronounced than wetter or drier years.

Adults

Results for H1 regarding attraction flows and olfactory cues are presented as part of the corresponding discussion under H3.

H4/HOS

Juveniles

Plan Area flows have considerable importance for downstream migrating juvenile salmonids and would be affected by the north Delta diversions, as discussed above for winter-run Chinook above (Impact AQUA-42 for Alternative 1A). Under H4, Sacramento River flows below the NDD during the juvenile winter-run migration period (November–May) would be reduced 5% to 23% compared to NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Note that *CM1 Water Facilities and Operation* includes bypass flow criteria that will be managed in real time to minimize adverse effects of diversions at the north Delta intakes on downstream-migrating salmonids.

Through-Delta survival by juvenile winter-run Chinook salmon under Scenario H4 averaged 33.3% across all years, 25.7% in drier years up to 46% in wetter years (for further details, refer to *BDCP Appendix 5.C, Section 5C.5.3.1.3.1*). Average survival under Scenario H4 was generally similar to NAA, with slightly lower survival for H4 in wetter years (0.9% less, a 3% relative decrease) (Table 11-4-23).

Overall, the similarity in through-Delta survival these scenarios is explained by the relatively low overlap of the winter-run Delta entry distribution with the spring period that has differing outflows for the Alternative 4 operations scenarios. In addition, the DPM has less representation of intermediate-outflow years where the differences among the Alternative 4 operations scenarios are more pronounced than wetter or drier years.

Adults

Results for H4 regarding attraction flows and olfactory cues are presented as part of the corresponding discussion under H3.

NEPA Effects: Upstream of the Delta, the effects of Alternative 4 are uncertain, with the effects analysis showing conflicting lines of evidence regarding whether or not additional adverse effects would occur as a result of re-operation of Shasta reservoir. Modeling analyses indicate that some scenarios of Alternative 4 would potentially improve upstream conditions whereas some scenarios could degrade upstream conditions compared to NAA. Within the Delta, adult attraction flows under Alternative 4 would not be substantially different from those under NAA and, therefore, the effects of Alternative 4 on adult migration would be expected to be similar to NAA.

Near-field effects of Alternative 4 NDD on winter-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating winter-run Chinook salmon, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus the level of impacts associated with 3 new intakes would be considerably lower than those expected from having 5 new intakes in the river. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 12% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Alternative 4 also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for winter-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 4 predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 4 would be similar to those estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of, the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon. However, until these efforts are completed and their results are fully analyzed, the overall cumulative effect of Alternative 4 on winter-run Chinook salmon migration remains uncertain.

CEQA Conclusion: In general, Alternative 4 would not reduce migration conditions for winter-run Chinook salmon relative to Existing Conditions.

Upstream of the Delta

H3/ESO

Flows in the Sacramento River upstream of Red Bluff were examined during the July through November juvenile emigration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). A reduction in flow may reduce the ability of juvenile winter-run to migrate effectively through the Sacramento River. Flows under H3, combined with climate change, for juvenile migrants would be up to 14% lower than under Existing Conditions during November depending on water year type. However, flows under H3, combined with climate change, would generally be similar to those under Existing Conditions during the rest of the juvenile winter-run Chinook salmon migration period (July through October) with few exceptions.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be higher (by up to 14%, but mostly <8%) under H3 in August through October depending on month, water year type, and location. There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 during July and November.

Flows in the Sacramento River upstream of Red Bluff were examined during the adult winter-run Chinook salmon upstream migration period (December through August). Flows under H3 would generally be similar to flows under Existing Conditions throughout the adult migration period, except during May and June, in which flows would be up to 20% greater under H3, combined with climate change, and during August, in which flows would be up to 26% lower under H3, combined with climate change. These flow reductions would not be frequent enough to cause a biologically meaningful effect on adult migrants.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 during December through July. Mean monthly water temperature would be up to 14% higher under H3 in August depending on water year.

H1/LOS

Flows in the Sacramento River upstream of Red Bluff during the July through November juvenile emigration period under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) except in wetter water year types during September and November, as a results of not implementing Fall X2 requirements for delta smelt. Reductions during November would be too low of magnitude (3% to 12% lower) to have biologically meaningful effects on emigrating juveniles. Flow reductions during both months would occur only during wetter water years when flow reductions are less critical to emigrating juveniles and, therefore, would not cause biologically meaningful effects.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be higher (by up to 13%, but mostly <8%) under H1 in August through October depending on month, water year type, and location. There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 during July and November.

Flows in the Sacramento River upstream of Red Bluff during the adult winter-run Chinook salmon upstream migration period (December through August) would generally be similar to or greater than flows under H3.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix

11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 during December through July. Mean monthly water temperature would be up to 13% higher under H1 in August depending on water year.

H4/HOS

Flows in the Sacramento River upstream of Red Bluff during the July through November juvenile emigration period under H4 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature would be higher (by up to 12%, but mostly <8%) under H4 in August through October depending on month, water year type, and location. There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 during July and November.

Flows in the Sacramento River upstream of Red Bluff during the adult winter-run Chinook salmon upstream migration period (December through August) under H4 would generally be similar to flows under H3, except during June in which flows would be up to 12% lower under H4 and during August, in which flows would be up to 13% greater under H4. These flow reductions and increases would not be of sufficient frequency or magnitude to cause biologically meaningful effects on migrating adults. Water temperatures in the Sacramento River under H4 would be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 during December through July. Mean monthly water temperature would be up to 12% higher under H4 in August depending on water year.

Through-Delta

Juveniles

During the juvenile winter-run Chinook salmon emigration period (November through May), mean monthly flows in the Sacramento River below the NDD under H3 averaged across years would be lower (15% to 27% lower monthly mean) compared to Existing Conditions. Potential predation losses at the three north Delta intakes would range from considerably less than 1% (bioenergetics modeling) to 11.7% (conservative upper bound based on 5% loss per intake) of the annual production that reaches the north Delta. In addition, the three intake structures would permanently displace approximately 13.7 acres of in-water habitat.

Through-Delta survival by juvenile winter-run Chinook salmon, as estimated by the Delta Passage Model under Scenario H3, would be slightly lower than Existing Conditions for H3 (1.6% less, a 5% relative decrease), with the greatest reduction in drier years (2.0% lower, a 7% relative decrease) (Table 11-4-23).

Under Scenarios H1 and H4, average survival was 1.6% less (5% relative decrease) than Existing Conditions, with a 2.3% reduction under H4 in drier years (an 8% relative decrease).

Adults

Flows in the Sacramento River downstream of the north Delta intake diversions would be reduced. These changes would slightly decrease the olfactory cues for migrating adult salmon. Under Scenario H3, the proportion of Sacramento River water was reduced no more than 7% during peak migration (December through February) and reduced by 10–11% in March-May compared to Existing Conditions (Table 11-4-24). Scenario H1 results would be similar to Scenario H3. The reductions in percentage are small in comparison with the magnitude of change in dilution (20% or more) reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect adult Chinook salmon migration. The Sacramento River would still represent a substantial proportion of Delta outflows. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 for Alternative 1A.

Summary of CEQA Conclusion

Collectively, these results indicate that the effect would be less than significant because it does not have the potential to substantially reduce migration habitat or substantially interfere with the movement of fish. Upstream flows and water temperatures would not be difference between Alternative 4 and Existing Conditions for any scenario. Although upper Sacramento River flows under Alternative 4 would be lower than under Existing Conditions during August and November, flows during the remaining months of the juvenile emigration and adult immigration periods would be similar to or greater than flows under Existing Conditions. Further, winter-run Chinook salmon juvenile survival through the Delta would be similar between Alternative 4 and Existing Conditions during all water year types. Due to similarities in migration conditions between Alternative 4 and Existing Conditions, it is concluded that the impact would be less than significant and no mitigation would be required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for winter-run Chinook salmon under Alternative 1A (Impacts AQUA-43 through AQUA-45) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on winter-run Chinook salmon are the same as those described under Alternative 1A (Impacts AQUA-43 through AQUA-45). The effects would not be adverse, and would generally be beneficial. Specifically for AQUA-44, the effects of contaminants on winter-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on winter-run Chinook salmon are uncertain.

CEQA Conclusion: All three of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required, for the reasons identified for Alternative 1A.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for winter-run Chinook salmon under Alternative 1A (Impacts AQUA-46 through AQUA-54) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (CM12)

Impact AQUA-47: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Winter-Run ESU) (CM13)

Impact AQUA-48: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Winter-Run ESU) (CM14)

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (CM15)

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (CM16)

Impact AQUA-51: Effects of Illegal Harvest Reduction on Chinook Salmon (Winter-Run ESU) (CM17)

Impact AQUA-52: Effects of Conservation Hatcheries on Chinook Salmon (Winter-Run ESU) (CM18)

Impact AQUA-53: Effects of Urban Stormwater Treatment on Chinook Salmon (Winter-Run ESU) (CM19)

Impact AQUA-54: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Winter-Run ESU) (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on winter-run Chinook salmon are the same as those described under Alternative 1A (Impacts AQUA-46 through AQUA-54). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

Spring-Run Chinook Salmon

Construction and Maintenance of CM1

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

The potential effects of construction of the water conveyance facilities on spring-run Chinook salmon would be similar to those described for Alternative 1A (Impact AQUA-55) except Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less. Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-55, the effect would not be adverse for spring-run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-55, the impact of the construction of water conveyance facilities on spring-run Chinook salmon would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

NEPA Effects: The potential effects of maintenance of the water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A (Impact AQUA-56) except that only three intakes would need to be maintained under Alternative 4 rather than five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-56, the impact would not be adverse for spring-run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-56, the impact of maintenance of the water conveyance facilities on spring-run Chinook salmon would not be significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Average entrainment of juvenile spring-run Chinook salmon at the south Delta export facilities would be reduced 40% under the Scenario H3 compared to NAA (Table 11-4-25). The greatest reduction would be in wet years, when entrainment would be reduced 63% (~58,000 fish) compared to NAA. Entrainment loss under Scenario H4 would further reduce south Delta entrainment relative to the Scenario H3.

Table 11-4-25. Juvenile Spring-Run Chinook Salmon Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 4 (Scenario H3)

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-54,712 (-62%)	-58,340 (-63%)
Above Normal	-7,576 (-28%)	-10,644 (-36%)
Below Normal	-784 (-12%)	-1,579 (-22%)
Dry	-766 (-5%)	-1,960 (-11%)
Critical	-2,937 (-25%)	-1,316 (-13%)
All Years	-14,145 (-37%)	-15,755 (-40%)

Note: Estimated annual number of fish lost, based on normalized data.

The proportion of the annual spring-run Chinook salmon index of abundance (assumed to be 750,000 juveniles approaching the Delta) lost at the south Delta facilities averaged 5.3% across all years under the NAA, and decreased to 3.2% under Alternative 4 Scenario H3. The greatest improvement was in wet years, when the proportion lost decreased by 7.8% under Alternative 4 Scenario H3 (4.5%) compared to NAA (12.3%). Entrainment under Scenario H1 would be similar to Scenario H3, while conditions under Scenario H4 are expected to further reduce entrainment losses relative to both Scenarios H3 and H1.

Water Exports from SWP/CVP North Delta Intake Facilities

The effect of Alternative 4 on entrainment and impingement at the north Delta facilities would be the same as described for Alternative 1A (Impact AQUA-57), but the degree would be less because Alternative 4 would have fewer intakes. State-of-the-art fish screens operated with an adaptive management plan would be expected to eliminate entrainment risk for juvenile spring-run Chinook salmon.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

Entrainment to the NBA would be the same as described for Alternative 1A (Impact AQUA-57). Entrainment and impingement effects would be minimal because intakes on the Sacramento River would have state-of-the-art screens installed.

Predation Associated with Entrainment

Entrainment-related predation loss of spring-run Chinook salmon at the south Delta facilities would be no greater and may be lower than baseline due to a reduction in entrainment loss. Entrainment-related predation losses are expected to decrease under Scenario H4 compared to Scenario H3, while conditions under Scenario H1 would be similar to Scenario H3.

Predation at the north Delta would be increased at the proposed North Delta intake facilities on the Sacramento River. Bioenergetics modeling with a median predator density predicts a predation loss of about 8,200 juveniles, or 0.2% of the spring-run juvenile population under Alternative 4 (Table 11-4-26). This is well under the criteria of a 5% population loss, thus the impact from predation loss would not be adverse.

Table 11-4-26. Juvenile Spring-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion (NDD) Intakes for Alternative 4 (Three Intakes)

Striped Bass at NDD (Three Intakes)			Spring-Run Chinook Consumed	
Density Assumption	Bass per 1,000 feet of Intake	Total Number of Bass	Number	Percentage of Annual Juvenile Production
Low	18	86	1,243	0.03%
Median	119	571	8,217	0.20%
High	219	1,051	15,122	0.36%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (Appendix 5F Biological Stressors).

NEPA Effects: In conclusion, Alternative 4 would reduce overall entrainment losses of juvenile spring-run Chinook salmon relative to NAA. The population benefit would be small because entrainment losses affect about 5% of annual juvenile spring-run Chinook salmon production. Conditions under Scenario H4 would further reduce entrainment losses compared to Scenario H3 and Scenario H1. The effect of Alternative 4 would not be adverse and may provide some benefit.

CEQA Conclusion: Entrainment losses of juvenile spring-run Chinook salmon at the south Delta facilities will be substantially reduced under the Scenario H3 operations for Alternative 4 for all water year types (37% average reduction in entrainment index) compared to existing biological conditions (Table 11-4-25). The proportion of the annual spring-run Chinook index of abundance entrained at the south Delta facilities averaged 5.0% across all years under Existing Conditions, and would decrease to 3.2% under Alternative 4. The greatest improvement would be in wet years, when the proportion lost would decrease by 7% under Scenario H3 (4.5%) compared to Existing Conditions (11.8%). Under Scenario H4, entrainment losses are expected to further decrease relative to Existing Conditions. Entrainment at the NBA would be minimal. Predation loss at the north Delta intakes would have minor population level effects on spring-run Chinook salmon (<0.4% of the annual index of abundance). Overall, impacts to spring-run Chinook salmon under Alternative 4 would be beneficial because of the reductions in entrainment losses at the south Delta facilities across all water-years compared to existing biological conditions. No mitigation would be required.

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

In general, the effects of Alternative 4 on spawning and egg incubation habitat for spring-run Chinook salmon relative to the NAA are uncertain.

H3/ESO

Sacramento River

There has been a small, inconsistent spawning population (<400 individuals) in the mainstem Sacramento River primarily upstream of Red Bluff Diversion Dam over the past decade (Azat 2012).

Flows in the Sacramento River upstream of Red Bluff were examined during the spring-run Chinook salmon spawning and incubation period (September through January) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 during all months except November would generally be similar to those under NAA with few exceptions. Flows under H3 during November would be 5% to 18% lower than flows during NAA depending on water year type.

Shasta Reservoir storage volume at the end of September influences flows downstream of the dam during the spring-run spawning and egg incubation period (September through January). Storage under H3 would be similar to (<5% different from) storage under NAA in all water year types (Table 11-4-27) so there would be no biologically meaningful effects.

Table 11-4-27. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Alternative 4 (Scenario H3)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-605 (-18%)	-93 (-3%)
Above Normal	-677 (-21%)	-62 (-2%)
Below Normal	-443 (-15%)	-89 (-4%)
Dry	-535 (-22%)	-24 (-1%)
Critical	-392 (-33%)	-10 (-1%)

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September At Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-15 for Bend Bridge and in Table 11-4-28 for Red Bluff. There would be no difference in levels of concern between NAA and H3 at Bend Bridge. At Red Bluff, there would be 2 (4%) and 3 (23%) more years with a "red" and "orange" level of concern, respectively, under H3 that would not be biologically meaningful to spring-run Chinook salmon spawners and eggs, as this is a small proportion of the 82 year period.

Table 11-4-28. Differences between Baseline and H3 Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Red Bluff, October through April

Level of Concern[a]	EXISTING CONDITIONS vs. H3	NAA vs. H3
Red	38 (317%)	2 (4%)
Orange	10 (167%)	3 (23%)
Yellow	-3 (-23%)	-2 (-17%)
None	-45 (-88%)	-3 (-33%)

[a] For definitions of levels of concern, see Table 11-4-14.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days under H3 would be up to 11% lower than under NAA during May and June and up to 11% higher during July through September (Table 11-4-16). At Red Bluff, total degree-days under H3 would be 5% higher than those under NAA during October, 7% lower during April, and similar during remaining months (Table 11-4-29).

Table 11-4-29. Differences between Baseline and H3 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Red Bluff, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
October	Wet	1,262 (491%)	93 (7%)
	Above Normal	514 (198%)	37 (5%)
	Below Normal	798 (382%)	92 (10%)
	Dry	1,164 (237%)	93 (6%)
	Critical	926 (154%)	3 (0%)
	All	4,664 (257%)	318 (5%)
November	Wet	96 (9,600%)	6 (7%)
	Above Normal	67 (NA)	6 (10%)
	Below Normal	52 (NA)	4 (8%)
	Dry	159 (1,988%)	8 (5%)
	Critical	102 (2,550%)	-8 (-7%)
	All	476 (3,662%)	16 (3%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	9 (NA)	0 (0%)
	Above Normal	5 (NA)	1 (25%)
	Below Normal	29 (322%)	8 (27%)
	Dry	64 (457%)	0 (0%)
	Critical	24 (2,400%)	-3 (-11%)
	All	131 (546%)	6 (4%)
April	Wet	260 (226%)	-1 (0%)
	Above Normal	204 (146%)	-25 (-7%)
	Below Normal	229 (290%)	-1 (0%)
	Dry	248 (133%)	-72 (-14%)
	Critical	137 (1,142%)	-14 (-9%)
	All	1,078 (203%)	-113 (-7%)

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under H3 would be similar to mortality under NAA in dry and critical years, less in dry years, but greater in wet, above normal, and below normal (11% to 29% greater) water years (Table 11-4-30). Relative increases of 11% mortality of the spring-run population under wet and above normal water years would be negligible to the overall population, particularly because this represents a 3% to 4% increase on an absolute scale. However, the 29% relative increase in mortality in below normal years would have an effect on the spring-run population. Combining all water years, there would be no effect of H3 on egg mortality (3% absolute change).

Table 11-4-30. Difference and Percent Difference in Percent Mortality of Spring-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	18 (174%)	3 (11%)
Above Normal	26 (195%)	4 (11%)
Below Normal	41 (349%)	12 (29%)
Dry	54 (275%)	-3 (-3%)
Critical	22 (30%)	0 (0%)
All	32 (141%)	3 (6%)

SacEFT predicts that there would be a 6% relative decrease (3% on an absolute scale) in the percentage of years with good spawning availability, measured as weighted usable area, under H3 relative to NAA (Table 11-4-31). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under H3 relative to NAA. SacEFT predicts that there would be a 12% decrease on an absolute scale (35% relative decrease) in the percentage of years with good (lower) egg incubation conditions under H3 relative to NAA. SacEFT predicts that there would be a 6% relative decrease (2% on an absolute scale) in the percentage of years with good (lower) redd dewatering risk under H3 relative to NAA.

Table 11-4-31. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Spring-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3	NAA vs. H3
Spawning WUA	-24 (-34%)	-3 (-6%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-64 (-74%)	-12 (-35%)
Redd Dewatering Risk	-17 (-35%)	-2 (-6%)
Juvenile Rearing WUA	4 (18%)	4 (18%)
Juvenile Stranding Risk	-7 (-37%)	-2 (-14%)

WUA = Weighted Usable Area.

There is an apparent discrepancy in results of the SacEFT model and Reclamation egg mortality model with regard to conditions for spring-run salmon eggs. SacEFT predicts that egg incubation habitat would decrease (12% absolute scale decrease) and the Reclamation egg mortality model predicts that overall egg mortality would be unaffected by the H3, except in below normal water years. The SacEFT uses mid-August through early March as the egg incubation period, based on

Vogel and Marine (1991), and the reach between ACID Dam and Battle Creek for redd locations. The Reclamation egg mortality model uses the number of days after Julian week 33 (mid-August) that it takes to accumulate 750 temperature units to hatching and another 750 temperature units to emergence. Temperatures units are calculated by subtracting 32°F from daily river temperature and are computed on a daily basis. As a result, egg incubation duration is generally mid-August through January, but is dependent on river temperature. The Reclamation model uses the reach between ACID Dam and Jelly's Ferry (approximately 5 river miles downstream of Battle Creek), which includes 95% of Sacramento River spawning locations based on 2001–2004 redd survey data (Reclamation 2008). These differences in egg incubation period and location likely account for the difference between model results. Although the SacEFT model has been peer-reviewed, the Reclamation egg mortality model has been extensively reviewed and used in prior biological assessments and BiOps. Therefore, both results are considered valid and were considered in drawing conclusions about spring-run egg mortality in the Sacramento River.

Clear Creek

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under H3 would generally be similar to flows under NAA throughout the spring-run spawning and egg incubation period for all water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest reduction in flows under H3 would be the same as that under NAA in all water year types (Table 11-4-32).

Water temperatures were not modeled in Clear Creek.

Table 11-4-32. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	0 (NA)	0 (NA)
Above Normal	-27 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-67 (NA)	0 (0%)
Critical	-33 (-50%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) where spring-run Chinook salmon primarily spawn during September through January. Flows under H3 would not differ from NAA because minimum Feather River flows are included in the FERC settlement agreement (California Department of Water Resources 2006) and would be met for all model scenarios (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Oroville Reservoir storage volume at the end of September influences flows downstream of the dam during the spring-run spawning and egg incubation period. Storage volume at the end of September under H3 would be similar to storage under NAA in wet, above normal, and below normal water years and 18% and 11% greater in dry and critical water years (Table 11-4-33).

Table 11-4-33. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Alternative 4 (Scenario H3)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-978 (-34%)	36 (2%)
Above Normal	-823 (-35%)	-32 (-2%)
Below Normal	-571 (-28%)	38 (3%)
Dry	-170 (-12%)	183 (18%)
Critical	-100 (-10%)	88 (11%)

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the egg incubation period compared to the flow in September when spawning is assumed to occur. Minimum flows in the low-flow channel during October through January were identical between H3 and NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of H3 on redd dewatering in the Feather River low-flow channel.

Mean monthly water temperatures in the low-flow channel would not differ between NAA and H3 (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Effects of H3 on water temperature-related spawning and egg incubation conditions for spring-run Chinook salmon in the Feather River were analyzed by comparing the percent of months between September through January over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4-34). In general, differences in the percent of months exceeding the threshold between NAA and H3 would be negligible (<5% on an absolute scale), although there would be a 6% reduction (absolute scale) in the percent of months exceeding the threshold by >3°F under H3 relative to NAA during October and in the percent of months exceeding the threshold by >5°F during October and November.

Table 11-4-34. Differences between Baseline and H3 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, September through January

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3					
September	0 (0%)	1 (1%)	7 (8%)	25 (34%)	44 (109%)
October	63 (283%)	59 (800%)	48 (780%)	46 (1,850%)	31 (1,250%)
November	60 (2,450%)	56 (4,500%)	42 (3,400%)	35 (NA)	19 (NA)
December	4 (NA)	2 (NA)	1 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
NAA vs. H3					
September	0 (0%)	0 (0%)	0 (0%)	1 (1%)	2 (3%)
October	-1 (-1%)	1 (2%)	-1 (-2%)	-1 (-3%)	-6 (-16%)
November	-4 (-6%)	-2 (-4%)	-6 (-13%)	2 (8%)	-6 (-25%)
December	0 (0%)	1 (100%)	0 (0%)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

The effects of H3 on water temperature-related spawning and egg incubation conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the September through January spring-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-4-35). Combining all water year types, there would be a small (5% to 7%) reduction in degree-months exceeded under H3 relative to NAA during October and November and no other differences between NAA and H3. Results are highly variable when separating out by water year type, ranging from a 9% more degree-months under H3 in below normal water years during September to a 17% fewer degree-months under H3 in dry water years during October. Overall, there would be many more water year types within months with reductions in exceedances under H3 than increases in exceedances.

Table 11-4-35. Differences between Baseline and H3 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, September through January

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
September	Wet	30 (28%)	5 (4%)
	Above Normal	14 (33%)	4 (8%)
	Below Normal	39 (65%)	8 (9%)
	Dry	71 (103%)	-17 (-11%)
	Critical	54 (83%)	-8 (-6%)
	All	208 (60%)	-8 (-1%)
October	Wet	79 (1,580%)	-17 (-17%)
	Above Normal	30 (300%)	-5 (-11%)
	Below Normal	50 (714%)	-4 (-7%)
	Dry	81 (1,157%)	1 (1%)
	Critical	41 (513%)	0 (0%)
	All	281 (759%)	-25 (-7%)
November	Wet	57 (NA)	1 (2%)
	Above Normal	23 (767%)	-2 (-7%)
	Below Normal	32 (3,200%)	-2 (-6%)
	Dry	46 (NA)	-5 (-10%)
	Critical	26 (NA)	-2 (-7%)
	All	184 (4,600%)	-10 (-5%)
December	Wet	1 (NA)	0 (0%)
	Above Normal	2 (NA)	1 (100%)
	Below Normal	3 (NA)	0 (0%)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	6 (NA)	1 (20%)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

H1/LOS

Sacramento River

Flows in the Sacramento River between Keswick and upstream of RBDD under H1 during the September through January spring-run Chinook salmon spawning and egg incubation period would generally be up to 23% greater than flows under H3 during January, similar to flows under H3 during September, October, and December, and up to 16% lower during November depending on water year type. However, these increases and reductions in flows would be too infrequent or of too low a magnitude to have a biologically meaningful effect on spring-run Chinook salmon spawning and egg incubation habitat. Shasta Reservoir storage at the end of September under H1 would be similar to storage under H3 (Table 11-4-36).

Table 11-4-36. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Shasta Reservoir for H1, H3, and H4 Scenarios

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	331 (12.2%)	10 (0.4%)
Above Normal	170 (6.8%)	43 (1.7%)
Below Normal	-11 (-0.4%)	125 (5.2%)
Dry	74 (3.8%)	71 (3.7%)
Critical	10 (1.3%)	55 (6.9%)

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September at Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern”, as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-20 for Bend Bridge and in Table 11-4-37 for Red Bluff. There would be no difference in levels of concern between NAA and H1 at Bend Bridge. At Red Bluff, there would be 6 (13%) fewer years with a “red” level of concern.

Table 11-4-37. Differences between Baseline and H3 Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Red Bluff, October through April

Level of Concern[a]	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
Red	30 (250%)	-6 (-13%)	38 (317%)	2 (4%)
Orange	15 (250%)	8 (62%)	9 (150%)	2 (15%)
Yellow	-2 (-15%)	-1 (-8%)	-5 (-38%)	-4 (-33%)
None	-43 (-84%)	-1 (-11%)	-42 (-82%)	0 (0%)

[a] For definitions of levels of concern, see Table 11-4-14.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days under H1would be up to 11% to 12% lower than under NAA during May and June and 8% to 16% higher during July through September (Table 11-4-21). At Red Bluff, total degree-days under H1 would be 10% lower than those under H1 during November, 5% higher during March, and similar during remaining months (Table 11-4-38).

Table 11-4-38. Differences between Baseline and H3 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Red Bluff, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
October	Wet	1,084 (422%)	-85 (-6%)	1,261 (491%)	92 (6%)
	Above Normal	452 (174%)	-25 (-3%)	498 (192%)	21 (3%)

	Critical	135 (1,125%)	-16 (-10%)	131 (1,092%)	-20 (-12%)
	All	1,120 (211%)	-71 (-4%)	1,175 (221%)	-16 (-1%)

NA = could not be calculated because the denominator was 0.

Clear Creek

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under H1 would generally be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would generally be similar between H1 and H3, results of the redd dewatering analysis would be similar between H1 and H3. Therefore, no analysis of redd dewatering risk was conducted for H1 in Clear Creek. Due to similar flows between H1 and H3, effects of H1 on spring-run Chinook salmon spawning and egg incubation habitat in Clear Creek would not be different from effects of H3.

Feather River

H1 flows in the Feather River low-flow channel during the spring-run Chinook salmon spawning and egg incubation period (September through January) would be similar between H1 and H3 (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Oroville Reservoir storage volume at the end of September under H1 would generally be similar to or greater than storage under H3 depending on water year type (Table 11-4-39). Higher storage during wetter water year types would generally benefit spring-run Chinook spawning and egg incubation habitat.

Table 11-4-39. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Oroville Reservoir for H1, H3, and H4 Scenarios

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	388 (20.2%)	19 (1%)
Above Normal	178 (11.5%)	82 (5.3%)
Below Normal	81 (5.6%)	-48 (-3.3%)
Dry	62 (5.2%)	137 (11.5%)
Critical	50 (5.6%)	207 (23.4%)

Mean monthly water temperatures in the low-flow channel would not differ between NAA and H1 (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Differences in the percent of months exceeding the 56°F threshold between NAA and H1 would generally be negligible (<5% on an absolute scale) except during October and November, during which the exceedances would be between 17% and 26% (absolute scale) lower under H1 (Table 11-4-40). This represents a moderate benefit of H1 on spring-run spawning habitat conditions in the Feather River.

Table 11-4-40. Differences between Baselines and H1 and H4 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, September through January

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0

EXISTING CONDITIONS vs. H4					
September	0 (0%)	0 (0%)	6 (7%)	19 (25%)	40 (97%)
October	46 (206%)	49 (667%)	41 (660%)	37 (1,500%)	36 (1,450%)
November	46 (1,850%)	41 (3,300%)	30 (2,400%)	22 (NA)	15 (NA)
December	2 (NA)	1 (NA)	1 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
NAA vs. H4					
September	0 (0%)	-1 (-1%)	-1 (-1%)	-5 (-5%)	-2 (-3%)
October	-19 (-21%)	-9 (-13%)	-9 (-16%)	-10 (-20%)	-1 (-3%)
November	-19 (-28%)	-17 (-29%)	-19 (-38%)	-10 (-31%)	-10 (-40%)
December	-1 (-33%)	0 (0%)	0 (0%)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

During September, exceedances above the 56°F threshold under H1 would not differ from those under NAA across all water years (Table 11-4-41). Total degree-months above the 56°F threshold under H1 would be higher than those under NAA in wetter water years and lower in drier water year types. During October and November, exceedances above the threshold under H1 would be 76 to 112 (33% to 38%) fewer degree-months than exceedances under NAA. There would be no meaningful differences between NAA and H1 during December and January.

Table 11-4-41. Differences between Baseline Scenarios and H1 and H4 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, September through April

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4

	Dry	32 (NA)	-19 (-37%)	41 (NA)	-10 (-20%)
	Critical	23 (NA)	-5 (-18%)	9 (NA)	-19 (-68%)
	All	118 (2,950%)	-76 (-38%)	155 (3,875%)	-39 (-20%)
December	Wet	0 (NA)	-1 (-100%)	0 (NA)	-1 (-100%)
	Above Normal	1 (NA)	0 (0%)	1 (NA)	0 (0%)
	Below Normal	1 (NA)	-2 (-67%)	3 (NA)	0 (0%)
	Dry	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Critical	1 (NA)	1 (NA)	1 (NA)	1 (NA)
	All	3 (NA)	-2 (-40%)	5 (NA)	0 (0%)
January	Wet	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

Due to generally similar flows, reservoir storage, and water temperatures between H1 and H3, effects of H1 on spring-run Chinook salmon spawning and egg incubation habitat in the Feather River would generally not be different from effects of H3, except for beneficial effects of reservoir storage under H1 in wetter water year types and in the percent of months and total degree-months exceeding the 56°F threshold.

H4/HOS

Sacramento River

Flows in the Sacramento River between Keswick and upstream of RBDD under H4 during the September through January spring-run Chinook salmon spawning and egg incubation period would generally be similar to flows under H3. Shasta Reservoir storage at the end of September under H4 would be similar to storage under H3 (Table 11-4-27).

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September at Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H4 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-20 for Bend Bridge and in Table 11-4-37 for Red Bluff. There would be no difference in levels of concern between NAA and H4 at Bend Bridge or at Red Bluff.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days under H4 would be up to 5% lower than under NAA during August and similar during other months (Table 11-4-21). At Red Bluff, exceedances above the threshold under H4 would be 15 degree-days (10%) higher than those under Existing Conditions during March, and similar during remaining months (Table 11-4-38). On an absolute scale, the 15 degree-day increase during March, because it is the sum of the 82-year period, would not translate into a biologically meaningful effect on spring-run Chinook salmon.

Clear Creek

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under H4 would generally be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would generally be similar between H4 and H3, results of the redd dewatering analysis would be similar between H4 and H3. Therefore, no analysis of redd dewatering risk was conducted for H4 in Clear Creek. Due to similar flows between H4 and H3, effects of H4 on spring-run Chinook salmon spawning and egg incubation habitat in Clear Creek would not be different from effects of H3.

Feather River

Flows in the Feather River low-flow channel during the spring-run Chinook salmon spawning and egg incubation period (September through January) would be similar between H4 and H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).* Oroville Reservoir storage volume at the end of September under H4 would generally be similar to or greater than storage under H3 depending on water year type (Table 11-4-39). Higher storage in drier water year types would generally benefit spring-run Chinook salmon spawning and rearing habitat. Mean monthly water temperatures in the low-flow channel would not differ between NAA and H4 (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Differences in the percent of months exceeding the threshold between NAA and H4 would generally be negligible (<5% on an absolute scale) during all months except November, in which there would be up to 19% fewer months exceeding the threshold under H4 (Table 11-4-40).

Total degree-days of exceedance above the 56°F threshold under H4 would be similar to those under NAA in all months of the period except November, in which the total would be 20% lower. However, a reduction of 39 degree-days would not be biologically meaningful for the 82-year period.

Due to generally similar flows, reservoir storage, and water temperatures between H4 and H3, effects of H4 on spring-run Chinook salmon spawning and egg incubation habitat in the Feather River would generally not be different from effects of H3, except for beneficial effects of reservoir storage under H4 in drier water year types.

NEPA Effects: Alternative 4 does not propose any changes in Shasta Reservoir operating criteria, and CALSIM results show that Reclamation could operate Shasta in such a manner that it does not affect upstream storage or flows substantially as compared to the NAA. Available analytical tools show conflicting results regarding the temperature effects of relatively small changes in predicted summer and fall flows. Several models (CALSIM, SRWQM, and Reclamation Egg Mortality Model) generally show no change in upstream conditions as a result of Alternative 4. However, one model, SacEFT, shows adverse effects under some conditions. After extensive investigation of these results, they appear to be a function of high model sensitivity to relatively small changes in estimated upstream conditions, which may or may not accurately predict adverse effects. Temperature and end of September storage criteria from the NMFS (2009a) BiOp for Shasta reservoir are maintained, in order to minimize adverse effects to spawning and incubating salmonids including spring-run Chinook salmon. However, the new NDD structures allow for spring time deliveries of water south of the Delta that are currently constrained under the NAA. For this reason, additional spring storage criteria may be necessary to ensure Shasta operations similar to what was modeled. These discussions will occur in the Section 7 consultation with Reclamation on Shasta and system-wide operations, which is outside the scope of BDCP. In conclusion, Alternative 4 modeling results support a finding that effects are uncertain. Alternative 4 does not propose any changes to Shasta operating criteria, but modeled results are mixed and operations that match the CALSIM modeling are not assured. Model results will be submitted to independent peer review to confirm that adverse effects are not reasonably anticipated to occur.

Considering that Alternative 4 modeling results do not predict significant adverse changes in Feather River flows or temperatures (in the low-flow channel) during the spring-run spawning or incubation period, it is not expected that Alternative 4 will result in an adverse effect on spring-run Chinook salmon spawning and egg incubation habitat in the Feather River. Because the High Outflow Scenario of Alternative 4 (Scenario H3) results in changes to Oroville reservoir releases in some springs and summers, which, in turn, could affect the cold water pool and fall temperatures in the low-flow channel, temperature and biological modeling results will be submitted to independent peer review to confirm that adverse effects are not reasonably anticipated to occur.

CEQA Conclusion: In general, Alternative 4 would not affect the quantity and quality of spawning and egg incubation habitat for spring-run Chinook salmon relative to Existing Conditions.

H3/ESO

Sacramento River

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At Keswick, temperatures under H3 during September and October would both and 6% greater, respectively, than those under Existing Conditions, but not different in other months during the period. At Red Bluff, temperatures under H3 during September and October would be 5% and 6% greater, respectively, than those under Existing Conditions, but not different in other months during the period.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September At Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-15 for Bend Bridge and in Table 11-4-28 for Red Bluff. At Bend Bridge, there would be a 61% increase in the number of years with a "red" level of concern under H3 relative to Existing Conditions. At Red Bluff, there would be 317% and 167% increases in the number of years with "red" and "orange" levels of concern under H3 relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days under H3 would be 132% to 273% higher than that under Existing Conditions depending on month throughout the period (Table 11-4-16). At Red Bluff, total degree-days under H3 would be 203% to 3,662% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4-29).

Flows in the Sacramento River upstream of Red Bluff were examined during the spring-run Chinook salmon spawning and incubation period (September through January). Flows under H3 during all months but November would generally be similar to flows under Existing Conditions with few exceptions. Flows under H3 during November would be 9% to 14% lower than flows under NAA depending on water year type.

Shasta Reservoir Storage volume at the end of September would be 15% to 33% lower under H3 relative to Existing Conditions (Table 11-4-27).

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under H3 would be 30% to 349% greater than mortality under Existing Conditions depending on water year type (Table 11-4-30).

SacEFT predicts that there would be a 34% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under H3 relative to Existing Conditions (Table 11-4-31). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under H3 relative to Existing Conditions. SacEFT predicts that there would be a 74% decrease in the percentage of years with good (lower) egg incubation conditions under H3 relative to Existing Conditions. SacEFT predicts that there would be a 35% decrease in the percentage of years with good (lower) redd dewatering risk under H3 relative to Existing

Conditions. These results indicate that spawning and egg incubation conditions for spring-run Chinook salmon under H3 would be substantially lower relative to Existing Conditions.

Clear Creek

Flows in Clear Creek were examined during the spring-run Chinook salmon spawning and egg incubation period (September through January). Flows under H3 would generally be similar to flows under Existing Conditions with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest reduction in flows under H3 would be similar to or lower magnitude than that under Existing Conditions in wet and below normal water years (Table 11-4-32). The greatest reduction in flows under H3 would be 27 cfs to 67cfs lower (worse) than Existing Conditions in above normal, dry, and critical years.

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River low-flow channel under H3 are not different from Existing Conditions during the September through January spring-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in October through January(800 cfs) would be equal to or greater than the spawning flows in September (773 cfs) for all model scenarios.

Oroville Reservoir storage volume at the end of September would be 10% to 35% lower under H3 relative to Existing Conditions depending on water year type (Table 11-4-33).

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. Minimum flows in the low-flow channel during October through January were identical between H3 and Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of H3 on redd dewatering in the Feather River low-flow channel.

Mean monthly water temperatures in the low-flow channel under H3 would be up to 10% higher under H3 relative to Existing Conditions during the September through January spawning and egg incubation period(Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Effects of H3 on water temperature in the Feather River were analyzed by determining the percent of months between September and October over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4-34). In general, the percent of months exceeding the threshold under H3 would be similar to or greater by up to 63% (absolute scale) than the percent under Existing Conditions. This comparison includes the effects of climate change.

The effects of H3 on water temperature in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the September and October spring-run Chinook salmon spawning period for all 82 years (Table 11-4-35). Total degree-months would be 60% to 4,600% higher under H3 relative to Existing Conditions regardless of month or water year type. This comparison includes the effects of climate change.

H1/LOS

Sacramento River

Flows in the Sacramento River between Keswick and upstream of RBDD under H1 during the September through January spring-run Chinook salmon spawning and egg incubation period would generally be up to 23% greater than flows under H3 during January, similar to flows under H3 during September, October, and December, and up to 16% lower during November depending on water year type. However, these increases and reductions in flows would be too infrequent or too low of magnitude to have a biologically meaningful effect on spring-run Chinook salmon spawning and egg incubation habitat. Shasta Reservoir storage at the end of September under H1 would be similar to storage under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both Keswick and Red Bluff, temperatures under H1 during September and October would be 5% and 6% greater, respectively, than those under Existing Conditions, but not different in other months during the period.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September At Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern”, as defined in Table 11-4-14. Differences between baselines and H1 and H4 scenarios in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-20 for Bend Bridge and in Table 11-4-37 for Red Bluff. At Bend Bridge, there would be a 61% increase in the number of years with a “red” level of concern under H1 relative to Existing Conditions. At Red Bluff, there would be 250% increases in the number of years with “red” and “orange” levels of concern under H1 relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days under H1 would be 153% to 255% higher than that under Existing Conditions depending on month throughout the period (Table 11-4-21). At Red Bluff, total degree-days under H1 would be 211% to 3,185% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4-38).

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., egg mortality model, SacEFT) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, conclusions for H1 would be similar to those for H3.

Clear Creek

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under H1 would generally be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would generally be similar between H1 and H3, results of the redd dewatering analysis would be similar between H1 and H3. Therefore, no analysis of redd dewatering risk was conducted for H1 in Clear Creek. Due to similar flows between H1 and H3, effects of H1 on spring-run Chinook salmon spawning and egg incubation habitat in Clear Creek would not be different from effects of H3.

Feather River

Flows in the Feather River low-flow channel during the spring-run Chinook salmon spawning and egg incubation period (September through January) would be similar between H1 and H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Oroville Reservoir storage volume at the end of September under H1 would generally be similar to or greater than storage under H3 depending on water year type (Table 11-4-39). Higher storage during wetter water year types would generally benefit spring-run Chinook spawning and egg incubation habitat. Mean monthly water temperatures in the low-flow channel would be up to 9% higher under H1 relative to Existing Conditions during the September through January spawning and egg incubation period(Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

The percent of months exceeding the 56°F NMFS temperature threshold under H1 would be similar to or greater by up to 46% (absolute scale) than the percent under Existing Conditions during September through November, but similar during December and January (Table 11-4-40). This comparison includes the effects of climate change.

Total degree-months exceeding the 56°F NMFS threshold under H1 would be 63% to 2,950% higher relative to Existing Conditions regardless of month or water year type during September through November, but similar during December and January (Table 11-4-41). This comparison includes the effects of climate change.

Due to generally similar flows, reservoir storage, and water temperatures between H1 and H3, effects of H1 on spring-run Chinook salmon spawning and egg incubation habitat in the Feather River would generally not be different from effects of H3, except for beneficial effects of reservoir storage under H1 in wetter water year types.

H4/HOS

Sacramento River

Water temperatures in the Sacramento River under H4 would not differ from those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Sacramento River between Keswick and upstream of RBDD under H4 during the September through January spring-run Chinook salmon spawning and egg incubation period would generally be similar to flows under H3. Shasta Reservoir storage at the end of September under H4 would be similar to storage under H3 (Table 11-4-27).

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., egg mortality model, SacEFT) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, effects of H4 on spring-run Chinook salmon spawning and egg incubation habitat in the Sacramento River would not be different from effects of H3.

Clear Creek

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under H4 would generally be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would generally be similar between H4 and H3, results of the redd dewatering analysis would be similar between H4 and H3. Therefore, no analysis of redd dewatering risk was conducted for H4 in Clear Creek. Due to similar flows between H4 and H3, effects of H4 on spring-run Chinook salmon spawning and egg incubation habitat in Clear Creek would not be different from effects of H3.

Feather River

Flows in the Feather River low-flow channel during the spring-run Chinook salmon spawning and egg incubation period (September through October) would be similar between H4 and H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).* Oroville Reservoir storage volume at the end of September under H4 would generally be similar to or greater than storage under H3 depending on water year type (Table 11-4-33). Higher storage in drier water year types would generally benefit spring-run Chinook salmon spawning and rearing habitat. Mean monthly water temperatures in the low-flow channel would be up to 9% higher under H4 relative to Existing Conditions during the September through January spawning and egg incubation period(Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

There would be an increased percent of months (up to 49% on an absolute scale) under H4 above the 56°F threshold compared to Existing Conditions during September through November and no change in December and January (Table 11-4-40).

The number of degree-months exceeding the threshold under H4 would be 67% to 3,875% higher than the number under Existing Conditions during September through November, but no there would be no differences during December and January (Table 11-4-41).

Due to generally similar flows, reservoir storage, and water temperatures between H4 and H3, effects of H4 on spring-run Chinook salmon spawning and egg incubation habitat in the Feather River would generally not be different from effects of H3, except for beneficial effects of reservoir storage under H4 in drier water year types.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-58 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, when compared to the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above, which is directly related to the inclusion of climate change effects in Alternative 4.

There are biologically meaningful flow reductions and temperature increases in the Sacramento River that would lead to increased egg mortality and overall reduced habitat conditions in spring-run spawning and egg incubation habitat conditions. Flows in the Feather River low-flow channel do not differ between Alternative 4 and Existing Conditions. However, water temperature analyses in the Feather River low-flow channel using the NMFS thresholds indicate that there would be moderate to large negative effects on temperature conditions during spring-run Chinook salmon spawning and egg incubation.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow and reservoir storage outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows and reservoir storage in the locations and during the months analyzed above would generally be similar between future conditions without the BDCP (NAA) and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning and egg incubation habitat for spring-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

In general, Alternative 4 would not affect the quantity and quality of rearing habitat for fry and juvenile spring-run Chinook salmon relative to the NAA.

H3/ESO

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). At Keswick, flows under H3 would generally be up to 23% lower during November than under NAA and similar in the remaining months. Upstream of Red Bluff, flows under H3 would generally be up to 18% lower during November than under NAA and similar in the remaining months. These results indicate that there would very few reductions in flows due to H3 in the Sacramento River.

As reported in Impact AQUA-40, May Shasta storage volume under H3 would be similar to or greater than storage under NAA for all water year types (Table 11-4-12) so there would be no biologically meaningful effects on downstream flows.

As reported in Impact AQUA-58, September Shasta storage volume under H3 would be similar to (<5% difference from) storage under NAA in all water year types (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

SacEFT predicts that the percentage of years with good juvenile rearing WUA conditions under H3 would be 18% greater than that under NAA (Table 11-4-31). However, the percentage of years with good (lower) juvenile stranding risk conditions under H3 would be 14% lower than under NAA. On an absolute scale, juvenile stranding risk would decrease in only 2% of years. This reduction would not have a biologically meaningful effect on spring-run Chinook salmon.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality would be similar to (<5% different from) NAA.

Clear Creek

Flows in Clear Creek during the November through March rearing period under H3 would generally be similar to flows under NAA with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during November through June were reviewed to determine flow-related effects on larval and juvenile spring-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low-flow channel throughout this period under H3 would not differ from those under NAA. In the high-flow channel, flows under H3 would generally be lower by up to 50% (monthly mean of up to 19% lower) than flows under NAA during July through September, generally greater by up to 79% (monthly mean of up to 48% higher) during February through June, and similar during January and October through December.

May Oroville storage volume under H3 would be similar to storage under NAA in all water year types (Table 11-4-42).

As reported in Impact AQUA-58, September Oroville storage volume under H3 would be similar to volume under NAA in wet, above normal, and below normal water years and 11% to 18% greater than volume under NAA during dry and critical water years (Table 11-4-33). Consequently, there would be minimal effects on downstream flows.

Table 11-4-42. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Alternative 4 (Model Scenario H3)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-67 (-2%)	-21 (-1%)
Above Normal	-192 (-5%)	-36 (-1%)
Below Normal	-362 (-11%)	-9 (0%)
Dry	-532 (-19%)	-12 (-1%)
Critical	-372 (-20%)	-56 (-4%)

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

The percent of months exceeding the 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during May through August (Table 11-4-43). In general, differences in the percent of months exceeding the threshold between NAA and H3 would be negligible (<5% on an absolute scale), although there are some small (up to 9% on an absolute scale) increases and decreases in percent of months exceeding the threshold during June and August depending on the degrees above the threshold.

Table 11-4-43. Differences between Baseline and H3 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 63°F Threshold, May through August

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3					
May	6 (NA)	2 (NA)	1 (NA)	0 (NA)	0 (NA)
June	31 (56%)	46 (168%)	38 (775%)	17 (NA)	5 (NA)
July	0 (0%)	0 (0%)	1 (1%)	27 (37%)	53 (134%)
August	0 (0%)	12 (14%)	41 (70%)	59 (209%)	56 (563%)
NAA vs. H3					
May	0 (0%)	0 (0%)	0 (0%)	0 (NA)	0 (NA)
June	-2 (-3%)	-5 (-6%)	-4 (-8%)	-4 (-18%)	0 (0%)
July	0 (0%)	0 (0%)	0 (0%)	1 (1%)	-1 (-1%)
August	0 (0%)	0 (0%)	0 (0%)	6 (8%)	9 (15%)

NA = could not be calculated because the denominator was 0.

The effects of H3 on water temperature-related juvenile rearing conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during May through August for all 82 years (Table 11-4-44). Combining all water year types, there would be no difference in total degree-months exceeded between NAA and H3 except during June (6% lower). There would be no differences in exceedances during May and July, but small increases and decreases (up to 13%) in degree-months within June and August depending on water year type.

Table 11-4-44. Differences between Baseline and H3 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Feather River above Thermalito Afterbay, May through August

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
May	Wet	1 (NA)	0 (0%)
	Above Normal	1 (NA)	0 (0%)
	Below Normal	0 (NA)	0 (NA)
	Dry	2 (NA)	0 (0%)
	Critical	4 (NA)	0 (0%)
	All	8 (NA)	0 (0%)
June	Wet	24 (160%)	-5 (-11%)
	Above Normal	13 (93%)	-4 (-13%)
	Below Normal	20 (154%)	-2 (-6%)
	Dry	31 (135%)	-2 (-4%)
	Critical	26 (433%)	1 (3%)
	All	114 (161%)	-12 (-6%)
July	Wet	43 (36%)	2 (1%)
	Above Normal	20 (45%)	0 (0%)
	Below Normal	27 (46%)	-1 (-1%)
	Dry	38 (54%)	2 (2%)
	Critical	38 (73%)	6 (7%)
	All	166 (48%)	9 (2%)
August	Wet	43 (48%)	10 (8%)
	Above Normal	20 (80%)	2 (5%)
	Below Normal	33 (87%)	4 (6%)
	Dry	48 (120%)	-5 (-5%)
	Critical	31 (74%)	-9 (-11%)
	All	175 (75%)	2 (1%)

NA = could not be calculated because the denominator was 0.

H1/LOS

Sacramento River

Flows during this period would generally be similar between H1 and H3, except during November, in which flows would be 3% to 17% lower, depending on water year type. Due to their low magnitude and frequency, these flow reductions would not have biologically meaningful effects on spring-run Chinook salmon rearing. September Shasta storage volume under H1 would generally be similar to September storage volume under H3 (Table 11-4-36).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

Clear Creek

Flows in Clear Creek during the November through March rearing period under H1 would generally be similar to flows under H3. Therefore, results for H1 regarding larval and juvenile spring-run Chinook salmon rearing habitat in Clear Creek would be similar to those under H3.

Feather River

Flows in the Feather River low-flow channel during November through June would not differ between H1 and H3 (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows in the high-flow channel under H1 during November through June juvenile rearing period would generally be similar to or greater than flows under H3. May and September Oroville storage under H1 would generally be similar to or greater than storage under H3 (Table 11-4-39, Table 11-4-45).

Table 11-4-45. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Oroville Reservoir for H1, H3, and H4 Scenarios

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	2 (0.1%)	-374 (-10.9%)
Above Normal	-5 (-0.2%)	-487 (-14.7%)
Below Normal	77 (2.6%)	-391 (-13.5%)
Dry	167 (7.5%)	69 (3.1%)
Critical	83 (5.7%)	372 (25.6%)

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

Differences in the percent of months exceeding the 63°F threshold between NAA and H1 would generally be negligible (<5% on an absolute scale) during May and between 0% and 23% (absolute scale) lower under H1 during June through August (Table 11-4-46). This represents a small to moderate benefit of H1 on spring-run Chinook salmon juvenile rearing habitat conditions in the Feather River.

Table 11-4-46. Differences between Baselines and H1 and H4 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 63°F Threshold, May through August

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H1					
May	2 (NA)	2 (NA)	0 (NA)	0 (NA)	0 (NA)
June	26 (47%)	27 (100%)	23 (475%)	7 (NA)	2 (NA)
July	0 (0%)	0 (0%)	1 (1%)	25 (34%)	47 (119%)
August	0 (0%)	12 (14%)	36 (62%)	48 (170%)	41 (413%)
NAA vs. H1					
May	-4 (-60%)	0 (0%)	-1 (-100%)	0 (NA)	0 (NA)
June	-7 (-8%)	-23 (-30%)	-19 (-39%)	-14 (-65%)	-2 (-50%)
July	0 (0%)	0 (0%)	0 (0%)	-1 (-1%)	-7 (-8%)
August	0 (0%)	0 (0%)	-5 (-5%)	-5 (-6%)	-6 (-11%)
EXISTING CONDITIONS vs. H4					
May	2 (NA)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
June	26 (47%)	31 (114%)	33 (675%)	15 (NA)	4 (NA)
July	0 (0%)	0 (0%)	1 (1%)	25 (34%)	51 (128%)
August	0 (0%)	12 (14%)	41 (70%)	53 (187%)	48 (488%)
NAA vs. H4					
May	-4 (-60%)	-1 (-50%)	-1 (-100%)	0 (NA)	0 (NA)
June	-7 (-8%)	-20 (-25%)	-9 (-18%)	-6 (-29%)	-1 (-25%)
July	0 (0%)	0 (0%)	0 (0%)	-1 (-1%)	-4 (-4%)
August	0 (0%)	0 (0%)	0 (0%)	0 (0%)	1 (2%)

NA = could not be calculated because the denominator was 0.

Combining all water year types, total degree-months above the 63°F threshold under H1 would generally be similar (<5% difference) to those under NAA during May, July, and August but 9% lower during June (Table 11-4-47). Results by water year type are generally similar to those by combining all water year types, except during August, in which total degree-months under H1 would generally be higher under NAA in wetter water years and lower in drier water year types.

Table 11-4-47. Differences between Baseline and H1 and H4 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Feather River above Thermalito Afterbay, May through August

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
May	Wet	1 (NA)	0 (0%)	1 (NA)	0 (0%)
	Above Normal	1 (NA)	0 (0%)	1 (NA)	0 (0%)
	Below Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Dry	2 (NA)	0 (0%)	2 (NA)	0 (0%)
	Critical	4 (NA)	0 (0%)	4 (NA)	0 (0%)
	All	8 (NA)	0 (0%)	8 (NA)	0 (0%)
June	Wet	25 (167%)	-4 (-9%)	24 (160%)	-5 (-11%)
	Above Normal	13 (93%)	-4 (-13%)	13 (93%)	-4 (-13%)
	Below Normal	18 (138%)	-4 (-11%)	18 (138%)	-4 (-11%)
	Dry	30 (130%)	-3 (-5%)	30 (130%)	-3 (-5%)
	Critical	23 (383%)	-2 (-6%)	23 (383%)	-2 (-6%)
	All	109 (154%)	-17 (-9%)	108 (152%)	-18 (-9%)
July	Wet	43 (36%)	2 (1%)	43 (36%)	2 (1%)
	Above Normal	20 (45%)	0 (0%)	20 (45%)	0 (0%)
	Below Normal	27 (46%)	-1 (-1%)	27 (46%)	-1 (-1%)
	Dry	39 (55%)	3 (3%)	40 (56%)	4 (4%)
	Critical	38 (73%)	6 (7%)	39 (75%)	7 (8%)
	All	167 (48%)	10 (2%)	169 (49%)	12 (2%)
August	Wet	42 (47%)	9 (7%)	42 (47%)	9 (7%)
	Above Normal	21 (84%)	3 (7%)	21 (84%)	3 (7%)
	Below Normal	30 (79%)	1 (1%)	32 (84%)	3 (4%)
	Dry	43 (108%)	-10 (-11%)	47 (118%)	-6 (-6%)
	Critical	33 (79%)	-7 (-9%)	32 (76%)	-8 (-10%)
	All	169 (72%)	-4 (-1%)	174 (74%)	1 (0.2%)

NA = could not be calculated because the denominator was 0.

Overall, due to similarities in flows, water temperatures, and storage volume between H1 and H3, results for H1 regarding larval and juvenile spring-run Chinook salmon rearing habitat in the Feather River would be similar to those for H3, although temperature conditions in the Feather River would be slightly better under H1.

H4/HOS

Sacramento River

Flows during this period would generally be similar between H4 and H3. September Shasta storage volume under H4 would generally be similar to September storage volume under H3 (Table 11-4-36). Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

Clear Creek

Flows in Clear Creek during the November through March rearing period under H4 would generally be similar to flows under H3. Therefore, results for H4 regarding larval and juvenile spring-run Chinook salmon rearing habitat in Clear Creek would be similar to those under H3.

Feather River

Flows in the Feather River low-flow channel during November through June would not differ between H4 and H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the high-flow channel under H4 during November through June juvenile rearing period would generally be similar to or greater than flows under H3, except during June, in which flows would be up to 39% lower than under H3. Because these reductions occur in only one month at the end of the rearing period, they are not expected to have biologically meaningful effects on spring-run rearing habitat. May storage would be 11% to 15% lower under H4 relative to H3 in wet, above normal, and below normal water years (Table 11-4-45). September Oroville storage under H4 would generally be similar to or greater than storage under H3 (Table 11-4-39).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

Differences in the percent of months exceeding the 63°F threshold between NAA and H4 would be negligible (<5% on an absolute scale) during May, July, and August and between 1% and 20% (absolute scale) lower under H4 during June (Table 11-4-46). This represents a small to moderate benefit of H4 on spring-run spawning habitat conditions in the Feather River.

Combining all water year types, total degree-months above the 63°F threshold under H4 would be similar (<5% difference) to those under NAA during May, July, and August, but 9% lower during June (Table 11-4-47). Results by water year type are generally similar to those by combining all water year types, except during August, in which total degree-months are generally higher under NAA in wetter water years and lower in drier water year types.

Overall, due to similarities in flows and water temperatures between H4 and H3, results for H4 regarding larval and juvenile spring-run Chinook salmon rearing habitat in the Feather River would be similar to those for H3, although temperature conditions in the Feather River would be better under H4.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because habitat would not be substantially reduced. Although SacEFT predicts that rearing habitat conditions in the Sacramento River would be reduced by Alternative 4, SALMOD predicts no substantial effects on spring-run rearing habitat. In the Feather River, habitat conditions would improve under Alternative 4 relative to the NAA, particularly in H1 and H4 scenarios. There would be no effects in Clear Creek.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of rearing habitat for spring-run Chinook salmon would be not be affected relative to the CEQA baseline.

H3/ESO

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). At Keswick, flows under H3 would be up to 22% greater during February and similar in the remaining months. Upstream of Red Bluff, flows under H3 would generally be up to 26% lower during November than under Existing Conditions and similar in the remaining months. These results indicate that there would very few reductions in flows due to H3 in the Sacramento River.

As reported in Impact AQUA-40, Shasta Reservoir storage volume at the end of May under H3 would be similar to volume under Existing Conditions in wet and above normal water years and 8% to 25% lower than volume under Existing Conditions in below normal, dry, and critical water years (Table 11-4-19). As reported in AQUA-58, Shasta Reservoir storage volume at the end of September under H3 would be 15% to 33% lower relative to Existing Conditions (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both sites, mean monthly water temperature under H3 would be similar to those under Existing Conditions in all months except August through October, in which temperatures would be 5% to 6% higher under H3.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under H3 would be 18% lower than under Existing Conditions (Table 11-4-31). In addition, the percentage of years with good (low) juvenile stranding risk under H3 is predicted to be 37% lower than under Existing Conditions. This indicates that the quantity and quality of juvenile rearing habitat in the Sacramento River would be lower under H3 relative to Existing Conditions.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality under H3 would be 32% lower than under Existing Conditions.

Clear Creek

Flows in Clear Creek during the November through March rearing period under H3 would generally be similar to flows under Existing Conditions, except during March, in which flows would be up to 29% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not model in Clear Creek.

Feather River

Relatively constant flows in the low-flow channel throughout the November through June rearing period under H3 would not differ from those under Existing Conditions. In the high-flow channel, flows under H3 would generally be up to 61% lower than flows under Existing Conditions during January, February, and December, up to 209% greater than flows under Existing Conditions during April through June, and similar during March and November.

May Oroville storage volume under H3 would be similar to volume under Existing Conditions in wet years and 5% to 20% lower than volume under Existing Conditions in other water year types (Table 11-4-42).

As reported in Impact AQUA-58, September Oroville storage volume would be 10% to 35% lower under H3 relative to Existing Conditions depending on water year type (Table 11-4-33).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H3 would be 6% to 10% higher during November through March and not different during April through June. In the high-flow channel, mean monthly water temperatures under H3 would be 6% to 8% higher during November through February and not different during March through June.

Effects of H3 on water temperature-related effects on spring-run Chinook salmon juvenile rearing conditions in the Feather River were analyzed by comparing the percent of months between May and August over the 82-year CALSIM modeling period that exceed a 63°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4-43). In general, the percent of months exceeding the threshold under H3 would be similar or up to 59% greater (absolute scale) than those under Existing Conditions. This comparison includes the effects of climate change.

The effects of H3 on water temperature-related juvenile rearing conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during May through August for all 82 years (Table 11-4-44). Combining all water year types, there would be a very small difference (8 degree-months) between Existing Conditions and H3 during May, but up to 161% increase in degree-months during June, July, and August. This comparison includes the effects of climate change.

H1/LOS

Sacramento River

Flows during this period would generally be similar between H1 and H3, except during November, in which flows would be 3% to 17% lower, depending on water year type. Due to their low magnitude and frequency, these flow reductions would not have biologically meaningful effects on spring-run Chinook salmon rearing. September Shasta storage volume under H1 would generally be similar to May and September storage volume under H3 (Table 11-4-36).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, there would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month except August through October, which would be 5% to 6% higher.

Clear Creek

Flows in Clear Creek during the November through March rearing period under H1 would generally be similar to flows under H3. Therefore, results for H1 regarding larval and juvenile spring-run Chinook salmon rearing habitat in Clear Creek would be similar to those under H3.

Feather River

Flows in the Feather River low-flow channel during November through June would not differ between H1 and H3 (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows in the high-flow channel under H1 during November through June juvenile rearing period would generally be similar to or greater than flows under H3. May and September Oroville storage under H1 would generally be similar to or greater than storage under H1 (Table 11-4-39, Table 11-4-45).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H1 would be 6% to 9% higher during November through March and not different during April through June. In the high-flow channel, mean monthly water temperatures under H1 would be 6% to 8% higher during November through February and not different during March through June.

Differences in the percent of months exceeding the 63°F threshold between Existing Conditions and H1 would generally be negligible (<5% on an absolute scale) during May and between 0% and 48% (absolute scale) higher under H1 during June through August (Table 11-4-46). This comparison includes the effects of climate change.

Combining all water year types, there would be a very small difference (8 degree-months) between Existing Conditions and H1 during May, but up to 154% increase in degree-months during June, July, and August. (Table 11-4-47). This comparison includes the effects of climate change. Results by water year type are similar to those by combining all water year types but differ in magnitude of differences between Existing Conditions and H1.

Overall, due to similarities in flows, water temperatures, and storage volume between H1 and H3, results for H1 regarding larval and juvenile spring-run Chinook salmon rearing habitat in the Feather River would be similar to those for H3.

H4/HOS

Sacramento River

Flows during this period would generally be similar between H4 and H3. September Shasta storage volume under H4 would generally be similar to September storage volume under H3 (Table 11-4-36).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, there would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month except August through October, which would be 5% to 6% higher.

Clear Creek

Flows in Clear Creek during the November through March rearing period under H4 would generally be similar to flows under H3. Therefore, results for H4 regarding larval and juvenile spring-run Chinook salmon rearing habitat in Clear Creek would be similar to those under H3.

Feather River

Flows in the Feather River low-flow channel during November through June would not differ between H4 and H3 (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows in the high-flow channel under H4 during November through June juvenile rearing period would generally be similar to or greater than flows under H3, except during June, in which flows would be up to 39% lower than under H3. Because these reductions occur in only one month at the end of the rearing period, they are not expected to have biologically meaningful effects on spring-run rearing habitat. May storage would be 11% to 15% lower under H4 relative to H3 in wet, above normal, and below normal water years (Table 11-4-39). September Oroville storage under H4 would generally be similar to or greater than storage under H3 (Table 11-4-45).

Mean monthly water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H4 would be 5% to 9% higher during November through March and not different during April through June. In the high-flow channel, mean monthly water temperatures under H4 would be 6% to 8% higher during November through February and not different during March through June.

Differences in the percent of months exceeding the 63°F threshold between Existing Conditions and H4 would be negligible (<5% on an absolute scale) during May and between 0% and 53% (absolute scale) lower under H4 during June, July, and August (Table 11-4-46). This comparison includes the effects of climate change.

Combining all water year types, total degree-months above the 63°F threshold under H4 would be similar to those under Existing Conditions during May, but 49% to 152% greater than those under Existing Conditions during June through August (Table 11-4-47). Results by water year type are generally similar to those by combining all water year types, although magnitudes of differences vary by water year type within months. This comparison includes the effects of climate change.

Overall, due to similarities in flows and water temperatures between H4 and H3, results for H4 regarding larval and juvenile spring-run Chinook salmon rearing habitat in the Feather River would be similar to those for H3.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-59 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat, contrary to the NEPA conclusion set forth above. There would be small to moderate flow-related effects of Alternative 4 on spring-run Chinook salmon in the Sacramento and Feather rivers and temperature-related effects in the Feather River. Both SacEFT and SALMOD predict reduced habitat conditions for spring-run Chinook salmon in the Sacramento River. Exceedances above NMFS temperature thresholds would be higher under Alternative 4 relative to Existing Conditions. Results would be similar among model scenarios.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between future conditions without BDCP and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for spring-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

In general, the effects of Alternative 4 on spring-run Chinook salmon migration conditions relative to the NAA are uncertain.

Upstream of the Delta

H3/ESO

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were evaluated during the December through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 12% greater than flows under NAA during May and similar to flows under NAA during December through April.

Flows in the Sacramento River upstream of Red Bluff were evaluated during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 during May and June would generally be up to 12% greater than flows under NAA and similar to flows under NAA during April, July, and August.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Clear Creek

Flows in Clear Creek during the November through May juvenile Chinook salmon spring-run migration period under H3 would generally be similar to or greater than flows under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek during the April through August adult spring-run Chinook salmon upstream migration period under H3 would be similar to flows under NAA, except in critical water years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 during April and May would be up to 23% greater than flows under NAA and similar to flows under NAA in the remaining months.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 during July and August would generally be up to 53% lower than flows under NAA, up to 65% greater than flows under NAA during May and June, and similar to flows under NAA during April. Although these reductions would be of moderate to large magnitude, flows under H3 during these months would generally exceed flows suggested by NMFS during the BDCP planning process at similar frequencies as those under NAA (Table 11-4-48). Therefore, these reduced flows would not affect spring-run Chinook salmon in a biologically meaningful way.

Table 11-4-48. Differences (Percentage Differences) in the Percentage of Years Exceeding NMFS Suggested Minimum Flows in the Feather River High-Flow Channel (at Thermalito)

	EXISTING CONDITIONS vs. H3	NAA vs. H3
Above Normal Water Year Type		
October	0 (0%)	0 (0%)
November	0 (0%)	0 (0%)
December	9.1 (50%)	-18.2 (-40%)
January	-27.3 (-60%)	0 (0%)
February	0 (0%)	0 (0%)
March	9.1 (25%)	9.1 (25%)
April	0 (NA)	0 (NA)
May	9.1 (100%)	9.1 (100%)
June	18.2 (25%)	0 (0%)
July	0 (0%)	0 (0%)
August	9.1 (10%)	0 (0%)
September	36.4 (57.2%)	0 (0%)
Below Normal Water Year Type		
October	-7.7 (-9.1%)	0 (0%)
November	-7.7 (-10%)	0 (0%)
December	0 (0%)	0 (0%)
January	-35.8 (-83.4%)	-7.2 (-50.3%)
February	-14.3 (-33.3%)	0 (0%)
March	-21.4 (-100%)	-7.1 (-100%)
April	7.1 (NA)	7.1 (NA)
May	7.1 (NA)	7.1 (NA)
June	28.6 (44.5%)	0 (0%)
July	0 (0%)	0 (0%)
August	0 (0%)	0 (0%)
September	-35.7 (-45.4%)	-50 (-53.8%)

NA = could not be calculated because the denominator was 0.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

H1/LOS

Sacramento River

Flows under H1 in the Sacramento River upstream of Red Bluff during the December through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model*

Results utilized in the Fish Analysis). Because flows would be similar between H1 and H3, results for H1 regarding migration conditions for spring-run Chinook salmon in the Sacramento River would be similar to those for H3.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Clear Creek

Flows under H1 in Clear Creek during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would be similar between H1 and H3, results for H1 regarding migration conditions for spring-run Chinook salmon in Clear Creek would be similar to those for H3.

Feather River

Flows under H1 in the Feather River at the confluence with the Sacramento River during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This lack of reduction in flows is further confirmed by evaluating the exceedance of flows suggested by NMFS during the BDCP planning process for the Feather River (Table 11-4-49). Flows under H1 in both above and below normal water years during both periods would generally be similar to exceedances under H3. Because flows would be similar between H1 and H3, results for H1 regarding migration conditions for spring-run Chinook salmon in the Feather River would be similar to those for H3.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Table 11-4-49. Differences (Percentage Differences) in the Percentage of Years Exceeding NMFS Suggested Minimum Flows in the Feather River High-Flow Channel (at Thermalito) between the H3 Model Scenario and H1 and H4 Model Scenarios

	H3 vs. H1	H3 vs. H4
Above Normal Water Year Type		
October	9.1 (12.5%)	9.1 (12.5%)

August	0 (0%)	-7.1 (-7.1%)
September	0 (0%)	-7.1 (-7.1%)

NA = could not be calculated because the denominator was 0.

H4/HOS

Sacramento River

Flows under H4 in the Sacramento River upstream of Red Bluff during the December through May juvenile spring-run Chinook salmon migration period would generally be similar to flows under H3. Flows under H4 during the April through August adult upstream migration period would generally be similar to flows under H3, except during June, in which flows would be up to 12% lower under H4, and during August, in which flows would be up to 13% greater under H4. These differences in flows between H4 and H3 scenarios would not be large or frequent enough to have biologically meaningful effects on spring-run Chinook salmon adult migration conditions. Therefore, because flows and water temperatures would be similar between H4 and H3, results for H4 regarding migration conditions for spring-run Chinook salmon in the Sacramento River would be similar to those for H3.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Clear Creek

Flows under H4 in Clear Creek during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would be similar between H4 and H3, results for H4 regarding migration conditions for spring-run Chinook salmon in Clear Creek would be similar to those for H3.

Feather River

Flows under H4 in the Feather River at the confluence with the Sacramento River during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), except during April and May in which flows would be up to 100% greater under H4*.* The exceedance of monthly flows in the Feather River suggested by NMFS during the BDCP planning process would differ between H4 and H3 (Table 11-4-49). Flows during the April through August adult upstream migration period would vary by month. flows would be lower under H4 relative to H3 during June through August and higher during January, February and May of above normal water years, but there would be no difference between H4 and H3 in below normal years.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Through-Delta

Juveniles

Scenario H3 operations would reduce OMR reverse flows (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), with a corresponding increase in net positive downstream flows, during the outmigration period of Chinook salmon through the interior Delta channels. Conditions under Scenario H1 and Scenario H3 would result in slightly decreased OMR flows in April and May relative to NAA, however flows during these months would still be net positive (flowing towards the sea). OMR flows under Scenario H4 would generally be improved compared to NAA conditions during all water year types throughout the migration period. These improved net positive downstream flows would be substantial benefits of the proposed operations.

Flows downstream of the north Delta intakes would be reduced, which may increase predation potential. During the juvenile spring-run Chinook salmon emigration period (December through May), mean monthly flows under Scenario H3 in the Sacramento River below the NDD would be lower (14% to 23% reduced in monthly mean across years) compared to NAA. Flows would be up to 27% to 28% lower in April and November of above normal years. Flows below the NDD would be similar for Scenarios H3 and H1. Under the high spring outflow Scenario, H4, flows during April and May would not decrease as much (5% to 9% lower) compared to NAA.

The three North Delta intake facilities proposed on the Sacramento River under Alternative 4 would displace aquatic habitat and attract predatory fish to the structure. Potential predation at the three North Delta intakes was estimated in two ways. Bioenergetics modeling with a median predator density predicts a predation loss of about 8,200 juveniles, or 0.2% of the spring-run juvenile population under Alternative 4 (Table 11-4-50). A conservative assumption of 5% loss per intake would yield a cumulative loss of 12% of juvenile spring-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate. In addition, the three intake structures would result in a permanent loss of 13.7 acres aquatic habitat and 7,450 linear feet of shoreline. This topic is discussed further in Impact AQUA-42 for Alternative 1A.

Table 11-4-50. Juvenile Spring-Run Chinook Salmon Predation Loss at the proposed North Delta Diversion intakes for Alternative 4 (Three Intakes)

Striped Bass at NDD (Three Intakes)			Spring-Run Chinook Consumed	
Density Assumption	Bass per 1,000 feet of Intake	Total Number of Bass	Number	Percentage of Annual Juvenile Production
Low	18	86	1,243	0.03%
Median	119	571	8,217	0.20%
High	219	1,051	15,122	0.36%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (Appendix 5F Biological Stressors).

As estimated by the Delta Passage Model, through-Delta survival under Scenario H3 by juvenile spring-run Chinook salmon Alternative 4 averaged 29% across all years, ranging from about 24% in drier years to 38% in wetter years (Table 11-4-51). Scenario H3 survival was similar to NAA in both drier years (0.5% less survival, or 2% less in relative difference) and wetter years (2.5% reduced survival, or 6% less in relative difference) (Table 11-4-51).

Survival under Scenario H1 (low outflow) was similar to Scenario H3 and NAA (averages around 21%) (Table 11-4-51). Average survival under Scenario H4 (high outflow) was 30.7%, compared to 29.1% for Scenarios H1 and H3 and 30.3% for NAA. In wetter years, Scenario H4 had 2% greater survival, a 5% relative difference compared to NAA. This difference was driven by appreciably higher survival in wetter years (the above-normal year of 1980 and the wet year of 1984) as a result of greater outflow under Scenario H4.

Table 11-4-51. Through-Delta Survival (%) of Emigrating Juvenile Spring-Run Chinook Salmon under Alternative 4 (Scenarios H3, H1 and H4)

Water Year Type	Average Percentage Survival					Difference in Percentage Survival (Relative Difference)					
	Scenario					EXISTING CONDITIONS vs. Alt 4 Scenario			NAA vs. Alt 4 Scenario		
	EXISTING CONDITIONS	NAA	H3	H1	H4	H3	H1	H4	H3	H1	H4
Wetter Years	42.1	40.4	37.9	37.9	42.4	-4.2 (-10%)	-4.2 (-10%)	0.3 (1%)	-2.5 (-6%)	-2.5 (-6%)	2.0 (5%)
Drier Years	24.8	24.3	23.7	23.8	23.7	-1.0 (-4%)	-1.0 (-4%)	-1.1 (-5%)	-0.5 (-2%)	-0.5 (-2%)	-0.6 (-3%)
All Years	31.3	30.3	29.1	29.1	30.7	-2.2 (-7%)	-2.2 (-7%)	-0.6 (-2%)	-1.3 (-4%)	-1.2 (-4%)	0.4 (1%)

Note: Average Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and Above Normal Water Years (6 years).
Drier = Below Normal, Dry and Critical Water Years (10 years).
H3 = ESO operations, H1 = Low Outflow, H4 = High Outflow.

Adults

As described for winter-run Chinook, attraction flows and olfactory cues in the west Delta would be altered because of shifts in exports from the south Delta to the north Delta. Flows in the Sacramento River downstream of the north Delta intake diversions would be reduced, with concomitant proportional increases in San Joaquin River flows. The flow changes under Scenario H3 would slightly decrease the olfactory cues for migrating adult salmon in the Sacramento River (by 9% or less compared to NAA) and slightly increase the olfactory cues for the San Joaquin River (Table 11-4-52). Conditions under Scenario H4 are expected to reduce the magnitude of this effect because it would involve fewer exports from the north Delta compared to Scenario H3 and Scenario 1.

Table 11-4-52. Percentage (%) of Water at Collinsville that Originated in the Sacramento during the Adult Spring-Run Chinook Salmon Migration Period for Alternative 4 (Scenario H3)

Month	EXISTING CONDITIONS	NAA	A4 (H3)	EXISTING CONDITIONS vs. A4 (H3)	NAA vs. A4 (H3)
March	78	76	68	-10	-8
April	77	75	66	-11	-9
May	69	65	59	-10	-6
June	64	62	58	-6	-4

Shading indicates 10% or greater absolute difference.

NEPA Effects: Upstream of the Delta, these results indicate that the effect would not be adverse because it does not have the potential to substantially interfere with the movement of fish. Flows in the Sacramento River and Clear Creek and water temperatures in the Sacramento and Feather Rivers would generally not be affected by Alternative 4. Flows under H3 and H4 scenarios in the Feather River would be lower during summer months due to the Fall X2 standard, although flows would otherwise not differ among scenarios.

Near-field effects of Alternative 4 NDD on spring-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating spring-run Chinook salmon, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus the level of impacts associated with 3 new intakes would be considerably lower than those expected from having 5 new intakes in the river. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 12% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Alternative 4 also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for spring-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 4 predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 4 would be similar to those estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of, the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon. However, until these efforts are completed and their results are fully analyzed, the overall cumulative effect of Alternative 4 on spring-run Chinook salmon migration remains uncertain.

CEQA Conclusion: In general, Alternative 4 would not affect migration conditions for spring-run Chinook salmon relative to the CEQA baseline.

Upstream of the Delta

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were examined during December through May juvenile spring-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 during May would generally be up to 14% greater than flows under Existing Conditions, and similar to flows under Existing Conditions during December through April.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through May juvenile Chinook salmon spring-run emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type, except in critical years during January and wet years during May (5% lower in both).

Flows in the Sacramento River upstream of Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 during May and June would generally be up to 20% greater than flows under Existing Conditions, up to 26% lower during August, and similar to flows under Existing Conditions during April and July.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month except August, in which temperatures would be 6% greater under H3.

Clear Creek

Flows in Clear Creek were examined during the November through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be greater than flows under Existing Conditions during March, but similar during the remaining months.

Flows in Clear Creek were examined during the April through August adult spring-run Chinook salmon upstream migration period. Flows under H3 would generally be similar to flows under Existing Conditions, with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile Chinook salmon spring-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 16% lower than flows under Existing Conditions during November, and similar during December through May.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month except November and December, in which temperatures under H3 would be 5% greater.

Flows were examined for the Feather River at the confluence with the Sacramento River during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 64% lower than flows under Existing Conditions during July and August, and similar during April through June. However, the frequencies of exceedance above flow thresholds suggested by NMFS during the BDCP planning process under H3 would be similar to those under Existing Conditions during the two periods in above normal water years (Table 11-4-48). The frequencies of exceedance during the two periods in below normal water years would be lower during January through March.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month except July and August, in which temperatures under H3 would be 6% greater.

H1/LOS

Sacramento River

Flows under H1 in the Sacramento River upstream of Red Bluff during the December through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would be similar between H1 and H3, results for H1 regarding migration conditions for spring-run Chinook salmon in the Sacramento River would be similar to those for H3.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month except August, in which temperatures would be 6% greater under H1.

Clear Creek

Flows under H1 in Clear Creek during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would be similar between H1 and H3, results for H1 regarding migration conditions for spring-run Chinook salmon in Clear Creek would be similar to those for H3.

Feather River

Flows under H1 in the Feather River at the confluence with the Sacramento River during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This lack of reduction in flows is further confirmed by evaluating the exceedance of flows suggested by NMFS during the BDCP planning process for the Feather River (Table 11-4-49). Flows under H1 in both above and below normal water years during both periods would generally be similar to exceedances under H3. Because flows would be similar between H1 and H3, results for H1 regarding migration conditions for spring-run Chinook salmon in the Feather River would be similar to those for H3.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month except November and December, in which temperatures under H1 would be 5% greater.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month except July and August, in which temperatures under H1 would be 6% greater.

H4/HOS

Sacramento River

Flows under H4 in the Sacramento River upstream of Red Bluff during the December through May juvenile spring-run Chinook salmon migration period would generally be similar to flows under H3. Flows under H4 during the April through August adult upstream migration period would generally be similar to flows under H3, except during June, in which flows would be up to 12% lower under H4, and during August, in which flows would be up to 13% greater under H4. These differences in flows between H4 and H3 scenarios would not be large or frequent enough to have biologically meaningful effects on spring-run Chinook salmon adult migration conditions. Therefore, because flows and water temperatures would be similar between H4 and H3, results for H4 regarding migration conditions for spring-run Chinook salmon in the Sacramento River would be similar to those for H3.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month except August, in which temperatures would be 6% greater under H4.

Clear Creek

Flows under H4 in Clear Creek during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flows would be similar between H4 and H3, results for H4 regarding migration conditions for spring-run Chinook salmon in Clear Creek would be similar to those for H3.

Feather River

Therefore, no further temperature analyses were conducted in the Feather River to assess spring-run Chinook salmon migration conditions. Flows under H4 in the Feather River at the confluence with the Sacramento River during the November through May juvenile spring-run Chinook salmon migration period and the April through August adult upstream migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), except during April and May in which flows would be up to 100% greater under H4. The exceedance of monthly flows in the Feather River suggested by NMFS during the BDCP planning process would be similar between H4 and H3 (Table 11-4-49). Flows during the April through August adult upstream migration period would vary by month. Flows during April and May would be up to 100% greater under H4, whereas flows during July through August would be up to 39% lower under H4. The exceedance of monthly flows in the Feather River suggested by NMFS during the BDCP planning process would be lower under H4 relative to H3 during June through August of above normal water years, but there would be no difference between H3 and H4 in below normal years. These results indicate that flows would be reduced in the Feather River by H4 relative to H3.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month except November and December, in which temperatures under H4 would be 5% greater.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month except July and August, in which temperatures under H4 would be 6% to 7% greater.

Through-Delta

Juveniles

As described above, Scenarios H3 and H1 operations have similar through-Delta survival averaged across all years compared to Existing Conditions (2.2% reduced survival, or 7% less in relative difference) (Table 11-4-51). Survival under the high outflow Scenario H4 would be similar to Existing Conditions (0.6% less averaged for all years, a 2% relative difference), particularly in wetter years. Overall reductions in OMR reverse flows under all flow scenarios for Alternative 4 would be beneficial (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Conditions under Scenario H4 would further improve OMR flow conditions (i.e., less reverse) relative to the Scenario H3 and H1. Flows below the north Delta intakes would be reduced, which may increase predation potential. The impact is considered less than significant due to similar or slightly greater survival between Alternative 4 and Existing Conditions during all water year types. No mitigation would be required.

Adults

As described above, attraction flows will be altered because of shifts in exports from the south Delta to the north Delta These changes would slightly decrease the olfactory cues for migrating adult salmon in the Sacramento River (reduced by 10–11% in March-May under the Scenario H3 compared to Existing Conditions) and slightly increase olfactory cues for the San Joaquin River (Table 11-4-52). Conditions between all flow scenarios under Alternative 4 would be similar; there would only be small changes in olfactory cues for migrating adult salmon. Overall, impacts related to migration conditions for spring-run Chinook salmon are considered less than significant. No mitigation is required.

Summary of CEQA Conclusion

Collectively, the results indicate that the effects would be less than significant because it would not substantially reduce the suitability of migration habitat or interfere with the movement of fish. Flows in the Sacramento River and Clear Creek and water temperatures in the Sacramento and Feather Rivers would generally not be affected by Alternative 4. Flows would be lower in 2 months of the 5-month adult migration period, although there would be no other flow reductions in the Feather River. Further, Alternative 4 would not reduce spring-run Chinook salmon juvenile survival through the Delta due to similar survival between Alternative 4 scenarios and Existing Conditions during all water year types and adult migration cues would not differ between Alternative 4 scenarios and Existing Conditions. No mitigation is necessary.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for spring-run Chinook salmon under Alternative 1A (Impacts AQUA-61 through AQUA-63) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on spring-run Chinook salmon are the same as those described under Alternative 1A (Impacts AQUA-61 through AQUA-63). The effects would not be adverse, and would generally be beneficial. Specifically for AQUA-62, the effects of contaminants on spring-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on spring-run Chinook salmon are uncertain.

CEQA Conclusion: All three of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, for the reasons identified for Alternative 1A, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for spring-run Chinook salmon under Alternative

1A (Impacts AQUA-64 through AQUA-72) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (CM12)

Impact AQUA-65: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Spring-Run ESU) (CM13)

Impact AQUA-66: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Spring-Run ESU) (CM14)

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (CM15)

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (CM16)

Impact AQUA-69: Effects of Illegal Harvest Reduction on Chinook Salmon (Spring-Run ESU) (CM17)

Impact AQUA-70: Effects of Conservation Hatcheries on Chinook Salmon (Spring-Run ESU) (CM18)

Impact AQUA-71: Effects of Urban Stormwater Treatment on Chinook Salmon (Spring-Run ESU) (CM19)

Impact AQUA-72: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Spring-Run ESU) (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on spring-run Chinook salmon are the same as those described under Alternative 1A(Impacts AQUA-64 through AQUA-72). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

Fall-/Late Fall–Run Chinook Salmon

Construction and Maintenance of CM1

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

The potential effects of construction of the water conveyance facilities on fall-run/late fall-run Chinook salmon would be similar to those described for Alternative 1A, Impact AQUA-73, except that Alternative 4 would include three intakes instead of five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less. Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-73, the effect would not be adverse for fall-run/late fall-run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-73, the impact of construction of the water conveyance facilities on fall-run/late fall-run Chinook salmon would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: The potential effects of the maintenance of the water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A, Impact AQUA-74, except that only three intakes would need to be maintained under Alternative 4 rather than five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-74, the impact would not be adverse for fall-run/late fall-run Chinook salmon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-74, the impact of maintenance of the water conveyance facilities on fall-run/late fall-run Chinook salmon would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Overall entrainment under Alternative 4 at the south Delta export facilities would be reduced for all water year types (Table 11-4-53). Under Scenario H3, average entrainment across all years would be reduced 44% (~24,000 fish) for fall-run Chinook salmon and reduced 34% (627 fish) for late fall-run Chinook salmon compared to NAA.

Table 11-4-53. Juvenile Fall-Run and Late Fall-Run Chinook Salmon Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 4 (Scenario H3)

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A4 (H3)	NAA vs. A4 (H3)
Fall-run Chinook Salmon		
Wet	-80,609 (-63%)	-80,786 (-63%)
Above Normal	-13,488 (-41%)	-13,962 (-42%)
Below Normal	-3,504 (-26%)	-3,864 (-28%)
Dry	-1,890 (-10%)	-3,538 (-17%)
Critical	-12,803 (-31%)	-7,626 (-21%)
All Years	-23,960 (-44%)	-24,016 (-44%)
Late fall-run Chinook Salmon		
Wet	-2,801 (-47%)	-2,714 (-46%)
Above Normal	-259 (-45%)	-245 (-44%)
Below Normal	-21 (-38%)	-18 (-34%)
Dry	-45 (-33%)	-29 (-24%)
Critical	-51 (-31%)	-38 (-25%)
All Years	-708 (-37%)	-627 (-34%)

Shading indicates10% or greater increased entrainment.

Note: Estimated annual number of fish lost, based on normalized data.

The annual juvenile population that approaches the Delta is assumed to be 23 million fall-run Chinook salmon and 1 million late fall-run Chinook salmon (juvenile index of abundance). The proportion of juvenile index of abundance lost at the south Delta facilities is very low for both runs under NAA (fall-run 0.24%, late fall-run 0.19% averaged for all years), and under Scenario H3 decreases to negligible levels (fall-run 0.13%; late fall-run 0.12% A4_LLT).

In general, most covered fish species occur within the Plan Area during winter-spring and, therefore, there would be little difference in south Delta entrainment between Scenarios H3 and H1 based on the similarity of south Delta export pumping for these scenarios. Lower south Delta export pumping during the spring under Scenario H4 would result in lower entrainment during this period.

Entrainment under Scenario H1 would be similar to Scenario H3, while conditions under Scenario H4 are expected to further reduce entrainment losses.

Water Exports from SWP/CVP North Delta Intake Facilities

The impact would be similar in type to Alternative 1A, but the degree would be less because Alternative 4 would have fewer intakes. Thus under Alternative 4 there would be about a 40% reduction in impingement and predation risk relative to Alternative 1A (Impact AQUA-75).

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The impact of entrainment to the NBA would be the same as described for Alternative 1A (Impact AQUA-75). Entrainment and impingement effects would be minimal because intakes on the Sacramento River would have state-of-the-art screens installed.

Predation Associated with Entrainment

Entrainment-related predation loss at the south Delta facilities would be no greater and may be lower than baseline (NAA), due to a reduction in entrainment loss. Scenario H3 Entrainment-related predation losses are expected to decrease under Scenario H4 compared to Scenario H3, while predation losses would be similar or slightly increased under Scenario H1 compared to Scenario H3.

Predation at the north Delta would be increased due to the installation of the proposed SWP/CVP North Delta intake facilities on the Sacramento River. Bioenergetics modeling with a median predator density predicts a predation loss under Alternative 4 of less than 0.6% of the annual juvenile production (155,000 fall-run juveniles, 0.25% annual production; 25,000 late fall-run juveniles, 0.58% annual production) (Table 11-4-54).

Table 11-4-54. Fall-Run and Late Fall-Run Chinook Salmon Juvenile Predation Loss at the Proposed North Delta Diversion (NDD) Intakes for Alternative 4 (Three Intakes)

Striped Bass at NDD (Three Intakes)			Fall-Run Chinook		Late Fall-Run Chinook	
Density	Bass per 1,000 Feet of Intake	Total Number of Bass	Number Consumed (LLT)	Percentage of Annual Production	Number Consumed (LLT)	Percentage of Annual Production
Low	18	86	23,395	0.04%	3,795	0.09%
Median	119	571	154,665	0.25%	25,089	0.58%
High	219	1,051	284,636	0.46%	46,172	1.07%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (Appendix 5F Biological Stressors).

NEPA Effects: In conclusion, Alternative 4 would reduce overall entrainment losses of juvenile fall-run Chinook salmon and late fall-run Chinook salmon relative to NAA. The population benefit would be minor because entrainment losses affect less than 0.6% of annual juvenile index of abundance. Conditions under Scenario H4 would further reduce entrainment losses compared to Scenario H3 and Scenario H1. The effect of Alternative 4 would not be adverse.

CEQA Conclusion: Scenario H3 would substantially reduce entrainment at the south Delta facilities for fall-run (44% less) and late fall-run Chinook salmon (37% less) compared to Existing Conditions. Proportional losses of the juvenile population (juvenile index of abundance) would be slightly reduced from already-low levels (less that 0.25% average). Under Scenario H4, entrainment losses are expected to further decrease relative to Existing Conditions. Entrainment at the NBA would be minimal. Overall, impacts to fall-run and late fall-run Chinook salmon under Alternative 4 would be less than significant. No mitigation would be required.

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 4 would not affect the quantity and quality of spawning and egg incubation habitat for fall-/late fall-run Chinook salmon relative to the NAA.

H3/ESO

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be greater than or similar to NAA, except during October in below normal years (8% lower) and all water year types during November (5% to 18% lower, depending on water year type).

Shasta Reservoir storage at the end of September would affect flows during the fall-run spawning and egg incubation period. As reported in Impact AQUA-58, end of September Shasta Reservoir storage under H3 would be similar to storage under NAA in all water year types (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-28. There would be 2 (4%) and 3 (23%) more years with a "red" and "orange" level of concern, respectively, under H3 that would not be biologically meaningful to fall-run Chinook salmon spawners and eggs, as this is a small proportion of the 82 year period.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H3 would be 5% higher than those under NAA during October, 7% lower during April, and similar during remaining months (Table 11-4-29).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under H3 would be lower than or similar to mortality under NAA in all water year types including wet, above normal, and below normal years (5% to 9% greater, respectively, but absolute increase of 1% and 2% of fall-run population) (Table 11-4-55). These results indicate that H3 would have negligible effects on fall-run Chinook salmon egg mortality.

Table 11-4-55. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	11 (110%)	1 (6%)
Above Normal	12 (111%)	1 (5%)
Below Normal	13 (124%)	2 (9%)
Dry	17 (116%)	0 (0%)
Critical	9 (31%)	-1 (-1%)
All	12 (89%)	1 (3%)

SacEFT predicts that there would be a 54% increase in the percentage of years with good spawning habitat availability for fall-run Chinook salmon, measured as weighted usable area, under H3 relative to NAA (Table 11-4-56). SacEFT predicts that there would be a 12% reduction in the percentage of years with good (lower) redd scour risk under H3 relative to NAA. SacEFT predicts that there would be no difference in the number of years with good egg incubation conditions between H3 and NAA. SacEFT predicts that there would be a 7% increase in redd dewatering risks under H3 relative to NAA.

Table 11-4-56. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Fall-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3	NAA vs. H3
Spawning WUA	6 (13%)	19 (54%)
Redd Scour Risk	-3 (-5%)	-8 (-12%)
Egg Incubation	-25 (-27%)	0 (0%)
Redd Dewatering Risk	2 (7%)	2 (7%)
Juvenile Rearing WUA	5 (15%)	-2 (-5%)
Juvenile Stranding Risk	-9 (-29%)	2 (10%)

WUA = Weighted Usable Area.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be up to 12% greater than flows under NAA during May, and similar during February through April.

Shasta Reservoir storage at the end of September would affect flows during the fall-run spawning and egg incubation period. As reported in Impact AQUA-58, end of September Shasta Reservoir storage under H3 would be similar to storage under NAA in all water year types (Table 11-4-27).

The Reclamation egg mortality model predicts that late fall-run Chinook salmon egg mortality in the Sacramento River under H3 would be similar to or lower than mortality under NAA in all water years, including below normal water years in which, although there would be an 8% relative increase, the absolute increase would be <1% of the late fall-run population (Table 11-4-57).

Table 11-4-57. Difference and Percent Difference in Percent Mortality of Late Fall-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	4 (193%)	-0.3 (-5%)
Above Normal	4 (150%)	-1 (-13%)
Below Normal	4 (301%)	0.4 (8%)
Dry	4 (161%)	-1 (-7%)
Critical	3 (141%)	-0.1 (-2%)
All	4 (183%)	-0.3 (-4%)

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-28. There would be 2 (4%) and 3 (23%) more years with a "red" and "orange" level of concern, respectively, under H3 that would not be biologically meaningful to late fall-run Chinook salmon spawners and eggs, as this is a small proportion of the 82 year period.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H3 would be 5% higher than those under NAA during October, 7% lower during April, and similar during remaining months (Table 11-4-29).

SacEFT predicts that there would be no difference in the percentage of years with good spawning availability for late fall-run Chinook salmon, measured as weighted usable area, between NAA and H3 (Table 11-4-58). SacEFT predicts that there would be no difference in redd scour risk between NAA and H3. SacEFT predicts that there would be a negligible difference in the percentage of years with good (lower) egg incubation conditions and redd dewatering risk between H3 and NAA.

Table 11-4-58. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Late Fall-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3	NAA vs. H3
Spawning WUA	-4 (-8%)	0 (0%)
Redd Scour Risk	-6 (-7%)	0 (0%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	-3 (-5%)	2 (4%)
Juvenile Rearing WUA	-3 (-7%)	-21 (-33%)
Juvenile Stranding Risk	-30 (-42%)	-4 (-9%)

WUA = Weighted Usable Area.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Clear Creek flows below Whiskeytown Reservoir were examined for the September through February fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to flows under NAA with few exceptions.

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning is assumed to occur. The greatest monthly reduction in Clear Creek flows during September through February under H3 would be similar to those under NAA in all water year types (Table 11-4-59).

Table 11-4-59. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through February Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	0 (NA)	0 (NA)
Above Normal	-27 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-67 (NA)	0 (0%)
Critical	-33 (-50%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Fall-Run

Flows in the Feather River in the low-flow and high-flow channels were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the low-flow channel under H3 would be identical to those under NAA. Flows in the high-flow channel under H3 would generally be greater than those under NAA during October, and similar during November through January.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel during November through January were identical between H3 and NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of H3 on redd dewatering in the Feather River low-flow channel.

Mean monthly water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

Effects of H3 on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were analyzed by comparing the percent of months between October through April over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold at Gridley (Table 11-4-60). In general, differences in the percent of months exceeding the threshold between NAA and H3 would be negligible (<5% on an absolute scale), although there would be a 6% reduction (absolute scale) in months exceeding the threshold by >3°F and >4°F during November.

Table 11-4-60. Differences between Baseline and H3 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 56°F Threshold, October through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3					
October	2 (3%)	14 (16%)	27 (37%)	51 (124%)	63 (340%)
November	62 (1,667%)	41 (3,300%)	26 (NA)	12 (NA)	5 (NA)
December	1 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	4 (NA)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
March	38 (517%)	27 (733%)	11 (900%)	7 (NA)	4 (NA)
April	20 (28%)	23 (41%)	40 (128%)	42 (243%)	27 (244%)
NAA vs. H3					
October	0 (0%)	0 (0%)	4 (4%)	2 (3%)	4 (5%)
November	4 (6%)	1 (3%)	-6 (-19%)	-6 (-33%)	-1 (-20%)
December	0 (0%)	-1 (-100%)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (0%)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
March	1 (3%)	2 (9%)	1 (11%)	0 (0%)	0 (0%)
April	0 (0%)	0 (0%)	-2 (-3%)	0 (0%)	0 (0%)

NA = could not be calculated because the denominator was 0.

The effects of H3 on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the October through April fall-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-4-61). Combining all water year types, there would be no difference in total degree-months exceeded between NAA and H3. Large relative differences between NAA and H3 during December and February are mathematical artifacts due to small values of degree-months for NAA and would not translate into biologically meaningful effects on fall-run Chinook salmon. Results by water year type are generally similar to monthly results, except in dry water years during November (19% reduction). Overall, this method indicates that there would be no effect of H3 on temperature-related fall-run Chinook salmon spawning and egg incubation conditions in the Feather River.

Table 11-4-61. Differences between Baseline and H3 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River at Gridley, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
October	Wet	98 (134%)	-4 (-2%)
	Above Normal	35 (80%)	-1 (-1%)
	Below Normal	49 (89%)	0 (0%)
	Dry	74 (140%)	3 (2%)
	Critical	47 (115%)	3 (4%)
	All	303 (114%)	1 (0.2%)
November	Wet	37 (NA)	0 (0%)
	Above Normal	19 (950%)	0 (0%)
	Below Normal	20 (2,000%)	-1 (-5%)
	Dry	25 (NA)	-6 (-19%)
	Critical	20 (2,000%)	2 (11%)
	All	121 (3,025%)	-5 (-4%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	1 (NA)	-1 (-50%)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	1 (NA)	-1 (-50%)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	2 (NA)	1 (100%)
	Dry	1 (NA)	1 (NA)
	Critical	1 (NA)	-1 (-50%)
	All	4 (NA)	1 (33%)
March	Wet	5 (NA)	0 (0%)
	Above Normal	3 (300%)	1 (33%)
	Below Normal	23 (2,300%)	2 (9%)
	Dry	24 (600%)	1 (4%)
	Critical	17 (425%)	0 (0%)
	All	72 (720%)	4 (5%)
April	Wet	37 (264%)	-1 (-2%)
	Above Normal	27 (117%)	0 (0%)
	Below Normal	21 (53%)	-4 (-6%)
	Dry	42 (86%)	1 (1%)
	Critical	33 (114%)	2 (3%)
	All	160 (103%)	-2 (-1%)

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under H3 would be similar to or lower than mortality under NAA in all water years, including above normal water years in which, although there would be a 15% relative increase, the absolute increase would be 2% of the fall-run population (Table 11-4-62).

Table 11-4-62. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Feather River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	19 (1,391%)	0.2 (1%)
Above Normal	14 (1,269%)	2 (15%)
Below Normal	13 (759%)	0.4 (3%)
Dry	16 (718%)	-3 (-14%)
Critical	21 (427%)	-3 (-9%)
All	17 (806%)	-1 (-3%)

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 8% lower than flows under NAA during November, and similar in the remaining three months.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. The greatest reduction in American River flows during November through January under H3 would be 9% to 49% greater in magnitude than under NAA in above normal below normal, dry, and critical water years and 9% lower in magnitude than NAA in wet water years (Table 11-4-63).

Table 11-4-63. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in the American River at Nimbus Dam during the October through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-21 (-95%)	4 (9%)
Above Normal	-14 (-45%)	-4 (-9%)
Below Normal	-42 (-219%)	-15 (-32%)
Dry	-19 (-42%)	-22 (-49%)
Critical	8 (15%)	-4 (-10%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in October, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-64). The percent of months exceeding the threshold under H3 would generally be similar to the percent under NAA, except for the >5.0°F exceedance category during November, which would be 5% lower (absolute scale) under H3.

Table 11-4-64. Differences between Baseline and H3 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 56°F Threshold, November through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3					
November	47 (103%)	54 (200%)	58 (427%)	54 (2,200%)	35 (2,800%)
December	2 (NA)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	4 (NA)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
March	33 (270%)	25 (333%)	14 (550%)	11 (900%)	6 (NA)
April	25 (35%)	31 (50%)	35 (76%)	38 (119%)	32 (118%)
NAA vs. H3					
November	0 (0%)	-4 (-4%)	-2 (-3%)	0 (0%)	-5 (-12%)
December	1 (100%)	0 (0%)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (0%)	0 (0%)	0 (NA)	0 (NA)	0 (NA)
March	-4 (-8%)	0 (0%)	0 (0%)	0 (0%)	1 (25%)
April	-1 (-1%)	0 (0%)	0 (0%)	-1 (-2%)	2 (4%)

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-65). Total degree-months would be similar between NAA and H3 for all months.

Table 11-4-65. Differences between Baseline and H3 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the American River at the Watt Avenue Bridge, November through April

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
November	Wet	78 (312%)	-4 (-4%)
	Above Normal	35 (318%)	-1 (-2%)
	Below Normal	42 (525%)	-1 (-2%)
	Dry	49 (377%)	-2 (-3%)
	Critical	36 (225%)	-2 (-4%)
	All	240 (329%)	-10 (-3%)
December	Wet	1 (NA)	1 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	2 (NA)	0 (0%)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	3 (NA)	1 (50%)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	4 (NA)	0 (0%)
	All	4 (NA)	0 (0%)
March	Wet	12 (600%)	0 (0%)
	Above Normal	9 (NA)	0 (0%)
	Below Normal	11 (367%)	0 (0%)
	Dry	24 (600%)	-1 (-3%)
	Critical	19 (190%)	-1 (-3%)
	All	75 (395%)	-2 (-2%)
April	Wet	58 (207%)	0 (0%)
	Above Normal	34 (155%)	0 (0%)
	Below Normal	40 (111%)	-1 (-1%)
	Dry	45 (59%)	0 (0%)
	Critical	40 (68%)	5 (5%)
	All	217 (98%)	4 (1%)

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under H3 would be similar to mortality under NAA (Table 11-4-66).

Table 11-4-66. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the American River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	24 (160%)	1 (1%)
Above Normal	22 (207%)	-1 (-2%)
Below Normal	21 (171%)	-1 (-3%)
Dry	16 (99%)	-0.2 (-1%)
Critical	9 (44%)	-1 (-2%)
All	19 (128%)	-0.3 (-1%)

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to flows under NAA throughout the period.

Water temperatures throughout the Stanislaus River would be similar under NAA and H3 throughout the October through January period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff during October through January under H1 would generally be similar to flows under H3, except in November when flows would be up to 12% lower than under H3 depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This magnitude of flow reduction is not expected to have a biologically meaningful effect on fall-run Chinook salmon spawning and egg incubation habitat. September Shasta storage volume under H1 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern”, as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-67. There would be 6 (13%) fewer years with a “red” level of concern under H1 relative to NAA.

Table 11-4-67. Differences between Baseline Scenarios and H1 and H4 Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Red Bluff, October through April

Level of Concern[a]	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
Red	30 (250%)	-6 (-13%)	38 (317%)	2 (4%)
Orange	15 (250%)	8 (62%)	9 (150%)	2 (15%)
Yellow	-2 (-15%)	-1 (-8%)	-5 (-38%)	-4 (-33%)
None	-43 (-84%)	-1 (-11%)	-42 (-82%)	0 (0%)

[a] For definitions of levels of concern, see Table 11-4-14.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H1 would be 5% higher than those under NAA during March, 10% lower during November, and similar during remaining months (Table 11-4-68).

Table 11-4-68. Differences between Baseline Scenarios and H1 and H4 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Red Bluff, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
October	Wet	1,084 (422%)	-85 (-6%)	1,261 (491%)	92 (6%)
	Above Normal	452 (174%)	-25 (-3%)	498 (192%)	21 (3%)

	Critical	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	Wet	9 (NA)	0 (0%)	9 (NA)	0 (0%)
	Above Normal	6 (NA)	2 (50%)	5 (NA)	1 (25%)
	Below Normal	29 (322%)	8 (27%)	35 (389%)	14 (47%)
	Dry	63 (450%)	-1 (-1%)	65 (464%)	1 (1%)
	Critical	25 (2,500%)	-2 (-7%)	26 (2,600%)	-1 (-4%)
	All	132 (550%)	7 (5%)	140 (583%)	15 (10%)
April	Wet	259 (225%)	-2 (-1%)	262 (228%)	1 (0.3%)
	Above Normal	202 (144%)	-27 (-7%)	205 (146%)	-24 (-7%)
	Below Normal	230 (291%)	0 (0%)	255 (323%)	25 (8%)
	Dry	294 (158%)	-26 (-5%)	322 (173%)	2 (0.4%)
	Critical	135 (1,125%)	-16 (-10%)	131 (1,092%)	-20 (-12%)
	All	1,120 (211%)	-71 (-4%)	1,175 (221%)	-16 (-1%)

NA = could not be calculated because the denominator was 0.

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff during February through May under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H1 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-67. There would be 6 (13%) fewer years with a "red" level of concern under H1 relative to NAA.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H1 would be 5% higher than those under NAA during March, 10% lower during November, and similar during remaining months (Table 11-4-68).

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek flows below Whiskeytown Reservoir during October through January would generally be similar between H1 and H3 (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*). As a result, no additional flow analyses were conducted for H1. Overall, results for H1 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River low-flow and high-flow channels during October through January would generally be similar between H1 and H3 (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*).

Differences in the percent of months exceeding the 56°F NMFS threshold between NAA and H1 would be negligible (<5% on an absolute scale) during all months except October, November, March, and April, in which the percent of months under H1 would be similar to or up to 21% lower than those under NAA (Table 11-4-69).

Table 11-4-69. Differences between Baselines and H1 and H4 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 56°F Threshold, October through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H1					
October	2 (3%)	12 (14%)	21 (29%)	38 (94%)	53 (287%)

March	25 (333%)	14 (367%)	7 (600%)	5 (NA)	2 (NA)
April	-5 (-7%)	1 (2%)	21 (68%)	23 (136%)	15 (133%)
NAA vs. H4					
October	0 (0%)	-1 (-1%)	-1 (-1%)	-6 (-7%)	-5 (-6%)
November	-15 (-24%)	-9 (-21%)	-11 (-35%)	-7 (-40%)	1 (20%)
December	0 (0%)	-1 (-100%)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	-2 (-67%)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-12 (-28%)	-11 (-39%)	-2 (-22%)	-2 (-33%)	-1 (-33%)
April	-25 (-27%)	-22 (-28%)	-21 (-29%)	-19 (-31%)	-12 (-32%)

NA = could not be calculated because the denominator was 0.

Combining all water year types, there would be no difference between NAA and H1 in total degree-months exceeded in all months except October and November, during which degree-months would be lower by 9% and 28%, respectively (Table 11-4-70). Large relative differences between NAA and H1 during some months are due to small values of degree-months for NAA and would not translate into biologically meaningful effects on fall-run Chinook salmon. Results by water year type are generally similar to monthly results. Overall, this method indicates that there would be benefits of H1 on temperature-related fall-run Chinook salmon spawning and egg incubation conditions in the Feather River.

Table 11-4-70. Differences between Baselines and H1 and H4 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River at Gridley, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
October	Wet	78 (107%)	-24 (-14%)	106 (145%)	4 (2%)

	Critical	32 (110%)	1 (2%)	33 (114%)	2 (3%)
	All	159 (103%)	-3 (-1%)	102 (66%)	-60 (-19%)

NA = could not be calculated because the denominator was 0.

Due to similar flows and water temperatures between H1 and H3, results under H1 would be similar to results for analyses under H3.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during October through January would generally be similar between H1 and H3 with few exceptions that would not be biologically meaningful (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-71). The percent of months exceeding the threshold under H1 would similar to or up to 11% lower (absolute scale) than the percent under NAA.

Table 11-4-71. Differences between Baseline Scenarios and H1 and H4 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 56°F Threshold, November through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H1					
November	26 (57%)	23 (86%)	22 (164%)	19 (750%)	11 (900%)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	2 (20%)	4 (50%)	6 (250%)	2 (200%)	1 (NA)
April	11 (16%)	7 (12%)	10 (22%)	10 (31%)	2 (9%)
NAA vs. H1					
November	-2 (-3%)	-10 (-12%)	-6 (-8%)	-11 (-20%)	-9 (-21%)
December	1 (100%)	0 (0%)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	-2 (-67%)	-1 (-100%)	0 (NA)	0 (NA)	0 (NA)
March	-10 (-20%)	-10 (-31%)	-1 (-8%)	-2 (-20%)	0 (0%)
April	-1 (-1%)	-6 (-7%)	-7 (-9%)	-9 (-12%)	-5 (-9%)
EXISTING CONDITIONS vs. H4					
November	43 (95%)	51 (186%)	49 (364%)	46 (1,850%)	32 (2,600%)
December	1 (NA)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	1 (NA)	1 (NA)	0 (NA)	0 (NA)	0 (NA)
March	27 (220%)	17 (233%)	11 (450%)	10 (800%)	4 (NA)
April	26 (37%)	25 (40%)	27 (59%)	30 (92%)	25 (91%)
NAA vs. H4					
November	-4 (-4%)	-7 (-9%)	-11 (-15%)	-9 (-15%)	-7 (-18%)
December	0 (0%)	0 (0%)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	-2 (-67%)	0 (0%)	0 (NA)	0 (NA)	0 (NA)
March	-10 (-20%)	-7 (-23%)	-2 (-15%)	-1 (-10%)	-1 (-25%)
April	0 (0%)	-6 (-7%)	-7 (-9%)	-10 (-14%)	-5 (-9%)

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-72). Total degree-months would be similar between NAA and H1 for all months.

Table 11-4-72. Differences between Baseline Scenarios and H1 and H4 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the American River at the Watt Avenue Bridge, November through April

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
November	Wet	78 (312%)	-4 (-4%)	77 (308%)	-5 (-5%)
	Above Normal	33 (300%)	-3 (-6%)	32 (291%)	-4 (-9%)
	Below Normal	43 (538%)	0 (0%)	43 (538%)	0 (0%)
	Dry	46 (354%)	-5 (-8%)	50 (385%)	-1 (-2%)
	Critical	38 (238%)	0 (0%)	38 (238%)	0 (0%)
	All	238 (326%)	-12 (-4%)	240 (329%)	-10 (-3%)
December	Wet	1 (NA)	1 (NA)	1 (NA)	1 (NA)
	Above Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Below Normal	2 (NA)	0 (0%)	2 (NA)	0 (0%)

	Below Normal	39 (108%)	-2 (-3%)	40 (111%)	-1 (-1%)
	Dry	45 (59%)	0 (0%)	45 (59%)	0 (0%)
	Critical	36 (61%)	1 (1%)	35 (59%)	0 (0%)
	All	210 (95%)	-3 (-1%)	210 (95%)	-3 (-1%)

NA = could not be calculated because the denominator was 0.

Due to similar flows and water temperatures between H1 and H3, results for additional analyses (e.g., risk of redd dewatering, Reclamation egg mortality model) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to flows under NAA throughout the period.

Water temperatures throughout the Stanislaus River would be similar under NAA and H1 throughout the October through January period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff during October through January under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H4 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H4 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-67. There would be 2 (4%) and 2 (15%) more years with a "red" and orange level of concern, respectively, under H1 relative to NAA. It is not likely that these differences would be biologically meaningful.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H4 would be 10% higher than those under NAA during March and similar during remaining months (Table 11-4-68).

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff during February through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H4 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H4 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-67. There would be 2 (4%) and 2 (15%) more years with a "red" and orange level of concern, respectively, under H1 relative to NAA. It is not likely that these differences would be biologically meaningful.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H4 would be 10% higher than those under NAA during March and similar during remaining months (Table 11-4-68).

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek flows below Whiskeytown Reservoir during October through January would generally be similar between H4 and H3 (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*). As a result, no additional flow analyses were conducted for H4. Overall, results for H4 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River low-flow channel during October through January would be similar between H4 and H3 (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the high-flow channel would generally be similar to those under H3, except during October, in which flows would be up to 27% lower depending on water year type. Because flow reductions would occur in only one month, they are not expected to have a biologically meaningful effect on fall-run Chinook salmon spawning and egg incubation.

Differences in the percent of months exceeding the 56°F NMFS threshold between NAA and H4 would be negligible (<5% on an absolute scale) during all months except October, November, March, and April, in which the percent of months under H4 would be similar to or up to 25% lower than those under NAA (Table 11-4-69). This method indicates that there would be benefits of H1 on temperature-related fall-run Chinook salmon spawning and egg incubation conditions in the Feather River.

Combining all water year types, there would be no difference between NAA and H1 in total degree-months exceeded in all months except November, March, and April, during which degree-months would be lower by 8%, 5%, and 19%, respectively (Table 11-4-70). Large relative differences between NAA and H1 during some months are mathematical artifacts due to small values of degree-months for NAA and would not translate into biologically meaningful effects on fall-run Chinook salmon. Splitting monthly results into water year types yields highly variable outcomes. There would be small increases and decreases in degree-months under H4 relative to NAA depending on month and water year type. Overall, this method indicates that there would be benefits of H1 on temperature-related fall-run Chinook salmon spawning and egg incubation conditions in the Feather River.

Due to generally similar flows and water temperatures between H4 and H3, results under H4 would be similar to results for analyses under H3.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during October through January would generally be similar between H4 and H3, except during October, in which flows would be 6% to 13% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* Because flow reductions would occur in only one month and would be low in magnitude, they are not expected to have a biologically meaningful effect on fall-run Chinook salmon spawning and egg incubation.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-71). The percent of months exceeding the threshold under H4 would similar to or up to 11% lower (absolute scale) than the percent under NAA.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-72). Total degree-months would be similar between NAA and H4 for all months.

Due to generally similar flows and water temperatures between H4 and H3, results for additional analyses (e.g., risk of redd dewatering, Reclamation egg mortality model) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to flows under NAA throughout the period.

Water temperatures throughout the Stanislaus River would be similar under NAA and H4 throughout the October through January period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results* *utilized in the Fish Analysis*). Flows under H4 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, it is concluded that the effect is not adverse because habitat conditions are not substantially reduced. There are no reductions in flows under Alternative 4 or increases in temperatures that would translate into biologically meaningful effects on fall-/late fall-run Chinook salmon. In all rivers, there are no large or consistent differences relative to NAA. Biological modeling results also indicate that Alternative 4 would not substantially affect fall-/late fall-run Chinook salmon spawning and egg incubation habitat relative to the NEPA point of comparison. There would generally be no differences among scenarios.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of spawning and egg incubation habitat for fall-/late fall-run Chinook salmon would not be affected relative to the CEQA baseline.

H3/ESO

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* Flows under H3 would be up to 14% lower than flows under Existing Conditions during November, and similar during the remaining three months.

Shasta storage volume at the end of September would be 15% to 33% lower under H3 relative to Existing Conditions (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 during the period, except during October, in which temperatures would be 6% higher under H3.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-28. There would be 38 (317%) and 10 (167%) more years with "red" and "orange" levels of concern under H3 than under Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H3 would be 203% to 3,662% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4-29).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under H3 would be 31% to 124% greater than mortality under Existing Conditions (Table 11-4-55).

SacEFT predicts that there would be a 13% increase in the percentage of years with good spawning availability, measured as weighted usable area, under H3 relative to Existing Conditions (Table 11-4-56). SacEFT predicts that there would be a 5% reduction in the percentage of years with good (lower) redd scour risk under H3 relative to Existing Conditions. SacEFT predicts that there would be a 27% decrease in the percentage of years with good (lower) egg incubation conditions under H3 relative to Existing Conditions. SacEFT predicts that there would be a 7% increase in the percentage of years with good (lower) redd dewatering risk under H3 relative to Existing Conditions.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 14% greater than flows under Existing Conditions during May, and similar during the other three months.

Storage volume at the end of September would be 15% to 33% lower under H3 relative to Existing Conditions (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-28. There would be 38 (317%) and 10 (167%) more years with “red” and “orange” levels of concern under H3 than under Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H3 would be 203% to 3,662% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4-29).

The Reclamation egg mortality model predicts that late fall-run Chinook salmon egg mortality in the Sacramento River under H3 would be 141% to 301% greater than mortality under Existing Conditions (Table 11-4-57). However, absolute differences in the percent of the late-fall population subject to mortality would be minimal in all water years.

SacEFT predicts that there would be a 8% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under H3 relative to Existing Conditions (Table 11-4-58). SacEFT predicts that there would be a 7% decrease in the percentage of years with good (lower) redd scour risk under H3 relative to Existing Conditions. SacEFT predicts that there would be no difference in the percentage of years with good (lower) egg incubation conditions under H3 relative to Existing Conditions. SacEFT predicts that there would be a 5% decrease in the percentage of years with good (lower) redd dewatering risk under H3 relative to Existing Conditions.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir under H3 during the September through February fall-run spawning and egg incubation period would generally be similar to flows under Existing Conditions with few exceptions.

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in September when spawning occurred. Clear Creek flows would be reduced during October through February under H3) in above normal, dry, and critical water years and increased in below normal water years (Table 11-4-59).

Feather River

Fall-Run

Flows in the Feather River low-flow channel during October through January under H3 would be identical to those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the high-flow channel under H3 would generally be up to 46% lower than flows under Existing Conditions during December and January, up to 33% greater during October, and similar during November.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel were identical between H3 and Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, there would be no effect of Alternative 4 on redd dewatering in the Feather River low-flow channel. Mean monthly water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be under H3 relative to Existing Conditions by 7% to 10% higher in the low-flow channel and 6% to 8% higher in the high-flow channel depending on month.

Effects of H3 on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were analyzed by comparing the percent of months between October through April over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold at Gridley (Table 11-4-60). In general, the percent of months exceeding the threshold under H3 would be up to 63% greater than the percent under Existing Conditions in all months except December, January, and February, during which the percent would not differ from Existing Conditions. This comparison includes the effects of climate change.

The effects of H3 on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the October through April fall-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-4-61). In general, total degree-months under H3 would be up to 303 degree-months (114%) greater than under Existing Conditions in all months except December, January, and February, during which degree-months would not differ from Existing Conditions. This comparison includes the effects of climate change. The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under H3 would be 427% to 1,391% greater than mortality under Existing Conditions (Table 11-4-62).

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River under H3 would generally be up to 33% lower than flows under Existing Conditions during November through January, but generally similar to flows under Existing Conditions during October.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month over the incubation period compared to the flow in October when spawning is assumed to occur. The greatest monthly reduction in American River flows during November through January under H3 would be 45% to 219% greater magnitude than those under Existing Conditions in all years except critical (15% lower magnitude)(Table 11-4-63).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly temperatures under H3 would be 5% to 12% greater than those under Existing Conditions depending on month.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-64). The percent of months exceeding the threshold under H3 would be up to 58% greater (absolute scale) than the percent under Existing Conditions during November, March, and April and similar to the percent under Existing Conditions during December through February.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-65). Total degree-months under H3 would be 98% to 395% greater than total degree-months under Existing Conditions during November, March and April and similar to total degree months under Existing Conditions during December through February.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under H3 would be 44% to 207% greater than mortality under Existing Conditions (Table 11-4-66).

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be up 6% to 7% lower than those under Existing Conditions in all months except January, in which flows would be similar between Existing Conditions and H3.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would not be different from those under Existing Conditions during October, but 6% higher during November through January.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar in all months of the period except January, in which flows would be 5% greater under H3.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be up to 14% lower than flows under Existing Conditions during October and November, up to 15% greater than flows under Existing Conditions during December, and similar to flows under Existing Conditions during January.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff during October through January under H1 would generally be similar to flows under H3, except in November when flows would be up to 12% lower than under H3 depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This magnitude of flow reduction is not expected to have a biologically meaningful effect on fall-run Chinook salmon spawning and egg incubation habitat. September Shasta storage volume under H1 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 during the period, except during October, in which temperatures would be 5% higher under H1.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-67. There would be 250% increases in the number of years with "red" and "orange" levels of concern under H1 relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H1would be 211% to 3,185% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4-68).

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff during February through May under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

September Shasta storage volume under H1 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H1in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-67. There would be 250% increases in the number of years with "red" and "orange" levels of concern under H1 relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H1would be 211% to 3,185% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4-68).

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek flows below Whiskeytown Reservoir during October through January would generally be similar between H1 and H3 (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*). As a result, no additional flow analyses were conducted for H1. Overall, results for H1 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River low-flow and high-flow channels during October through January would generally be similar between H1 and H3 (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be under H1 relative to Existing Conditions by 5% to 9% higher in the low-flow channel and 6% to 8% higher in the high-flow channel depending on month.

Differences in the percent of months exceeding the 56°F NMFS threshold between Existing Conditions and H1 would be negligible (<5% on an absolute scale) during all months except October, November, March, and April, in which the percent of months under H1 would be similar to or up to 53% lower (absolute scale) than those under Existing Conditions (Table 11-4-60). This comparison includes the effects of climate change.

Combining all water year types, there would be no difference between Existing Conditions and H1 in total degree-months exceeded in all months except October, November, March, and April during which degree-months under H1 would be greater by up to 253 degree-months (95%) (Table 11-4-61). This comparison includes the effects of climate change.

Due to generally similar flows and water temperatures between H1 and H3, results under H1 would be similar to results for analyses under H3.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during October through January would generally be similar between H1 and H3 with few exceptions that would not be biologically meaningful (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly temperatures under H1 would be 5% to 12% greater than those under Existing Conditions depending on month.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-71). The percent of months exceeding the threshold under H1 would be up to 26% greater (absolute scale) than the percent under Existing Conditions during November, March, and April and similar to the percent under Existing Conditions during December through February.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-72). Total degree-months under H1 would be 95% to 384% greater than total degree-months under Existing Conditions during November, March and April and similar to total degree months under Existing Conditions during December through February.

Due to similar flows and water temperatures between H1 and H3, results for additional analyses (e.g., risk of redd dewatering, Reclamation egg mortality model) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be 6% to 7% lower than those under Existing Conditions in all months except January, in which flows would be similar between Existing Conditions and H1.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would not be different from those under Existing Conditions during October, but 6% higher during November through January.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would 5% lower than flows under Existing Conditions during October, similar during November and December, and 5% greater during January.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be up to 14% lower than flows under Existing Conditions during October and November and up to 18% greater than flows under Existing Conditions during December and January.

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff during October through January under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H4 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 during the period, except during October, in which temperatures would be 5% higher under H4.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern”, as defined in Table 11-4-14. Differences between baselines and H1in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-67. There would be 317% and 150% increases in the number of years with “red” and “orange” levels of concern, respectively, under H1 relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H1would be 221% to 3,408% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4-68).

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff during February through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H4 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 during the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H1in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-67. There would be 317% and 150% increases in the number of years with "red" and "orange" levels of concern, respectively, under H1 relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under H1would be 221% to 3,408% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-4-68).

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., Reclamation egg mortality model, SacEFT) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek flows below Whiskeytown Reservoir during October through January would generally be similar between H4 and H3 (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*). As a result, no additional flow analyses were conducted for H4. Overall, results for H4 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River low-flow channel during October through January would be similar between H4 and H3 (*Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the high-flow channel would generally be similar to those under H3, except during October, in which flows would be up to 27% lower depending on water year type. Because flow reductions would occur in only one month, they are not expected to have a biologically meaningful effect on fall-run Chinook salmon spawning and egg incubation.

Mean monthly water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be under H4 relative to Existing Conditions by 7% to 9% higher in the low-flow channel and 6% to 8% higher in the high-flow channel depending on month.

Differences in the percent of months exceeding the 56°F NMFS threshold between Existing Conditions and H4 would be negligible (<5% on an absolute scale) during all months except October, November, March, and April, in which the percent of months under H4 would be similar to or up to 54% lower (absolute scale) than those under Existing Conditions.

Combining all water year types, there would be no difference between Existing Conditions and H4 in total degree-months exceeded in all months except October, November, March, and April, during which degree-months under H4 would be greater by up to 309 degree-months (116%).

Due to generally similar flows and water temperatures between H4 and H3, results under H4 would be similar to results for analyses under H3.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during October through January would generally be similar between H4 and H3, except during October, in which flows would be 6% to 13% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because flow reductions would occur in only one month and would be low in magnitude, they are not expected to have a biologically meaningful effect on fall-run Chinook salmon spawning and egg incubation.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly temperatures under H4 would be 5% to 12% greater than those under Existing Conditions depending on month.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-71). The percent of months exceeding the threshold under H4 would be up to 51% greater (absolute scale) than the percent under Existing Conditions during November, March, and April and similar to the percent under Existing Conditions during December through February.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-72). Total degree-months under H4 would be 95% to 395% greater than total degree-months under Existing Conditions during November, March and April and similar to total degree months under Existing Conditions during December through February.

Due to generally similar flows and water temperatures between H4 and H3, results for additional analyses (e.g., risk of redd dewatering, Reclamation egg mortality model) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be 6% to 8% lower than those under Existing Conditions in all months except January, in which flows would be similar between Existing Conditions and H4.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would not be 5% to 6% higher throughout the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be similar to those under Existing Conditions throughout the period, except during January, in which flows would be 6% greater.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be up to 14% lower than flows under Existing Conditions during October and November and up to 18% greater than flows under Existing Conditions during December and January.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-76 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat of fish, contrary to the NEPA conclusion set forth above. There would be moderate to substantial flow reductions under Alternative 4 in the Feather and American Rivers, and substantial increases in temperatures and temperature exceedances above thresholds in the Sacramento, Feather, and American Rivers, all of which would affect the fall-run Chinook salmon rearing habitat. Biological models, including the Reclamation egg mortality model and SacEFT, predict substantially degraded spawning and egg incubation habitat conditions in the Sacramento, Feather, and American Rivers. These results are generally consistent among scenarios.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for fall-/late fall-run Chinook salmon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 4 would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall-run Chinook salmon relative to the NAA.

H3/ESO

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish*

Analysis). Flows in the Sacramento River upstream of Red Bluff under H3 would be greater than or similar to flows under NAA throughout the period.

Shasta Reservoir storage at the end of September would affect flows during the fall-run larval and juvenile rearing period. As reported in AQUA-58, end of September Shasta Reservoir storage under H3 would be similar to storage under NAA in all water year types (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

SacEFT predicts that there would be a 5% decrease in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under H3 relative to NAA (Table 11-4-56). SacEFT predicts that there would be a 10% increase in the percentage of years with “good” (lower) juvenile stranding risk under H3 relative to NAA.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under H3 would be similar to mortality under NAA.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the March through July late fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Upstream of Red Bluff, flows under H3 would generally be up to 12% greater than under NAA during May and June, and similar in the remaining months of the period.

Shasta Reservoir storage at the end of September and May would affect flows during the late fall-run larval and juvenile rearing period. As reported in AQUA-156, end of September Shasta Reservoir storage under H3 would be similar to storage under NAA in all water year types (Table 11-4-27).

As reported in AQUA-40, May Shasta storage volume under H3 would be similar to or greater than storage under NAA for all water year types (Table 11-4-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

SacEFT predicts that there would be a 33% decrease in the percentage of years with good juvenile rearing availability for late fall-run Chinook salmon, measured as weighted usable area, under H3 relative to NAA (Table 11-4-58). SacEFT predicts that there would be a 9% reduction in the percentage of years with “good” (lower) juvenile stranding risk under H3 relative to NAA, which would be negligible on an absolute scale (4% difference).

SALMOD predicts that late fall-run smolt equivalent habitat-related mortality under H3 would be similar (<5% difference) to mortality under NAA.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined the January through May fall-run Chinook salmon rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to flows under NAA with few exceptions.

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low-flow channel throughout this period under H3 would not differ from those under NAA. In the high-flow channel, flows under H3 would generally be up to 79% greater than flows under NAA during February through June, and would be similar during December and January.

As reported in AQUA-59, May Oroville storage volume under H3 would be similar to storage under NAA in all water year types (Table 11-4-42).

As reported in AQUA-58, September Oroville storage volume under H3 would be similar to volume in wet, above normal, and below normal water years and 11% to 18% greater than volume under NAA during dry and critical water years (Table 11-4-39).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 during January and May would generally be up to 24% higher than flows under NAA, and similar during January through April.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for H3 are not different from those under NAA, for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures throughout the Stanislaus River would be similar between NAA and H3 throughout the January through May fall-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis for H3 are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta for H3 are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff during January through May under H1 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H1 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., SacEFT, SALMOD) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Late Fall-Run

Sacramento River flows upstream of Red Bluff during March through July under H1 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). May and September Shasta storage volume under H1 would generally be similar to storage volume under H3 (Table 11-4-19, Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., SacEFT, SALMOD) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir during January through May under H1 would be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Due to similar flows between H1 and H3, results for H1 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) Thermalito Afterbay during December through June under H1 would be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the high-flow channel under H1 would generally be similar to or greater than flows under H3.

May and September Oroville storage under H1 would generally be similar to or greater than storage under H1 (Table 11-4-39, Table 11-4-45).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during January through May under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Due to similar flows and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for H1 are not different from those under NAA, for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures throughout the Stanislaus River would be similar between NAA and H1 throughout the January through May fall-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis for H1 are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta for H1 are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Water temperatures in the Sacramento River under H1 would be similar to those under H3.

Fall-Run

Sacramento River flows upstream of Red Bluff during January through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H4 would generally be similar to September storage volume under H3 (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., SacEFT, SALMOD) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Late Fall-Run

Sacramento River flows upstream of Red Bluff during March through July under H1 would generally be similar to or greater than flows under H3, except during June, in which flows would be up to 12% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This magnitude of flow reduction is not expected to have a biologically meaningful effect on fall-run Chinook salmon rearing habitat. May and September Shasta storage volume under H4 would generally be similar to storage volume under H3 (Table 11-4-19, Table 11-4-36).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., SacEFT, SALMOD) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir during January through May under H4 would be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Due to similar flows between H4 and H3, results for H4 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) Thermalito Afterbay during December through June under H4 would generally be greater than those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), except during June, in which flows would be up to 39% lower under H4 than under H3. Because flow reductions would occur in only one month during the seven month period, they are not expected to have biologically meaningful effects on fall-run Chinook salmon rearing habitat.

May and September Oroville storage under H4 would generally be similar to or greater than storage under H3 (Table 11-4-39, Table 11-4-45).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

Due to similar or increased flows, similar reservoir storage, and similar water temperatures between H4 and H3, results for H4 would be similar to or better than those for H3.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during January through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Due to similar flows and water temperatures between H4 and H3, results for H4 would be similar to those for H3.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for H4 are not different from those under NAA, for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures throughout the Stanislaus River would be similar between NAA and H4 throughout the January through May fall-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis for H4 are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta for H4 are not different from those under NAA, for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Taken together, these results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat of fish. Changes in flow rates and water temperatures are generally small and infrequent under Alternative 4 relative to the NAA. Therefore, there would be no biologically meaningful effects to fall- or late fall-run Chinook salmon, except for a moderate reduction in juvenile rearing habitat for late fall-run Chinook salmon as predicted by SacEFT. Because this effect is isolated, it would not cause the impact to be adverse, particularly in combination with modeled flow outputs indicating that flows, which drive rearing habitat availability, would increase during the rearing period. Additionally, SALMOD does not predict habitat-related effects on late fall-run Chinook salmon in the Sacramento River. Results would generally not differ among scenarios.

CEQA Conclusion: In general, Alternative 4 would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall-run Chinook salmon relative to Existing Conditions.

H3/ESO

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 14% greater than flows under Existing Conditions during May and similar during January through April.

As reported in AQUA-58, end of September Shasta Reservoir storage would be 15% to 33% lower under H3 relative to Existing Conditions, depending on water year type (Table 11-4-27).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period.

SacEFT predicts that there would be a 15% increase in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under H3 relative to Existing Conditions (Table 11-4-56). SacEFT predicts that there would be a 29% reduction in the percentage of years with “good” (lower) juvenile stranding risk under H3 relative to Existing Conditions.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under H3 would be 9% lower than mortality under Existing Conditions.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the March through July late fall-run Chinook salmon juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 20% greater during May and June, and similar in the remaining months.

As reported in AQUA-58, Shasta Existing Conditions storage volume at the end of September under H3 would be 15% to 33% lower relative to Existing Conditions (Table 11-4-27).

As reported in AQUA-40, Shasta Reservoir storage volume at the end of May under H3 would be similar to volume under Existing Conditions in wet and above normal water years and 8% to 25% lower than volume under Existing Conditions in below normal, dry, and critical water years (Table 11-4-19).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period.

SacEFT predicts that there would be an 7% reduction in the percentage of years with good juvenile rearing availability for late fall-run Chinook salmon, measured as weighted usable area, under H3 relative to Existing Conditions (Table 11-4-58). SacEFT predicts that there would be a 42% reduction in the percentage of years with “good” (lower) juvenile stranding risk under H3 relative to Existing Conditions.

SALMOD predicts that late fall-run smolt equivalent habitat-related mortality under H3 would be 7% higher than mortality under Existing Conditions.

Clear Creek

No temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined from January through May fall-run Chinook salmon rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 29% greater than flows under Existing Conditions during March and similar to flows under Existing Conditions in the remaining 4 months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Relatively constant flows in the low-flow channel throughout the period under H3 would not differ from those under Existing Conditions. In the high-flow channel, flows under H3 would generally be up to 46% during December, up to 142% greater during March through June, and similar to flows under Existing Conditions during January and February.

As reported under AQUA-59, May Oroville storage volume under H3 would be lower than Existing Conditions by 5% to 20% depending on water year type, except in wet years, in which storage would be similar to Existing Conditions (Table 11-4-42).

As reported in AQUA-58, September Oroville storage volume would be 10% to 35% lower under A4_L H3 LT relative to Existing Conditions depending on water year type (Table 11-4-33).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H3 would be 5% to 9% lower than those under Existing Conditions during December through March, but not different from those under Existing Conditions during April through June. In the high-flow channel, mean monthly water temperatures under H3 would be 6% to 8% lower than those under Existing Conditions during December through February, but not different from those under Existing Conditions during March through June.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 31% lower than flows under Existing Conditions during January and May, up to 27% greater than flows under Existing Conditions during February and March, and similar to flows under Existing Conditions during April.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 5% to 7% lower than those under Existing Conditions in all months during the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for H3 would be up to 36% lower than Existing Conditions in January through May fall-run larval and juvenile rearing period in most water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 5% to 7% lower than those under Existing Conditions in all months during the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to flows under Existing Conditions throughout the period except during January, in which flows would be greater under H3.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be 14% greater than flows under Existing Conditions during January, similar to flows under Existing Conditions during February and March, and 8% to 12% lower than flows under Existing Conditions during April and May.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff during January through May under H1 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H1 would generally be similar to September storage volume under H3 (Table 11-4-27, Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., SacEFT, SALMOD) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Late Fall-Run

Sacramento River flows upstream of Red Bluff during March through July under H1 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

May and September Shasta storage volume under H1 would generally be similar to storage volume under H3 (Table 11-4-19, Table 11-4-36).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period.

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for additional analyses (e.g., SacEFT, SALMOD) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir during January through May under H1 would be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Due to similar flows between H1 and H3, results for H1 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) Thermalito Afterbay during December through June under H1 would be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the high-flow channel under H1 would generally be similar to or greater than flows under H3. May and September Oroville storage under H1 would generally be similar to or greater than storage under H1 (Table 11-4-39, Table 11-4-45).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H1 would be 5% to 9% lower than those under Existing Conditions during December through March, but not different from those under Existing Conditions during April through June. In the high-flow channel, mean monthly water temperatures under H1 would be 6% to 8% lower than those under Existing Conditions during December through February, but not different from those under Existing Conditions during March through June.

Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during January through May under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Due to similar flows and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 5% to 7% lower than those under Existing Conditions in all months during the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for H1 would be up to 36% lower than Existing Conditions in January through May fall-run larval and juvenile rearing period in most water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 5% to 7% lower than those under Existing Conditions in all months during the period except April, in which temperatures would not differ between H1 and Existing Conditions.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be similar to flows under Existing Conditions throughout the period except during January, in which flows would be 5% greater under H1.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be 14% and 12% greater than flows under Existing Conditions during January and February, respectively, similar to flows under Existing Conditions during March, and 8% and 12% lower than flows under Existing Conditions during April and May, respectively.

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff during January through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). September Shasta storage volume under H4 would generally be similar to September storage volume under H3 (Table 11-4-27). Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., SacEFT, SALMOD) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Late Fall-Run

Sacramento River flows upstream of Red Bluff during March through July under H4 would generally be similar to or greater than flows under H3, except during June, in which flows would be up to 12% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This magnitude of flow reduction is not expected to have a biologically meaningful effect on fall-run Chinook salmon rearing habitat.

May and September Shasta storage volume under H4 would generally be similar to storage volume under H3 (Table 11-4-19, Table 11-4-36).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month or water year type throughout the period.

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for additional analyses (e.g., SacEFT, SALMOD) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir during January through May under H4 would be similar to those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Due to similar flows between H4 and H3, results for H4 would be similar to those for H3.

Feather River

Water temperatures in the Feather River under H4 would be similar to those under H3.

Fall-Run

Flows in the Feather River both above (low-flow channel) Thermalito Afterbay during December through June under H4 would generally be greater than those under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), except during June, in which flows would be up to 39% lower under H4 than under H3. Because flow reductions would occur in only one month during the seven month period, they are not expected to have biologically meaningful effects on fall-run Chinook salmon rearing habitat. May and September Oroville storage under H4 would generally be similar to or greater than storage under H3 (Table 11-4-39, Table 11-4-45).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H4 would be 5% to 9% lower than those under Existing Conditions during December through March, but not different from those under Existing Conditions during April through June. In the high-flow channel, mean monthly water temperatures under H4 would be 6% to 8% lower than those under Existing Conditions during December through February, but not different from those under Existing Conditions during March through June.

Due to similar or increased flows, similar reservoir storage, and similar water temperatures between H4 and H3, results for H4 would be similar to or better than those for H3.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during January through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Due to similar flows and water temperatures between H4 and H3, results for H4 would be similar to those for H3.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 5% to 7% lower than those under Existing Conditions in all months during the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River for H4 would be up to 36% lower than Existing Conditions in January through May fall-run larval and juvenile rearing period in most water year types (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 5% to 7% lower than those under Existing Conditions in all months during the period except April, in which temperatures would not differ between H4 and Existing Conditions.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined for the January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be similar to flows under Existing Conditions throughout the period except during January, in which flows would be 6% greater under H4.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined for January through May fall-run Chinook salmon larval and juvenile rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be 14% and 12% greater than flows under Existing Conditions during January and February, respectively, similar to flows under Existing Conditions during March, and 8% and 12% lower than flows under Existing Conditions during April and May, respectively.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, these results indicate that the impact would not be significant because it does not have the potential to substantially reduce the amount of suitable habitat of fish, and no mitigation is necessary. Flows in all rivers examined would not be sufficiently high and frequent to cause biologically meaningful effects to fall- and late fall-run Chinook salmon.

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, the effects of Alternative 4 on fall- and late fall-run Chinook salmon migration conditions relative to the NAA are uncertain.

Upstream of the Delta

H3/ESO

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for juvenile fall-run migrants during February through May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 12% greater than flows under NAA during May and similar to flows under NAA during February through April.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined for the adult fall-run Chinook salmon upstream migration period (September through October) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to or greater than those under NAA except during above normal years during September (6% lower) and below normal years during September and October (13% and 8% lower, respectively).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the September through October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff for juvenile late fall-run migrants (January through March) under H3 would generally be similar to flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff during the adult late fall-run Chinook salmon upstream migration period (December through February) under H3 would be generally be similar to flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in the Clear Creek below Whiskeytown Reservoir were examined for juvenile fall-run migrants during February through May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to those under NAA with few exceptions.

Flows in Clear Creek below Whiskeytown Reservoir were examined during the adult fall-run Chinook salmon upstream migration period (September through October) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to flows under NAA with few exceptions.

Feather River

Fall-Run

Flows in the Feather River at the confluence with the Sacramento River were reviewed for the fall-run juvenile migration period (February through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 23% greater than flows under NAA during April and May and similar to flows under NAA during February and March.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River were reviewed for the September through October fall-run Chinook salmon adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 27% lower than flows under NAA in September but up to 22% greater than flows under NAA in October.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the September through October fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 24% greater than flows under NAA during May, and similar to flows under NAA during February through April.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Flows in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows H3 would generally be up to 17% lower during September and similar to flows under NAA during October.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to those under NAA in all months and water year types throughout the period.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to those under NAA in all months and water year types throughout the period.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to those under NAA in all months and water year types throughout the period.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to those under NAA in all months and water year types throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to those under NAA in all months and water year types throughout the period.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to those under NAA in all months and water year types throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for the juvenile fall-run Chinook salmon downstream migration period (February through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would generally be similar to flows under NAA throughout the period.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined for the adult fall-run Chinook salmon upstream migration period (September through October) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be 25% lower during September relative to those under NAA, but there would be no difference in flows between NAA and H1 during October.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the September through October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for the juvenile fall-run Chinook salmon downstream migration period (January through March) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would generally be similar to flows under H3 throughout the period.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined for the adult fall-run Chinook salmon upstream migration period (December through February) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under H1 would generally be similar to flows under H3 throughout the period.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in the Clear Creek below Whiskeytown Reservoir during February through May under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Clear Creek below Whiskeytown Reservoir during September through October under H1 would generally be similar to flows under H3. Due to similar flows between H1 and H3, results for H1 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River at the confluence with the Sacramento River during the February through May juvenile late fall-run Chinook salmon emigration period under H1 would be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River during September through October under H1 would be similar to flows under H3 except in wet and above normal water years during September during which flows would be 65% and 40% lower than flows under H3, respectively. Although large reductions, they occur in the wettest water year types and, therefore, are not expected to have biologically meaningful effects on fall-run Chinook salmon.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the September through October fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation*

Temperature Model Results utilized in the Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month throughout the period. There would be a 6% reduction in water temperatures under H1 in wet years during September.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River during February through May under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Flows in the American River at the confluence with the Sacramento River during September through October under H1 would generally be similar to flows under H3 except in wet and above normal water years during September during which flows would be 38% and 19% lower than flows under H3, respectively. Although small to moderate reductions, they occur in the wettest water year types and, therefore, are not expected to have biologically meaningful effects on fall-run Chinook salmon.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to those under NAA in all months and water year types throughout the period.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to those under NAA in all months and water year types throughout the period.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to those under NAA in all months and water year types throughout the period.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to those under NAA in all months and water year types throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to those under NAA in all months and water year types throughout the period.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to those under NAA in all months and water year types throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for the juvenile fall-run Chinook salmon downstream migration period (February through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would generally be similar to flows under NAA throughout the period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the*

Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined for the adult fall-run Chinook salmon upstream migration period (September through October) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be 6% higher during September relative to those under NAA, but there would be no difference in flows between NAA and H4 during October.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the September through October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for the juvenile fall-run Chinook salmon downstream migration period (January through March) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would generally be similar to flows under NAA throughout the period.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were examined for the adult fall-run Chinook salmon upstream migration period (December through February) (Appendix 11C, CALSIM II Model Results utilized in the Fish Analysis). Flows under H4 would generally be similar to flows under NAA throughout the period.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in the Clear Creek below Whiskeytown Reservoir during February through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Clear Creek below Whiskeytown Reservoir during September through October under H4 would generally be similar to flows under H3. Due to similar flows between H4 and H3, results for H4 would be similar to those for H3.

Feather River

Fall-Run

Flows in the Feather River at the confluence with the Sacramento River during the February through May juvenile late fall-run Chinook salmon emigration period under H4 would be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River during September through October under H4 would be higher than, similar to, or lower than flows under H1 depending on month and water year type. On average, flows would be 5% and 6% lower under H4 relative to H3 in September, and October, respectively. These reductions would not be of high enough magnitude to have a biologically meaningful effect on fall-run Chinook salmon adult migration.

American River

Water temperatures in the American River under H4 would be the same as those under H3.

Fall-Run

Flows in the American River at the confluence with the Sacramento River during February through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Flows in the American River at the confluence with the Sacramento River under H4 would generally be greater than flows under H3 during September and generally lower than flows under H3 during October depending on water year type. On average, flows under H4 would be 16% higher during September and 8% lower during October. The September increase would have a small to moderate biologically meaningful effect on fall-run Chinook salmon adult migration although October decrease would be too small to have a biologically meaningful effect.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to those under NAA in all months and water year types throughout the period.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to those under NAA in all months and water year types throughout the period.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to those under NAA in all months and water year types throughout the period.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to those under NAA in all months and water year types throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to those under NAA in all months and water year types throughout the period.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to those under NAA in all months and water year types throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Sacramento River

Fall-Run

Juveniles

Alternative 4 operations would generally reduce OMR reverse flows under Scenarios H3 and H1 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), with a corresponding increase in net positive downstream flows, during the migration period of Chinook salmon through the interior Delta channels. Conditions under Scenario H4 would further improve overall average OMR flows compared to NAA. These improved net positive downstream flows would be substantial benefits of the proposed operations.

Predation risk at the north Delta would be increased due to the installation of the proposed SWP/CVP North Delta intake facilities on the Sacramento River. Bioenergetics modeling with a median predator density predicts a predation loss under Alternative 4 of less than 0.6% of the annual juvenile production (0.25% fall run; 0.58% late fall-run) (Table 11-4-73). A conservative assumption of 5% loss per intake would yield a cumulative loss of about 13% of juvenile fall-run and late fall-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate. For a discussion of this topic see Impact AQUA-42 for Alternative 1A.

Table 11-4-73. Fall-Run and Late Fall-Run Chinook Salmon Juvenile Predation Loss at the proposed North Delta Diversion intakes for Alternative 4 (Three Intakes)

Striped Bass at NDD (Three Intakes)			Fall-Run Chinook		Late Fall-Run Chinook	
Density	Bass per 1,000 Feet of Intake	Total Number of Bass	Number Consumed (LLT)	Percentage of Annual Production	Number Consumed (LLT)	Percentage of Annual Production
Low	18	86	23,395	0.04%	3,795	0.09%
Median	119	571	154,665	0.25%	25,089	0.58%
High	219	1,051	284,636	0.46%	46,172	1.07%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (Appendix 5F Biological Stressors).

H3/ESO and H1/LOS

Flows below the north Delta intakes would be reduced during the juvenile emigration period for fall-run Chinook (February through May) and late fall-run Chinook salmon (January through March), which may increase predation potential. Mean monthly flows would decrease about 14% to 21% under H3, and decrease 15% to 27% under H1, with reductions up to 28% in April of above normal years compared to NAA.

Under Scenario H3, Through-Delta survival of Sacramento River fall-run Chinook salmon, as estimated by the Delta Passage Model, averaged 24.4% across all years, 21.7% in drier years and 29% in wetter years (Table 11-4-74). Compared to NAA, average survival under Scenario H3 would be similar across all years. Juvenile survival under Scenario H1 (low outflow) was similar to Scenario H3.

H4/HOS

Under the high outflow scenario H4, mean monthly flows would decrease by about 5% to 23% during the emigration period, with the greatest relative reduction of 28% in November of below normal years. Under H4, flow decreases in April and May would be less than 10% compared to NAA. Survival under Scenario H4 would be slightly greater than NAA (3% relative difference).

Overall, Alternative 4 would not have an adverse effect on Sacramento River fall-run Chinook salmon juvenile survival due to minor differences in survival for most operations, and slight increase in survival for the high outflow operations Scenario H4.

Table 11-4-74. Through-Delta Survival (%) of Emigrating Juvenile Fall-Run Chinook Salmon under Alternative 4 (Scenarios H3, H1 and H4)

Water Year Type	Average Percentage Survival – Scenario: EXISTING CONDITIONS	NAA	H3	H1	H4	Difference in Percentage Survival (Relative Difference) – EXISTING CONDITIONS vs. Alt 4 Scenario: H3	H1	H4	NAA vs. Alt 4 Scenario: H3	H1	H4
Sacramento											
Wetter	34.5	31.1	29.0	29.0	32.2	-5.5 (-15%)	-5.5 (-16%)	-2.3 (-7%)	-2.1 (-6%)	-2.1 (-7%)	1.1 (3%)

Drier	15.6	15.9	15.8	15.8	16.1	0.2 (1%)	0.2 (1%)	0.5 (3%)	-0.1 (-1%)	-0.1 (-1%)	0.2 (1%)
All Years	16.2	15.9	16.3	16.4	16.8	0.1 (1%)	0.2 (1%)	0.6 (4%)	0.5 (3%)	0.5 (3%)	0.9 (6%)
San Joaquin											
Wetter	19.3	20.3	17.0	17.0	16.7	-2.4 (-12%)	-2.3 (-12%)	-2.6 (-13%)	-3.3 (-16%)	-3.3 (-16%)	-3.6 (-18%)
Drier	10.0	9.5	11.0	11.0	10.7	1.0 (10%)	1.0 (10%)	0.7 (7%)	1.4 (14%)	1.5 (16%)	1.2 (13%)
All Years	13.5	13.6	13.2	13.2	12.9	-0.3 (-2%)	-0.3 (-2%)	-0.6 (-4%)	-0.3 (-3%)	-0.4 (-3%)	-0.7 (-5%)

Note: Average Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and Above Normal Water Years (6 years).
Drier = Below Normal, Dry and Critical Water Years (10 years).
H3 =ESO operations, H1 = Low Outflow, H4 = High Outflow.

Adults

Attraction flows and olfactory cues in the west Delta for migrating adults would be altered because of shifts in exports from the south Delta to the North Delta under Alternative 4. Sacramento River flows downstream of the north Delta diversion would be reduced, with concomitant increase in San Joaquin River flow contribution.

Results of fingerprint simulation modeling (DSM2 modeling of percentage of water at Collinsville that originated in the Sacramento River water) for Scenario H3 predicted a minimal reduction in Sacramento River source water September–November (1–3% less) compared with NAA (Table 11-4-75). The effect would be even lower under Scenario H4 because exports from the north Delta would be lower than under Scenario H3 and H1. Studies indicate that a 10% or less reduction in source flows that provides olfactory cues would not adversely affect adult attraction (Fretwell 1989). The reduction in olfactory cues under Scenario H3 is small and is expected to be within the broad range of olfactory cues and migration conditions that currently occur within the lower reach of the Sacramento River.

Table 11-4-75. Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Adult Fall-Run and Late Fall-Run Chinook Salmon Migration Period for Alternative 4 (Scenario H3)

	Scenario			Percentage Difference	
Month	EXISTING CONDITIONS	NAA	A4 (H3)	EXISTING CONDITIONS vs. A4 (H3)	NAA vs. A4 (H3)
Fall-Run—Sacramento River					
September	60	65	63	3	-2
October	60	68	67	7	-1
November	60	66	63	3	-3
December	67	66	66	-1	0
Fall-Run—San Joaquin River					
September	0.3	0.1	1.2	0.9	1.1
October	0.2	0.3	3.3	3.1	3
November	0.4	1.0	4.9	4.5	3.9
December	0.9	1.0	2.9	2	1.9
Late Fall-Run—Sacramento River					
December	67	66	66	-1	0
January	76	75	73	-3	-2
February	75	72	68	-7	-4
March	78	76	68	-10	-8

Shading indicates 10% or greater absolute difference.

Late Fall-Run

Juveniles

Alternative 4 operations would generally reduce OMR reverse flows under all flow scenarios (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), with a corresponding increase in net positive downstream flows that would benefit juveniles migrating through the Delta. Reduced flows below the north Delta intakes may increase predation potential. Through-Delta survival by emigrating juvenile late fall-run Chinook salmon under Scenario H3 averaged 23% across all years, 20.5% in drier years, and 27.3% in wetter years (Table 11-4-76). Juvenile survival under the Scenario H3 was similar or slightly greater than under NAA for drier, wetter and all years averaged (around 1% more in relative difference) (Table 11-4-76). Overall, Alternative 4 would not have an adverse effect on late fall-run Chinook salmon juvenile survival due to similar survival between Alternative 4 and NAA during all water year types.

Table 11-4-76. Through-Delta Survival (%) of Emigrating Juvenile Late Fall-Run Chinook Salmon under Alternative 4 (Scenarios H3, H1, and H4)

Water Year Type	Average Percentage Survival					Difference in Percentage Survival (Relative Difference)					
	Scenario					EXISTING CONDITIONS vs. Alt 4 Scenario			NAA vs. Alt 4 Scenario		
	EXISTING CONDITIONS	NAA	H3	H1	H4	H3	H1	H4	H3	H1	H4
Wetter	28.8	27.3	27.3	26.9	27.2	-1.4 (-5%)	-1.9 (-7%)	-1.6 (-5%)	0.0 (0%)	-0.4 (-2%)	-0.1 (0%)
Drier	18.8	20.2	20.5	19.7	20.2	1.7 (9%)	0.9 (5%)	1.4 (7%)	0.3 (1%)	-0.5 (-2%)	0.0 (0%)
All Years	22.5	22.9	23.0	22.4	22.8	0.5 (2%)	-0.1 (0%)	0.3 (1%)	0.2 (1%)	-0.5 (-2%)	-0.1 (0%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and Above Normal Water Years (6 years).
Drier = Below Normal, Dry and Critical Water Years (10 years)

Adults

Flows in the Sacramento River downstream of the north Delta intake diversions would be reduced under Alternative 4, with concomitant proportional increases in San Joaquin River flows. Under Scenario H3, the percentage of Sacramento River water at Collinsville would be unchanged in December, and slightly reduced (2% to 8%) in January through March compared to NAA (Table 11-4-75). This effect would be less under Scenario H4 compared to Scenarios H3 and H1 because it would involve fewer exports from the north Delta. The effect on olfactory cues for migrating adults late fall-run Chinook salmon would be negligible because the change in flow proportions is less than 10%.

Mokelumne River

Fall-Run

Juveniles

Through-Delta survival of Mokelumne River fall-run Chinook salmon under Scenario H3 averaged 16% across all years and water year types (Table 11-4-58). Survival under Scenario H3 was similar to NAA averaged across all years (0.5% greater, or 3% more in relative difference) and in drier years (a 1% relative difference), and 1.5% increase in survival (an 9% relative difference) in wetter years. Juvenile survival under Scenario H1 (low outflow) and H4 (high outflow) was similar to Scenario H3 and NAA in drier years, slightly increased averaged across all years. In wetter years, survival increased 1.5% (10% relative difference) under Scenario H1 and 2.3% under Scenario H4 (a 15% relative difference). Overall, Alternative 4 would not have an adverse effect on fall-run Chinook salmon juvenile survival due to minor differences in survival for most operations, and slight increase in survival for the high outflow years or operations Scenario H4.

San Joaquin River

Fall-Run

Juveniles

Under Alternative 4 Scenario H3 operations, through-Delta survival by juvenile fall-run Chinook salmon emigrating from the San Joaquin River averaged 13% across all years, 11% in drier years, and 17% in wetter years (Table 11-4-74). Compared to NAA, average survival was similar for all years averaged for all operations scenarios (H3, H1, and H4). Survival is slightly increased in drier years (1% greater, a 13-16% relative difference). Survival is greatest in wetter years, but is slightly reduced relative to NAA by about 3% (16–18% relative difference for Scenarios H1, H3, and H4). Overall, Alternative 4 would not have an adverse effect on through-Delta migration due to minor differences in survival.

Adults

The percentage of water at Collinsville that originated from the San Joaquin River is very small (no more than 1% under NAA) during the fall-run migration period (September to December). The fingerprinting analysis showed a small increase in olfactory cues from the San Joaquin River passing downstream through the Delta under Scenario H3 (Table 11-4-75). Although the relative change is substantial (i.e., close to double the percentage of flow in the San Joaquin under Scenario H3 than under NAA), the percentage of flow attributable to San Joaquin River water under all scenarios is quite low (no more than 5%). Scenario H4 would not have as great a relative change because exports at the north Delta diversion would be lower than under Scenarios H3 and H1. Overall, Alternative 4 operations conditions would incremental increase olfactory cues associated with attraction flows in the lower San Joaquin River, but the increase would be small. This would not be an adverse effect on adult fall-run Chinook salmon migrating to the San Joaquin River.

NEPA Effects: Upstream of the Delta, these results indicate that the effect would not be adverse because it does not have the potential to substantially interfere with the movement of fish. Although some flow reductions are predicted, these flows would not be of sufficient magnitude to cause biologically meaningful effect on fall- and late fall-run Chinook salmon migration.

Near-field effects of Alternative 4 NDD on fall- and late fall-run Chinook salmon related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating fall- and late fall-run Chinook salmon, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus the level of impacts associated with 3 new intakes would be considerably lower than those expected from having 5 new intakes in the river. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 13% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Alternative 4 also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for fall- and late fall-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 4 predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 4 would be similar to those estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of, the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for Chinook salmon. However, until these efforts are completed and their results are fully analyzed, the overall cumulative effect of Alternative 4 on fall- and late fall-run Chinook salmon migration remains uncertain. Similarly, the impact on the fall-run Chinook salmon commercial fishery would be uncertain.

CEQA Conclusion: In general, Alternative 4 would not affect the migration conditions for fall-/late fall-run Chinook salmon relative to Existing Conditions.

Upstream of the Delta

H3/ESO

Sacramento River

Fall-Run

Flows in the Sacramento River upstream of Red Bluff were examined for juvenile fall-run migrants during February through May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 14% greater than those under Existing Conditions during May, and similar to flows under Existing Conditions during February through April.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month throughout the period. There would be a 5% increase in water temperatures in wet water years during May.

Flows in the Sacramento River upstream of Red Bluff were examined during the adult fall-run Chinook salmon upstream migration period (September through October) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to or those under Existing Conditions with some exceptions.

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the September through October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 5% and 6% greater than those under H3 during September and October, respectively.

Late Fall-Run

Flows in the Sacramento River upstream of Red Bluff for juvenile late fall-run migrants (January through March) under H3 would generally be similar to flows under Existing Conditions, with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type, except in critical years during January (5% higher).

Flows in the Sacramento River upstream of Red Bluff during the adult late fall-run Chinook salmon upstream migration period (December through February) under H3 would generally be similar to flows under Existing Conditions, with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month throughout the period, except in critical years during January (5% higher).

Clear Creek

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined during the juvenile fall-run Chinook salmon upstream migration period (February through May). Flows under H3 would generally be greater than those under Existing Conditions during March and similar to flows under Existing Conditions during February, April, and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in Clear Creek below Whiskeytown Reservoir during the adult fall-run Chinook salmon upstream migration period (September through October) under H3 would generally be similar to those under Existing Conditions with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Water temperature modeling was not conducted in Clear Creek

Feather River

Fall-Run

Flows in the Feather River at the confluence with the Sacramento River during the fall-run juvenile migration period (February through May) under H3 would generally be similar to flows under Existing Conditions, with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month throughout the period.

Flows in the Feather River at the confluence with the Sacramento River were examined during the September through October fall-run Chinook salmon adult migration period. Flows under H3 would generally be up to 108% greater than flows under Existing Conditions during both months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the September through October fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month throughout the period.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be up to 27% greater than flows under Existing Conditions during February and March, up to 31% lower during May, and similar to flows under Existing Conditions during April.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 5% to 7% higher than under Existing Conditions in all month except April, in which there would be no difference.

Flows in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be 27% to 51% lower than flows under Existing Conditions during September and similar to flows under Existing Conditions during October.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 6% and 12% higher than those under Existing Conditions during September and October, respectively.

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 throughout this period would generally be lower than Existing Conditions (up to 36% lower), except in wet water years, in which flows would be similar or up to 8% greater than flows under Existing Conditions.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 6% higher than those under Existing Conditions in every month of the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be up to 17%lower than flows under Existing Conditions.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 6% higher than those under Existing Conditions during September but there would be no difference in mean monthly water temperatures between H3 and Existing Conditions during October.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would generally be similar to flows under Existing Conditions in all months. Wetter water years under H3 would have similar or greater flows than those under Existing Conditions, whereas drier years would have lower flows under H3.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be 8% lower than those under Existing Conditions in September and similar in October.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to or up to 15% greater than those under Existing Conditions during February and March, but up to 18% lower than flows under Existing Conditions during April and May.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be 27% lower than under Existing Conditions during September but would be similar during October.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Fall-Run

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period. Flows under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month throughout the period, except in wet water years during May (5% increase) (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the September through October adult fall-run Chinook salmon upstream migration period. Flows under H1 would generally be similar to flows under H3(Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 5% and 6% greater than those under Existing Conditions during September and October, respectively (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Due to similar flows and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

Late Fall-Run

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period. Mean monthly flows under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type, except in critical years during January (5% higher). (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period. Mean monthly flows under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month throughout the period, except in critical years during January (5% higher) (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Due to similar flows and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

Clear Creek

Fall-Run

Flows in the Clear Creek below Whiskeytown Reservoir during February through May under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Clear Creek below Whiskeytown Reservoir during September through October under H1 would generally be similar to flows under H3. Due to similar flows between H1 and H3, results for H1 would be similar to those for H3.

Water temperature modeling was not conducted in Clear Creek.

Feather River

Water temperatures under H1 would be similar to flows under H3.

Fall-Run

Mean monthly flows and water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period. Flows under H1 would be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month throughout the period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean monthly flows and water temperatures in the Feather River at the confluence with the Sacramento River were examined during the September through October fall-run Chinook salmon adult upstream migration period. Flows under H1 would be similar to flows under H3 except in wet and above normal water years during September during which flows would be 65% and 40% lower than flows under H3, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Although large reductions, they occur in the wettest water year types and, therefore, are not expected to have biologically meaningful effects on fall-run Chinook salmon. Mean monthly water temperatures during September would be 6% higher under H1 than under Existing Conditions, but there would be no differences during October (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

American River

Fall-Run

Mean monthly flows and water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period. Flows under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 5% to 7% higher than under Existing Conditions in all month except April, in which there would be no difference (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period Flows during September through October under H1 would generally be similar to flows under H3 except in wet and above normal water years during September during which flows would be 38% and 19% lower than flows under H3, respectively (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Although small to moderate reductions, they occur in the wettest water year types and, therefore, are not expected to have biologically meaningful effects on fall-run Chinook salmon. Mean monthly water temperatures under H1 would be 7% and 10% higher than those under Existing Conditions during September and October, respectively (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 throughout this period would generally be lower than Existing Conditions (up to 36% lower), except in wet water years, in which flows would be similar or up to 7% greater than flows under Existing Conditions.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 6% higher than those under Existing Conditions in every month of the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be up to 17% lower than flows under Existing Conditions.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 6% higher than those under Existing Conditions during September but there would be no difference in mean monthly water temperatures between H1 and Existing Conditions during October.

Flows and water temperatures in the Stanislaus River would be similar between H1 and H3. Therefore, results for H1 would be similar to those for H3.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would generally be similar to flows under Existing Conditions in all months. Wetter water years under H1 would have similar or greater flows than those under Existing Conditions, whereas drier years would have lower flows under H1.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be 8% and 5% lower than those under Existing Conditions in September and October, respectively.

Water temperature modeling was not conducted in the San Joaquin River.

Flows in the San Joaquin River would generally be similar between H1 and H3. Therefore, results for H1 would be similar to those for H3

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to or up to 15% higher than those under Existing Conditions during February and March, but up to 18% lower than flows under Existing Conditions during April and May.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be 27% lower than under Existing Conditions during September but would be similar during October.

Water temperature modeling was not conducted in the Mokelumne River.

Flows in the Mokelumne River would be similar between H1 and H3. Therefore, results for H1 would be similar to those for H3.

H4/HOS

Sacramento River

Fall-Run

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period. Flows under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month throughout the period, except in wet water years during May (5% increase) (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the September through October adult fall-run Chinook salmon upstream migration period. Flows under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would not be different from those under Existing Conditions during September but would be 6% greater than those under Existing Conditions during October (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Due to generally similar flows and water temperatures between H4 and H3, results for H4 would be similar to those for H3.

Late Fall-Run

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period. Mean monthly flows under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in water temperature between Existing Conditions and H4 in any month or water year type. (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean monthly flows and water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period. Mean monthly flows under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month throughout the period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Due to similar flows and water temperatures between H4 and H3, results for H4 would be similar to those for H3.

Clear Creek

Fall-Run

Flows in the Clear Creek below Whiskeytown Reservoir during February through May under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the*

Fish Analysis). Flows in the Clear Creek below Whiskeytown Reservoir during September through October under H4 would generally be similar to flows under H3. Due to similar flows between H4 and H3, results for H4 would be similar to those for H3.

Water temperature modeling was not conducted in Clear Creek.

Feather River

Water temperatures under H4 would be similar to flows under H3.

Fall-Run

Mean monthly flows and water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period. Flows under H4 would be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month throughout the period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean monthly flows and water temperatures in the Feather River at the confluence with the Sacramento River were examined during the September through October fall-run Chinook salmon adult upstream migration period. Flows under H4 would be higher than, similar to, or lower than flows under H3 depending on month and water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). On average, flows would be 5% and 6% lower under H4 relative to H3 in September, and October, respectively. These reductions would not be of high enough magnitude to have a biologically meaningful effect on fall-run Chinook salmon adult migration. Mean monthly water temperatures under H4 would be similar to those under Existing Conditions during September, but 5% higher during October (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

American River

Fall-Run

Mean monthly flows and water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period. Flows under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 5% to 7% higher than under Existing Conditions in all month except April, in which there would be no difference (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were examined during the September and October adult fall-run Chinook salmon upstream migration period Flows under H4 would generally be greater than flows under H3 during September and generally lower than flows under H3 during October depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). On average, flows under H4 would be 16% higher during September and 8% lower during October. The September increase would have a small to moderate biologically meaningful effect on fall-run Chinook salmon adult migration although October decrease would be too small to have a biologically meaningful effect. Mean monthly water temperatures under H4 would be 6% and 11% higher than those under Existing Conditions during

September and October, respectively (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Stanislaus River

Fall-Run

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 throughout this period would generally be lower than Existing Conditions (up to 36% lower), except in wet water years, in which flows would be similar or up to 7% greater than flows under Existing Conditions.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 6% higher than those under Existing Conditions in every month of the period.

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be up to 17% lower than flows under Existing Conditions.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 6% higher than those under Existing Conditions during September but there would be no difference in mean monthly water temperatures between H4 and Existing Conditions during October.

Flows and water temperatures in the Stanislaus River would be similar between H4 and H3. Therefore, results for H4 would be similar to those for H3.

San Joaquin River

Fall-Run

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would generally be similar to flows under Existing Conditions in all months. Wetter water years under H4 would have similar or greater flows than those under Existing Conditions, whereas drier years would have lower flows under H4.

Flows in the San Joaquin River at Vernalis were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be 8% lower than those under Existing Conditions in September but similar during October, respectively.

Water temperature modeling was not conducted in the San Joaquin River.

Flows in the San Joaquin River would be generally similar between H4 and H3. Therefore, results for H4 would be similar to those for H3.

Mokelumne River

Fall-Run

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to or up to 15% higher than those under Existing Conditions during February and March, but up to 18% lower than flows under Existing Conditions during April and May.

Flows in the Mokelumne River at the Delta were examined during the September and October adult fall-run Chinook salmon upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be 27% lower than under Existing Conditions during September but would be similar during October.

Water temperature modeling was not conducted in the Mokelumne River.

Flows in the Mokelumne River would be similar between H4 and H3. Therefore, results for H4 would be similar to those for H3.

Through-Delta

Sacramento River

Fall-Run

Juveniles

As described above, Scenario H3 operations would reduce overall OMR reverse flows and reduce Sacramento River flows below the north Delta diversions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Survival of Sacramento River juveniles under Scenarios H3 and H1 averaged for all years was similar to Existing Conditions, with a slight increase in drier years (about 1% greater, or a 5% relative difference) and about 5% decrease (a 16% relative difference) in wetter years (Table 11-4-74). Under Scenario H4 average survival was similar (1% relative decrease) to Existing Conditions for all years, drier years and wetter years.

Adults

The percentage of Sacramento River origin flow at Collinsville, would be slightly increased (3–7% in September to November) under Scenario H3 compared to Existing Conditions (Table 11-4-75). This would not significantly affect olfactory cues for adults migrating to the Sacramento River because the change is less than 10%.

Late Fall-Run

Juveniles

As described above, Alternative 4 operations would reduce OMR reverse flows and reduce Sacramento River flows below the north Delta diversions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Conditions under Scenario H4 would further improve OMR flow conditions relative to the Scenario H3 and LOS. As estimated by DPM, through-Delta survival by emigrating juvenile late fall-run Chinook salmon under Scenario H3 was slightly increased averaged across all years (0.5% greater survival, a 2% relative difference) compared to Existing Conditions (Table 11-4-76). Survival was greater in drier years (1.7% increase, a 9% relative difference) but reduced in wetter years (1.4%, a 5% relative difference).

Adults

As described above, the percentage of Sacramento River water would be slightly reduced in December and March (1% to 10% less) compared to NAA (Table 11-4-75). This effect would be less under Scenario H4 compared to Scenarios H3 and H1 due to reduced north Delta exports. Olfactory cues would be slightly decreased, but the impact would be less minor because flow changes are than 10% for the bulk of the late fall-run migration.

Overall, the impact on migration conditions from Alternative 4 operations (Scenarios H3, H1 and H4) is considered less than significant due to similar juvenile survival during all water year types and minor effect on olfactory cues.

Overall, conditions would be similar across all flow scenarios under Alternative 4. No mitigation would be required.

Mokelumne River

Fall-Run

Through-Delta survival of emigrating juveniles estimated by DPM under Alternative 4 operations (Scenarios H3, H1, and H4) was similar to Existing Conditions for all years, drier years, and wetter years (less than 1% absolute difference in survival, and no more than 5% relative difference) (Table 11-4-74).

San Joaquin River

Fall-Run

Juveniles

Under Alternative 4 (all operation Scenarios H3, H1 and H4), mean survival of juveniles migrating from the San Joaquin River averaged around 13% (Table 11-4-74). Alternative 4 survival was similar to Existing Conditions for all years (less than 1% absolute difference, a 2–4% relative difference). Survival was slightly greater in drier years (about 1 % greater survival, or 10% more in relative difference) and slightly reduced in wetter years (about 2% decrease, or 12–13% less in relative difference).

Adults

As described above, the percentage of San Joaquin River water is very small (no more than 1% under NAA) during the fall-run migration period (September to December). Under Scenario H3 operations, this would increase by 1–3% in September and October, 4.5% in November, and 2% in December (Table 11-4-75). Olfactory cues for adults migrating to the San Joaquin River would be slightly increased under all flows scenarios for Alternative 4.

Summary of CEQA Conclusion

Collectively, these results indicate that the impact is less than significant because movement conditions would not be substantially reduced, and no mitigation is necessary. Flows under Alternative 4 would generally be similar to or higher than flows under Existing Conditions in all rivers except the American River. In the American River, there would be flow reductions during half of the adult migration period. However, these flow reductions are not expected to affect the fall-run population at a population scale. These results would be similar among scenarios. The impact of Alternative 4 across the operational range (Scenarios H3, H1 low outflow, and H4 high outflow) on through-Delta migration conditions would be negligible due to similar juvenile survival and minor effect on olfactory cues for adults. Similarly, the impact on the fall-run Chinook salmon commercial fishery would be less than significant. No mitigation would be required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for fall- and late fall-run Chinook salmon under Alternative 1A (Impacts AQUA-79 through AQUA-81) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on fall- and late fall-run Chinook salmon are the same as those described under Alternative 1A (Impacts AQUA-79 through AQUA-81). The effects would not be adverse, and would generally be beneficial. Specifically for AQUA-80, the effects of contaminants on fall- and late fall-run Chinook salmon with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on fall- and late fall-run Chinook salmon are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for fall- and late fall-run Chinook salmon under Alternative 1A (Impacts AQUA-82 through AQUA-90) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM12)

Impact AQUA-83: Effects of Invasive Aquatic Vegetation Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM13)

Impact AQUA-84: Effects of Dissolved Oxygen Level Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM14)

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM15)

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM16)

Impact AQUA-87: Effects of Illegal Harvest Reduction on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM17)

Impact AQUA-88: Effects of Conservation Hatcheries on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM18)

Impact AQUA-89: Effects of Urban Stormwater Treatment on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM19)

Impact AQUA-90: Effects of Removal/Relocation of Nonproject Diversions on Chinook Salmon (Fall-/Late Fall–Run ESU) (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on fall-run and late fall-run Chinook salmon are the same as those described under Alternative 1A (Impacts AQUA-82 through AQUA-90). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

Steelhead

Construction and Maintenance of CM1

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

The potential effects of construction of the water conveyance facilities on steelhead would be similar to those described for Alternative 1A, Impact AQUA-91, except Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less. Additionally, construction and excavation at Clifton

Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-91, the effect would not be adverse for steelhead.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-91, the impact of the construction of the water conveyance facilities on steelhead would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A, Impact AQUA-92, except that only three intakes would be maintained under Alternative 4 rather than five under Alternative 1A. As concluded in Impact AQUA-92, the impact would not be adverse for steelhead.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-92, the impact of the maintenance of water conveyance facilities on steelhead would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Water Exports from SWP/CVP South Delta Facilities

Alternative 4 south Delta export facilities, as estimated by the salvage density method, by about 51% (~4,500 fish; Table 11-4-77) across all years compared to NAA. Losses under Scenario H3 would be greatest in below normal (~7,500 fish) and lowest in wet water years (~2,000 fish). Conditions under Scenario H1 would be similar to Scenario H3, while conditions under Scenario H4 would further reduce entrainment loss at the south Delta facilities due to decreased exports.

Table 11-4-77. Juvenile Steelhead Annual Entrainment at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 4 (Scenario H3)

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-4,179 (-67%)	-4,271 (-68%)
Above Normal	-7,045 (-54%)	-7,389 (-55%)
Below Normal	-4,368 (-37%)	-3,638 (-33%)
Dry	-2,181 (-29%)	-1,591 (-23%)
Critical	-1,208 (-21%)	-858 (-16%)
All Years	-4,648 (-52%)	-4,506 (-51%)
	Shading indicates 10% or greater increased entrainment.	

Note: Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

The impact would be similar in type to Alternative 1A, Impact AQUA-93, but the degree would be less because Alternative 4 would have fewer intakes, therefore, under Alternative 4 there would be about a 40% reduction in impingement and predation risk relative to Alternative 1A.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The impact and conclusion are the same as for Alternative 1A (Impact AQUA-93). Entrainment and impingement effects on juvenile steelhead would be minimal for Alternative 4 because intakes would have state-of-the-art screens installed.

Predation Associated with Entrainment

Entrainment-related predation loss at the south Delta facilities would be no greater and may be lower than baseline (NAA), due to a reduction in entrainment. Conditions under Scenario H4 would further reduce entrainment-related predation loss compared to Scenario H3, while conditions under Scenario H1 would be similar to Scenario H3.

Predation at the north Delta would be increased due to the construction of the proposed SWP/CVP water export facilities on the Sacramento River. It is assumed that per capita steelhead predation losses would be similar to those predicted for spring-run Chinook salmon, although slightly reduced because of the larger size of steelhead outmigrants. Bioenergetics modeling with a median predator density of 0.12 predators per foot (0.39 predators per meter) of intake predicts a predation loss of about 0.2% of the juvenile spring-run juvenile population (Table 11-4-30).

NEPA Effects: In conclusion, operations under Alternative 4 under all flow scenarios (e.g., H3, H1, H4) would reduce entrainment at the south Delta facilities and minimize or avoid entrainment with screens at the north Delta intakes and NBA alternative intake. Predation loss at the south Delta would be reduced and predation at the north Delta intakes would likely have a very minor impact on the overall steelhead population. The overall effect under Alternative 4 would not be adverse.

CEQA Conclusion: As described above, entrainment losses of juvenile steelhead would decrease under Alternative 4 (A4_LLT) compared to existing biological conditions at the south Delta export facilities (Table 11-4-77). The screened intakes of the north Delta diversion and NBA alternative intake, as designed, would exclude juvenile salmonids. The impact of predation associated with entrainment would be the same as described above as predation loss at the south Delta (no greater and possibly lower compared with Existing Conditions), but increased slightly at the north Delta intakes. There would likely be a minor increase in predation loss under Alternative 4, but the population level effect would likely be small. Entrainment loss under Scenario H4 is expected to be less compared to Scenario H3 and Scenario H1. Overall, the impact would be less than significant, no mitigation is required.

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

In general, Alternative 4 would have negligible effects on spawning and egg incubation habitat for steelhead relative to the NAA.

H3/ESO

Sacramento River

The primary steelhead spawning and egg incubation period extends from January through April. Results of the CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (Keswick Dam to upstream of RBDD) were summarized by month and water-year type based on estimated flows at RBDD (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality. Mean monthly flows under H3 would be similar to those under NAA, except for a small increase in mean monthly flow during February in below normal years (6%). Overall results indicate negligible project-related effects on flow.

SacEFT predicts that there would be negligible differences (≤5%) between NAA and H3 in spawning metrics including percentage of years with good spawning availability, measured as weighted usable area, redd scour risk, percentage of years with good (lower) egg incubation conditions, and redd dewatering risk. Results indicate negligible project-related effects on steelhead habitat metrics related to spawning and egg incubation in the Sacramento River.

Mean monthly water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location Based on negligible effects (≤5%) on mean monthly flow, SacEFT metrics related to spawning and egg incubation, and water temperature conditions compared to NAA, project-related effects of H3 on flow would not affect steelhead spawning conditions in the Sacramento River.

Table 11-4-78. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Steelhead Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. H3	NAA vs. H3
Spawning WUA	-2 (-4%)	-5 (-10%)
Redd Scour Risk	-3 (-4%)	0 (0%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	0 (0%)	3 (6%)
Juvenile Rearing WUA	-6 (-15%)	-10 (-22%)
Juvenile Stranding Risk	-12 (-35%)	2 (10%)

WUA = Weighted Usable Area.

Clear Creek

The primary spawning and egg incubation period for Clear Creek is January through April. Results of the CALSIM analyses of instream flows for the Clear Creek were summarized by month and water-year type for January through April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality.

Flows in Clear Creek during January through April under H3 would generally be similar to those under NAA. Therefore, H3 would have negligible effects on mean monthly flows in Clear Creek for the primary steelhead spawning and egg incubation period of January to April.

Redd dewatering risk was evaluated for Clear Creek based on flow reductions for each month during the incubation period (January through April); results are summarized in Table 11-4-79. The greatest monthly reduction in flows under H3 would be similar to that under NAA.

No water temperature modeling was conducted in Clear Creek.

Based on mean monthly flows and flow reductions, there would be no effects of H3 on steelhead spawning and egg incubation habitat conditions.

Table 11-4-79. Comparisons of Greatest Monthly Reduction (Percent Change) in Instream Flow under Model Scenarios in Clear Creek during the January–April Steelhead Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-25 (-38%)	0 (0%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in the month when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Effects of H3 on flow during the spawning and egg incubation period (January through April) in the Feather River were evaluated using the results of CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (low-flow channel) based on estimated flows above Thermalito Afterbay (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the high-flow channel were characterized based on information in the Feather River at Thermalito Afterbay (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality.

Flows in the Feather River high-flow channel during January through April under H3 would be similar to or greater than flows under NAA, with few exceptions. The increases in flow would have beneficial effects of varying magnitudes on spawning and egg incubation habitat in all water year types.

Steelhead spawning and egg incubation on the Feather River occurs primarily in Hatchery Ditch and the low-flow channel in the general vicinity of the Feather River Hatchery. Instream flows affect physical habitat quality and availability through changes in wetted channel width, water depth, and water velocities. Results of IFIM studies (WUA versus flow relationships) provide information on the spawning habitat conditions in the low-flow channel. Results of CALSIM modeling show that instream flows in the Feather River low-flow channel were the same for NAA and H3 regardless of month and water year type and range from 700 to 800 cfs under all conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, H3 is not expected to affect physical habitat conditions for steelhead spawning and egg incubation within the Feather River low-flow channel.

Water temperatures in the low-flow channel of the Feather River are determined largely by cold water pool storage in Oroville Reservoir and instream flow releases. Because instream flows in the low-flow channel would be the same under H3 and NAA, any simulated changes in water temperatures under H3 would be attributed to changes in reservoir storage. Reservoir storage in May and September provides an indicator of cold water pool availability. May Oroville storage volume under H3 would be similar to storage under NAA in all water year types (Table 11-4-45). September Oroville storage volume under H3 would be similar to volume in wet, above normal, and below normal water years and 11% to 18% greater than volume under NAA during dry and critical water years (Table 11-4-39).

Effects of H3 on water temperature-related spawning and egg incubation conditions for steelhead in the Feather River were analyzed by comparing the percent of months between January through April over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4-80). Differences in the percent of months exceeding the threshold between NAA and H3 would be negligible (<5% on an absolute scale).

Table 11-4-80. Differences between Baseline and H3 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, January through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	10 (800%)	2 (NA)	1 (NA)	1 (NA)	1 (NA)
April	44 (514%)	23 (475%)	15 (NA)	7 (NA)	2 (NA)
NAA vs. H3					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	1 (13%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
April	0 (0%)	-4 (-12%)	-2 (-14%)	1 (20%)	1 (100%)

NA = could not be calculated because the denominator was 0.

The effects of H3 on water temperature-related spawning and egg incubation conditions for steelhead in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the January through Aril steelhead spawning period for all 82 years (Table 11-4-81). There would be no difference (<5% on a relative scale) in total degree-months exceeded between NAA and H3 for any month or water year type.

Overall for the Feather River, these results indicate that the effects of H3 on flow and water temperatures would not affect steelhead spawning conditions in the Feather River.

Table 11-4-81. Differences between Baseline and H3 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, January through April

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	2 (NA)	0 (0%)
	Dry	3 (NA)	1 (50%)
	Critical	8 (800%)	0 (0%)
	All	13 (1,300%)	1 (8%)
April	Wet	4 (NA)	1 (33%)
	Above Normal	12 (600%)	1 (8%)
	Below Normal	15 (375%)	-1 (-5%)
	Dry	24 (480%)	-2 (-6%)
	Critical	20 (NA)	-3 (-13%)
	All	75 (682%)	-4 (-4%)

NA = could not be calculated because the denominator was 0.

American River

The primary steelhead spawning and egg incubation period for the American River extends from January through April. Results of the CALSIM analyses of instream flows within the lower American River at the confluence with the Sacramento River were summarized by month and water-year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation and rapid reductions in flow can dewater redds leading to mortality. Mean monthly flows under H3 would be similar to flows under NAA during all months and water year types with few exceptions.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-64). Steelhead spawn and eggs incubate in the American River between January and April. During this period, the percent of months exceeding the threshold under H3 would similar to or up to 5% lower (absolute scale) than the percent under NAA.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-65). During the January through April steelhead spawning and egg incubation period, total degree-months would be similar between NAA and H3.

Based on mean monthly flows and water temperature effects, effects under H3 in the American River would consist primarily of negligible effects (<5%) on mean monthly flows and water temperatures and would not have biologically meaningful effects on steelhead spawning and egg incubation conditions in the American River.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 throughout this period would generally be identical to flows under NAA.

Water temperatures throughout the Stanislaus River would be similar under NAA and H3 throughout the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 throughout this period would generally be identical to flows under NAA.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Flows in the Sacramento River at Keswick and upstream of Red Bluff during January through April under H1 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Water temperatures would be similar between H1 and H3. Due to similar flows and water temperatures between H1 and H3, results for additional analyses (e.g., SacEFT) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to or better than those for H3.

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-71). Steelhead spawn and eggs incubate in the American River between January and April. During this period, the percent of months exceeding the threshold under H1 would similar to or up to 11% lower (absolute scale) than the percent under NAA.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-72). During the January through April steelhead spawning and egg incubation period, total degree-months would be similar between NAA and H1.

Clear Creek

Flows in the Clear Creek during January through April under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek. Due to similar flows between H1 and H3, results for additional analyses (e.g., redd dewatering risk,) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Feather River

Flows in the Feather River above Thermalito Afterbay (low-flow channel) during January through April under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Feather River below Thermalito Afterbay (high-flow channel) during January through April under H1 would generally be similar to or greater than flows under H3. May and September Oroville storage under H1 would generally be similar to or greater than storage under H3 (Table 11-4-45, Table 11-4-39).

Differences in the percent of months exceeding the 56°F threshold between NAA and H1 would generally be negligible (<5% on an absolute scale) during January through March (Table 11-4-82). During April, the percent of months exceeding the threshold under H1 would be similar to or up to 12% lower (absolute scale) than the percent under NAA. This represents a small benefit of H1 to steelhead spawning habitat conditions in the Feather River.

Table 11-4-82. Differences between Baselines and H1 and H4 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, January through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H1					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	4 (300%)	2 (NA)	1 (NA)	1 (NA)	0 (NA)
April	32 (371%)	16 (325%)	12 (NA)	4 (NA)	1 (NA)
NAA vs. H1					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-5 (-50%)	0 (0%)	0 (0%)	0 (0%)	-1 (-100%)
April	-12 (-23%)	-11 (-35%)	-5 (-29%)	-2 (-40%)	0 (0%)
EXISTING CONDITIONS vs. H4					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	5 (400%)	1 (NA)	1 (NA)	1 (NA)	0 (NA)
April	27 (314%)	14 (275%)	14 (NA)	2 (NA)	1 (NA)
NAA vs. H4					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-4 (-38%)	-1 (-50%)	0 (0%)	0 (0%)	-1 (-100%)
April	-17 (-33%)	-14 (-42%)	-4 (-21%)	-4 (-60%)	0 (0%)

NA = could not be calculated because the denominator was 0.

Total degree-months above the 56°F threshold under H1 would be similar to (<3 degree months) those under NAA throughout the period regardless of month or water year type (Table 11-4-83).

Table 11-4-83. Differences between Baselines and H1 and H4 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River at above Thermalito Afterbay, January through April

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
January	Wet	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	Wet	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)	0 (NA)	0 (NA)
	Below Normal	2 (NA)	0 (0%)	3 (NA)	1 (50%)
	Dry	3 (NA)	1 (50%)	2 (NA)	0 (0%)
	Critical	6 (600%)	-2 (-22%)	7 (700%)	-1 (-11%)
	All	11 (1,100%)	-1 (-8%)	12 (1,200%)	0 (0%)
April	Wet	5 (NA)	2 (67%)	3 (NA)	0 (0%)
	Above Normal	12 (600%)	1 (8%)	6 (300%)	-5 (-38%)
	Below Normal	15 (375%)	-1 (-5%)	11 (275%)	-5 (-25%)
	Dry	23 (460%)	-3 (-10%)	25 (500%)	-1 (-3%)
	Critical	21 (NA)	-2 (-9%)	24 (NA)	1 (4%)
	All	77 (700%)	-2 (-2%)	68 (618%)	-11 (-12%)

NA = could not be calculated because the denominator was 0.

Due to similar or better flows, reservoir storage, and water temperatures between H1 and H3, results for H1 would be similar to or better than those for H3.

American River

Flows in the American River at the confluence with the Sacramento River during January through April under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Water temperatures would be similar between H1 and H3. Due to similar flows and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

H4/HOS

Sacramento River

Flows in the Sacramento River at Keswick and upstream of Red Bluff during January through April under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-71). Steelhead spawn and eggs incubate in the American River between January and April. During this period, the percent of months exceeding the threshold under H4 would similar to or up to 11% lower (absolute scale) than the percent under NAA.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-72). During the January through April steelhead spawning and egg incubation period, total degree-months would be similar between NAA and H4.

Due to similar flows and water temperatures between H4 and H3, results for additional analyses (e.g., SacEFT) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Clear Creek

Flows in the Clear Creek during January through April under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek. Due to similar flows between H4 and H3, results for additional analyses (e.g., redd dewatering risk,) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Feather River

Flows in the Feather River above Thermalito Afterbay (low-flow channel) during January through April under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Feather River below Thermalito Afterbay (high-flow channel) during January through April under H4 would generally be similar to or greater than flows under H3.

May storage would be 11% to 15% lower under H4 relative to H3 in wet, above normal, and below normal water years (Table 11-4-39). September Oroville storage under H4 would generally be similar to or greater than storage under H4 (Table 11-4-45).

Differences in the percent of months exceeding the 56°F threshold in the Feather River at Gridley between NAA and H4 would generally be negligible (<5% on an absolute scale) during January through March (Table 11-4-69). The percent of months exceeding the threshold under H4 would be similar to or up to 25% lower (absolute scale) than the percent under NAA. This represents a small benefit of H4 to steelhead spawning habitat conditions in the Feather River.

Total degree-months above the 56°F threshold in the Feather River at Gridley under H4 would be similar to those under NAA during October through February (Table 11-4-70). During March and April, degree-months under H4 would be 5% to 19% lower under H4, representing a small benefit of H4 to steelhead spawning habitat conditions in the Feather River.

Due to similar or better flows, reservoir storage, and water temperatures between H4 and H3, results for H4 would be similar to or better than those for H3.

American River

Flows in the American River at the confluence with the Sacramento River during January through April under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Differences in the percent of months exceeding the 56°F threshold between NAA and H4 would generally be negligible (<5% on an absolute scale) during January through March (Table 11-4-82). During April, the percent of months exceeding the threshold under H4 would be similar to or up to 17% lower (absolute scale) than the percent under NAA. This represents a small benefit of H4 to steelhead spawning habitat conditions in the Feather River.

Total degree-months above the 56°F threshold under H4 would be similar to (<3 degree months) those under NAA during January through March (Table 11-4-83). During April, degree-months under H4 would be 11 degree-months (12%) lower than under NAA, representing a small benefit of H4 to steelhead spawning habitat conditions in the Feather River.

Due to similar or better flows and water temperatures between H4 and H3, results for H1 would be similar to or better than those for H3.

NEPA Effects: Collectively, these results indicate that the effects of Alternative 4 on flow would not be adverse because they would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg development. There would be negligible effects on mean monthly flows water temperatures, and reservoir storage, for the applicable locations analyzed. There would be beneficial effects from increases in mean monthly flow (to 44%) for some months and water year types during the spawning period in the Feather River below Thermalito Afterbay, and a beneficial effect from a moderate increase (18%) in cold water pool availability in Oroville Reservoir which would help offset increased water temperatures in the Feather River attributable to the project (10%)Further, the SacEFT model predicts that there would be no effects to spawning and egg incubation habitat in the Sacramento River.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, spawning and egg incubation habitat for steelhead would not be affected relative to the CEQA baseline.

H3/ESO

Sacramento River

The primary steelhead spawning and egg incubation period extends from January through April. Results of the CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (Keswick Dam to upstream of RBDD) were summarized by month and water-year type based on estimated flows at RBDD (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation and rapid reductions in flow can dewater redds leading to mortality. Comparisons of Alternative 4 to Existing Conditions, indicate primarily negligible effects (<5%) on mean monthly flow during January through April, with the exception of small increases in flow (to 15%) in wet and critical water years, and a single, small decrease (-10%) during March in below normal years that would not have biologically meaningful negative effects. The small to moderate increases in flow would have a beneficial effect on spawning conditions, particularly in critical water years (January and March).

SacEFT predicts no changes (0% difference) or negligible effect (<5% difference) in spawning habitat, egg incubation, redd dewatering risk, and redd scour risk for Alternative 4 compared to Existing Conditions (Table 11-4-78).

Mean monthly water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period at either location.

Overall in the Sacramento River, effects of H3 on flow would consist of negligible effects (<5%) or small increases (to 15%) in mean monthly flow throughout the January to April spawning period, and negligible effects (<5%) on spawning metrics calculated with SacEFT, and negligible effects on water temperature.

Clear Creek

Results of the CALSIM analyses of instream flows for Clear Creek were summarized by month and water-year type for January through April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation and rapid reductions in flow can dewater redds leading to mortality. Comparisons of H3 to Existing Conditions, indicate no meaningful reductions (>5%) in mean monthly flow for any month or water type year. There would be primarily negligible effects (<5%), with small to substantial increases in mean monthly flow in wet years for January through March, ranging from 17% to 54%, and small increases in critical years for January through April (8% to 10%). Increases in flow would have a beneficial effect on spawning conditions. These results indicate that effects of flow under H3 would not have negative effects on steelhead spawning conditions in Clear Creek.

In terms of redd dewatering risk, comparison of greatest monthly flow reduction (Table 11-4-79) indicates no project-related effects (all values 0%) with the exception of an increase in the greatest monthly flow reduction in wet years (-38%) for H3 relative to Existing Conditions. Based on the fact that this flow reduction is in wet years, it would not have biologically meaningful negative effects on steelhead redd dewatering risk.

No water temperature modeling was conducted in Clear Creek.

The effects of H3 on mean monthly Clear Creek flows would consist of negligible effects and beneficial increases in flow (to 54%) with no reductions in flow for any month or water year type throughout the spawning period, and a moderate increase in flow reductions during wet years (-38%), when effects of flow reductions would be less critical for redd dewatering. Overall, H3 would not cause biologically meaningful effects on steelhead spawning conditions.

Feather River

Results of the CALSIM analyses of instream flows for the Feather River below Thermalito Afterbay (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January through April indicate variable effects depending on the specific month and water year type, with primarily decreases in mean monthly flows during January and February (-6% to -46%) for all but wet water years (negligible effects during January and an increase of 31% during February). Effects of H3 during March and April would consist primarily of increases in flow ranging from 12% to 58% with the exception of a substantial decrease (-58%) during March in below normal years and negligible effects (<5%) during March in drier water year types and during April in wetter water year types. The most substantial decreases in flow would occur in below normal years for January through March and would be somewhat offset by a substantial increase during April, although this would occur late in the spawning period. In general, for the remaining water year types, decreases in flow during January and February would be somewhat offset by increases during March and April and net effects would not have biologically meaningful negative effects on spawning conditions.

Comparisons for the low-flow channel indicate there would be no changes in conditions for H3 relative to Existing Conditions. Flows are predicted to range from 700 to 800 cfs under all conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Therefore, H3 is not expected to affect physical habitat conditions for steelhead spawning and egg incubation within the Feather River low-flow channel.

Water temperatures in the low-flow channel of the Feather River are determined largely by coldwater pool storage in Oroville Reservoir and instream flow releases. Because instream flows in the low-flow channel would be the same under H3 and Existing Conditions, any simulated changes in water temperatures under H3 would be attributed to changes in reservoir storage. Reservoir storage in May and September provides an indicator of coldwater pool availability. Results of CALSIM modeling of Oroville Reservoir storage in May are shown in Table 11-4-45, and results for September are shown in Table 11-4-39.

Comparison of results indicates that May storage in Oroville Reservoir for H3 would be reduced relative to Existing Conditions for all water year types, with negligible (≤5%) effects in wet and above normal years and small (-11%) to moderate (-20%) reductions for the remaining water years (Table 11-4-45). Results for September storage indicate that effects on storage from H3 would consist of substantial (to -35%) decreases in storage for wetter water years and small (-10%) to moderate (-28%) reductions for the drier water year types (Table 11-4-39). The reductions in storage would reduce cold water pool availability and would contribute to negative effects on water temperature in the Feather River.

Mean monthly water temperatures in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River*

Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis). In the low-flow channel, mean monthly water temperatures under H3 would be 5% to 7% greater than those under Existing Conditions during January through March and similar to temperatures under Existing Conditions during April. In the high-flow channel, mean monthly water temperatures under H3 would be 6% greater than those under Existing Conditions during January and February and similar to temperatures under Existing Conditions during March and April.

Effects of H3 on water temperature-related spawning and egg incubation conditions for steelhead in the Feather River were analyzed by comparing the percent of months between January through April over the 82-year CALSIM modeling period that exceed a 56°F temperature threshold in the low-flow channel (above Thermalito Afterbay) (Table 11-4-80). Differences in the percent of months exceeding the threshold between Existing Conditions and H3 would be negligible (<5% on an absolute scale) during January and February and for most degrees above the threshold evaluated for March, except for the >1.0 degree category. During April, the percent of months exceeding the threshold under H3 would be similar to or up to 44% (absolute scale) higher than the percent under Existing Conditions.

The effects of H3 on water temperature-related spawning and egg incubation conditions for steelhead in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the January through Aril steelhead spawning period for all 82 years (Table 11-4-81). There would be no difference (<5% on a relative scale) in total degree-months exceeded between Existing Conditions and H3 during January, February, and in all water years types except critical during March, in which there would be 8 more degree-months (800% increase) under H1 relative to Existing Conditions. An increase of 8 degree-months, although relatively large, is not expected to cause a biologically meaningful effect to steelhead. During April, the total number of degree months would be 4 to 24 degree-months (up to 600%) higher under H1 compared to Existing Conditions.

Overall, the effects of H3 on flows in the Feather River above Thermalito Afterbay would include substantial decreases in mean monthly flow (to -46%) during some months and water year types that would be partially offset by increases in other months and/or water year types, with the exception of more persistent, substantial reductions in flow in below normal years. There would be substantial increases in the exceedance of water temperature thresholds in the low-flow channel during April, coupled with a reduction in coldwater pool availability in the Oroville Reservoir (to -35% depending on month and water year type), that would affect steelhead egg survival.

American River

Results of the CALSIM analyses of instream flows within the lower American River at the confluence with the Sacramento River were summarized by month and water-year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January through April. Lower flows can reduce the instream area available for spawning and egg incubation and rapid reductions in flow can dewater redds leading to mortality. Comparisons indicate there would be primarily increases in mean monthly flows (to 27%) for H3 compared to Existing Conditions in wetter water years for January through March, and decreases (to -19%) in drier water years when flow changes would have more substantial effects on spawning conditions. Effects during April consist of negligible effects or small increases or decreases that would occur toward the end of the spawning period and would not have biologically meaningful effects. Flow decreases in drier water years would be most substantial in January, at the start of the spawning period, and would be partially offset by small increases in

February and March, with the exception of critical water years when flow reductions would persist. These results indicate that the effects of H3 on flows in the American River at the confluence during the steelhead spawning and egg incubation period would include moderate reductions in mean monthly flow (to –19%) that would have biologically meaningful effects on spawning conditions in drier water years, particularly in critical years. Mean monthly water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature under H3 would be 5% to 7% lower than those under Existing Conditions during January through March, and temperatures would not differ between H3 and Existing Conditions during April.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-64). Steelhead spawn and eggs incubate in the American River between January and April. During January and February, the percent of month exceeding the threshold under Existing Conditions and H3 would be similar. During March and April, the percent of months exceeding the threshold under H3 would be up to 38% greater (absolute scale) than the percent under Existing Conditions.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-65). During the January and February, there would be no difference in total degree-months above the threshold between Existing Conditions and H3. During March and April, total degree-months under H3 would be 395% and 98% greater than those under Existing Conditions, respectively.

Overall in the American River, effects of flow reductions in drier water years, particularly critical years, would contribute incremental negative effects to regional steelhead spawning conditions.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 throughout this period would be up to 36% lower flows under Existing Conditions in all months with few exceptions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River was evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 6% higher than those under Existing Conditions in all months.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to flows under Existing Conditions during March, up to 18% greater during February, and up to 14% lower during April.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Flows in the Sacramento River at Keswick and upstream of Red Bluff during January through April under H1 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period at either location, except for critical years during January at Red Bluff (5% higher).

Due to similar flows and water temperatures between H1 and H3, results for additional analyses (e.g., SacEFT) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to or better than those for H3.

Clear Creek

Flows in the Clear Creek during January through April under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek. Due to similar flows between H1 and H3, results for additional analyses (e.g., redd dewatering risk,) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Feather River

Flows in the Feather River above Thermalito Afterbay (low-flow channel) during January through April under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Feather River below Thermalito Afterbay (high-flow channel) during January through April under H1 would generally be similar to or greater than flows under H3. May and September Oroville storage under H1 would generally be similar to or greater than storage under H3 (Table 11-4-39, Table 11-4-45).

Mean monthly water temperatures in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H1 would be 5% to 7% greater than those under Existing Conditions during January through March and similar to temperatures under Existing Conditions during April. In the high-flow channel, mean monthly water temperatures under H1 would be 6% greater than those under Existing Conditions during January and February and similar to temperatures under Existing Conditions during March and April.

Differences in the percent of months exceeding the 56°F threshold between Existing Conditions and H1 would generally be negligible (<5% on an absolute scale) during January through March (Table 11-4-82). During April, the percent of months exceeding the threshold under H1 would be similar to or up to 32% higher (absolute scale) than the percent under Existing Conditions. This represents a small negative effect of H1 to steelhead spawning habitat conditions in the Feather River.

Total degree-months above the 56°F threshold under H1 would be similar to those under Existing Conditions during January, February, and all water year types except critical water years in March, in which there would be 6 more degree-months (600% increase) under H1 relative to Existing Conditions (Table 11-4-83). An increase of 6 degree-months, although relatively large, is not expected to cause a biologically meaningful effect to steelhead. During April, the total number of degree months would be 4 to 24 degree-months (up to 600%) higher under H1 compared to Existing Conditions.

Due to similar or better flows, reservoir storage, and water temperatures between H1 and H3, results for H1 would be similar to or better than those for H3.

American River

Flows in the American River at the confluence with the Sacramento River during January through April under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature under H1 would be 5% to 7% lower than those under Existing Conditions during January through March, and temperatures would not differ between H1 and Existing Conditions during April.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-71). Steelhead spawn and eggs incubate in the American River between January and April. During January and February, the percent of month exceeding the threshold under Existing Conditions and H1 would be similar. During March and April, the percent of months exceeding the threshold under H1 would be up to 11% greater (absolute scale) than the percent under Existing Conditions.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-72). During the January and February, there would be no difference in total degree-months above the threshold between Existing Conditions and H1. During March and April, total degree-months under H1 would be 384% and 95% greater than those under Existing Conditions, respectively.

Due to similar flows and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II*

Model Results utilized in the Fish Analysis). Flows under H1 throughout this period would be up to 36% lower flows under Existing Conditions in all months with few exceptions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River was evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 6% higher than those under Existing Conditions in all months.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would generally be similar to flows under Existing Conditions during March, up to 18% greater during February, and up to 14% lower during April.

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Flows in the Sacramento River at Keswick and upstream of Red Bluff during January through April under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period at either location, except for critical years during January at Red Bluff (5% higher).

Due to similar flows and water temperatures between H4 and H3, results for additional analyses (e.g., SacEFT) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Clear Creek

Flows in the Clear Creek during January through April under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek. Due to similar flows between H4 and H3, results for additional analyses (e.g., redd dewatering risk) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Feather River

Flows in the Feather River above Thermalito Afterbay (low-flow channel) during January through April under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Feather River below Thermalito Afterbay (high-flow channel) during January through April under H4 would generally be similar to or greater than flows under H3.

May storage would be 11% to 15% lower under H4 relative to H3 in wet, above normal, and below normal water years (Table 11-4-45). Regardless, there would be no differences in water temperatures between H4 and H3 scenarios during any month or water year type. September Oroville storage under H4 would generally be similar to or greater than storage under H4 (Table 11-4-39).

Mean monthly water temperatures in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H4 would be 5% to 7% greater than those under Existing Conditions during January through March and similar to temperatures under Existing Conditions during April. In the high-flow channel, mean monthly water temperatures under H4 would be 6% greater than those under Existing Conditions during January and February and similar to temperatures under Existing Conditions during March and April.

Differences in the percent of months exceeding the 56°F threshold between Existing Conditions and H4 would generally be negligible (<5% on an absolute scale) during January through March except for the >1.0 degree category for March (5% higher) (Table 11-4-82). During April, the percent of months exceeding the threshold under H4 would be similar to or up to 27% higher (absolute scale) than the percent under Existing Conditions. This represents a small negative effect of H4 to steelhead spawning habitat conditions in the Feather River.

Total degree-months above the 56°F threshold under H4 would be similar to those under Existing Conditions during January, February, and all water year types except critical water years in March, in which there would be 7 more degree-months (700% increase) under H1 relative to Existing Conditions (Table 11-4-83). An increase of 7 degree-months, although relatively large, is not expected to cause a biologically meaningful effect to steelhead. During April, the total number of degree months would be 3 to 25 degree-months (up to 500%) higher under H1 compared to Existing Conditions.

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for H4 would be similar to or better than those for H3.

American River

Flows in the American River at the confluence with the Sacramento River during January through April under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the*

Fish Analysis). Mean monthly water temperature under H4 would be 5% to 7% lower than those under Existing Conditions during January through March, and temperatures would not differ between H4 and Existing Conditions during April.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-4-71). Steelhead spawn and eggs incubate in the American River between January and April. During January and February, the percent of month exceeding the threshold under Existing Conditions and H4 would be similar. During March and April, the percent of months exceeding the threshold under H4 would be up to 30% greater (absolute scale) than the percent under Existing Conditions.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-4-72). During the January and February, there would be no difference in total degree-months above the threshold between Existing Conditions and H4. During March and April, total degree-months under H4 would be 395% and 95% greater than those under Existing Conditions, respectively.

Due to similar flows and water temperatures between H4 and H3, results for H4 would be similar to those for H3.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 throughout this period would be up to 36% lower flows under Existing Conditions in all months with few exceptions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River was evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 6% higher than those under Existing Conditions in all months.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would generally be similar to flows under Existing Conditions during March, up to 18% greater during February, and up to 14% lower during April.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-94 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above.

Alternative 4 would reduce steelhead spawning conditions through reduced mean monthly flows (to -58%), substantial increases in exposure to critical water temperatures, and substantial reductions in cold water pool availability that would also affect water temperatures in the Feather River, and through moderate reductions in mean monthly flows in the American River, particularly during drier water years. These effects would degrade spawning conditions and increase egg mortality. Alternative 4 would not have significant effects on steelhead spawning conditions in the Sacramento River and Clear Creek. Results would generally be similar among scenarios.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration conditions for steelhead. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

In general, the effects of Alternative 4 on steelhead rearing conditions would be negligible relative to the NAA

H3/ESO

Sacramento River

Juvenile steelhead rear within the Sacramento River and its tributaries throughout the year because juveniles inhabit upstream areas for a period of 1 to 2 years before migrating downstream to the ocean. Results of the CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (Keswick Dam to upstream of Red Bluff) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for effects of H3. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles, leading to mortality.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

In general, effects of H3 on mean monthly flow would consist of primarily negligible increases in flow (to 20%) relative to NAA throughout the year, with the exception of isolated, small reductions in flow and more persistent flow reductions in all water year types during November (to -23%).

SacEFT predicts that there would be a 22% reduction in years classified as good juvenile rearing habitat conditions under H3 compared to NAA, but there would be a 10% increase in the percentage of years classified "good" with respect to juvenile stranding risk (Table 11-4-78). The decrease in the percentage of years when juvenile rearing habitat is classified as good for H3 would contribute to an incremental reduction in good habitat conditions and an increase in the risk of mortality to juvenile steelhead resulting from stranding.

Based on mean monthly flows, SacEFT rearing metrics, and water temperature effects, project-related effects under Alternative 4 in the Sacramento River would not have biologically meaningful negative effects on steelhead rearing conditions. Effects of H3 consist primarily of negligible effects that would not have biologically meaningful effects on rearing success with the exception of a moderate decrease (-22%) in rearing habitat conditions based on SacEFT, that would be partially offset by a small beneficial effect on stranding risk (10%).

Clear Creek

Steelhead rear in Clear Creek throughout the year. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality. Instream flows estimated from the modeling each month and water-year type were used to compare among model scenarios (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). In general, flows under H3 would generally be similar to those under NAA with few exceptions.

Evaluation of the minimum instream flows in Clear Creek indicates that H3 would have no effect (0%) on minimum instream flows in any water year type (Table 11-4-84).

Table 11-4-84. Minimum Monthly Instream Flow (cfs) for Model Scenarios in Clear Creek during the Year-Round Juvenile Steelhead Rearing Period

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-50 (-100%)	0 (0%)
Above Normal	0 (0%)	0 (0%)
Below Normal	0 (0%)	0 (0%)
Dry	-50 (-100%)	0 (0%)
Critical	-50 (-100%)	0 (NA)

Note: Minimum flows occurred between October and March.
NA = could not be calculated because the denominator was 0.

Denton (1986) developed flow recommendations for steelhead in Clear Creek using IFIM (Figure 11-1A-4). The current Clear Creek management regime uses flows slightly lower than those recommended by Denton. Results from a new IFIM study on Clear Creek are currently being analyzed. Depending on results of this study the flow regime could be adjusted in the future. It is expected that the modeled flows will be suitable for the existing steelhead populations in Clear Creek. No change in effect on steelhead in Clear Creek is anticipated.

No water temperature modeling was conducted in Clear Creek.

These results indicate that effects of H3 on flows would not affect juvenile steelhead rearing habitats in Clear Creek.

Feather River

The low-flow channel is the primary reach of the Feather River utilized by steelhead spawning and rearing. Although there is relatively little natural steelhead production in the river, most steelhead spawning and rearing appears to occur in the low-flow channel in habitats associated with well-vegetated side channels (Cavallo et al. 2003; California Department of Water Resources unpublished data). Because these habitats are relatively uncommon they could limit natural steelhead production. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality.

There would be no change in flows for H3 relative to NAA in the low-flow channel. Flow in the low-flow channel is projected to remain between 700 and 800 cfs except during occasional flood control releases. This flow is less than pre-dam levels during all months of the year as a result of water diversions through the Thermalito Afterbay. The significance of these flow conditions for steelhead spawning and rearing is uncertain. Feather River screw trap data indicate that Chinook salmon initiate emigration regardless of flow regime (i.e., they do not wait for a high-flow pulse). This is likely true for steelhead as well.

The river channel downstream of Thermalito (high-flow channel) offers few of the habitat types upon which steelhead appear to rely in the low-flow channel. Experiments and fish observations also indicate that predation risk for juvenile steelhead is higher downstream of the Thermalito outlet (California Department of Water Resources 2004). Increased predation risk is likely a function of water temperature, where warm water nonnative species such as striped bass, largemouth bass, and smallmouth bass are more prevalent, and in general, predators have greater metabolic requirements. Thus, summer temperatures that exceed 65°F and the absence of preferred steelhead habitat currently appear to limit steelhead rearing in the river downstream of the Thermalito outlet. Comparisons of CALSIM data by month and water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate that flows under H3 would generally be greater than or similar to those under NAA in the high-flow channel in all months except July through September. During July through September, flows under H3 would be up to 50% lower than those under NAA depending on month, water-year type and comparison.

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period at either location.

Effects of H3 on water temperature-related juvenile rearing conditions for steelhead in the Feather River were analyzed by comparing the percent of months between May through August over the 82-year CALSIM modeling period that exceed a 63°F temperature threshold in the low-flow channel (above Thermalito Afterbay) and by comparing the percent of months between October and April that exceed a 56°F threshold at Gridley. Results for the low-flow channel (above Thermalito Afterbay) and Gridley are presented for spring-run rearing and fall-run spawning and egg incubation in Impacts AQUA-59 and AQUA-76, respectively. In the low-flow channel and at Gridley, there would generally be no differences between NAA and H3 on the percent of months exceeding the threshold.

The effects of H3 on water temperature-related juvenile rearing conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 63°F NMFS threshold during May through August in the low-flow channel and the 56°F threshold during October through April at Gridley. Results for the low-flow channel (above Thermalito Afterbay) and Gridley are presented for spring-run rearing and fall-run spawning and egg incubation in Impacts AQUA-59 and AQUA-76, respectively. In the low flow channel and at Gridley, there would be small increases and decreases in exceedances above the thresholds, but overall no biologically meaningful effects.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be greater than or similar to flows under NAA in all months except August and September. Flows during August and September would be up to 28% lower under H3 than under NAA. Because these reductions would occur only during these months and would be generally low to moderate, they are not expected to cause biologically meaningful effects on steelhead juvenile rearing habitat.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4-85). During May, June, and October, the percent of months exceeding the threshold under H3 would similar to or up to 14% lower (absolute scale) than the percent under NAA. During July through September, the percent of months exceeding the threshold would mostly be similar between NAA and H3 with one or two degree categories in which there would be increases of up to 7% on an absolute scale in percent of months exceeding the threshold under H3.

Table 11-4-85. Differences between Baseline and H3 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 65°F Threshold, May through October

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3					
May	41 (206%)	33 (225%)	23 (211%)	21 (340%)	10 (200%)
June	35 (54%)	35 (65%)	32 (79%)	21 (68%)	17 (82%)
July	0 (0%)	1 (1%)	36 (57%)	42 (117%)	42 (243%)
August	0 (0%)	2 (3%)	19 (23%)	51 (105%)	67 (216%)
September	15 (17%)	46 (86%)	58 (181%)	63 (392%)	53 (717%)
October	75 (1,525%)	63 (2,550%)	42 (NA)	27 (NA)	12 (NA)
NAA vs. H3					
May	-4 (-6%)	-1 (-3%)	-5 (-13%)	-5 (-15%)	-2 (-14%)
June	0 (0%)	-4 (-4%)	-9 (-11%)	-14 (-21%)	-10 (-21%)
July	0 (0%)	0 (0%)	1 (1%)	6 (9%)	4 (7%)
August	0 (0%)	0 (0%)	0 (0%)	2 (3%)	7 (8%)
September	0 (0%)	1 (1%)	5 (6%)	5 (7%)	0 (0%)
October	0 (0%)	0 (0%)	-4 (-8%)	-2 (-8%)	1 (11%)

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4-86). Total degree-months exceeding the threshold would be similar between NAA and H3 or up to 12% lower under H3 in all months except July, in which degree-months would be 8% higher under H3.

Table 11-4-86. Differences between Baseline and H3 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 65°F in the American River at the Watt Avenue Bridge, May through October

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
May	Wet	20 (333%)	-1 (-4%)
	Above Normal	24 (NA)	-3 (-11%)
	Below Normal	18 (600%)	-5 (-19%)
	Dry	24 (109%)	-10 (-18%)
	Critical	34 (179%)	2 (4%)
	All	120 (240%)	-17 (-9%)
June	Wet	47 (276%)	-21 (-25%)
	Above Normal	21 (88%)	-11 (-20%)
	Below Normal	28 (97%)	-10 (-15%)
	Dry	35 (51%)	-5 (-5%)
	Critical	47 (94%)	-3 (-3%)
	All	178 (95%)	-50 (-12%)
July	Wet	54 (69%)	5 (4%)
	Above Normal	10 (37%)	4 (12%)
	Below Normal	26 (76%)	5 (9%)
	Dry	71 (115%)	20 (18%)
	Critical	48 (59%)	2 (2%)
	All	209 (74%)	36 (8%)
August	Wet	106 (134%)	-2 (-1%)
	Above Normal	32 (78%)	-1 (-1%)
	Below Normal	54 (96%)	17 (18%)
	Dry	91 (134%)	10 (7%)
	Critical	69 (87%)	5 (3%)
	All	352 (109%)	29 (4%)
September	Wet	83 (346%)	9 (9%)
	Above Normal	46 (288%)	10 (19%)
	Below Normal	49 (175%)	2 (3%)
	Dry	81 (193%)	-5 (-4%)
	Critical	55 (112%)	2 (2%)
	All	314 (197%)	18 (4%)
October	Wet	48 (4,800%)	-6 (-11%)
	Above Normal	27 (NA)	1 (4%)
	Below Normal	39 (NA)	0 (0%)
	Dry	37 (NA)	0 (0%)
	Critical	31 (620%)	1 (3%)
	All	182 (3,033%)	-4 (-2%)

NA = could not be calculated because the denominator was 0.

These results indicate that effects of H3 on flow and water temperatures would not reduce juvenile rearing conditions in the American River.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to flows under NAA throughout the period.

Mean monthly water temperatures throughout the Stanislaus River would be similar under NAA and H3 throughout the year-round period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Year-round flows in the Sacramento River at Keswick and upstream of Red Bluff under H1 would generally be similar to flows under H3, except during September and November, during which flows would be up to 46% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated reductions would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

Due to similar flows and water temperatures between H1 and H3, results for additional analyses (e.g., SacEFT, minimum mean monthly flow comparisons) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Clear Creek

Year-round flows in the Clear Creek under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek. Due to similar flows between H1 and H3, results for additional analyses (e.g., minimum mean monthly flow comparisons) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Feather River

Year-round flows in the Feather River above Thermalito Afterbay (low-flow channel) under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows in the Feather River below Thermalito Afterbay (high-flow channel) under H1 would generally be similar to or greater than flows under H3, except during September during which flows would be up to 83% lower than flows under NAA. This isolated reduction would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

May and September Oroville storage under H1 would generally be similar to or greater than storage under H3 (Table 11-4-45, Table 11-4-39).

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period at either location.

The analysis evaluating the percent of months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be a small benefit of H1 relative to NAA in the low flow channel and at Gridley.

The analysis evaluating the total degree-months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that exceedances under H1 would generally be similar to or lower than those under NAA in the low flow channel and at Gridley, representing a small benefit of H1.Due to similar flows, reservoir storage, and water temperatures between H1 and H3, results for H1 would be similar to or better than those for H3.

American River

Year-round flows in the American River at the confluence with the Sacramento River under H1 would generally be similar to flows under H3, except during September, during which flows would be up to 38% (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated flow reductions would not have biologically meaningful effects on steelhead fry and juvenile habitat because they only occur during one of 12 months.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4-87). During May, June, and October, the percent of months exceeding the threshold under H1 would similar to or up to 26% lower (absolute scale) than the percent under NAA. During July through September, the percent of months exceeding the threshold would mostly be similar between NAA and H1 with one or two degree categories in which there would be increases of up to 10% on an absolute scale and decreases of up to 9% on an absolute scale in percent of months exceeding the threshold under H1.

Table 11-4-87. Differences between Baseline Scenarios and H1 and H4 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 65°F Threshold, May through October

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H1					
May	20 (100%)	16 (108%)	5 (44%)	5 (80%)	1 (25%)
June	19 (29%)	19 (35%)	11 (27%)	9 (28%)	7 (35%)
July	0 (0%)	1 (1%)	9 (14%)	15 (41%)	11 (64%)
August	0 (0%)	2 (3%)	17 (21%)	46 (95%)	46 (148%)

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4-88). Total degree-months exceeding the threshold would be similar between NAA and H1 or up to 12% lower under H1 in all months except July and September, in which degree-months would be 10% and 9%, higher, respectively, under H1.

Table 11-4-88. Differences between Baseline Scenarios and H1 and H4 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 65°F in the American River at the Watt Avenue Bridge, May through October

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
May	Wet	21 (350%)	0 (0%)	22 (367%)	1 (4%)

	All	157 (2,617%)	-29 (-15%)	175 (2,917%)	-11 (-6%)

NA = could not be calculated because the denominator was 0.

Due to similar flows and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to flows under NAA throughout the period.

Mean monthly water temperatures throughout the Stanislaus River would be similar under NAA and H1 throughout the year-round period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Year-round flows in the Sacramento River at Keswick and upstream of Red Bluff under H4 would generally be similar to flows under H3, except during May and June, during which flows would be up to 13% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These small and isolated reductions would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

Due to similar flows and water temperatures between H4 and H3, results for additional analyses (e.g., SacEFT, minimum mean monthly flow comparisons) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Clear Creek

Year-round flows in the Clear Creek under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek. Due to similar flows between H4 and H3, results for additional analyses (e.g., minimum mean monthly flow comparisons) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Feather River

Year-round flows in the Feather River above Thermalito Afterbay (low-flow channel) under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Feather River below Thermalito Afterbay (high-flow channel) under H4 during January through May and November through December would generally be similar to or greater than flows under H3. However, flows during June through October would generally be up to 39% lower under H4.

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period at either location.

The analysis evaluating the percent of months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be a small to moderate benefits of H4 relative to NAA in the low-flow channel and at Gridley.

The analysis evaluating the total degree-months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that exceedances under H4 would generally be similar to or lower than those under NAA in the low flow channel and at Gridley, representing a small benefit of H4.

May storage would be 11% to 15% lower under H4 relative to H3 in wet, above normal, and below normal water years (Table 11-4-45). September Oroville storage under H4 would generally be similar to or greater than storage under H4 (Table 11-4-39).

Due to similar flows, reservoir storage, and water temperatures between H4 and H3, results for H4 would be similar to or better than those for H3.

American River

Year-round flows in the American River at the confluence with the Sacramento River under H4 would generally be similar to flows under H3, except during June and October, during which flows would be up to 22% (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated flow reductions would not have biologically meaningful effects on steelhead fry and juvenile habitat because they only occur during two of 12 months.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results* *utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4-87). During May, June, and October, the percent of months exceeding the threshold under H4 would similar to or up to 26% lower (absolute scale) than the percent under NAA. The percent of months exceeding the threshold would generally be similar between NAA and H4 throughout the period, except during August, in which there would be no differences between NAA and H4.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4-88). Total degree-months exceeding the threshold would be similar between NAA and H4 throughout the period, except during September, in which total degree-months would be 13% lower under H4.

Due to similar flows and water temperatures between H4 and H3, results for H4 would be similar to those for H3.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to flows under NAA throughout the period.

Mean monthly water temperatures throughout the Stanislaus River would be similar under NAA and H4 throughout the year-round period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to flows under NAA throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, these results indicate that the effect of Alternative 4 is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of fry and juvenile mortality. Effects of Alternative 4 on flows and water temperatures would be small and infrequent in the Sacramento River and Clear Creek, and effects in the Feather River and the American River would be more variable, but in general, the overall effects are expected to be slightly beneficial, despite the increased flow variations Water temperatures in the Sacramento, Feather, American and Stanislaus Rivers would not be affected by Alternative 4. Reduced June through October flows under H4 in the Feather River high-flow channel would affect the steelhead population there, but flows in the low-flow channel would be unaffected by H4. Overall, Alternative 4 is not expected to have biologically meaningful negative effects on steelhead rearing conditions.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of rearing habitat for steelhead would not be affected relative to the CEQA baseline.

H3/ESO

Sacramento River

Comparisons of CALSIM outputs of flow by month and water year type for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were used to evaluate effects of H3 compared to Existing Conditions. Results indicate negligible effects with isolated, small decreases in flow (to -17%) and more frequent, beneficial increases in flow (to 55%) throughout the year, with the exception of a greater prevalence of small to moderate flow reductions in drier water years during August, September and November (to -26%). The most substantial effects on juvenile rearing habitats would occur from reductions in flow in drier water year types in August (-26%) and September (-14%). Based on the infrequency and magnitude of these decreases, and negligible effects or beneficial increases in flow for the remainder of the year, the flow reductions are not expected to have biologically meaningful negative effects on juvenile steelhead rearing conditions in the Sacramento River.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, mean monthly water temperatures under H3 would generally be similar to those under Existing Conditions, except during August through October, in which there would be 5% to 6% higher temperatures under H3.

SacEFT predicts that there would be a 15% decrease in the percentage of years with good juvenile rearing habitat under H3 compared to Existing Conditions (Table 11-4-78). SacEFT predicts there would be a decrease of 35% in occurrence of years with "good" conditions for juvenile stranding risk (Table 11-4-78). This would contribute incrementally to decreased juvenile habitat conditions and could increase the potential for mortality due to stranding.

Based on the incremental effects of reductions in mean monthly flows (up to 26% lower) for several months during drier water year types, including the warmer summer/early fall months of August and September, and increased risk of juvenile stranding (35%), effects of H3 on flows would have biologically meaningful effects on juvenile rearing conditions in the Sacramento River.

Clear Creek

Comparisons of mean monthly flows for Clear Creek were used to evaluate effects of H3 relative to Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality. Effects of H3 year-round consist primarily of no change (0%) or negligible change (<5%) with respect to Existing Conditions, with the exception of isolated decreases in flow in critical years during August (-25%), September (-28%), and October (-6%), and occasional increases in flow (to 54% during January in wet years; otherwise to 17% and typically in wet or critical years) that would have beneficial effects. The decreases in flow would be of a frequency and magnitude to not cause biologically meaningful negative effects.

Evaluation of minimum instream flows for H3 relative to Existing Conditions (Table 11-4-84) indicates no effect (0%) for above normal and below normal years, and decreases for the remaining water year types (-50 cfs or -100%). This reduction corresponds to a substantial decrease in total flow during drier water years based on relatively small quantities of flow (e.g., as low as 85 cfs in the summer months in drier water years, and more typically between 150 and 200 in other months). These reductions in minimum instream flows would affect juvenile rearing habitat and could increase stranding risk, particularly in drier water years.

No water temperature modeling was conducted in Clear Creek.

While effects of H3 on mean monthly flow would consist predominantly of negligible effects, there would be moderate to substantial reductions in minimum instream flows, particularly during drier water years, that would affect juvenile rearing habitat and increase stranding risk in Clear Creek.

Feather River

The low-flow channel is the primary reach of the Feather River utilized by steelhead spawning and rearing. There would be no change in flows for H3 relative to Existing Conditions in the low-flow channel (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Comparisons using CALSIM data by month and water year type for the Feather River at Thermalito (high-flow channel) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate variable effects of H3 relative to Existing Conditions. H3 would cause some substantial increases in mean monthly flows for some months and water year types. With some exceptions for specific water year types, there would be increases in mean monthly flows during March through June (to 135%), wetter years during July through September (to 209%), and October (to 33%). These are some of the most substantial flow increases calculated for H3 relative to Existing Conditions; effects in drier water year types would be particularly beneficial for juvenile rearing habitats. H3 would cause decreases in mean monthly flow for some of the remaining months/water year types; moderate (greater than approximately 12%) decreases would occur in drier water year types (with greater potential for adverse effects) during January (-46% in below normal years), February (-45% in below normal years and -10% in dry years), March (-53% in below normal years), July (to -61% in all drier year types), and September (to -46% in below normal and dry years). This constitutes a fairly broad range of substantial flow reductions throughout the year occurring in drier water years when potential effects on juvenile rearing conditions would be greatest.

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H3 would be similar to those under Existing Conditions between April and September, but would be 5% to 10% higher between October and March. In the high-flow channel, mean monthly water temperatures under H3 would be 5% to 8% higher than those under Existing Conditions during October through February, and similar in the remaining months.

Effects of H3 on water temperature-related juvenile rearing conditions for steelhead in the Feather River were analyzed by comparing the percent of months between May through August over the 82-year CALSIM modeling period that exceed a 63°F temperature threshold in the low-flow channel (above Thermalito Afterbay) and by comparing the percent of months between October and April that exceed a 56°F threshold at Gridley. Results for the low-flow channel (above Thermalito Afterbay) and Gridley are presented for spring-run rearing and fall-run spawning and egg incubation in Impacts AQUA-59 and AQUA-76, respectively. In the low-flow channel and at Gridley, there would generally be moderate to large increases in the percent of months exceeding the threshold between H3 and Existing Conditions. This comparison includes the effects of climate change.

The effects of H3 on water temperature-related juvenile rearing conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 63°F NMFS threshold during May through August in the low-flow channel and the 56°F threshold during October through April at Gridley. Results for the low-flow channel (above Thermalito Afterbay) and Gridley are presented for spring-run rearing and fall-run spawning and egg incubation in Impacts AQUA-59 and AQUA-76, respectively. In the low-flow channel and at Gridley, there would be moderate to large increases in total degree-months exceeding the temperature threshold during some months. This comparison includes the effects of climate change.

Overall in the Feather River, effects of H3 on mean monthly flow would consist of substantial increases and decreases for various months and water year types. There would be relatively frequent, substantial flow reductions in drier water years that would affect juvenile rearing habitat conditions and contribute to stranding risk. Further, there would be moderate to large increases in the exceedance of temperature thresholds in the low-flow channel and at Gridley.

American River

CALSIM outputs were used to compare mean monthly flows by month and water year type for H3 for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality. Comparisons of H3 to Existing Conditions indicate highly variable results, with primarily decreases in mean monthly flow for H3 relative to Existing Conditions, but some moderate increases in flow for certain months and water year types. Increases would primarily occur during January through March and June, with the largest increases generally occurring in wetter water years (to 25%) and less prevalent and/or smaller flow increases in drier water years. There would be primarily decreases in mean monthly flow during January in drier water years (to -19%), and for most water year types during May, and July through December (to -54%). The effects of H3 on mean monthly flow would consist of decreases in mean monthly flow in below normal, dry, and/or critical water years during each month of the year with reductions ranging from -9% to -54% depending on the specific month and water year type. This constitutes prevalent, substantial reductions in mean monthly flow, particularly during drier water years, that would have biologically meaningful effects on juvenile rearing conditions in the American River.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature under H3 would be 5% to 11% lower than those under Existing Conditions during January through March, May, and September through November, and similar in the remaining 5 months.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4-85). The percent of months under H3 would be greater by up to 75% (absolute difference) than those under Existing Conditions during all months examined.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4-86). Total degree-months exceeding the threshold under H3 would be 74% to 3,033% greater than those under Existing Conditions for all months.

These results indicate that effects of H3 on flows (reductions to -54% during each month of the year in drier water year types) and water temperatures would affect juvenile steelhead rearing conditions in the American River throughout most of the year, particularly during drier water years.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be flow reductions (up to 36%) under H3 relative to Existing Conditions in all months.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the year-round juvenile steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 5% to 6% lower in all months except June, July, and October.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be 5% to 33% lower than flows under Existing Conditions during May through October, similar to flows under Existing Conditions during November through April.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to flows under Existing Conditions during March, up to 14% greater than flows under Existing Conditions during December through February, and up to 46% lower than flows under Existing Conditions during the remaining 8 months.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Year-round flows in the Sacramento River at Keswick and upstream of Red Bluff under H1 would generally be similar to flows under H3, except during September and November, during which flows would be up to 46% lower than flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated reductions would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 5% to 6% higher under H1 than those under Existing Conditions during August through October, but would not differ in other months.

Due to similar flows and water temperatures between H1 and H3, results for additional analyses (e.g., SacEFT, minimum mean monthly flow comparisons) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Clear Creek

Year-round flows in the Clear Creek under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek. Due to similar flows between H1 and H3, results for additional analyses (e.g., minimum mean monthly flow comparisons) under H1 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H1. Overall, results for H1 would be similar to those for H3.

Feather River

Year-round flows in the Feather River above Thermalito Afterbay (low-flow channel) under H1 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows in the Feather River below Thermalito Afterbay (high-flow channel) under H1 would generally be similar to or greater than flows under H3, except during September during which flows would be up to 83% lower than flows under NAA. This isolated reduction would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H1 would be similar to those under Existing Conditions between April and September, but would be 5% to 9% higher between October and March. In the high-flow channel, mean monthly water temperatures under H1 would be 6% to 8% higher than those under Existing Conditions during October through February, and similar in the remaining months.

The analysis evaluating the percent of months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be a small to moderate negative effects of H1 relative to Existing Conditions in multiple months in the low flow channel and at Gridley. This comparison includes the effects of climate change.

The analysis evaluating the total degree-months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be small to moderate negative effects of H1 relative to Existing Conditions in multiple months in the low flow channel and at Gridley. This comparison includes the effects of climate change.

May and September Oroville storage under H1 would generally be similar to or greater than storage under H3 (Table 11-4-45, Table 11-4-39).

Due to similar flows and water temperatures, and similar or greater reservoir storage under H1 compared to H3, results for H1 would be similar to or better than those for H3.

American River

Year-round flows in the American River at the confluence with the Sacramento River under H1 would generally be similar to flows under H3, except during September, during which flows would be up to 38% (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated flow reductions would not have biologically meaningful effects on steelhead fry and juvenile habitat because they only occur during one of 12 months.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature under H1 would be 5% to 10% lower than those under Existing Conditions during August through March and May through December, and similar in the remaining 3 months.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4-87). The percent of months under H1 would be greater by up to 46% (absolute difference) than those under Existing Conditions during all months examined.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4-88). Total degree-months exceeding the threshold under H1 would be 77% to 2,617% greater than those under Existing Conditions for all months.

Due to similar flows and water temperatures between H1 and H3, results for H1 would be similar to those for H3.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be flow reductions (up to 36%) under H1 relative to Existing Conditions in all months.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the year-round juvenile steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 5% to 6% lower in all months except June, July, and October.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be 5% to 33% lower than flows under Existing Conditions during May through October, similar to flows under Existing Conditions during November through April.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 would be similar to flows under Existing Conditions during March, up to 14% greater than flows under Existing Conditions during December through February, and up to 46% lower than flows under Existing Conditions during the remaining 8 months.

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Year-round flows in the Sacramento River at Keswick and upstream of Red Bluff under H4 would generally be similar to flows under H3, except during May and June, during which flows would be up to 13% lower than flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These small and isolated reductions would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, mean monthly water temperatures under H4 would generally be similar to those under Existing Conditions, except during August through October, in which there would be 5% to 6% higher temperatures under H4.

Due to similar flows and water temperatures between H4 and H3, results for additional analyses (e.g., SacEFT, minimum mean monthly flow comparisons) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Clear Creek

Year-round flows in the Clear Creek under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). No water temperature modeling was conducted in Clear Creek. Due to similar flows between H4 and H3, results for additional analyses (e.g., minimum mean monthly flow comparisons) under H4 would be similar to results for analyses under H3. As a result, these additional analyses were not conducted for H4. Overall, results for H4 would be similar to those for H3.

Feather River

Year-round flows in the Feather River above Thermalito Afterbay (low-flow channel) under H4 would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Feather River below Thermalito Afterbay (high-flow channel) under H4 during January through May and November through December would generally be similar to or greater than flows under H3. However, flows during June through October would generally be up to 39% lower under H4. Despite these differences, very few steelhead rear in the high-flow channel and, therefore, these reductions are not expected to cause a biologically meaningful effect.

Mean monthly water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In the low-flow channel, mean monthly water temperatures under H1 would be similar to those under Existing Conditions between April and September, but would be 5% to 19% higher between October and March. In the high-flow channel, mean monthly water temperatures under H1 would be 5% to 8% higher than those under Existing Conditions during July, August, and October through February, and similar in the remaining 5 months.

The analysis evaluating the percent of months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be a small to moderate negative effects of H4 relative to Existing Conditions in multiple months in the low flow channel and at Gridley. This comparison includes the effects of climate change.

The analysis evaluating the total degree-months exceeding water temperature thresholds from NMFS presented in Impacts AQUA-59 and AQUA-76 indicates that there would be small to moderate negative effects of H4 relative to Existing Conditions in multiple months in the low flow channel and at Gridley. This comparison includes the effects of climate change.

May storage would be 11% to 15% lower under H4 relative to H3 in wet, above normal, and below normal water years (Table 11-4-45). September Oroville storage under H4 would generally be similar to or greater than storage under H4 (Table 11-4-39).

American River

Year-round flows in the American River at the confluence with the Sacramento River under H4 would generally be similar to flows under H3, except during June and October, during which flows would be up to 22% (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated flow reductions would not have biologically meaningful effects on steelhead fry and juvenile habitat because they only occur during two of 12 months.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperature under H4 would be 5% to 11% lower than those under Existing Conditions during May and August through March, and similar in the remaining 3 months.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-4-87). The percent of months under H4 would be greater by up to 72% (absolute difference) than those under Existing Conditions during all months examined.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-4-88). Total degree-months exceeding the threshold under H4 would be 68% to 2,917% greater than those under Existing Conditions for all months.

Due to similar flows and water temperatures between H4 and H3, results for H4 would be similar to those for H3.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be flow reductions (up to 36%) under H4 relative to Existing Conditions in all months.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the year-round juvenile steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 5% to 6% lower in all months except June, July, and October.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be 5% to 33% lower than flows under Existing Conditions during May through October, similar to flows under Existing Conditions during November through April.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 would be similar to flows under Existing Conditions during March, up to 14% greater than flows under Existing Conditions during December through February, and up to 46% lower than flows under Existing Conditions during the remaining 8 months.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Collectively, these results of the Impact AQUA-95 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of fry and juvenile mortality, contrary to the NEPA conclusion set forth above. Juvenile rearing conditions in all locations analyzed would be negatively affected under Alternative 4 by moderate to substantial reductions in mean monthly flows for large portions of the year-round rearing period in the Feather, American, Stanislaus, San Joaquin, and Mokelumne Rivers. Water temperatures and the exceedances above applicable NMFS thresholds would be higher in the Sacramento, Feather, American, and Stanislaus Rivers. Degraded rearing conditions for juvenile steelhead would reduce their survival and growth in these waterways.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for steelhead. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

Upstream of the Delta

In general, the effects of Alternative 4 on steelhead migration conditions relative to the NAA are uncertain.

H3/ESO

Sacramento River

Juveniles

Sacramento River flow upstream of Red Bluff during the juvenile steelhead migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) is used to represent flow conditions in the mainstem of the upper river below Keswick Dam. Flows under H3 during this period would generally be similar to flows under NAA, except during November, during which flows would be up to 18% lower than flows under NAA. These reductions would not have a biologically meaningful effect on steelhead juvenile migration because reductions occur during only one of eight months of the period.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Overall, these results indicate that H3 would not have biologically meaningful effects on juvenile migration conditions.

Adults

Instream flows upstream of Red Bluff were compared monthly over the period from September through March under H3 and NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 during this period would generally be similar to flows under NAA, except during November, during which flows would be up to 18% lower than flows under NAA. These reductions would not have a biologically meaningful effect on steelhead adult migration because reductions occur during only one of seven months of the period.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Kelts

Average Sacramento River flows upstream of Red Bluff under H3 during March and April (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) would generally be similar to flows under NAA. Therefore, H3 would not affect kelt migration in the Sacramento River.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Overall in the Sacramento River, these results indicate that H3 would not have biologically meaningful effects on juvenile, adult, or kelt steelhead migration in the Sacramento River.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows in Clear Creek at Whiskeytown were evaluated for the juvenile steelhead migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to or greater than flows under NAA throughout the period. These results indicate that effects of H3 on flows would not affect juvenile steelhead migration conditions in Clear Creek.

Adults

Flows in Clear Creek at Whiskeytown were evaluated for the September through March adult steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to or greater than flows under NAA throughout the period. These results indicate that effects of Alternative 4 on flows would not affect adult steelhead migration conditions in Clear Creek.

Kelts

Flows in Clear Creek at Whiskeytown were evaluated for the March through April kelt steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to or greater than flows under NAA throughout the period. These results indicate that H3 would not affect kelt steelhead migration conditions in Clear Creek.

Overall in Clear Creek, these results indicate that effects of H3 on flows would not affect juvenile, adult, or kelt steelhead migration.

Feather River

Juveniles

Flows in the Feather River at Thermalito Afterbay (high-flow channel) and at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the high-flow channel under H3 would generally be similar to or greater than flows under NAA throughout the period. Increases in flow would have a beneficial effect on migration conditions, particularly in drier water years during some months (up to 54% greater flows).

Flows under H3 in the Feather River at the confluence with the Sacramento River during October through May would generally be similar to or greater than flows under NAA, except in above normal water years during November (6% lower) and December (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated reductions would not have biologically meaningful effects on juvenile steelhead migration conditions.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Overall, there would be no biologically meaningful effects H3 on juvenile migration conditions in the Feather River.

Adults

Flows in the Feather River at Thermalito Afterbay (high-flow channel) and at the confluence with the Sacramento River were evaluated during the September through March adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). e Flows in the high-flow channel under H3 would generally be similar to or greater than flows under NAA, except during September, in which flows would be up to 42% lower depending on water year type. These flow reductions would be isolated and would, therefore, not have a biologically meaningful effect on adult steelhead migration conditions. Flows in the Feather River at the confluence with the Sacramento River under H3 would generally be similar to or greater than flows under NAA, except during September, in which flows would be up to 27% lower depending on water year type. These flow reductions would be isolated and would, therefore, not have a biologically meaningful effect on adult steelhead migration conditions.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period

(Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Kelts

Flows in the Feather River at the Thermalito Afterbay and at the confluence with the Sacramento River were evaluated during the March and April kelt migration period. Flows at Thermalito under H3 during March and April would generally be similar to or up to 54% greater than flows under NAA. Flows at the confluence with the Sacramento River would generally be similar to or up to 14% greater than flows under NAA. These results indicate that H3 would not affect kelt steelhead migration conditions in the Feather River.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Overall in the Feather River, H3 would not have biologically meaningful effects on juvenile, adult, or kelt steelhead migration.

American River

Juveniles

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for the juvenile steelhead migration period (October through May). Flows under H3 would generally be similar to flows under NAA, except during November, in which flows would be up to 8% lower depending on water year type, and during May, in which flows would be up to 24% greater depending on water year type. Increases and decreases would be too rare to have biologically meaningful effects on juvenile steelhead migration.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Based on generally negligible effects or increases in mean monthly flow and negligible effects on water temperature, effects of H3 on flows would not affect juvenile steelhead migration in the American River.

Adults

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for the September through March adult migration period. Flows would generally be similar to flows under NAA, except during September and November, in which flows would be up to 18% lower depending on month and water year type.

These reductions would be too rare to cause biologically meaningful effects on adult steelhead migration.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Kelts

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for the March through April kelt migration period. Flows under H3 would generally be similar to flows under NAA during this period, except for small reductions in flows in dry and critical years during March (5% to 6% lower).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Overall in the American River, the effects of H3 on flows would not affect juvenile, adult, or kelt migration conditions.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River for H3 are not different from flows under NAA for any month. Therefore, there would be no effect of H3 on juvenile, adult, or kelt migration in the Stanislaus River.

Further, mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River for H3 are not different from flows under NAA for any month. Therefore, there would be no effect of H3 on juvenile, adult, or kelt migration in the Stanislaus River.

San Joaquin River

Flows in the San Joaquin River at Vernalis for H3 are not different from flows under NAA for any month. Therefore, there would be no effect of H3 on juvenile, adult, or kelt migration in the San Joaquin River.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta for H3 are not different from flows under NAA for any month. Therefore, there would be no effect of H3 on juvenile, adult, or kelt migration in the Mokelumne River.

Water temperature modeling was not conducted in the Mokelumne River.

H1/LOS

Sacramento River

Juveniles

Flows under H1 in the Sacramento River upstream of Red Bluff during the October through May juvenile steelhead migration period would generally be similar to flows under H3, except during November, in which flows would be up to 12% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This reduction would not occur at a high enough frequency to have a meaningful effect on juvenile steelhead migration habitat.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Overall, results for H1 would be similar to those for H3.

Adults

Flows under H1 in the Sacramento River upstream of Red Bluff during the September through March adult steelhead migration period would generally be similar to flows under H3, except during November, in which flows would be up to 12% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. This reduction would not occur at a high enough frequency to have a meaningful effect on juvenile steelhead migration habitat.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

Kelts

Flows under H1 in the Sacramento River upstream of Red Bluff during the March through April adult steelhead migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows under H1 in Clear Creek at Whiskeytown during the October through May juvenile migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H1 would be similar to those for H3.

Adults

Flows under H1 in Clear Creek at Whiskeytown during the September through March adult migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H1 would be similar to those for H3.

Kelts

Flows under H1 in Clear Creek at Whiskeytown during the March through April kelt migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H1 would be similar to those for H3.

Feather River

Juveniles

Flows under H1 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

Adults

Flows under H1 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the September through March adult migration period would generally be similar to or greater than flows under H3, except during September, in which flows would be up to 83% lower depending on water year type and location (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Although large, these flow reductions would not have biologically meaningful effects because they occur in only one of seven months.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

Kelts

Flows under H1 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

American River

Juveniles

Flows under H1 in the American River at the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to flows under H3 with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

Adults

Flows under H1 in the American River at the confluence with the Sacramento River during the September through March adult migration period would generally be similar to flows under H3 with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

Kelts

Flows under H1 in the American River at the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to flows under H3 with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results* *utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River for H1 are not different from flows under NAA for any month. Therefore, there would be no effect of H1on juvenile, adult, or kelt migration in the Stanislaus River.

Further, mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River for H1 are not different from flows under NAA for any month. Therefore, there would be no effect of H1 on juvenile, adult, or kelt migration in the Stanislaus River.

San Joaquin River

Flows in the San Joaquin River at Vernalis for H1 are not different from flows under NAA for any month. Therefore, there would be no effect of H1 on juvenile, adult, or kelt migration in the San Joaquin River.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta for H1 are not different from flows under NAA for any month. Therefore, there would be no effect of H1 on juvenile, adult, or kelt migration in the Mokelumne River.

Water temperature modeling was not conducted in the Mokelumne River.

H4/HOS

Sacramento River

Juveniles

Flows under H4 in the Sacramento River upstream of Red Bluff during the October through May juvenile steelhead migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall, results for H4 would be similar to those for H3.

Adults

Flows under H4 in the Sacramento River upstream of Red Bluff during the September through March adult steelhead migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

Kelts

Flows under H4 in the Sacramento River upstream of Red Bluff during the March through April adult steelhead migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows under H4 in Clear Creek at Whiskeytown during the October through May juvenile migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H4 would be similar to those for H3.

Adults

Flows under H4 in Clear Creek at Whiskeytown during the September through March adult migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H4 would be similar to those for H3.

Kelts

Flows under H4 in Clear Creek at Whiskeytown during the March through April kelt migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H4 would be similar to those for H3.

Feather River

Juveniles

Flows under H4 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to or greater than flows under H3, except during October, in which flows would be up to 27% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

These flow reductions would not cause biologically meaningful effects on juvenile steelhead migration conditions because they occur during only one of eight months during the period.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

Adults

Flows under H4 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the September through March adult migration period would generally be similar to flows under H3, except during September and October, in which flows would be up to 32% lower depending on water year type and location (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These flow reductions would be high enough and would occur at a high enough frequency to have biologically meaningful effects on adult migration conditions.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall results for H4 would be worse for adult migration conditions than those for H3.

Kelts

Flows under H4 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

American River

Juveniles

Flows under H4 in the American River at the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to flows under H3, except during October in which flows would be up to 13% lower under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be large or frequent enough to have biologically meaningful effects on juvenile steelhead migration conditions.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

Adults

Flows under H4 in the American River at the confluence with the Sacramento River during the September through March adult migration period would generally be similar to flows under H3, except during October in which flows would be up to 13% lower under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be large or frequent enough to have biologically meaningful effects on adult steelhead migration conditions.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

Kelts

Flows under H4 in the American River at the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River for H4 are not different from flows under NAA for any month. Therefore, there would be no effect of H4 on juvenile, adult, or kelt migration in the Stanislaus River.

Further, mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River for H4 are not different from flows under NAA for any month. Therefore, there would be no effect of H4 on juvenile, adult, or kelt migration in the Stanislaus River.

San Joaquin River

Flows in the San Joaquin River at Vernalis for H4 are not different from flows under NAA for any month. Therefore, there would be no effect of H4 on juvenile, adult, or kelt migration in the San Joaquin River.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta for H4 are not different from flows under NAA for any month. Therefore, there would be no effect of H4 on juvenile, adult, or kelt migration in the Mokelumne River.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Sacramento River

Juveniles

Alternative 4 operations would generally reduce OMR reverse flows under all flow scenarios, with a corresponding increase in net positive downstream flows, during the outmigration period of steelhead through the interior Delta channels (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Conditions under Scenario H4 would further improve overall average OMR flows relative to other flow scenarios under Alternative 4. These improved net positive downstream flows would be substantial benefits of the proposed operations.

Predation at the north Delta would be increased due to the construction of the proposed SWP/CVP water export facilities on the Sacramento River. It is assumed that per capita steelhead predation losses would be similar to those predicted for spring-run Chinook salmon, although slightly reduced because of the larger size of steelhead outmigrants. Bioenergetics modeling with a median predator density of 0.12 predators per foot (0.39 predators per meter) of intake predicts a predation loss of about 0.2% of the juvenile spring-run population (Table 11-4-26).

Based on DPM results for Chinook salmon (Impact 42 for Alternative 4), steelhead survival would not be expected to change more than 1% under Alternative 4. Also, steelhead juveniles are larger than Chinook salmon juveniles in general, and therefore would be less vulnerable to predation during migration. Therefore the effect on juvenile steelhead outmigration success through the Delta under Alternative 4 would not be adverse.

Adults

The upstream adult steelhead migration occurs from September–March, peaking during December-February. The steelhead kelt downstream migration occurs from January–April. The proportion of Sacramento River water in the Delta under Alternative 4 would to be similar (<10% difference) to NAA throughout the adult steelhead upstream migration (Table 11-4-89). Under Alternative 4 Scenario H3 Sacramento River flows at Rio Vista would be reduced, but the effect would similar or improved relative to Alternative 1A's effects (Impact AQUA-96) in all months of the adult upstream migration and kelt downstream migration periods, except in October. Rio Vista flows would be similar between all the flow scenarios under Alternative 4 from October–March. However, in September, average flows under Scenario H4 at Rio Vista would be 46% less compared to Scenario H3 and 67% less compared to NAA. Because the effect under Alternative 1A would not be adverse, Alternative 4 would also not have an adverse effect on adult and kelt steelhead migration through the Delta.

San Joaquin River

Juveniles

The only changes to San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. There no flow changes associated with the Alternatives. Alternative 4 would have no effect on steelhead migration success through the Delta.

Adults

Alternative 4 Scenario H3 would slightly increase the proportion of San Joaquin River water in the Delta in September through December by 1.1 to 3.9 % (compared to NAA) (Table 11-4-89). The proportion of San Joaquin River water under Scenario H3 would be similar or slightly more than NAA. Conditions under Scenario H4 are expected to reduce the magnitude of this effect because it would involve fewer exports from the north Delta compared to Scenario H3 and the LOS.

Table 11-4-89. Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Adult Steelhead Migration Period for Alternative 4

Month	EXISTING CONDITIONS	NAA	A4	EXISTING CONDITIONS vs. A4	NAA vs. A4
Sacramento River					
September	60	65	63	3	-2
October	60	68	67	7	-1
November	60	66	63	3	-3
December	67	66	66	-1	0
January	76	75	73	-3	-2
February	75	72	68	-7	-4
March	78	76	68	-10	-8
San Joaquin River					
September	0.3	0.1	1.2	0.9	1.1
October	0.2	0.3	3.3	3.1	3
November	0.4	1.0	4.9	4.5	3.9
December	0.9	1.0	2.9	2	1.9
January	1.6	1.7	3.1	1.5	1.4
February	1.4	1.5	3.4	2	1.9
March	2.6	2.8	5.5	2.9	2.7
	Shading indicates 10% or greater absolute difference.				

NEPA Effects: Upstream of the Delta, these results indicate that the effect is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. Effects of Alternative 4 in all locations analyzed would consist primarily of negligible effects on mean monthly flow and water temperatures for the juvenile, adult, and kelt migration periods. Effects of Alternative 4 on upstream water temperatures would also be negligible.

Near-field effects of Alternative 4 NDD on Sacramento River steelhead related to impingement and predation associated with three new intake structures could result in negative effects on juvenile migrating steelhead, although there is high uncertainty regarding the overall effects. It is expected that the level of near-field impacts would be directly correlated to the number of new intake structures in the river and thus the level of impacts associated with 3 new intakes would be considerably lower than those expected from having 5 new intakes in the river. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to more significant effects (~ 12% mortality above current baseline levels). CM15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction surveys to better understand how to minimize losses associated with the three new intake structures will be implemented as part of the final NDD screen design effort. Alternative 4 also includes an Adaptive Management Program and Real-Time Operational Decision-Making Process to evaluate and make limited adjustments intended to provide adequate migration conditions for steelhead. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

Two recent studies (Newman 2003 and Perry 2010) indicate that far-field effects associated with the new intakes could cause a reduction in smolt survival in the Sacramento River downstream of the NDD intakes due to reduced flows in this area. The analyses of other elements of Alternative 4 predict improvements in smolt condition and survival associated with increased access to the Yolo Bypass, reduced interior Delta entry, and reduced south Delta entrainment. The overall magnitude of each of these factors and how they might interact and/or offset each other in affecting salmonid survival through the plan area is uncertain, and remains an area of active investigation for the BDCP.

The DPM is a flow-based model being developed for BDCP which attempts to combine the effects of all of these elements of BDCP operations and conservation measures to predict smolt migration survival throughout the entire Plan Area. The current draft of this model predicts that smolt migration survival under Alternative 4 would be similar to those estimated for NAA. Further refinement and testing of the DPM, along with several ongoing and planned studies related to salmonid survival at and downstream of, the NDD are expected to be completed in the foreseeable future. These efforts are expected to improve our understanding of the relationships and interactions among the various factors affecting salmonid survival, and reduce the uncertainty around the potential effects of BDCP implementation on migration conditions for steelhead. However, until these efforts are completed and their results are fully analyzed, the overall cumulative effect of Alternative 4 on steelhead migration remains uncertain.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of migration habitat for steelhead would not be reduced relative to Existing Conditions.

Upstream of the Delta

H3/ESO

Sacramento River

Juveniles

Flows in the Sacramento River just upstream of Red Bluff Diversion Dam were evaluated for the juvenile migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in* *the Fish Analysis*). Effects of H3 compared to Existing Conditions consist primarily of negligible effects (<5%) during October through May, with small increases (to 15%) or decreases (to -17%) in flow. Increases would have a beneficial effect on migration conditions and decreases would be infrequent, would be of greatest magnitude in wetter water years when effects on migration conditions would be less critical, and therefore are not expected to have biologically meaningful negative effects on migration conditions.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in all months but October, in which temperatures under H3 would be 6% greater than those under Existing Conditions.

Adults

Flows during the adult migration period (September through March) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) would be as described for that portion of the juvenile migration period immediately above with the addition of September. Effects of H3 in September consist of substantial increases in mean monthly flow in wet (39%) and above normal (55%) years, small decreases in below normal (-11%) and dry years (to -14%), and negligible effects in critical years. These effects would not alter the conclusion of no biologically meaningful negative effects for the entire migration period of September through March.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in all months except September and October, in which temperatures under H3 would be 6% greater than those under Existing Conditions.

Kelts

Effects of H3 on flows during the kelt migration period of March and April consist primarily of negligible effects (<5%), with infrequent, small increases (to 6%) and a single decrease in flow (-10%) during March in below normal water years that would not have biologically meaningful effects on migration conditions. These results indicate that effects of H3 on flows would not affect kelt migration in the Sacramento River at Red Bluff.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period.

Overall in the Sacramento River, the effects of H3 on flows would not affect juvenile, adult, or kelt steelhead migration.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows in Clear Creek were evaluated for the juvenile migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Effects of H3 compared to Existing Conditions consist primarily of negligible effects (<5%) for October through May or small increases (to 10%) in flow and a single, small decrease (-6% during October in critical years) in mean monthly flow that would not have biologically meaningful effects on migration conditions, with the exception of more substantial increases in mean monthly flows during January through March in wet years (to 54%) which would have beneficial effects on migration conditions. As discussed for effects of H3 on rearing conditions in Clear Creek above, no water temperature modeling was conducted in Clear Creek.

Adults

Effects of H3 on flows in Clear Creek during the adult migration period (September through March) would be as described for that portion of the juvenile migration period immediately above with the addition of September. Effects of H3 in September consist of negligible effects for all water year types except for a decrease in mean monthly flow in critical years of -28%. Based on the limited occurrence of this flow reduction, overall effects of H3 on flows would not have biologically meaningful effects on adult migration conditions. No water temperature modeling was conducted in Clear Creek.

Kelts

Effects of H3 on flows during the kelt migration period of March and April consist of negligible effects (<5%) or infrequent, small to moderate increases in mean monthly flow (to 29%) that would not affect migration conditions.

Overall in Clear Creek, the effects of H3 on flows would not affect juvenile, adult, or kelt steelhead migration.

Feather River

Juveniles

Flows in the Feather River above the Thermalito Afterbay (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were evaluated for the juvenile migration period (October through May). Effects of H3 compared to Existing Conditions consist of primarily increases in mean monthly flow for most water years during October (7% to 33%), critical years during January (18%), wet years during February (31%), wetter water years during March (12% and 22%), and drier water years during April (18% to 58%). Effects of H3 consist primarily of decreases in mean monthly flow during October and November in wet (to -27%) and below normal years (-9%), most water years in December (-38% in wet years, to -7% in drier water years), most water years during January and February (to -46%, with maximum reduction in below normal years), and another substantial reduction (-53%) during March in below normal years. Overall, the decreases in flows during drier water year types for a substantial portion of the juvenile migration period would have biologically meaningful effects on juvenile migration for this location.

Flows in the Feather River at the confluence with the Sacramento River were evaluated for the juvenile migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Effects of H3 compared to Existing Conditions consist of primarily increases in mean monthly flow during October (6% to 30%), during January through March in wetter water years (7% to 20%), and during April and May in drier water years (to 18%). There would be negligible effects (<5%) or decreases in mean monthly flow during November and December in wet years (to -20%), during January through March in below normal years (to -20%), and during May in wet years (-26%). Effects in drier water years would be most critical for migration conditions and would include negligible effects and relatively small increases (to 18%) or decreases (to -20%) in flow with no persistent trend throughout the migration period with the exception of small to moderate reductions during most months in below normal water years that would have negative effects on juvenile migration conditions at this location for that specific water year type.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in all months except November and December, in which temperatures under H3 would be 5% greater than temperatures under Existing Conditions.

Adults

Effects of H3 on flows in the Feather River above the Thermalito Afterbay during the adult migration period (September through March) would be as described for that portion of the juvenile migration period immediately above with the addition of September. Effects of H3 in September consist of substantial increases in mean monthly flow during wet (209%), above normal (128%) and critical (15%) years, and decreases during below normal (-27%) and dry (-46%) years. The substantial reductions in flows during drier water years would have biologically meaningful effects on migration conditions during September through March. Increases in flow in wet years are substantial (128 to 208%) and effects on migration would be positive. Effects of H3 on water temperatures were evaluated for adult migration conditions.

Effects of H3 on flows in the Feather River at the confluence during the adult migration period (September through March) would be as described for that portion of the juvenile migration period immediately above with the addition of September. Effects of H3 in September consist of variable effects depending on water year type with increases in mean monthly flow during wet (108%), above normal (68%), and critical (12%) years, and decreases during below normal (-18%) and dry (-28%) years. Effects of these substantial increases on flows in wetter water years (108%, 68%) would be beneficial. Effects of the reductions in flows for some drier water years would contribute incremental negative effects for the adult migration period and would have negative effects on migration condition in below normal water years.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in all months except November and December, in which temperatures under H3 would be 5% greater than temperatures under Existing Conditions.

These results indicate the effects of H3 on water temperatures in the Feather River would have negative effects on juvenile and adult migration conditions that could affect survival.

Kelts

Effects of H3 on flows during the kelt migration period of March and April consist of primarily negligible effects (<5%) or increases in mean monthly flow (to 58%) with the exception of a single decrease in flow during March in below normal years (-53%), that would occur following equally substantial flow reductions in below normal years during January and February. This negative effect would be partially offset by a substantial increase in flow during April in below normal years (43%) but could substantially affect migration conditions for the first half of the relatively short migration period for that water year type. Overall this effect is not expected to have biologically meaningful negative effects on kelt migration success. Effects of H3 on flows during the kelt migration period of March and April consist of primarily negligible effects (<5%) and increases in mean monthly flow (to 13%) with the exception of a single, moderate decrease (-20%) in below normal years that would not have biologically meaningful effects on kelt migration conditions.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period.

Overall in the Feather River, the effect of H3 on flows would consist of persistent and/or substantial reductions in flows during drier water years, and increased exposure to critical water temperatures, that would affect juvenile and adult migration conditions, particularly in drier water years, and would generally not affect kelt migration.

American River

Juveniles

Flows in the American River at the confluence with the Sacramento River were evaluated for the juvenile migration period (October through May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Effects of H3 compared to Existing Conditions consist of primarily increases in mean monthly flow during October (to 26%), wetter water years during January (to 25%), and all but critical years during February and March (to 27%). There would be reductions in flow for most/all water year types during November (to -33%), December (to -25%), drier water years during January (to -19%), critical years during February and March (to -15%), and all but dry years during May (to -31%). Flow reductions during most of the migration period in drier water year types would have biologically meaningful effects on juvenile migration.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 5% to 11% lower than those under Existing Conditions in all months during the period except December and April, in which there would be no difference in water temperatures between Existing Conditions and H3.

Adults

Effects of H3 on flows in the American River during the adult migration period (September through March) would be as described for that portion of the juvenile migration period immediately above with the addition of September. Effects of H3 in September consist of substantial decreases in mean monthly flow during all water year types ranging from -25% to -33%. This combined with the conclusions for the rest of the migration period described above as part of the juvenile migration period indicates that effects of H3 on flow reductions during most of the migration period in drier water year types would have biologically meaningful effects on adult migration. Effects of H3 on water temperatures were evaluated for adult migration conditions.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 5% to 11% lower than those under Existing Conditions in all months during the period except December, in which there would be no difference in water temperatures between Existing Conditions and H3.

Kelts

Effects of H3 on flows during the kelt migration period of March and April consist primarily of relatively small increases (to 16%) and decreases (to -9%) in flow that would tend to balance out effects during the kelt migration period and would not result in biologically meaningful negative effects.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 5% higher than those under Existing Conditions in March but temperatures would be similar between Existing Conditions and H3 during April.

Overall in the American River, the impacts of H3 on flows would affect juvenile and adult migration conditions and would negatively affect kelt migration conditions.

Stanislaus River

Juveniles

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be 6% to 16% lower than flows under Existing Conditions depending on month except during January, in which there would be no difference.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the October through May steelhead juvenile downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 6% higher than those under Existing Conditions in all months during the period except October, in which temperature would be similar between Existing Conditions and H3.

Adults

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be 6% to 16% lower than flows under Existing Conditions depending on month, except during January, in which there would be no differences.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 6% higher than those under Existing Conditions in all months during the period except October, in which temperature would be similar between Existing Conditions and H3.

Kelt

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be 8% to 11% lower than flows under Existing Conditions during March and April, respectively.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 6% higher than those under Existing Conditions during March and April.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Juveniles

Flows in the San Joaquin River at Vernalis were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would 5% greater than flows under Existing Conditions during January, and similar in the remaining 7 months of the period.

Adults

Flows in the San Joaquin River at Vernalis were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would 5% greater than flows under Existing Conditions during January, 8% lower during September, and similar in the remaining 5 months of the period.

Kelt

Flows in the San Joaquin River at Vernalis were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 similar to flows under Existing Conditions in both March and April.

Mokelumne River

Water temperature modeling was not conducted in the Mokelumne River.

Juveniles

Flows in the Mokelumne River at Delta were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be similar to flows under Existing Conditions during October and March, 8% to 12% lower than flows under Existing Conditions during November, April, and May, and 12% to 14% higher than flows under Existing Conditions during December through February.

Adults

Flows in the Mokelumne River at Delta were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be similar to flows under Existing Conditions during October and March, 9% to 27% lower than flows under Existing Conditions during September and November, and 12% to 14% higher than flows under Existing Conditions during December through February.

Kelt

Flows in the Mokelumne River at Delta were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H3 would be similar to flows under Existing Conditions during March and 8% lower during April.

H1/LOS

Sacramento River

Juveniles

Flows under H1 in the Sacramento River upstream of Red Bluff during the October through May juvenile steelhead migration period would generally be similar to flows under H3, except during November, in which flows would be up to 12% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. This reduction would not occur at a high enough frequency to have a meaningful effect on juvenile steelhead migration habitat.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in all months but October, in which temperatures under H1 would be 5% greater than those under Existing Conditions.

Overall, results for H1 would be similar to those for H3.

Adults

Flows under H1 in the Sacramento River upstream of Red Bluff during the September through March adult steelhead migration period would generally be similar to flows under H3, except during November, in which flows would be up to 12% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This reduction would not occur at a high enough frequency to have a meaningful effect on juvenile steelhead migration habitat.

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in all months except September and October, in which temperatures under H1 would be 5% greater than those under Existing Conditions.

Overall results for H1 would be similar to those for H3.

Kelts

Flows under H1 in the Sacramento River upstream of Red Bluff during the March through April adult steelhead migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows under H1 in Clear Creek at Whiskeytown during the October through May juvenile migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H1 would be similar to those for H3.

Adults

Flows under H1 in Clear Creek at Whiskeytown during the September through March adult migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H1 would be similar to those for H3.

Kelts

Flows under H1 in Clear Creek at Whiskeytown during the March through April kelt migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H1 would be similar to those for H3.

Feather River

Juveniles

Flows under H1 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in all months except December, in which temperatures under H1 would be 5% greater than temperatures under Existing Conditions.

Overall results for H1 would be similar to those for H3.

Adults

Flows under H1 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the September through March adult migration period would generally be similar to or greater than flows under H3, except during September, in which flows would be up to 83% lower depending on water year type and location (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Although large, these flow reductions would not have biologically meaningful effects because they occur in only one of seven months.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in all months except September and December, in which temperatures under H1 would be 5% greater than temperatures under Existing Conditions.

Overall results for H1 would be similar to those for H3.

Kelts

Flows under H1 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period.

Overall results for H1 would be similar to those for H3.

American River

Juveniles

Flows under H1 in the American River at the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to flows under H3 with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1would be 5% to 10% lower than those under Existing Conditions in all months during the period except April, in which there would be no difference in water temperatures between Existing Conditions and H1.

Overall results for H1 would be similar to those for H3.

Adults

Flows under H1 in the American River at the confluence with the Sacramento River during the September through March adult migration period would generally be similar to flows under H3 with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 5% to 10% lower than those under Existing Conditions in all months during the period.

Overall results for H1 would be similar to those for H3.

Kelts

Flows under H1 in the American River at the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to flows under H3 with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 5% higher than those under Existing Conditions in March but temperatures would be similar between Existing Conditions and H1 during April.

Overall results for H1 would be similar to those for H3.

Stanislaus River

Juveniles

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be 6% to 16% lower than flows under Existing Conditions depending on month except during January, in which there would be no difference.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the October through May steelhead juvenile downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 6% higher than those under Existing Conditions in all months during the period except October, in which temperature would be similar between Existing Conditions and H1.

Adults

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be 6% to 16% lower than flows under Existing Conditions depending on month, except during January, in which there would be no differences.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 6% higher than those under Existing Conditions in all months during the period except October, in which temperature would be similar between Existing Conditions and H1.

Kelt

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be 8% to 11% lower than flows under Existing Conditions during March and April, respectively.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 6% higher than those under Existing Conditions during March and April.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Juveniles

Flows in the San Joaquin River at Vernalis were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would 5% greater than flows under Existing Conditions during January, 5% lower during October, and similar in the remaining 6 months of the period.

Adults

Flows in the San Joaquin River at Vernalis were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would 5% greater than flows under Existing Conditions during January, 8% lower during September, and similar in the remaining 5 months of the period.

Kelt

Flows in the San Joaquin River at Vernalis were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 similar to flows under Existing Conditions in both March and April.

Mokelumne River

Water temperature modeling was not conducted in the Mokelumne River.

Juveniles

Flows in the Mokelumne River at Delta were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be similar to flows under Existing Conditions during October and March, 8% to 12% lower than flows under Existing Conditions during November, April, and May, and 12% to 14% higher than flows under Existing Conditions during December through February.

Adults

Flows in the Mokelumne River at Delta were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be similar to flows under Existing Conditions during October and March, 10% to 27% lower than flows under Existing Conditions during September and November, and 12% to 14% higher than flows under Existing Conditions during December through February.

Kelt

Flows in the Mokelumne River at Delta were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H1 would be similar to flows under Existing Conditions during March and 8% lower during April.

H4/HOS

Sacramento River

Juveniles

Flows under H4 in the Sacramento River upstream of Red Bluff during the October through May juvenile steelhead migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). \

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in all months but October, in which temperatures under H4 would be 5% greater than those under Existing Conditions.

Overall, results for H4 would be similar to those for H3.

Adults

Flows under H4 in the Sacramento River upstream of Red Bluff during the September through March adult steelhead migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in all months except October, in which temperatures under H4 would be 5% greater than those under Existing Conditions.

Overall results for H4 would be similar to those for H3.

Kelts

Flows under H4 in the Sacramento River upstream of Red Bluff during the March through April adult steelhead migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Juveniles

Flows under H4 in Clear Creek at Whiskeytown during the October through May juvenile migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H4 would be similar to those for H3.

Adults

Flows under H4 in Clear Creek at Whiskeytown during the September through March adult migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H4 would be similar to those for H3.

Kelts

Flows under H4 in Clear Creek at Whiskeytown during the March through April kelt migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Overall results for H4 would be similar to those for H3.

Feather River

Juveniles

Flows under H4 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to or greater than flows under H3, except during October, in which flows would be up to 27% lower depending on water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These flow reductions would not cause biologically meaningful effects on juvenile steelhead migration conditions because they occur during only one of eight months during the period.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in all months except October through December, in which temperatures under H4 would be 5% greater than temperatures under Existing Conditions.

Overall results for H4 would be similar to those for H3.

Adults

Flows under H4 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the September through March adult migration period would generally be similar to flows under H3, except during September and October, in which flows would be up to 32% lower depending on water year type and location (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These flow reductions would be high enough and would occur at a high enough frequency to have biologically meaningful effects on adult migration conditions.

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in all months except October through December, in which temperatures under H4 would be 5% greater than temperatures under Existing Conditions.

Overall results for H4 would be worse for adult migration conditions than those for H3.

Kelts

Flows under H4 in the Feather River at Thermalito Afterbay and the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period

(Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month or water year type throughout the period.

Overall results for H4 would be similar to those for H3.

American River

Juveniles

Flows under H4 in the American River at the confluence with the Sacramento River during the October through May juvenile migration period would generally be similar to flows under H3, except during October in which flows would be up to 13% lower under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be large or frequent enough to have biologically meaningful effects on juvenile steelhead migration conditions.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 5% to 11% lower than those under Existing Conditions in all months during the period except April, in which there would be no difference in water temperatures between Existing Conditions and H4.

Overall results for H4 would be similar to those for H3.

Adults

Flows under H4 in the American River at the confluence with the Sacramento River during the September through March adult migration period would generally be similar to flows under H3, except during October in which flows would be up to 13% lower under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be large or frequent enough to have biologically meaningful effects on adult steelhead migration conditions.

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 5% to 11% lower than those under Existing Conditions in all months during the period.

Overall results for H4 would be similar to those for H3.

Kelts

Flows under H4 in the American River at the confluence with the Sacramento River during the March through April kelt migration period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 5% higher than those under Existing Conditions in March but temperatures would be similar between Existing Conditions and H4 during April.

Overall results for H4 would be similar to those for H3.

Stanislaus River

Juveniles

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be 6% to 18% lower than flows under Existing Conditions depending on month, except during January, in which there would be no difference.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the October through May steelhead juvenile downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 6% higher than those under Existing Conditions in all months during the period except October, in which temperature would be similar between Existing Conditions and H4.

Adults

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be 6% to 16% lower than flows under Existing Conditions depending on month, except during January, in which there would be no differences.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 6% higher than those under Existing Conditions in all months during the period except October, in which temperature would be similar between Existing Conditions and H4.

Kelt

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be 8% to 11% lower than flows under Existing Conditions during March and April, respectively.

Mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 6% higher than those under Existing Conditions during March and April.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Juveniles

Flows in the San Joaquin River at Vernalis were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would 6% greater than flows under Existing Conditions during January and similar in the remaining 7 months of the period.

Adults

Flows in the San Joaquin River at Vernalis were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would 6% greater than flows under Existing Conditions during January, 8% lower during September, and similar in the remaining 5 months of the period.

Kelt

Flows in the San Joaquin River at Vernalis were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 similar to flows under Existing Conditions in both March and April.

Mokelumne River

Water temperature modeling was not conducted in the Mokelumne River.

Juveniles

Flows in the Mokelumne River at Delta were evaluated for the October through May steelhead juvenile downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be similar to flows under Existing Conditions during October and March, 8% to 12% lower than flows under Existing Conditions during November, April, and May, and 12% to 14% higher than flows under Existing Conditions during December through February.

Adults

Flows in the Mokelumne River at Delta were evaluated for the September through March steelhead adult upstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be similar to flows under Existing Conditions during October and March, 10% to 27% lower than flows under Existing Conditions during September and November, and 12% to 14% higher than flows under Existing Conditions during December through February.

Kelt

Flows in the Mokelumne River at Delta were evaluated for the March and April steelhead kelt downstream migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Mean monthly flows under H4 would be similar to flows under Existing Conditions during March and 8% lower during April.

Through-Delta

Based on DPM results for Chinook salmon, steelhead survival would not be expected to decrease more than 1%. Assuming similar effects on steelhead, Alternative 4 would have a minimal effect on steelhead migration success through the Delta. Therefore the impact to juvenile steelhead migration through the Delta would be negligible.

The proportion of Sacramento River water in the Delta under Alternative 4 Scenario H3 would be similar to NAA (<10% difference) during the entire adult steelhead upstream migration, except in March when the proportion of Sacramento River flows would be reduced by 10%. The reduction in olfactory cues in March may negatively affect adult steelhead migration conditions, however this month falls outside the peak migration season for this species, thus limiting its potential impact. Conditions between all flow scenarios under Alternative 4 (e.g., Scenarios H1 and H3) would be similar; there would only be small changes in olfactory cues for migrating adult salmon. Rio Vista flows under Scenario H3 would also be similar or improved compared to Alternative 1A for all the months of the adult steelhead upstream and kelt downstream migrations, except October. Flows at Rio Vista under Scenarios H1 and H4 are similar to conditions under Scenario H3 in all months of the steelhead migration period, except in September when flows under Scenario H1 would be very substantially reduced. Due to the overall similarity in olfactory cues and Rio Vista flows between Alternative 1A and Alternative 4 during the entire adult and kelt migration periods, effects on migration success would be expected to be similar to Alternative 1A. Olfactory cues and flows in the San Joaquin River basin would be improved or similar to Alternative 1A and Existing Conditions. Overall, the impact to steelhead adult and kelt migration under Alternative 4 is considered negligible.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-96 CEQA analysis indicate the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially interfere with the movement of fish, contrary to the NEPA conclusion set forth above. Alternative 4 would have negative effects on juvenile and adult migration conditions in drier water years in the Feather River and the American River, and increased occurrence of multi-year critical temperature exceedances would contribute to negative effects in the Feather River. Reduced migration conditions would delay or eliminate successful migration necessary to complete the steelhead life cycle. Alternative 4 would not affect migration conditions for steelhead in the Sacramento River and in Clear Creek. Water temperatures and exceedances of NMFS thresholds where applicable, would be greater in the Feather, American, and Stanislaus Rivers under Alternative 4 relative to the CEQA baseline. There would be no effects on through-Delta migration conditions because changes in juvenile survival and adult olfactory cues would be negligible.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in

the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration habitat for steelhead. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for steelhead under Alternative 1A (Impacts AQUA-97 through AQUA-99) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on steelhead are the same as those described under Alternative 1A (Impacts AQUA-97 through AQUA-99). The effects would not be adverse, and would generally be beneficial. Specifically for AQUA-98, the effects of contaminants on steelhead with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on steelhead are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for steelhead under Alternative 1A (Impacts AQUA-100 through AQUA-108) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (CM12)

Impact AQUA-101: Effects of Invasive Aquatic Vegetation Management on Steelhead (CM13)

Impact AQUA-102: Effects of Dissolved Oxygen Level Management on Steelhead (CM14)

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (CM15)

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (CM16)

Impact AQUA-105: Effects of Illegal Harvest Reduction on Steelhead (CM17)

Impact AQUA-106: Effects of Conservation Hatcheries on Steelhead (CM18)

Impact AQUA-107: Effects of Urban Stormwater Treatment on Steelhead (CM19)

Impact AQUA-108: Effects of Removal/Relocation of Nonproject Diversions on Steelhead (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on steelhead are the same as those described under Alternative 1A (Impacts AQUA-100 through AQUA-108). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

Sacramento Splittail

Construction and Maintenance of CM1

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: The potential effects of construction of the water conveyance facilities on Sacramento splittail would be similar to those described for Alternative 1A, Impact AQUA-109, except Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would 27.3 acres of dredging. As concluded for Alternative 1A, Impact AQUA-109, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-109, the impact of the construction of the water conveyance facilities on splittail would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A, Impact AQUA-110, except that only three intakes would need to be maintained under Alternative 4 rather than five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-110, the impact would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-110, the impact of the maintenance of water conveyance facilities on Sacramento splittail would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Water Exports from SWP/CVP South Delta Facilities

The salvage of splittail is considered an indicator of reproductive success more than of relative impact (Sommer et al. 1997); thus splittail salvage across EIR/EIS alternatives was predicted using a historical relationship between Yolo Bypass inundation and salvage density at CVP and SWP (*BDCP Effects Analysis, Appendix 5B – Entrainment; Section 5B.5.4.5.2*). When averaged across all WY types, estimated entrainment of juvenile splittail at the south Delta facilities would be 385% greater under Scenario H3 compared to NAA (Table 11-4-90). The greatest increase in total entrainment occurred in above normal water years (1,881%). These increases in predicted salvage are caused by the expected increase in overall juvenile splittail abundance resulting from additional floodplain inundation in the wetter year types. The amount of Yolo Bypass inundation was explicitly modeled only for Scenario H3 because Sacramento River flows at the Fremont Weir under the other scenarios (H1,H2, and H4), were similar to or greater than those under Scenario H3. The per capita rate of splittail entrainment, which is an index of entrainment risk of an individual splittail and is directly related to the amount of water exported, averaged across all years would be reduced 38% for juveniles (Table 11-4-91) and 52% for adults (Tables 11-4-92) compared to NAA. Adult entrainment and juvenile per capita entrainment are anticipated to be reduced in all water year types due to lower South Delta exports. Because Sacramento River and OMR flows are higher under the H4 flow scenario for Alternative 4 compared to NAA, this scenario is expected to decrease total and per capita entrainment loss at the south Delta more so than the other flow scenarios (i.e., Scenarios H1-H3).

Table 11-4-90. Juvenile Sacramento Splittail Entrainment Index[a] (Yolo Bypass days of inundation method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 4 (Scenario H3) (See *BDCP Effects Analysis, Appendix 5B – Entrainment, Section 5B.6.1.7.1)*

[a] Estimated annual number of fish lost, based on normalized data. Average (December–March).

Water Exports from SWP/CVP North Delta Intake Facilities

The north Delta intakes would be screened, and all splittail except larvae less than 10 mm long would be excluded from entrainment (*BDCP Effects Analysis – Appendix 5B Entrainment, Section B.6.2.4, hereby incorporated by reference*). The impact of Alternative 4 (3 intakes) is estimated to be lower compared to Alternative 1A (5 intakes), based on number of intakes. Potential impacts would be minimized by project's adaptive management plan, including monitoring of the new screens effectiveness and corrective measures if needed.

Water Export with a Dual Conveyance for the SWP North Bay Aqueduct

The effect of implementing dual conveyance for the NBA with an alternative Sacramento River intake would be the same as described under Alternative 1A (Impact AQUA-111). There would be potential for increased predation and impingement risk associated with the alternative intake. Screens on the Barker Slough pumping plant currently exclude fish greater than 25 mm, and the alternate intake on the Sacramento River would be screened to effectively exclude splittail greater than 10 mm in length (*BDCP Effects Analysis – Appendix 5B Entrainment, Section B.6.2.4, hereby incorporated by reference*). Therefore, for splittail it is concluded that the effect of dual North Bay Aqueduct conveyance would not be adverse.

Predation Associated with Entrainment

Per-capita entrainment-related predation loss of splittail at the south Delta facilities is not expected to be greater under Alternative 4 than the NAA because predicted per capita entrainment is lower due to lower south Delta exports. The predation loss would be lowest under Scenario H4 and highest under Scenarios H1 and H3. However, because predation of entrained splittail is not currently considered to be an important driver of splittail population dynamics, this variation in the predicted impact across Alternative 4 subscenarios, is not considered to be adverse in any of them.

Predation at the north Delta would be increased due to the installation of the proposed water export facilities on the Sacramento River, with three intakes for Alternative 4. These losses would be offset by the reduction in entrainment and predation loss at the SWP/CVP south Delta intakes, and the increased production of juvenile splittail resulting from CM2 (Yolo Bypass Fisheries Enhancement). Further, as described for Alternative 1A, the fishery agencies concluded that the predation was not a factor currently limiting splittail abundance.

NEPA Effects: In conclusion, the effect from entrainment and predation loss under Alternative 4 would not be adverse, because while predation loss of splittail would be potentially increased at the north Delta facilities, it would be offset by substantial reductions in per capita entrainment and associated predation at the south Delta facilities compared to the NAA, and increased production of juvenile splittail from the Yolo Bypass by CM2 (Yolo Bypass Fisheries Enhancement) actions.

CEQA Conclusion: Under Scenario H3 (described above as a conservative scenario relative to entrainment and entrainment-associated predation) total juvenile entrainment (based on Yolo Bypass inundation) would be 474% greater averaged across all years compared to Existing Conditions due to the expected substantially higher juvenile production under Alternative 4 from more floodplain inundation. Operational activities associated with reduced south Delta water exports would result in an overall decrease in the proportion of splittail population entrained for all water year types. For example, under Scenario H3, estimated juvenile entrainment (Per Capita method) and hence pre-screen predation losses would be 49% lower and adult entrainment and pre-screen predation losses would be 53% lower than Existing Conditions. Conditions under Scenario H1 would be similar to Scenario H3. Per capita entrainment and related predation loss at the south Delta would be further reduced under Scenarios H2 and H4 compared to Existing Conditions. Entrainment of splittail would also be reduced at the NBA. The impact and conclusion for predation associated with entrainment would be the same as described above.

In conclusion, the impact of Alternative 4 from entrainment and predation loss would be beneficial because of improvements in overall proportional entrainment, and no mitigation is required.

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

Sacramento splittail spawn in floodplains and channel margins and in side-channel habitat upstream of the Delta, primarily in the Sacramento River and Feather River. Floodplain spawning overwhelmingly dominates production in wet years. During low-flow years when floodplains are not inundated, spawning in side channels and channel margins would be much more critical.

In general, Alternative 4 would have beneficial effects on splittail spawning habitat relative to the NAA by increasing the quantity and quality of spawning habitat in the Yolo Bypass. There would be negligible effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River, with beneficial effects from moderate to substantial increases in mean monthly flow for some months and water year types for each location. There would be negligible negative effects on water temperatures in the Feather River and a beneficial effect from a decrease in exposure to critical high water temperatures.

H3/ESO

Floodplain Habitat

Effects of H3 on floodplain spawning habitat were evaluated for Yolo Bypass. Effects in Yolo Bypass were evaluated using a habitat suitability approach based on water depth (2 m threshold) and inundation duration (minimum of 30 days). Effects of flow velocity were ignored because flow velocity was generally very low throughout the modeled area for most conditions, with generally 80 to 90% of the total available area having flow velocities of 0.5 foot per second or less (a reasonable critical velocity for early life stages of splittail; Young and Cech 1996), and because habitat heterogeneity in the flooded Yolo Bypass is high (Sommer et al. 2004; 2005).

There would be three fewer 30–49 day events and one fewer in above normal years under H3 than under NAA, but four more events under H3 in below normal years, and one more event in dry and critical years categories (Table 11-4-93). There would be five fewer 50–69 day events under H3 than under NAA in wet years, one more event in above normal and below normal water years, and no difference in dry and critical years. And there would be seven, one, and one more >70 day inundation events under H3 relative to NAA in wet, above normal, and below normal water years, respectively, and no difference in dry and critical water years. These results indicate that overall project-related effects on occurrence of duration inundation events would benefit splittail spawning by increasing the occurrence of longer duration inundation events. The reduction in the frequency of 50-69 day events in wet years is misleading because it is due to the extension of duration of inundation, which results in the increased frequency of >70 day inundation events. In some cases, two 50-69 day events were combined into one >70 day event as a result of their extended durations. The >70 day inundation events likely contribute disproportionately to splittail production.

In terms of acreage of suitable splittail habitat in Yolo Bypass, there would be substantial increases in suitable spawning habitat acreages for H3 compared to NAA for all water year types (Table 11-4-94). Increases range from 5 to 832 acres. For wet, above normal, and below normal water years there would be project-related increases of 49%, 56%, and 192%, respectively. The increases in dry and critical years (7 and 5 acres, respectively) would establish small areas of suitable spawning habitat during these water year types compared to no suitable habitat under NAA. These results indicate that increases in inundated acreage in each water year type would result in increased habitat and have a beneficial effect on splittail spawning.

Table 11-4-93. Differences in Frequencies of Inundation Events (for 82-Year Simulations) of Different Durations on the Yolo Bypass under Different Scenarios and Water Year Types, February through June, from 15 2-D and Daily CALSIM II Modeling Runs

Number of Days of Continuous Inundation	Change in Number of Inundation Events for Each Scenario

Critical	0	0

Table 11-4-94. Increase in Splittail Weighted Habitat Area (acres and percent) in Yolo Bypass from Existing Biological Conditions to Alternative 4 by Water Year Type from 15 2-D and Daily CALSIM II Modeling Runs

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	979 (64%)	832 (49%)
Above Normal	690 (62%)	644 (56%)
Below Normal	244 (193%)	244 (193%)
Dry	7 (NA[a])	7 (NA[a])
Critical	5 (NA[a])	5 (NA[a])

[a] NA percent differences could not be computed because no splittail weighted habitat occurred in the bypass for NAA and Existing Conditions in those years (dividing by 0).

A potential effect of Alternative 4 is changes in inundation of the Sutter Bypass as a result of increased flow diversion at the Fremont Weir. The Fremont Weir notch with gates opened would increase the amount Sacramento River flow diverted from the river into the bypass when the river's flow is greater than about 14,600 cfs (Munévar pers. comm.). As much as about 6,000 cfs more flow would be diverted from the river with the opened notch than without the notch, resulting in a 6,000 cfs decrease in Sacramento River flow at the weir. A decrease of 6,000 cfs in the river, according to rating curves developed for the river at the Fremont Weir, could result in as much as 3 feet of reduction in river stage (Munévar pers. comm.), although understanding of how notch flows would affect river stage is incomplete (Kirkland pers. comm.). In any case, an analysis was conducted to determine whether there would be effects to the Sutter Bypass. Daily average inundated surface in the lower Sutter Bypass during December through June was estimated area for all scenarios. The analysis predicts that there would be very little differences between NAA and H3 in daily average inundation (Table 11-4-95). Therefore, H3 would not affect splittail spawning and rearing habitat in the Sutter Bypass.

Table 11-4-95. Differences (and Percent Change) in Daily Average (December–June) Lower Sutter Bypass Inundation (acres)

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-83 (-3.5)	13 (0.6)
Above Normal	49 (3.7)	42 (3.1)
Below Normal	-37 (-11.0)	6 (2.0)
Dry	-12 (-8.7)	-3 (-2.5)
Critical	1 (5.3)	0 (0.8)
All	1 (0.1)	0 (0)

Channel Margin and Side-Channel Habitat

Splittail spawning and larval and juvenile rearing also occur in channel margin and side-channel habitat upstream of the Delta. These habitats are likely to be especially important during dry years, when flows are too low to inundate the floodplains (Sommer et al. 2007). Side-channel habitats are affected by changes in flow because greater flows cause more flooding, thereby increasing availability of such habitat, and because rapid reductions in flow dewater the habitats, potentially stranding splittail eggs and rearing larvae. Effects of the BDCP on flows in years with low-flows are expected to be most important to the splittail population because in years of high-flows, when most production comes from floodplain habitats, the upstream side-channel habitats contribute relatively little production.

Effects on channel margin and side-channel habitat were evaluated by comparing flow conditions for the Sacramento River at Wilkins Slough and the Feather River at the confluence with the Sacramento River for the time-frame February through June. These are the most important months for splittail spawning and larval rearing (Sommer pers. comm.), and juveniles likely emigrate from the side-channel habitats during May and June if conditions become unfavorable.

Differences between model scenarios for monthly average flows during February through June by water-year type were determined for the Sacramento River at Wilkins Slough and for the Feather River at the confluence.

Flow comparisons of H3 to Existing Conditions in the Sacramento River at Wilkins Slough (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for February through June, indicate that H3 would have primarily negligible effects (<5%) or increases in monthly flow (to 39%), with the exception of a decrease in flow (-6%) during March in below normal years and a large decrease (-16%) during May in wet years when effects of flow reductions on rearing conditions would be less critical. These decreases in flow may reduce spawning success of splittail in wet water years. Flows during May and June would be up to 23% greater than flows under NAA depending on water year type. These increased flows would have beneficial effects on splittail. Modeling results also show that Sacramento splittail spawning temperature tolerances would not be exceeded in the Sacramento River under Alternative 4.

Flows in the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) during February through June would follow similar patterns to those of the Sacramento River at Wilkins Slough. Flows under H3 would generally be similar to or greater than flows under NAA. Flows under H3 during April, May, and June would be up to 65% greater than flows under NAA, which is a beneficial effect to splittail.

Simulated daily and monthly water temperatures in Sacramento River at Hamilton City and Feather River at the confluence with the Sacramento River, respectively, were used to investigate the potential effects of H3 on the suitability of water temperatures for splittail spawning and egg incubation. A range of 45°F to 75°F was selected as the suitable range for splittail spawning and egg incubation.

There would be no biologically meaningful difference (>5% absolute scale) between NAA and H3 in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F regardless of water year type (Table 11-4-96). In the Feather River, there would be differences between NAA and H3 in temperatures below 45°F. There would be a 7% and 6% reduction in the exceedance above the 75°F threshold for above and below normal water years, respectively, but no other differences.

Table 11-4-96. Difference (Percent Difference) in Percent of Days or Months[a] during February to June in Which Temperature Would Be below 45°F or above 75°F in the Sacramento River at Hamilton City and Feather River at the Confluence with the Sacramento River[b]

	EXISTING CONDITIONS vs. H3	NAA vs. H3
Sacramento River at Hamilton City		
Temperatures below 45°F		
Wet	-3.5 (-75%)	0 (0%)

Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)
Temperatures above 75°F		
Wet	14.6 (475%)	0 (0%)
Above Normal	10.9 (NA)	-7.3 (-40%)
Below Normal	20 (NA)	-5.7 (-22%)
Dry	27.8 (626%)	-1.1 (-3%)
Critical	25 (250%)	0 (0%)
All	19.5 (564%)	-2.2 (-9%)

NA = could not be calculated because the denominator was 0.

[a] Days were used in the Sacramento River and months were used in the Feather River.

[b] Based on the modeling period of 1922 to 2003.

These results indicate that H3 would cause negligible effects on splittail spawning conditions in channel margin and side-channel habitats resulting from changes in flow and water temperatures. Effects of H3 on mean monthly flow would consist of negligible effects or increases in flow (increases up to 23% in the Sacramento River and to 65% in the Feather River) for some months and water year types in the spawning period that would have beneficial effects on rearing conditions. There would be negligible or beneficial project-related effects on exceedance of critical water temperatures, and a beneficial effect from a decrease (-60%) in exposure to critical high water temperatures in the Feather River.

Stranding Potential

As indicated above, rapid reductions in flow can dewater channel margin and side-channel habitats, potentially stranding splittail eggs and rearing larvae. Due to a lack of quantitative tools and historical data to evaluate possible stranding effects, the following provides a narrative summary of potential effects. The Yolo Bypass is exceptionally well-drained because of grading for agriculture, which likely helps limit stranding mortality of splittail. Moreover, water stage decreases on the bypass are relatively gradual (Sommer et al. 2001). Stranding of Sacramento splittail in perennial ponds on the Yolo Bypass does not appear to be a problem under Existing Conditions (Feyrer et al. 2004). Yolo Bypass improvements would be designed, in part, to further reduce the risk of stranding by allowing water to inundate certain areas of the bypass to maximize biological benefits, while keeping water away from other areas to reduce stranding in isolated ponds. Actions under H3 to increase the frequency of Yolo Bypass inundation would increase the frequency of potential stranding events. For splittail, an increase in inundation frequency would also increase the production of Sacramento splittail in the bypass. While total stranding losses may be greater under H3 than under NAA, the total number of splittail would be expected to be greater under H3.

In the Yolo Bypass, Sommer et al. (2005) found these potential losses are offset by the improvement in rearing conditions. Henning et al. (2006) also noted the potential for stranding risk as wetlands desiccate and oxygen concentrations decline, but the seasonal timing of use by juveniles may decrease these risks. Sommer et al. (2005) addressed the question of stranding and concluded the potential improvements in habitat capacity outweighed the potential stranding problems that may exist in some years.

H1/LOS

Floodplain Habitat

Flows in the Sacramento River at Fremont Weir under H1 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). As a result, no inundation analyses in the Yolo Bypass were conducted for H1. Overall, floodplain habitat conditions for splittail under H1 would be similar to or better than conditions under H3.

Channel Margin and Side-Channel Habitat

Flows under H1 in the Sacramento River at Wilkins Slough during February through June would be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

There would be no biologically meaningful difference (>5% absolute scale) between NAA and H1 in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F regardless of water year type (Table 11-4-97). In the Feather River, there would be differences between NAA and H1 in temperatures below 45°F. There would be a 7% increase in the exceedance above the 75°F threshold for wet and above normal water years under H1 relative to NAA, but no other differences.

Table 11-4-97. Difference (Percent Difference) in Percent of Days or Months[a] during February to June in Which Temperature Would Be below 45°F or above 75°F in the Sacramento River at Hamilton City and Feather River at the Confluence with the Sacramento River[b]

NA = could not be calculated because the denominator was 0.

[a] Days were used in the Sacramento River and months were used in the Feather River.

[b] Based on the modeling period of 1922 to 2003.

Overall, channel margin and side-channel habitat conditions for splittail under H1 would be similar to or marginally worse than conditions under H3.

Stranding Potential

Because flows in the Yolo Bypass under H1 would generally be similar to flows under H3, stranding potential would not differ between H1 and H3. Therefore, the results for H1 would be the same as those for H3.

H4/HOS

Floodplain Habitat

Flows in the Sacramento River at Fremont Weir under H4 would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). As a result, no inundation analyses in the Yolo Bypass were conducted for H4. Overall, floodplain habitat conditions for splittail under H4 would be similar to or marginally better than conditions under H3.

Channel Margin and Side-Channel Habitat

Flows under H4 in the Sacramento River at Wilkins Slough during February through June would be similar to flows under H3, except during June, in which modeled flows would be up to 21% lower than under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions are not expected to affect splittail habitat in a biologically meaningful way because they occur in only one of five months of splittail presence.

There would be no biologically meaningful difference (>5% absolute scale) between NAA and H1 in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F regardless of water year type (Table 11-4-97). In the Feather River, there would be differences between NAA and H1 in temperatures below 45°F. There would be a 7% and 6% reduction in the exceedance above the 75°F threshold for above and below normal water years under H4 relative to NAA, but no other differences.

Overall, channel margin and side-channel habitat conditions for splittail under H4 would be similar to or marginally better than conditions under H3.

Stranding Potential

Because flows in the Yolo Bypass under H4 would generally be similar to flows under H3, stranding potential would not differ between H4 and H3. Therefore, the results for H4 would be the same as those for H3.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. The effects of H3 on splittail spawning habitat are largely beneficial due to increased inundation in the Yolo Bypass, negligible effects and beneficial effects in some months on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough (increases in mean monthly flow to 23%) and the Feather River (increases in mean monthly flow to 65%), and negligible or beneficial effects on water temperatures in the Sacramento and Feather Rivers).

CEQA Conclusion: In general, Alternative 4 would have beneficial effects on splittail spawning habitat relative to Existing Conditions by increasing the quantity of spawning habitat in the Yolo Bypass. There would be negligible effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River. There would be negative effects on water temperatures in the Feather River relative to Existing Conditions, but the benefits due to increased inundation in the Yolo Bypass would outweigh the detrimental effects of increased water temperatures in the Feather River because the Yolo Bypass is a more important spawning habitat to splittail than channel margin habitat in the Feather River as evidenced by the large amount of spawning activity when inundated.

H3/ESO

Floodplain Habitat

Comparisons of splittail weighted habitat area for H3 and Existing Conditions show relatively little difference between the two scenarios, with no change or relatively small increases or decreases in longer-duration inundation events for H3 compared to Existing Conditions, except for somewhat larger increases or decreases in wet water year types (Table 11-4-93). However, H3 would result in increased acreage of suitable spawning habitat compared to Existing Conditions (Table 11-4-94), with increases of between 5 and 979 acres of suitable spawning habitat depending on water year type. Increased areas for wet, above normal, and below normal water years are predicted to be 63%, 62%, and 193%, respectively for H3. Comparisons for dry and critical water years indicate project-related increases of 7 and 5 acres of suitable spawning habitat, respectively, compared to 0 acres for Existing Conditions. There would generally be no or small effects (9% to 11% lower in below normal and dry years) of H3 on splittail spawning and rearing habitat in the Sutter Bypass relative to Existing Conditions (Table 11-4-95). These results indicate that H3 would have beneficial effects on splittail habitat through increasing the acreage of suitable spawning habitats by up to 193%.

Channel Margin and Side-Channel Habitat

Flow comparisons of H3 to Existing Conditions for the Sacramento River at Wilkins Slough (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for February through June indicate that H3 would have primarily negligible effects (<5%) or increases in mean monthly flow (to 39%), with the exception of a small decrease in flow (-6%) during March in below normal years and a moderate decrease (-16%) during May in wet years when effects of flow reductions on rearing conditions would be less critical. These decreases in flow would have little or no biologically meaningful negative effects and the increases in flow during May and June would have a beneficial effect on channel margin and side-channel habitats. Modeling results also show that Sacramento splittail spawning temperature tolerances would not be exceeded in the Sacramento River.

Results for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) show variable effects of H3 depending on month and water year type. Results for February through April include mostly negligible effects (<5%) and small to moderate increases in mean monthly flow (to 20%), with the exception of a small decrease (-11%) during February, and a moderate decrease (-20%) during March, in below normal years. Effects of H3 during May and June consist of negligible (<5%) effects, and both flow increases (to 59%) and decreases (to -26%), depending on water year type. Decreases in drier water years when effects of flow reductions would be more critical for rearing conditions are limited to a small reduction (-10%) during June in critical years (late in the rearing period). Based on a prevalence of negligible (<5%) or beneficial effects on flow (increases to 59%), and isolated decreases that would be of small magnitude and/or not occur at the more critical times for rearing success, these results indicate that effects of Alternative 4 on flow would not have biologically meaningful negative effects on splittail spawning conditions in channel margin and side-channel habitats in the Feather River.

Simulated daily and monthly water temperatures in Sacramento River at Hamilton City and Feather River at the confluence with the Sacramento River, respectively, were used to investigate the potential effects of H3 on the suitability of water temperatures for splittail spawning and egg incubation. A range of 45°F to 75°F was selected as the suitable range for splittail spawning and egg incubation.

There would be no biologically meaningful difference (>5% absolute scale) between Existing Conditions and H3 in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F regardless of water year type (Table 11-4-96). In the Feather River, there would be differences between Existing Conditions and H3 in temperatures below 45°F. There would be a 11% to 28% increases in the exceedance above the 75°F threshold under H3 relative to Existing Conditions, respectively, but no other differences.

Stranding Potential

Because there would be little difference in flow conditions between H3 and Existing Conditions in Yolo Bypass, the project will not affect stranding potential.

H1/LOS

Because flows and water temperatures under H1 would be similar to those under H3, conclusions for H1 are similar to those under H3.

H4/HOS

Because flows and water temperatures under H4 would be similar to those under H3, conclusions for H4 are similar to those under H3.

Summary of CEQA Conclusion

Collectively, these results indicate that the impact is not significant because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. The effects of H3 on splittail spawning habitat are largely beneficial. Benefits due to increased inundation in the Yolo Bypass would outweigh increases in exceedance of critical high water temperatures in the Feather River because the Yolo Bypass is a more important spawning habitat to splittail than channel margin habitat in the Feather River as evidenced by the large amount of spawning activity when inundated.

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

H3/ESO

In general, Alternative 4 would have beneficial effects on splittail rearing habitat relative to the NAA by increasing the quantity and quality of rearing habitat in the Yolo Bypass. There would be beneficial effects on rearing conditions in channel margin and side-channel habitats from moderate to substantial increases in mean monthly flow during most of the rearing period in the Sacramento River and the Feather River. There would be a beneficial effect from reduced exposure to critical water temperatures in the Feather River.

Floodplains are important rearing habitats for juvenile splittail during periods of high flows when areas like the Yolo Bypass are inundated. During low flows when floodplains are not inundated, splittail rear in side-channel and channel margin habitat. Therefore, the previous impact discussion applies to rearing as well as spawning habitat for splittail for H3.

H1/LOS

Because flows and water temperatures under H1 would be similar to those under H3, conclusions for H1 are similar to those under H3.

H4/HOS

Because flows and water temperatures under H4 would be similar to those under H3, conclusions for H4 are similar to those under H3.

NEPA Effects: Based on the analyses above, the effect of Alternative 4 on splittail rearing habitat is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of mortality.

CEQA Conclusion: In general, Alternative 4 would have beneficial effects on splittail rearing habitat relative to Existing Conditions by increasing the quantity of rearing habitat in the Yolo Bypass through increased acreage subjected to periodic inundation. There would be negligible effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River**,** with beneficial effect due to moderate to substantial increases in mean monthly flow for some months and water year types during the rearing period. There would be negative effects on water temperatures in the Feather River relative to Existing Conditions, but the benefits due to increased inundation in the Yolo Bypass would outweigh the detrimental effects of increased water temperatures in the Feather River because the Yolo Bypass is a more important rearing habitat to splittail than channel margin habitat in the Feather River as evidenced by the large amount of rearing activity when inundated.

H3/ESO

As described above, floodplains are important rearing habitats for juvenile splittail during periods of high flows when areas like the Yolo Bypass are inundated. During low flows when floodplains are not inundated, splittail rear in side-channel and channel margin habitat. Therefore, the previous impact discussion applies to rearing as well as spawning habitat for splittail for H3.

H1/LOS

Because flows and water temperatures under H1 would be similar to those under H3, conclusions for H1 are similar to those under H3.

H4/HOS

Because flows and water temperatures under H4 would be similar to those under H3, conclusions for H4 are similar to those under H3.

Summary of CEQA Conclusion

Based on the analyses above, the impact of Alternative 4 on splittail rearing habitat is not significant because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of mortality, and no mitigation is necessary.

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

Upstream of the Delta

In general, Alternative 4 would not affect migration conditions for juvenile or adult splittail in the Sacramento River or the Feather River relative to the NAA based on negligible or beneficial effects on mean monthly flow during the migration period and negligible effects on exposure to critical water temperatures in the Feather River. Adults migrate upstream primarily in December through March and juvenile migrate primarily in April through July (Moyle et al. 2004).

H3/ESO

The effects of H3 on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. There would be benefits to channel margin and side-channel habitat in both locations from increases in mean monthly flow, and from decreased exposure to critical high water temperatures compared to NAA.

H1/LOS

The effects of H1 on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. These effects would be similar to those for H3.

H4/HOS

The effects of H4 on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. These effects would be similar to those for H3.

Through-Delta

Alternative 4 would generally reduce OMR reverse flows during the period of juvenile splittail migration through the Delta under all flow scenarios. Modeled OMR flows under Alternative 4 would be reduced slightly in May under all flow scenarios (i.e., Scenarios H1-H4), but flows would still be less negative. Modeled OMR flows would be increased in June and July under Alternative 4 flow scenarios compared to baseline conditions (NAA). Based on the modeling overall negative OMR flows decrease during the splittail migration period, the effect on the species under Alternative 4 would not be adverse and may provide a benefit to the species.

NEPA Effects: Therefore, the effect of Alternative 4 is not adverse because it would not substantially reduce or degrade migration habitat or substantially reduce the number of fish as a result of mortality.

CEQA Conclusion:

Upstream of the Delta

In general, effects of Alternative 4 would have beneficial effects on splittail migration conditions relative to Existing Conditions based on moderate to substantial increases in mean monthly flow in the Sacramento River and the Feather River. There would be a negative effect based on substantial increases in exposure to critical water temperatures in the Feather River but this would be offset by the more substantial beneficial effects from increases in mean monthly flow for much of the migration period, and lack of negative effects on water temperature in the Sacramento River, which is the migration route to the main spawning and rearing area, the Yolo Bypass.

H3/ESO

Effects of H3 on splittail migration conditions are the same as described for channel margin and side-channel habitats in Impact AQUA-112.

H1/LOS

The effects of H1 on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. These effects would be similar to those for H3.

H4/HOS

The effects of H4 on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. These effects would be similar to those for H3.

Through-Delta

Average modeled OMR flows would be greater under Scenario H3 than the CEQA baseline during the majority of the juvenile splittail migration through the Delta. Conditions would be similar between Scenarios H1 and H3. OMR flow conditions under Scenario H4 would further improve migration conditions for juvenile splittail. Therefore the impact on splittail migration survival would be less than significant and may provide a benefit to the species.

Summary of CEQA Conclusion

The impact is less than significant because it would not substantially reduce suitable migration habitat or substantially reduce the number of fish as a result of mortality and no mitigation is necessary. Effects of Alternative 4 on flow would not have negative effects on the availability of channel margin and main-channel habitat, and would have a beneficial effect through increases in mean monthly flow for some months and water year types during the migration period. Benefits to flow conditions in both rivers, and lack of negative effects on water temperatures in the Sacramento River, outweigh the negative effects of substantial increases in exposure to critical water temperatures in the Feather River. This is because the Sacramento River serves as the migration route to the primary splittail spawning and rearing area, the Yolo Bypass, and migration conditions in the Feather River are less critical for regional splittail survival.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for Sacramento splittail under Alternative 1A (Impacts AQUA-115 through AQUA-117) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on splittail are the same for Alternative 4, as those described under Alternative 1A (Impacts AQUA 115-through AQUA-117). The effects would not be adverse, and generally beneficial. Specifically for AQUA-116, the effects of contaminants on Sacramento splittail with respect to selenium, copper, ammonia and pesticides would not be adverse. The effects of methylmercury on Sacramento splittail are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for Sacramento splittail under Alternative 1A (Impacts AQUA-118 through AQUA-126) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (CM12)

Impact AQUA-119: Effects of Invasive Aquatic Vegetation Management on Sacramento Splittail (CM13)

Impact AQUA-120: Effects of Dissolved Oxygen Level Management on Sacramento Splittail (CM14)

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (CM15)

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (CM16)

Impact AQUA-123: Effects of Illegal Harvest Reduction on Sacramento Splittail (CM17)

Impact AQUA-124: Effects of Conservation Hatcheries on Sacramento Splittail (CM18)

Impact AQUA-125: Effects of Urban Stormwater Treatment on Sacramento Splittail (CM19)

Impact AQUA-126: Effects of Removal/Relocation of Nonproject Diversions on Sacramento Splittail (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on splittail are the same as those described under Alternative 1A (Impact s AQUA-118 through AQUA-126). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

Green Sturgeon

Construction and Maintenance of CM1

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

The potential effects of construction of the water conveyance facilities on green sturgeon would be similar to those described for Alternative 1A, Impact AQUA-127, except that Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less. Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-127, the effect would not be adverse for green sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-127, the impact of the construction of the water conveyance facilities on green sturgeon would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A, Impact AQUA-128, except that only three intakes would need to be maintained under Alternative 4 rather than five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-128, the impact would not be adverse for green sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-128, the impact of the maintenance of water conveyance facilities on green sturgeon would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

Water Exports

The potential entrainment effects under Alternative 4 would be the same as those under Alternative 1A. Operating new north Delta intakes and dual conveyance for SWP NBA have the potential to avoid or reduce entrainment as described for Alternative 1A; there would be no adverse effect.

Scenario H3 would substantially reduce entrainment of juvenile green sturgeon at the south Delta export facilities by about 51% relative to NAA (Table 11-4-98). Entrainment loss would be reduced 57% in wetter years and by 37% in drier years under Scenario H3 compared to NAA. Compared to the Scenario H3, entrainment losses of green sturgeon would be greater under Scenario H1 and reduced under the HOS. Under all flow scenarios, however, entrainment at the south Delta facilities would be substantially reduced compared to the NAA.

Table 11-4-98. Juvenile Green Sturgeon Entrainment Index at the SWP and CVP Salvage Facilities—Differences (Absolute and Percentage) between Model Scenarios for Alternative 4 (Scenario H3)

	Absolute Difference (Percent Difference)	
Water Year Type[b]	EXISTING CONDITIONS vs. A4 (H3)	NAA vs. A4 (H3)
Wet and Above Normal	-72 (-62%)	-59 (-57%)
Below Normal, Dry, and Critical	-23 (-47%)	-15 (-37%)
All Years	-95 (-57%)	-75 (-51%)

[a] Estimated annual number of fish lost, based on non-normalized data.
[b] Sacramento Valley water year-types.

Predation Associated with Entrainment

Entrainment-related predation loss of juvenile green sturgeon would not be greater under this Alternative and may be lower relative to baseline due to a reduction in entrainment loss. Conditions under Scenario H4 would likely reduce predation loss relative to Scenario H3, while conditions under Scenario H1 would likely increase predation loss slightly relative to Scenario H1. The impact and conclusion for predation risk associated with NPB structures and the north Delta intakes would be the same as described for Alternative 1A (Impact AQUA-129).

NEPA Effects: In conclusion, the effect of Alternative 4 on entrainment and associated predation of green sturgeon would not be adverse and may provide modest benefit due to reduced losses at the south Delta facilities.

CEQA Conclusion: As described above, the impact of the water operations on green sturgeon would be less than significant and no mitigation would be required.

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

In general, Alternative 4 would not affect spawning and egg incubation habitat for green sturgeon relative to the NAA.

H3/ESO

Sacramento River

Mean monthly flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Lower flows can reduce the instream area available for spawning and egg incubation. Flows under H3 would always be similar to or greater than flows under NAA except for lower flows in dry years during July upstream of Red Bluff and Keswick (7% lower). Also, flows can be lower or higher in individual months of individual years These results indicate that flows in the Sacramento River would increase overall under H3.

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

The number of days on which temperature exceeded 63°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above the 63°F threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-99. There would be no substantial differences between NAA and H3 in the number of years with each "level of concern".

Table 11-4-99. Differences between Baseline and H3 Scenarios in the Number of Years in Which Water Temperature Exceedances above 63°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. H3	NAA vs. H3
Red	10 (250%)	1 (8%)
Orange	1 (100%)	1 (100%)
Yellow	3 (150%)	0 (0%)
None	-14 (-19%)	-2 (-3%)

Total degree-days exceeding 63°F at Bend Bridge were summed by month and water year type during May through September (Table 11-4-100). Total degree-days under H3 would be 5% to 11% higher than under NAA during July through September and 10% to 11% lower during May and June.

Table 11-4-100. Differences between Baseline and H3 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
May	Wet	1,065 (282%)	-137 (-9%)
	Above Normal	228 (107%)	-127 (-22%)
	Below Normal	434 (198%)	-29 (-4%)
	Dry	246 (132%)	-168 (-28%)
	Critical	454 (205%)	44 (7%)
	All	2,427 (200%)	-417 (-10%)
June	Wet	500 (130%)	-211 (-19%)
	Above Normal	66 (45%)	-163 (-43%)
	Below Normal	276 (199%)	-76 (-15%)
	Dry	514 (273%)	-20 (-3%)
	Critical	623 (155%)	73 (8%)
	All	1,979 (157%)	-397 (-11%)
July	Wet	653 (126%)	47 (4%)
	Above Normal	347 (428%)	77 (22%)
	Below Normal	591 (402%)	135 (22%)
	Dry	1,313 (466%)	385 (32%)
	Critical	1,776 (216%)	-10 (-0.4%)
	All	4,680 (253%)	634 (11%)
August	Wet	2,091 (300%)	128 (5%)
	Above Normal	830 (203%)	171 (16%)
	Below Normal	1,246 (470%)	211 (16%)
	Dry	2,063 (308%)	453 (20%)
	Critical	2,732 (184%)	113 (3%)
	All	8,962 (254%)	1,076 (9%)
September	Wet	806 (109%)	97 (7%)
	Above Normal	586 (82%)	186 (17%)
	Below Normal	1,570 (210%)	424 (22%)
	Dry	2,425 (190%)	-171 (-4%)
	Critical	1,938 (93%)	47 (1%)
	All	7,325 (132%)	583 (5%)

Feather River

Flows were examined in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June green sturgeon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would be similar to or greater than flows under NAA in both locations except in below normal years during March (6% to 19% lower, depending on location). These results indicate that flows in the Feather River would increase overall under H3 independent of climate change.

Mean monthly water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H3 would be 6% greater than those under NAA during February but there would be no differences (<5%) between NAA and H3 in any other month during the period.

Water temperature-related effects of H3 on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures exceed a 64°F temperature threshold at Gridley (Table 11-4-101). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. The percent of months exceeding the threshold during May and June under H3 would be similar to or up to 27% lower than that under NAA, representing a small to moderate benefit of H3.

Table 11-4-101. Differences between Baselines and H3 in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 64°F Threshold, May through September

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. H3					
May	35 (108%)	28 (153%)	21 (213%)	15 (400%)	9 (350%)
June	5 (5%)	0 (0%)	4 (5%)	9 (13%)	12 (26%)
July	0 (0%)	0 (0%)	0 (0%)	10 (11%)	28 (41%)
August	0 (0%)	0 (0%)	9 (9%)	20 (25%)	35 (56%)
September	17 (25%)	16 (30%)	30 (104%)	36 (483%)	31 (1,250%)
NAA vs. H3					
May	-5 (-7%)	-10 (-17%)	-1 (-4%)	0 (0%)	-1 (-10%)
June	-1 (-1%)	-9 (-9%)	-12 (-13%)	-20 (-21%)	-27 (-31%)
July	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
August	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
September	19 (27%)	11 (19%)	9 (18%)	0 (0%)	5 (17%)

Water temperature-related effects of H3 on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-4-102). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. Combining water years, total degree-months exceeding the threshold during May and June under H3 would be 8% to 21% lower relative to NAA. Within months, total degree-months under H3 would be similar or up to 26% lower than that under NAA depending on water year type. These results indicate that there would be a small to moderate benefit of H3 to green sturgeon spawning and egg incubation temperature-related conditions in the Feather River.

Table 11-4-102. Differences between Baselines and H3 in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 64°F in the Feather River at Gridley, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
May	Wet	19 (317%)	-5 (-17%)
	Above Normal	12 (109%)	-2 (-8%)
	Below Normal	19 (238%)	-5 (-16%)
	Dry	28 (200%)	-1 (-2%)
	Critical	20 (118%)	0 (0%)
	All	98 (175%)	-13 (-8%)
June	Wet	18 (24%)	-49 (-35%)
	Above Normal	0 (0%)	-29 (-36%)
	Below Normal	0 (0%)	-32 (-33%)
	Dry	46 (49%)	-7 (-5%)
	Critical	36 (64%)	-3 (-3%)
	All	100 (29%)	-120 (-21%)
July	Wet	33 (20%)	17 (9%)
	Above Normal	17 (32%)	0 (0%)
	Below Normal	42 (62%)	10 (10%)
	Dry	87 (101%)	43 (33%)
	Critical	83 (105%)	29 (22%)
	All	262 (58%)	99 (16%)

	Critical	52 (260%)	-2 (-3%)
	All	141 (108%)	31 (13%)

San Joaquin River

Flows in the San Joaquin River under H3 would be the same as those under NAA throughout the March through June period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

H1/LOS

Sacramento River

Mean monthly flows in the Sacramento River at Keswick and upstream of Red Bluff during the March through July spawning and egg incubation period for green sturgeon would be similar between H1 and H3 although flows can be lower or higher in individual months of individual years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

There would be no differences between NAA and H1 in the number of years with each level of concern in the Sacramento River at Bend Bridge (Table 11-4-103).

Table 11-4-103. Differences between Baseline Scenarios and H1 and H4 Scenarios in the Number of Years in Which Water Temperature Exceedances above 63°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
Red	8 (200%)	-1 (-8%)	9 (225%)	0 (0%)
Orange	1 (100%)	1 (100%)	-1 (-100%)	-1 (-100%)
Yellow	0 (0%)	-3 (-60%)	-1 (-50%)	-4 (-80%)
None	-9 (-12%)	3 (5%)	-7 (-9%)	5 (8%)

Total degree-days exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under H1 would be 8% to 16% higher than under NAA during July through September and 11% to 12% lower during May and June (Table 11-4-104).

Table 11-4-104. Differences between Baseline Scenarios and H1 and H4 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4

	All	8,673 (156%)	1,931 (16%)	6,245 (112%)	-497 (-4%)

Feather River

Flows under H1 in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June period would generally be similar to or greater than flows under H3 except in critical years during February at Thermalito (5% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Mean monthly water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) between NAA and H1 in any month during the period.

The percent of months exceeding the 64°F NMFS threshold during May and June under H1 would be similar to or up to 27% lower than that under NAA, representing a small to moderate benefit of H1 (Table 11-4-105).

Table 11-4-105. Differences between Baselines and H1 and H4 Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 64°F Threshold, May through September

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISITING CONDITIONS vs. H1					
May	30 (92%)	21 (113%)	12 (125%)	12 (333%)	7 (300%)
June	4 (4%)	1 (1%)	0 (0%)	4 (6%)	12 (26%)
July	0 (0%)	0 (0%)	0 (0%)	9 (10%)	23 (34%)
August	0 (0%)	0 (0%)	9 (9%)	16 (20%)	32 (52%)
September	26 (38%)	32 (59%)	44 (157%)	52 (700%)	37 (1,500%)
NAA vs. H1					
May	-10 (-14%)	-17 (-30%)	-10 (-31%)	-2 (-13%)	-2 (-20%)
June	-2 (-3%)	-7 (-8%)	-16 (-17%)	-25 (-27%)	-27 (-31%)
July	0 (0%)	0 (0%)	0 (0%)	-1 (-1%)	-5 (-5%)
August	0 (0%)	0 (0%)	0 (0%)	-4 (-4%)	-2 (-3%)
September	27 (40%)	27 (46%)	23 (48%)	16 (37%)	11 (39%)
EXISITING CONDITIONS vs. H4					
May	21 (65%)	16 (87%)	9 (88%)	7 (200%)	6 (250%)
June	2 (3%)	4 (4%)	5 (6%)	10 (15%)	21 (44%)
July	0 (0%)	0 (0%)	0 (0%)	10 (11%)	28 (41%)
August	0 (0%)	0 (0%)	9 (9%)	20 (25%)	38 (62%)
September	11 (16%)	15 (27%)	33 (117%)	41 (550%)	35 (1,400%)
NAA vs. H4					
May	-19 (-26%)	-22 (-39%)	-14 (-42%)	-7 (-40%)	-4 (-30%)
June	-4 (-4%)	-5 (-5%)	-11 (-12%)	-19 (-20%)	-19 (-21%)
July	0 (0%)	0 (0%)	0 (0%)	0 (0%)	0 (0%)
August	0 (0%)	0 (0%)	0 (0%)	0 (0%)	4 (4%)
September	12 (18%)	10 (17%)	12 (25%)	5 (11%)	9 (30%)

Combining water years, total degree-months exceeding the 64°F NMFS threshold during May and June under H1 would be 7% to 21% lower relative to NAA. Within months, total degree-months under H1 would be similar or up to 36% lower than that under NAA depending on water year type. These results indicate that there would be a small to moderate benefit of H1 to green sturgeon spawning and egg incubation temperature-related conditions in the Feather River (Table 11-4-106).

Table 11-4-106. Differences between Baselines and H1 and H4 Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 64°F in the Feather River at Gridley, May through September

Month	Water Year Type	EXISITING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
May	Wet	20 (333%)	-4 (-13%)	15 (250%)	-9 (-30%)
	Above Normal	11 (100%)	-3 (-12%)	1 (9%)	-13 (-52%)
	Below Normal	21 (263%)	-3 (-9%)	16 (200%)	-8 (-25%)

	All	209 (160%)	99 (41%)	187 (143%)	77 (32%)

San Joaquin River

Flows under H1 in the San Joaquin River during the March through June period would be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. No water temperature modeling was in the San Joaquin River.

H4/HOS

Sacramento River

Mean monthly flows in the Sacramento River at Keswick and upstream of Red Bluff during the March through July spawning and egg incubation period for green sturgeon would generally be similar between H4 and H3, except during June in which flows would be up to 13% lower under H4 depending on water year type and 5% and 7% lower during July in dry years (Keswick and upstream of Red Bluff, respectively) although flows can be lower or higher in individual months of individual years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be large or frequent enough to have a biologically meaningful effect on green sturgeon spawning habitat.

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

There would be no differences between NAA and H4 in the number of years with each level of concern in the Sacramento River at Bend Bridge (Table 11-4-103).

Total degree-days exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under H4 would be similar to those under NAA in all months during the period except August, in which there would be a 5% reduction in exceedances (Table 11-4-104).

Feather River

Flows under H4 in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June period would generally be similar to or greater than flows under H3, except during June, in which flows would be up to 38% lower under H4 depending on water year type and during July in dry years at Thermalito when the flows would be 7% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. These reductions would not be large or frequent enough to have a biologically meaningful effect on green sturgeon spawning habitat.

Mean monthly water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) between NAA and H4 in any other month during the period.

The percent of months exceeding the 64°F NMFS threshold during May and June under H4 would be similar to or up to 22% lower than that under NAA, representing a small to moderate benefit of H4 (Table 11-4-105).

Combining water years, total degree-months exceeding the 64°F NMFS threshold during May and June under H4 would be 7% to 21% lower relative to NAA. Within months, total degree-months under H4 would be similar or up to 52% lower than that under NAA depending on water year type. These results indicate that there would be a small to moderate benefit of H4 to green sturgeon spawning and egg incubation temperature-related conditions in the Feather River (Table 11-4-106).

San Joaquin River

Flows under H4 in the San Joaquin River during the period would be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

No water temperature modeling was in the San Joaquin River.

NEPA Effects: Collectively, these results indicate that this effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. There would generally be higher flows in the Sacramento and Feather rivers that would benefit spawning and egg incubation conditions for green sturgeon. Water temperatures in the Sacramento River would not differ from those under NAA, and temperature conditions under Alternative 4 would be better than those under NAA in the Sacramento and Feather Rivers. Temperature conditions would slightly improve under H4 relative to H1 and H3 during spring months.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of spawning and egg incubation habitat for green sturgeon would not be affected relative to the CEQA baseline.

H3/ESO

Sacramento River

Mean monthly flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. Flows under H3 would generally be similar to or greater than those under Existing Conditions, except in July during critical years (10% and 9% lower, depending on location), in May during wet years (17% and 21% lower, depending on location), March during below normal years (10% to 18% lower, depending on location), and April during above normal years at Keswick (6% lower)*.* Also, flows can be lower or higher in individual months of individual years These results indicate that there would be few reductions and multiple increases in flows in the Sacramento River under H3 relative to Existing Conditions.

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period.

There would be 10 more years with a "red" NMFS level of concern in the Sacramento River at Bend Bridge under H3 than under Existing Conditions (Table 11-4-99).

Total degree-days exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under H3 would be 132% to 254% higher than under Existing Conditions during the May through September period (Table 11-4-100).

Feather River

Flows were examined in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June green sturgeon spawning and egg incubation period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*. At Thermalito, flows under H3 would generally be similar to or greater than those under Existing Conditions, except during March in below normal years and May in wet years, in which flows under H3 would be up to 53% lower than under Existing Conditions and except in above normal, below normal, and dry years during February (35%, 46%, and 14%, respectively).). At the confluence with the Sacramento River, flows under H3 would generally be similar to or greater than flows under Existing Conditions, except during March in below normal years, May in wet years, and in June in wet and critical years, in which flows under H3 would be up to 26% lower than under Existing Conditions, and in normal years during February (11% lower). These results indicate that there would generally be greater flows in the Feather River under H3 relative to Existing Conditions with few exceptions.

Water temperature-related effects of H3 on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures exceed a 64°F temperature threshold at Gridley (Table 11-4-101). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. The percent of months exceeding the threshold during May and June under H3 would be similar to or up to 35% greater than that under Existing Conditions, representing a small to moderate negative effect of H3. This analysis includes the effect of climate change.

Water temperature-related effects of H3 on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-4-102). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. Combining water years, total degree-months exceeding the threshold during May and June under H3 would be 29% to 175% greater relative to Existing Conditions. Within months, total degree-months under H3 would be similar or up to 317% lower than that under Existing Conditions depending on water year type. These results indicate that there would be a moderate to large negative effect of H3 on green sturgeon spawning and egg incubation temperature-related conditions in the Feather River. This analysis includes the effect of climate change.

San Joaquin River

Flows in the San Joaquin River under H3 similar to those under Existing Conditions throughout the March through June spawning and egg incubation period for green sturgeon, except during June, in which there would be a 30% flow reduction under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).*

No water temperatures modeling was conducted in the San Joaquin River.

H1/LOS

Sacramento River

Mean monthly flows in the Sacramento River at Keswick and upstream of Red Bluff during the March through July spawning and egg incubation period for green sturgeon would be similar between H1 and H3 although flows can be lower or higher in individual months of individual years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) except in critical years during July (16% lower).

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the*

Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period.

There would be 8 more years with a "red" NMFS level of concern in the Sacramento River at Bend Bridge under H1 than under Existing Conditions (Table 11-4-103).

Total degree-days exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under H1 would be 156% to 252% higher than under Existing Conditions during the May through September period (Table 11-4-104).

Feather River

Flows under H1 in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June period would generally be similar to or greater than flows under H3 except in below normal, dry and critical years (29%, 8%, and 13% lower, respectively) (Thermalito) and in critical years (7% lower) (Sacramento River confluence) during February (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).*

Mean monthly water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H1 would be 6% lower than those under Existing Conditions during February, but there would be no differences (<5%) in any other month during the period.

The percent of months exceeding the 64°F NMFS threshold during May and June under H1 would be similar to or up to 30% greater than that under Existing Conditions, representing a small to moderate negative effect of H1 (Table 11-4-105). This analysis includes climate change.

Combining water years, total degree-months exceeding the threshold during May and June under H1 would be 30% to 177% greater relative to Existing Conditions. Within months, total degree-months under H1 would be similar or up to 333% lower than that under Existing Conditions depending on water year type. These results indicate that there would be a moderate to large negative effect of H1 on green sturgeon spawning and egg incubation temperature-related conditions in the Feather River. This analysis includes the effect of climate change.

San Joaquin River

Flows in the San Joaquin River under H1 similar to those under Existing Conditions throughout the March through June spawning and egg incubation period for green sturgeon, except during June, in which there would be a 30% flow reduction under H1 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).*

No water temperature modeling was in the San Joaquin River.

H4/HOS

Sacramento River

Mean monthly flows in the Sacramento River at Keswick and upstream of Red Bluff during the March through July spawning and egg incubation period for green sturgeon would generally be similar between H4 and H3, except during June in which flows would be up to 13% lower under H4 depending on water year type and during July in critical years when flows would be 7% or 8% lower although flows can be lower or higher in individual months of individual years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be large or frequent enough to have a biologically meaningful effect on green sturgeon spawning habitat.

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month or water year type throughout the period, except in wet years during May (5% higher under H4).

There would be 9 more years with a "red" NMFS level of concern in the Sacramento River at Bend Bridge under H4 than under Existing Conditions (Table 11-4-103).

Total degree-days exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under H4 would be 112% to 220% higher than under Existing Conditions during the May through September period (Table 11-4-104).

Feather River

Flows under H1 in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June period would generally be similar to or greater than flows under H3, except during June, in which flows would be up to 38% lower under H4 depending on water year type and during February in below normal, dry and critical years (30%, 15%, and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. These reductions would not be large or frequent enough to have a biologically meaningful effect on green sturgeon spawning habitat.

Mean monthly water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures under H4 would be 6% lower than those under Existing Conditions during February, but there would be no differences (<5%) in any other month during the period.

The percent of months exceeding the 64°F NMFS threshold during May and June under H4 would be similar to or up to 21% greater than that under Existing Conditions, representing a small to moderate negative effect of H4 (Table 11-4-105). This analysis includes climate change.

Combining water years, total degree-months exceeding the threshold during May and June under H4 would be 52% to 136% greater relative to Existing Conditions. Within months, total degree-months under H4 would be similar or up to 250% lower than that under Existing Conditions depending on water year type. These results indicate that there would be a moderate to large negative effect of H4 on green sturgeon spawning and egg incubation temperature-related conditions in the Feather River. This analysis includes the effect of climate change.

San Joaquin River

Flows in the San Joaquin River under H1 similar to those under Existing Conditions throughout the March through June spawning and egg incubation period for green sturgeon, except during June, in which there would be a 30% flow reduction under H1 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis).*

No water temperature modeling was in the San Joaquin River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-130 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable spawning and egg incubation habitat for green sturgeon, contrary to the NEPA conclusion set forth above. Flows would generally not differ under Alternative 4 in the Sacramento, Feather, and San Joaquin Rivers and temperatures would not differ in the Sacramento River. However, exceedances above temperature thresholds by NMFS would be higher in the Sacramento and Feather Rivers. Results would generally be consistent among scenarios.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for green sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

In general, Alternative 4 would not affect the quantity and quality of green sturgeon larval and juvenile rearing habitat relative to the NAA.

H3/ESO

Water temperature was used to determine the potential effects of H3 on green sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Feather River

Mean monthly water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Water temperature-related effects of H3 on green sturgeon rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures exceed a 64°F temperature threshold at Gridley (Table 11-4-101). The percent of months exceeding the threshold under H3 would be similar to or up to 27% lower than that under NAA during May and June, similar to that under NAA during July and August, and similar to or up to 19% greater than that under NAA during September.

Water temperature-related effects of H3 on green sturgeon rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-4-102). Combining water years, total degree-months exceeding the threshold under H3 would be 8% to 31% lower relative to NAA during May and June and 13% to 126% higher during July through September. These results indicate that there would be both beneficial and negative temperature-related effects to green sturgeon rearing in the Feather River.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

H1/LOS

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Feather River

Mean monthly water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

The percent of months exceeding the 64°F NMFS threshold under H1 would be similar to or up to 27% lower than that under NAA during May and June, generally similar to that under NAA during July and August, and 11% to 27% greater than that under NAA during September. (Table 11-4-105).

Combining water years, total degree-months exceeding the 64°F NMFS threshold under H1 would be 7% to 21% lower relative to NAA during May and June and 11% to 41% higher during July through September (Table 11-4-106). These results indicate that there would be both beneficial and negative temperature-related effects of H1 on green sturgeon rearing in the Feather River.

Regardless of the results of these analyses, all current applicable regulatory standards for the Feather River in the NMFS BiOp (NMFS 2009) would be met under H1 at the same frequency as are being met currently under the NEPA point of comparison. Therefore, regardless of these results, H1 would be protective of green sturgeon as defined by NMFS (2009).

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

H4/HOS

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Feather River

Mean monthly water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

The percent of months exceeding the 64°F NMFS threshold under H4 would be similar to or up to 22% lower than that under NAA during May and June, similar to that under NAA during July and August, and 5% to 12% greater than that under NAA during September. (Table 11-4-105).

Combining water years, total degree-months exceeding the 64°F NMFS threshold under H4 would be 7% to 21% lower relative to NAA during May and June and 22% to 32% higher during July through September (Table 11-4-106). These results indicate that there would be both beneficial and negative temperature-related effects of H4 on green sturgeon rearing in the Feather River.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because it does not have the potential to substantially reduce the amount of suitable habitat. Water temperatures in the Sacramento and Feather rivers and exceedances of NMFS temperature thresholds in the Feather

River under Alternative 4 would be similar to those under NAA. These results would be consistent among scenarios.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of green sturgeon rearing habitat would not be affected relative to the CEQA baseline.

H3/ESO

Water temperature was used to determine the potential effects of H3 on green sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 during May through July and 5% to 6% lower during August through October.

Feather River

Mean monthly water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month throughout the period, except during October (6% higher under H3).

Water temperature-related effects of H3 on green sturgeon rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures exceed a 64°F temperature threshold at Gridley (Table 11-4-101). The percent of months exceeding the threshold under H3 would generally be greater by up to 35% than the percent under Existing Conditions during all months. These results include the effects of climate change.

Water temperature-related effects of H3 on green sturgeon rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-4-102). Combining water years, total degree-months exceeding the threshold under H3 would be 29% to 175% higher in all months. These results indicate that there would be negative temperature-related effects of H3 on green sturgeon rearing in the Feather River. These results include the effects of climate change.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

H1/LOS

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 during May through July and 5% to 6% lower during August through October.

Feather River

Mean monthly water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month throughout the period, except during October (5% higher under H1).

The percent of months exceeding the 64°F NMFS threshold under H1 would generally be greater by up to 52% than the percent under Existing Conditions during all months (Table 11-4-105). These results include the effects of climate change.

Combining water years, total degree-months exceeding the 64°F NMFS threshold under H1 would be 30% to 177% higher in all months (Table 11-4-106). These results indicate that there would be negative temperature-related effects of H1 on green sturgeon rearing in the Feather River. These results include the effects of climate change.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

H4/HOS

Sacramento River

Mean monthly water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 during May through July and 5% lower during August and October.

Feather River

Mean monthly water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H4 in any month throughout the period, except during July, August, and October (5% to 7% higher under H4).

The percent of months exceeding the 64°F NMFS threshold under H4 would generally be greater by up to 41% than the percent under Existing Conditions during all months (Table 11-4-105). These results include the effects of climate change.

Combining water years, total degree-months exceeding the 64°F NMFS threshold under H4 would be 52% to 143% higher in all months (Table 11-4-106). These results indicate that there would be negative temperature-related effects of H4 on green sturgeon rearing in the Feather River. These results include the effects of climate change.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-131 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable rearing habitat, contrary to the NEPA conclusion set forth above. Water temperatures be similar in the Sacramento River, although the exceedance above NMFS temperature thresholds in the Feather River would be higher under Alternative 4 than those under the CEQA baseline, which could increase stress, mortality, and susceptibility to disease for larval and juvenile green sturgeon. These results are consistent among scenarios.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for green sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

In general, effects of Alternative 4 on green sturgeon migration conditions relative to the NAA are uncertain.

Upstream of the Delta

H3/ESO

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick and Wilkins Slough and in the Feather River between Thermalito and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through June adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River flows at Keswick under H3 would generally be lower than flows under NAA during November, greater during May and June, and similar to flows under NAA in the remaining nine months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Sacramento River flows at Wilkins Slough under H3 would generally be lower than flows under NAA during November, greater during May and June, and similar to flows under NAA in the remaining nine months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Feather River flows at Thermalito under H3 would generally be lower than flows under NAA during July through September, greater during March through June and October, and similar to flows under NAA in the remaining four months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). However, given the benthic nature of green sturgeon and that flows in the Feather River would be consistent with the flow schedule provided by NMFS during the BDCP planning process, these reductions in summer flows are not expected to have a substantial effect on green sturgeon in the Feather River.

Feather River flows at the confluence with the Sacramento River under H3 would generally be lower than flows under NAA during July through September, greater during April through June and October, and similar to flows under NAA in the remaining five months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). However, given the benthic nature of green sturgeon and that flows in the Feather River would be consistent with the flow schedule provided by NMFS during the BDCP planning process, these reductions in summer flows are not expected to have a substantial effect on green sturgeon in the Feather River.

Larval transport flows were also examined by utilizing the positive correlation between white sturgeon year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved green sturgeon larval transport that results in improved year class strength. Results for white sturgeon presented in Impact AQUA-150 below suggest that, using the positive correlation between Delta outflow and year class strength, green sturgeon year class strength would be lower under H3 than those under NAA (up to 50% lower).

H1/LOS

Year-round flows under H1 in the Sacramento River at Keswick and Wilkins Slough would generally be similar to flows under H3, except during September and November, during which flows would be up to 46% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated reductions would not have biologically meaningful effects on green sturgeon migration habitat. Year-round flows in the Feather River below Thermalito Afterbay (high-flow channel) and at the confluence with the Sacramento River under H1 would generally be similar to or greater than flows under H3, except during September during which flows would be up to 83% lower. This isolated reduction would not have biologically meaningful effects on green sturgeon migration habitat. Overall, results for H1 would be the same as those for H3.

H4/HOS

Year-round flows in the Sacramento River at Keswick and Wilkins Slough under H4 would generally be similar to flows under H3, except during May and June, during which flows would be up to 21%

lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These small and isolated reductions would not have biologically meaningful effects on green sturgeon migration habitat. Flows in the Feather River below Thermalito Afterbay (high-flow channel) under H4 during January through May and November through December would generally be similar to or greater than flows under H3. However, flows during June through October would generally be up to 39% lower under H4. These reductions are expected to cause a biologically meaningful effect on green sturgeon migration habitat.

Through-Delta

The impact of Alternative 4 on in-Delta conditions for green sturgeon would be the same as described for splittail in Impact AQUA-114. The effect on green sturgeon would not be adverse.

NEPA Effects: Upstream flows (above north Delta intakes) are similar between Alternative 4 and NAA. However, due to the removal of water at the North Delta intakes, there are substantial differences in through-Delta flows between Alternative 4 and NAA (see Table 11-4-114 below). Analysis of white sturgeon year-class strength (USFWS 1995), used here as a surrogate for green sturgeon, found a positive correlation between year class strength and Delta outflow during April and May. However, this conclusion was reached in the absence of north Delta intakes and the exact mechanism that causes this correlation is not known at this time. One hypothesis suggests that the correlation is caused by high flows in the upper river resulting in improved migration, spawning, and rearing conditions in the upper river. Another hypothesis suggests that the positive correlation is a result of higher flows through the Delta triggering more adult sturgeon to move up into the river to spawn. It is also possible that some combination of these factors are working together to produce the positive correlation between high flows and sturgeon year-class strength.

The scientific uncertainty regarding which mechanisms are responsible for the positive correlation between year class strength and river/Delta flow will be addressed through targeted research and monitoring to be conducted in the years leading up to the initiation of north Delta facilities operations. If these targeted investigations determine that the primary mechanisms behind the positive correlation between high flows and sturgeon year-class strength are related to upstream conditions, then Alternative 4 would be deemed Not Adverse due to the similarities in upstream flow conditions between Alternative 4 and NAA. However, if the targeted investigations lead to a conclusion that the primary mechanisms behind the positive correlation are related to in-Delta and through-Delta flow conditions, then Alternative 4 would be deemed adverse due to the magnitude of reductions in through-Delta flow conditions in Alternative 4 as compared to NAA.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, migration conditions for green sturgeon would not change relative to the CEQA baseline.

Upstream of the Delta

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick and Wilkins Slough and in the Feather River between Thermalito and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through July adult migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*)*.* Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River flows between Keswick and Wilkins Slough under H3 would generally be lower than flows under Existing Conditions during August, September, and November by up to 29%, greater during February, May, and June, and similar to flows under Existing Conditions in the remaining six months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For Delta outflow, the percent of months exceeding outflow thresholds under H3 would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (8% to 50% lower on a relative scale) (see Table 11-4-114 below).

Feather River flows between Thermalito and the confluence with the Sacramento River under H3 would generally be lower than flows under Existing Conditions during January, February, July, August and December by up to 64%, greater during April through June, September, and October by up to 209%, and similar to flows under Existing Conditions in March and November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

H1/LOS

Year-round flows under H1 in the Sacramento River at Keswick and Wilkins Slough would generally be similar to flows under H3, except during September and November, during which flows would be up to 46% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These isolated reductions would not have biologically meaningful effects on green sturgeon migration habitat. Year-round flows in the Feather River below Thermalito Afterbay (high-flow channel) and at the confluence with the Sacramento River under H1 would generally be similar to or greater than flows under H3, except during September during which flows would be up to 83% lower. This isolated reduction would not have biologically meaningful effects on green sturgeon migration habitat. Overall, results for H1 would be the same as those for H3.

H4/HOS

Year-round flows in the Sacramento River at Keswick and Wilkins Slough under H4 would generally be similar to flows under H3, except during May and June, during which flows would be up to 21% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These small and isolated reductions would not have biologically meaningful effects on green sturgeon migration habitat. Flows in the Feather River below Thermalito Afterbay (high-flow channel) under H4 during January through May and November through December would generally be similar to or greater than flows under H3. However, flows during June through October would generally be up to 39% lower under H4. These reductions are expected to cause a biologically meaningful effect on green sturgeon migration habitat.

Through-Delta

As described above, the potential impact of Alternative 4 on in-Delta conditions for green sturgeon is considered less than significant, and no mitigation would be required.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-132 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially interfere with the movement of fish, contrary to the NEPA conclusion set forth above. The frequent small to large reductions in flows in the Sacramento and Feather Rivers would reduce the ability of all three life stages of green sturgeon to migrate successfully. Flow reductions during June through October under H4 would further reduce migration conditions for all three life stages. Exceedance of Delta outflow thresholds would be lower under Alternative 4 than under Existing Conditions, although there is high uncertainty that year class strength is due to Delta outflow or if both year class strength and Delta outflows co-vary with another unknown factor.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration conditions for green sturgeon. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for green sturgeon under Alternative 1A (Impacts AQUA-133 through AQUA-135) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on green sturgeon are the same for Alternative 4, as those described under Alternative 1A (Impacts AQUA 133-through AQUA-135). The effects would not be adverse, and would generally be beneficial. Specifically for AQUA-134, the effects of contaminants on green sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on green sturgeon are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for green sturgeon under Alternative 1A (Impacts AQUA-136 through AQUA-144) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (CM12)

Impact AQUA-137: Effects of Invasive Aquatic Vegetation Management on Green Sturgeon (CM13)

Impact AQUA-138: Effects of Dissolved Oxygen Level Management on Green Sturgeon (CM14)

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (CM15)

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (CM16)

Impact AQUA-141: Effects of Illegal Harvest Reduction on Green Sturgeon (CM17)

Impact AQUA-142: Effects of Conservation Hatcheries on Green Sturgeon (CM18)

Impact AQUA-143: Effects of Urban Stormwater Treatment on Green Sturgeon (CM19)

Impact AQUA-144: Effects of Removal/Relocation of Nonproject Diversions on Green Sturgeon (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on green sturgeon are the same as those described under Alternative 1A (Impacts AQUA-136 through AQUA-144). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

White Sturgeon

Construction and Maintenance of CM1

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

The potential effects of construction of the water conveyance facilities on white sturgeon would be similar to those described for Alternative 1A, Impact AQUA-145, except that Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less. Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-145, the effect would not be adverse for white sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-145, the impact of the construction of the water conveyance facilities on white sturgeon would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A, Impact AQUA-146, except that only three intakes would need to be maintained under Alternative 4, compared to the five intakes under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-146, the impact would not be adverse for white sturgeon.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-146, the impact of the maintenance of water conveyance facilities on white sturgeon would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Water Exports

The potential effects of the water operations under Alternative 4 would be the same as those described for green sturgeon (see Impact AQUA-129), which is a reduction in entrainment at the south Delta facilities, and avoidance or reduction of entrainment at the proposed north Delta diversion facilities and the NBA alternative intake. As concluded in Impact AQUA-129, the impact of Alternative 4 on white sturgeon would not be adverse.

Predation Associated with Entrainment

The potential effects would be the same as described for green sturgeon in Alternative 4 (see Impact AQUA-129).

NEPA Effects: In conclusion, the effect of Alternative 4 operations on entrainment and associated predation of white sturgeon would not be adverse and may provide modest benefit due to reduced losses at the south Delta facilities.

CEQA Conclusion: As described above for green sturgeon (Impact AQUA-129) the impact of water operations on white sturgeon would be less than significant and no mitigation would be required.

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

In general, Alternative 4 would not affect spawning and egg incubation habitat for white sturgeon relative to the NAA. Alternative 4 would provide flow-related benefits to green sturgeon spawning in the Feather River.

H3/ESO

Sacramento River

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon. Flows at Wilkins Slough and Verona during February through April under H3 would generally be similar to those under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows during May at both locations would generally be greater than flows under NAA.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-107. For the 61°F threshold, there would be 11 fewer (19% fewer) "red" years under H3 than under NAA. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between NAA and H3.

Table 11-4-107. Differences between Baselines and H3 Scenarios in the Number of Years in Which Water Temperature Exceedances above the 61°F and 68°F Thresholds Are Within Each Level of Concern, Sacramento River at Hamilton City, March through June

Level of Concern	EXISTING CONDITIONS vs. H3	NAA vs. H3
61°F threshold		
Red	38 (475%)	-11 (-19%)
Orange	-4 (-27%)	-1 (-8%)
Yellow	-13 (-42%)	8 (80%)
None	-21 (-75%)	4 (133%)
68°F threshold		
Red	0 (NA)	0 (NA)
Orange	0 (NA)	0 (NA)
Yellow	1 (NA)	-2 (-200%)
None	-1 (-1%)	2 (2%)

NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4-108, Table 11-4-109). Total degree-days exceeding the 61°F threshold under H3 would be 1 degree-day (6%) greater than those during March, which would not be biologically meaningful. During April through June, total degree days above 61°F would be 41 to 774 (9% to 16%) lower under H3 than under NAA. Total degree-days exceeding the 68°F threshold be similar between NAA and H3, except during May, in which exceedances would be 20 degree-days (30%) fewer under H3.

Table 11-4-108. Differences between Baseline and H3 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 61°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	5 (NA)	1 (25%)
	Dry	11 (NA)	0 (0%)
	Critical	1 (NA)	0 (0%)
	All	17 (NA)	1 (6%)
April	Wet	65 (542%)	-1 (-1%)
	Above Normal	59 (590%)	-9 (-12%)
	Below Normal	62 (1,033%)	0 (0%)
	Dry	113 (222%)	-31 (-16%)
	Critical	14 (1,400%)	0 (0%)
	All	313 (391%)	-41 (-9%)
May	Wet	990 (297%)	-125 (-9%)
	Above Normal	223 (102%)	-128 (-22%)
	Below Normal	380 (207%)	-69 (-11%)
	Dry	247 (122%)	-186 (-29%)
	Critical	368 (182%)	18 (3%)
	All	2,208 (194%)	-490 (-13%)
June	Wet	639 (111%)	-319 (-21%)
	Above Normal	124 (41%)	-242 (-36%)
	Below Normal	364 (173%)	-138 (-19%)
	Dry	578 (173%)	-124 (-12%)
	Critical	595 (159%)	49 (5%)
	All	2,300 (128%)	-774 (-16%)

NA = could not be calculated because the denominator was 0.

Table 11-4-109. Differences between Baseline and H3 Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 68°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Mar	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
Apr	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
May	Wet	35 (500%)	-1 (-2%)
	Above Normal	1 (NA)	-19 (-95%)
	Below Normal	1 (NA)	1 (NA)
	Dry	0 (NA)	-2 (-100%)
	Critical	2 (NA)	1 (100%)
	All	39 (557%)	-20 (-30%)
Jun	Wet	7 (NA)	-1 (-13%)
	Above Normal	1 (100%)	-3 (-60%)
	Below Normal	2 (NA)	0 (0%)
	Dry	0 (NA)	0 (NA)
	Critical	13 (NA)	-14 (-52%)
	All	23 (2,300%)	0 (NA)

NA = could not be calculated because the denominator was 0.

Feather River

Flows in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows at Thermalito Afterbay under H3 would generally be greater by up to 59% than those under NAA, with some exceptions. Flows at the confluence with the Sacramento River under H3 would be similar to or greater than flows under NAA, with some exceptions.

Mean monthly water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period. Mean monthly water temperatures would not differ between NAA and H3 at either location throughout the period.

San Joaquin River

Flows in the San Joaquin River at Vernalis under H3 during February through May would not be different from flows under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Water temperature modeling was not conducted for the San Joaquin River.

H1/LOS

Sacramento River

Flows under H1 in the Sacramento River at Wilkins Slough and Verona during February to May would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1in any month or water year type throughout the period.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-110. For the 61°F threshold, there would be 11 fewer (19% fewer) "red" years under H1 than under NAA. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between NAA and H1.

Table 11-4-110. Differences between Baselines and H1 and H4 Scenarios in the Number of Years in Which Water Temperature Exceedances above the 61°F and 68°F Thresholds Are within Each Level of Concern, Sacramento River at Hamilton City, March through June

Level of Concern	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
61°F threshold				
Red	38 (475%)	-11 (-19%)	51 (638%)	2 (4%)
Orange	-3 (-20%)	0 (0%)	-4 (-27%)	-1 (-8%)
Yellow	-16 (-52%)	5 (50%)	-23 (-74%)	-2 (-20%)
None	-19 (-68%)	6 (200%)	-24 (-86%)	1 (33%)
68°F threshold				
Red	0 (NA)	0 (NA)	0 (NA)	0 (NA)
Orange	0 (NA)	0 (NA)	0 (NA)	0 (NA)
Yellow	1 (NA)	-2 (-67%)	2 (NA)	-1 (-33%)
None	-1 (-1%)	2 (3%)	-2 (-2%)	1 (1%)

NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4-111, Table 11-4-112). Total degree-days exceeding the 61°F threshold under H1 would be 5 degree-days (31%) greater than those during March, which would not be biologically meaningful. During April, degree-days would be similar between NAA and H1. During May through June, total degree-days above 61°F would be 533 to 801 (14% to 16%) lower under H1 than under NAA. Total degree-days exceeding the 68°F threshold be similar between NAA and H3, except during May and June, in which exceedances would be 21 and 18 degree-days (32% and 43%, respectively) fewer under H1.

Table 11-4-111. Differences between Baselines and H1 and H4 Scenarios in Total Degree-Days (°F-days) by Month and Water Year Type for Water Temperature Exceedances above 61°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
March	Wet	0 (NA)	0 (NA)	0 (NA)	0 (NA)

	All	23 (2,300%)	-18 (-43%)	22 (2,200%)	-19 (-45%)

NA = could not be calculated because the denominator was 0.

Feather River

Flows under H1 in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February to May would generally be similar to flows under H3 with few exceptions.

Mean monthly water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period. Mean monthly water temperatures would not differ between NAA and H1 at either location throughout the period.

San Joaquin River

Flows under H1 in the San Joaquin River would be the same as those under H3.

Water temperature modeling was not conducted for the San Joaquin River.

H4/HOS

Sacramento River

Flows under H4 in the Sacramento River at Wilkins Slough and Verona during February to May would generally be similar to or greater than flows under H3 with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H4 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-110. For the 61°F threshold, there would be 2 more (4%) "red" years under H4 than under NAA, which would not be biologically meaningful. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between NAA and H4.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4-111, Table 11-4-112). Total degree-days exceeding the 61°F threshold under H4 would be 5 degree-days (31%) greater than those during March, which would not be biologically meaningful. During the remaining months, there would be no differences between NAA and H4 in total degree-days exceeding the 61°F threshold. Total degree-days exceeding the 68°F threshold be similar between NAA and H4, except during June, in which exceedances would be 19 degree-days (45%) fewer under H4.

Feather River

Flows under H4 in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February to May would generally be similar to or greater than flows under H3 with few exceptions.

Mean monthly water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period. Mean monthly water temperatures would not differ between NAA and H4 at either location throughout the period.

San Joaquin River

Mean monthly flows in the San Joaquin River at Vernalis under H4 during February through May would be similar to those under NAA (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Water temperature modeling was not conducted for the San Joaquin River.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. Flows under Alternative 4 would generally be higher in the Feather River under Alternative 4 relative to the NAA and generally similar to flows under the NAA in the Sacramento and San Joaquin Rivers. Alternative 4 would not affect temperatures in any river during the white sturgeon spawning and egg incubation period. Results would generally be similar among model scenarios

CEQA Conclusion: In general, Alternative 4 would not reduce spawning and egg incubation habitat for white sturgeon relative to Existing Conditions.

Sacramento River

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). At Wilkins Slough, flows under H3 during February through April would be similar to those under Existing Conditions with few exceptions, and greater by up to 28% than flows under Existing Conditions during May with few exceptions. At Verona, flows under H3 during February would be generally lower by up to 9% than flows under Existing Conditions with few exceptions. Flows under H3 during March and April would generally be similar to flows under Existing Conditions with few exceptions. Flows under H3 during May would generally be greater by up to 18% than flows under Existing Conditions with few exceptions.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H3 in any month or water year type throughout the period, except for a 5% increase in wet years during May.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H3 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-107. For the 61°F threshold, there would be 38 more (475% increase) "red" years under H3 than under Existing Conditions. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between Existing Conditions and H3.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4-108, Table 11-4-109). Total degree-days exceeding the 61°F threshold under H3 would be 17 degree-days (percent change unable to be calculated due to division by 0) to 2,300 degree-days (128%) higher depending on month. Total degree-days exceeding the 68°F threshold would not differ between Existing Conditions and H3 during March and April. During May and June, total degree-days would be 39 (557%) and 23 (2,300%) degree-days higher under H3, although these small absolute differences would not cause a biologically meaningful effect on white sturgeon.

Feather River

Flows in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows at Thermalito Afterbay under H3 during February would generally be lower by up to 45% than flows under Existing Conditions with few exceptions, and flows during March through May would generally be greater by up to 131% than those under Existing Conditions, with few exceptions. Flows at the confluence with the Sacramento River under H3 would generally be similar to or greater than flows under Existing Conditions, except in below normal years during February and March (11% and 20% lower, respectively) and wet years during May (26% lower). These results indicate that there would be few reductions in flows in the Feather River under H3 relative to Existing Conditions.

Mean monthly water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would not differ between Existing Conditions and H3 at either location throughout the period, except below Thermalito Afterbay during February, in which temperatures under H3 would be 6% higher than temperatures under Existing Conditions.

San Joaquin River

Mean monthly flows in the San Joaquin River at Vernalis under H3 during February through May would be similar to those under Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Water temperature modeling was not conducted for the San Joaquin River.

H1/LOS

Sacramento River

Flows under H1 in the Sacramento River at Wilkins Slough and Verona during the February through May white sturgeon spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period, except for a 5% increase in wet years during May.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above each threshold were further assigned a “level of concern”, as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-110. For the 61°F threshold, there would be 38 more (475% increase) “red” years under H1 than under Existing Conditions. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between Existing Conditions and H1.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4-108, Table 11-4-109). Total degree-days exceeding the 61°F threshold under H3 would be 21 degree-days (percent change unable to be calculated due to division by 0) to 2,273 degree-days (126%) higher depending on month. Total degree-days exceeding the 68°F threshold would not differ between Existing Conditions and H1 during March and April. During May and June, total degree-days would be 38 (543%) and 23 (2,300%) degree-days higher under H1, although these small absolute differences would not cause a biologically meaningful effect on white sturgeon.

Feather River

Flows under H1 in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February to May would generally be similar to flows under H3 with few exceptions.

Mean monthly water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would not differ between Existing Conditions and H1 at either location throughout the period, except below Thermalito Afterbay during February, in which temperatures under H1 would be 6% higher than temperatures under Existing Conditions.

San Joaquin River

Flows under H1 in the San Joaquin River would be the same as those under H3.

Water temperature modeling was not conducted for the San Joaquin River.

Results of these analyses for H1 would be the same as those for H3. Overall, results for H1 would be similar to those under H3.

H4/HOS

Sacramento River

Flows under H4 in the Sacramento River at Wilkins Slough and Verona during February to May would generally be similar to or greater than flows under H3 with few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and H1 in any month or water year type throughout the period, except for a 5% increase in wet years during May.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-4-13). The combination of number of days and degrees above each threshold were further assigned a "level of concern", as defined in Table 11-4-14. Differences between baselines and H1 in the highest level of concern across all months and all 82 modeled years are presented in Table 11-4-110. For the 61°F threshold, there would be 38 more (475% increase) "red" years under H1 than under Existing Conditions. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between Existing Conditions and H1.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-4-108, Table 11-4-109). Total degree-days exceeding the 61°F threshold under H3 would be 21 degree-days (percent change unable to be calculated due to division by 0) to 2,273 degree-days (126%) higher depending on month. Total degree-days exceeding the 68°F threshold would not differ between Existing Conditions and H1 during March and April. During May and June, total degree-days would be 38 (543%) and 23 (2,300%) degree-days higher under H1, although these small absolute differences would not cause a biologically meaningful effect on white sturgeon.

Feather River

Flows under H4 in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February to May would generally be similar to or greater than flows under H3 with few exceptions.

Mean monthly water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would not differ between Existing Conditions and H4 at either location throughout the period, except below Thermalito Afterbay during February, in which temperatures under H4 would be 6% higher than temperatures under Existing Conditions.

San Joaquin River

Flows under H4 in the San Joaquin River would be the same as those under H3.

Results of these analyses for H4 would be the same as those for H3. Overall, results for H4 would be similar to those under H3.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-148 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable spawning and egg incubation habitat for white sturgeon, contrary to the NEPA conclusion set forth above. There are small, infrequent reductions in flows in the Sacramento and Feather rivers that would not cause biologically meaningful effects to white sturgeon spawning and egg incubation habitat. However, there would be differences in exceedances of NMFS temperature thresholds in the Sacramento and Feather River that would cause a biologically meaningful effect to white sturgeon spawning and egg incubation. Results would generally be consistent among scenarios.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for white sturgeon. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

In general, Alternative 4 would not affect quantity and quality of white sturgeon larval and juvenile rearing habitat relative to the NAA.

H3/ESO

Water temperature was used to determine the potential effects of H3 on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H3 in any month or water year type throughout the period

Water temperatures were not modeled in the San Joaquin River.

H1/LOS

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water*

Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis). There would be no differences (<5%) in mean monthly water temperature between NAA and H1 in any month or water year type throughout the period.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H1in any month or water year type throughout the period.

Water temperatures were not modeled in the San Joaquin River.

H4/HOS

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA and H4 in any month or water year type throughout the period.

Water temperatures were not modeled in the San Joaquin River.

NEPA Effects: These results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. There would be no differences in water temperatures between Alternative 4 and the NEPA point of comparison. Results would be similar among scenarios.

CEQA Conclusion: In general, Alternative 4 would not affect the quantity and quality of white sturgeon larval and juvenile rearing habitat relative to Existing Conditions.

H3/ESO

Water temperature was used to determine the potential effects of H3 on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions and H3 during November through July and September, but 6% and 5% higher under H3 relative to Existing Conditions during August and October, respectively.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions and H3 during March through July and September, but 5% to 8% higher under H3 relative to Existing Conditions during October through February and August.

Water temperatures were not modeled in the San Joaquin River.

H1/LOS

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions and H1 during November through July and September, but 6% and 7% higher under H1 relative to Existing Conditions during August and September, respectively.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions and H1 during March through July and September, but 5% to 8% higher under H1 relative to Existing Conditions during October through February and August.

Water temperatures were not modeled in the San Joaquin River.

H4/HOS

Mean monthly water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions and H4 during November through July and September, but 5% higher under H4 relative to Existing Conditions during August and October.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions and H4 during March through June and September, but 6% to 8% higher under H4 relative to Existing Conditions during October through February and July through August.

Water temperatures were not modeled in the San Joaquin River.

Summary of CEQA Conclusion

These results indicate that the effect is less than significant because it does not have the potential to substantially reduce the amount of suitable habitat and no mitigation is required. There would be no differences in water temperatures between Alternative 4 and the CEQA baseline. Results would be similar among scenarios.

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

In general, effects of Alternative 4 on white sturgeon migration conditions relative to NAA are uncertain.

Upstream of the Delta

H3/ESO

Analyses for white sturgeon focused on the Sacramento River (North Delta to RM 143—i.e., Wilkins Slough and Verona CALSIM nodes). Larval transport flows were represented by the average number of months per year that exceeded thresholds of 17,700 cfs (Wilkins Slough) and 31,000 cfs (Verona) (Table 11-4-113). Exceedances of the 17,700 cfs threshold for Wilkins Slough and the 31,000 cfs threshold at Verona under H3 would generally be similar to those under NAA. Despite some large relative difference (up to 50%), these changes would be negligible on an absolute scale.

Table 11-4-113. Difference and Percent Difference in Number of Months in Which Flow Rates Exceed 17,700 and 5,300 cfs in the Sacramento River at Wilkins Slough and 31,000 cfs at Verona

	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wilkins Slough, 17,700 cfs[a]		
Wet	0 (-2%)	0 (0%)
Above Normal	0.3 (18%)	0.1 (5%)
Below Normal	-0.1 (-25%)	0 (0%)
Dry	0 (0%)	0 (0%)
Critical	0 (0%)	0 (0%)
Wilkins Slough, 5,300 cfs[b]		
Wet	-0.2 (-3%)	0 (0%)
Above Normal	-0.3 (-4%)	0.1 (1%)
Below Normal	0.3 (5%)	0.6 (12%)
Dry	0.4 (9%)	0.2 (3%)
Critical	0.2 (5%)	0.1 (2%)
Verona, 31,000 cfs[a]		
Wet	-0.5 (-21%)	-0.2 (-9%)
Above Normal	-0.2 (-10%)	0 (0%)
Below Normal	-0.2 (-43%)	-0.1 (-33%)
Dry	-0.2 (-60%)	-0.1 (-50%)
Critical	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] Months analyzed: February through May.
[b] Months analyzed: November through May.

Larval transport flows were also examined by utilizing the positive correlation between year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved larval transport that results in improved year class strength. The percentage of months exceeding flow thresholds under H3 would generally be lower than those under NAA (up to 50% lower) (Table 11-4-114).

These results indicate that, using the positive correlation between Delta outflow and year class strength, year class strength generally would be lower under H3.

Table 11-4-114. Difference and Percent Difference in Percentage of Months in Which Average Delta Outflow is Predicted to Exceed 15,000, 20,000, and 25,000 Cubic Feet per Second (cfs) in April and May of Wet and Above-Normal Water Years

Flow	Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
April			
15,000 cfs	Wet	-8 (-8%)	-8 (-8%)
	Above Normal	-17 (-18%)	-17 (-18%)
20,000 cfs	Wet	-8 (-9%)	-8 (-9%)
	Above Normal	-25 (-33%)	-17 (-25%)
25,000 cfs	Wet	-15 (-19%)	-12 (-15%)
	Above Normal	-17 (-29%)	-8 (-17%)
May			
15,000 cfs	Wet	-8 (-9%)	0 (0%)
	Above Normal	-17 (-20%)	8 (14%)
20,000 cfs	Wet	-35 (-41%)	-12 (-19%)
	Above Normal	-17 (-40%)	-8 (-25%)
25,000 cfs	Wet	-27 (-39%)	-15 (-27%)
	Above Normal	-17 (-50%)	-8 (-33%)
April/May Average			
15,000 cfs	Wet	-8 (-8%)	0 (0%)
	Above Normal	-25 (-25%)	-17 (-18%)
20,000 cfs	Wet	-19 (-22%)	-15 (-18%)
	Above Normal	-17 (-25%)	0 (0%)
25,000 cfs	Wet	-19 (-24%)	-8 (-11%)
	Above Normal	-25 (-50%)	-25 (-50%)

For juveniles, flows in the Sacramento River at Verona were examined during the year-round migration period (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows at Verona under H3 would be lower by up to 25% relative to NAA during January, July, August, and November, greater by up to 32% greater during May and June, and similar in the remaining six months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For adults, the average number of months per year during the November through May adult migration period in which flows in the Sacramento River at Wilkins Slough exceed 5,300 cfs was determined (Table 11-4-113). The average number of months exceeding 5,300 cfs under H3 would be similar to or greater than the number of months under NAA (up to 12% greater).

H1/LOS

Year-round flows under H1 in the Sacramento River at Wilkins Slough and Verona would be similar to those under H3, except during November at Wilkins Slough in which flows would be up to 13% lower under H1 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be frequent or large enough to have biologically meaningful effects on white sturgeon migration in the Sacramento River. Because flows under H1 in the Sacramento River would be similar to those under H3, additional flow threshold analyses were not warranted. Results of these analyses for H1 would be the same as those for H3. Overall, results for H1 would be similar to those for H3.

H4/HOS

Year-round flows under H1 in the Sacramento River at Wilkins Slough and Verona would be similar to those under H3, except during May and June at Wilkins Slough (up to 21% lower) and during June through August at Verona (up to 23% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be frequent or large enough to have biologically meaningful effects on white sturgeon migration in the Sacramento River. Because flows under H4 in the Sacramento River would be similar to those under H3, additional flow threshold analyses were not warranted. Results of these analyses for H4 would be the same as those for H3. Overall, results for H4 would be similar to those for H3.

Through-Delta

The impact of Alternative 4 on in-Delta movement conditions would be the same as described above for splittail (Impact AQUA-114). The effect on white sturgeon would not be adverse.

NEPA Effects: Upstream flows (above north Delta intakes) are similar between Alternative 4 and NAA (Table 11-4-113). However, due to the removal of water at the North Delta intakes, there are substantial differences in through-Delta flows between Alternative 4 and NAA (Table 11-4-114). Analysis of white sturgeon year-class strength (USFWS 1995) found a positive correlation between year class strength and Delta outflow during April and May. However, this conclusion was reached in the absence of north Delta intakes and the exact mechanism that causes this correlation is not known at this time. One hypothesis suggests that the correlation is caused by high flows in the upper river resulting in improved migration, spawning, and rearing conditions in the upper river. Another hypothesis suggests that the positive correlation is a result of higher flows through the Delta triggering more adult sturgeon to move up into the river to spawn. It is also possible that some combination of these factors are working together to produce the positive correlation between high flows and sturgeon year-class strength.

The scientific uncertainty regarding which mechanisms are responsible for the positive correlation between year class strength and river/Delta flow will be addressed through targeted research and monitoring to be conducted in the years leading up to the initiation of north Delta facilities operations. If these targeted investigations determine that the primary mechanisms behind the positive correlation between high flows and sturgeon year-class strength are related to upstream conditions, then Alternative 4 would be deemed Not Adverse due to the similarities in upstream flow conditions between Alternative 4 and NAA. However, if the targeted investigations lead to a conclusion that the primary mechanisms behind the positive correlation are related to in-Delta and through-Delta flow conditions, then Alternative 4 would be deemed adverse due to the magnitude of reductions in through-Delta flow conditions in Alternative 4 as compared to NAA.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, migration conditions for white sturgeon would not be affected relative to the CEQA baseline.

Upstream of the Delta

H3/ESO

The number of months per year with exceedances above the 17,700 cfs threshold for Wilkins Slough under H3 would generally be similar to or greater those under Existing Conditions, except in below normal years (25% lower)(Table 11-4-113). The number of months per year exceeding 31,000 cfs at Verona under H3 would generally be up to 60% lower than those under Existing Conditions except in critical years, in which there would be no change from Existing Conditions.

For Delta outflow, the percent of months exceeding outflow thresholds under H3 would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (8% to 50% lower on a relative scale) (Table 11-4-114).

For juveniles, flows in the Sacramento River at Verona were examined during the year-round migration period. In general, flows under H3 would be lower relative to Existing Conditions during January, February, July, August, and November (up to 29% lower), greater during May and June (up to 33% greater), and similar during the remaining five months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

For adult migration, the average number of months exceeding 5,300 cfs at Wilkins Slough under H3 would generally be greater than the number of months under Existing Conditions (up to 9% greater), except in wet and above normal water years, in which exceedances would be similar between H3 and Existing Conditions (Table 11-4-113).

H1/LOS

Year-round flows under H1 in the Sacramento River at Wilkins Slough and Verona would be similar to those under H3, except during November at Wilkins Slough in which flows would be up to 13% lower under H1 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be frequent or large enough to have biologically meaningful effects on white sturgeon migration in the Sacramento River. Because flows under H1 in the Sacramento River would be similar to those under H3, additional flow threshold analyses were not warranted. Results of these analyses for H1 would be the same as those for H3. Overall, results for H1 would be similar to those for H3.

H4/HOS

Year-round flows under H4 in the Sacramento River at Wilkins Slough and Verona would be similar to those under H3, except during May and June at Wilkins Slough (up to 21% lower) and during June through August at Verona (up to 23% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These reductions would not be frequent or large enough to have biologically meaningful effects on white sturgeon migration in the Sacramento River. Because flows under H4 in the Sacramento River would be similar to those under H3, additional flow threshold analyses were not warranted. Results of these analyses for H4 would be the same as those for H3. Overall, results for H4 would be similar to those for H3.

Through-Delta

As described above in Impact AQUA-150, the potential impact of Alternative 4 on white sturgeon is considered less than significant, and no mitigation would be required.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-150 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce migration conditions for green sturgeon, contrary to the NEPA conclusion set forth above. The exceedance of flow thresholds in the Sacramento River and for Delta outflow would be lower under Alternative 4 than under Existing Conditions, although there is high uncertainty that year class strength is due to Delta outflow or if both year class strength and Delta outflows are co-variable with another unknown factor. Juvenile migration flows in the Sacramento River at Verona would be up to 29% lower in five of 12 months relative to Existing Conditions. These reduced flows would have a substantial effect on the ability to migrate downstream, delaying or slowing rates of successful migration downstream and increasing the risk of mortality. There would be no effects of Alternative 4 on through-Delta migration conditions.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alterantive 4 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and Alternative 4 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and Alternative 4. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion of not adverse, and therefore would not in itself result in a significant impact on migration conditions for white sturgeon. Additionally, as described above in the NEPA Effects statement, further investigation is needed to better understand the association of Delta outflow to sturgeon recruitment, and if needed, adaptive management would be used to make adjustments to meet the biological goals and objectives. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for white sturgeon under Alternative 1A (Impacts AQUA-151 through AQUA-153) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on white sturgeon are the same for Alternative 4, as those described under Alternative 1A (Impacts AQUA 151-through AQUA-153). The effects would not be adverse, and would generally be beneficial. Specifically for AQUA-152, the effects of contaminants on white sturgeon with respect to copper, ammonia and pesticides would not be adverse. The effects of methylmercury and selenium on white sturgeon are uncertain.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for white sturgeon under Alternative 1A (Impacts AQUA-154 through AQUA-162) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (CM12)

Impact AQUA-155: Effects of Invasive Aquatic Vegetation Management on White Sturgeon (CM13)

Impact AQUA-156: Effects of Dissolved Oxygen Level Management on White Sturgeon (CM14)

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (CM15)

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (CM16)

Impact AQUA-159: Effects of Illegal Harvest Reduction on White Sturgeon (CM17)

Impact AQUA-160: Effects of Conservation Hatcheries on White Sturgeon (CM18)

Impact AQUA-161: Effects of Urban Stormwater Treatment on White Sturgeon (CM19)

Impact AQUA-162: Effects of Removal/Relocation of Nonproject Diversions on White Sturgeon (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on white sturgeon are the same as those described under Alternative 1A (Impacts AQUA-154 through AQUA-162). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

Pacific Lamprey

Construction and Maintenance of CM1

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

The potential effects of construction of the water conveyance facilities on Pacific lamprey would be similar to those described for Alternative 1A, Impact AQUA-163, except that Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less. Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-163, the effect would not be adverse for Pacific lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-163, the impact of the construction of the water conveyance facilities on Pacific lamprey would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A, Impact AQUA-164, except that only three intakes would need to be maintained under Alternative 4 rather than five under

Alternative 1A. As concluded in Alternative 1A, Impact AQUA-2, the impact would not be adverse for Pacific lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-164, the impact of the maintenance of water conveyance facilities on Pacific lamprey would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

Water Exports

The potential entrainment impacts of Alternative 4 on Pacific lamprey and river lamprey would be the same as described above for Alternative 1A for operating SWP/CVP south Delta export facilities and the proposed new SWP/CVP North Delta intakes (Impacts AQUA-165), non-physical barriers at the entrances to CCF and the DMC (Impacts AQUA-176), and decommissioning agricultural diversions in ROAs (Impacts AQUA-180). These actions would avoid or reduce potential entrainment and the effect would not be adverse and may be beneficial.

The analysis of Pacific lamprey and river lamprey entrainment at the SWP/CVP south Delta export facilities is combined because the salvage facilities do not distinguish between the two lamprey species. Under Scenario H3, average annual entrainment of lamprey at the south Delta export facilities would be substantially reduced by about 41% (Table 11-4-115) across all year types compared to the NAA. Entrainment losses would be similar between Scenario H3 and the Scenario H1, but would be further reduced under Scenario H4 compared to NAA. Therefore, Alternative 4 would not have adverse effects on lamprey.

Predation Associated with Entrainment

Entrainment-related predation loss of lamprey at the south Delta facilities would not be greater under this Alternative and may be lower due to a reduction in entrainment loss. Conditions under Scenario H4 would decrease predation loss relative to NAA and Scenario H3, while conditions would be similar between Scenario H1 and Scenario H3. Predation at the north Delta would be increased due to the installation of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta facilities is unknown because of the lack of knowledge about their distribution and population abundances in the Delta.

NEPA Effects: Overall, it is expected that the effect of predation loss on lamprey under Alternative 4 may be moderate, but would not be adverse.

CEQA Conclusion: Annual entrainment losses of lamprey would be decreased under Scenario H3 by 43% relative to existing biological conditions. Conditions would be similar between Scenario H3 and H1, while entrainment would be further decreased under Scenario H4. Lamprey predation loss at the south Delta facilities would not be increased relative to Existing Conditions and may be decreased due to reduction entrainment losses. Predation at the north Delta would be increased due to the installation of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta facilities is unknown because of the lack of knowledge about their distribution and population abundances in the Delta. Overall, it is expected that the effect of predation loss on lamprey under Alternative 4 may be moderate, but would be less than significant.

Table 11-4-115. Lamprey Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities for Alternative 4 (Scenario H3)

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. A4_LLT	NAA vs. A4_LLT
All Years	-1,462 (-43%)	-1,356 (-41%)

[a] Estimated annual number of fish lost, based on non-normalized data.

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

In general, Alternative 4 would not affect the quality and quantity of spawning and egg incubation habitat for Pacific lamprey relative to the NAA.

H3/ESO

Flow-related impacts to Pacific lamprey spawning habitat were evaluated by estimating effects of flow alterations on egg exposure, called redd dewatering risk, and effects on water temperature. Rapid reductions in flow can dewater redds leading to mortality. Locations for each river used in the dewatering risk analysis were based on available literature, personal conversations with agency experts, and spatial limitations of the CALSIM II model, and include the Sacramento River at Keswick, Sacramento River at Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and the American River at Nimbus Dam and at the confluence with the Sacramento River. Pacific lamprey spawn in these rivers between January and August so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage). Water temperature results from the SRWQM and the Reclamation Temperature Model were used to assess the exceedances of water temperatures under all model scenarios in the upper Sacramento, Trinity, Feather, and American rivers.

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, and substrate) of river lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, January to August.

There would be negligible differences between H3 and NAA in exposure to flow reductions in all rivers except for a small (6%) increase in the Feather River at Thermalito Afterbay (Table 11-4-116). These results indicate that H3 would not have biologically meaningful effects on Pacific lamprey redd cohorts predicted to experience a month-over-month change in flow of greater than 50% in all locations analyzed.

Table 11-4-116. Differences between Model Scenarios in Dewatering Risk of Pacific Lamprey Redd Cohorts[a]

Location	EXISTING CONDITIONS vs. H3	NAA vs. H3
Sacramento River at Keswick	20 (36%)	-2 (-3%)
Sacramento River at Red Bluff	20 (37%)	2 (3%)
Trinity River downstream of Lewiston	0 (0%)	0 (0%)
Feather River at Thermalito Afterbay	-36 (-24%)	6 (6%)
American River at Nimbus Dam	32 (38%)	-5 (-4%)
American River at Sacramento River Confluence	34 (36%)	-6 (-4%)

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%. Positive values indicate a higher value in H3 than in Existing Conditions or NAA.

Significant reduction in survival of eggs and embryos of Pacific lamprey were observed at 22°C (71.6°F; Meeuwig et al. 2005). Therefore, in the Sacramento River, this analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) using daily data from SRWQM. For other rivers, the analysis predicted the number of consecutive 2 month periods during which at least one month exceeds 22°C (71.6°F) using monthly averaged data from the Reclamation temperature model. Each individual day or month starts a new "egg cohort" such that there are 19,928 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from January 1 through August 31, and 648 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Exact spawning locations of Pacific lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

In most locations, egg cohort exposure would not differ between NAA and H3 (Table 11-4-117). However, the number of cohorts exposed under H3 would be 100% and 93% lower than those under NAA in the Sacramento River at Keswick and Trinity River at Lewiston, respectively. Also, the number of cohorts exposed under H3 would be 11% and 53% greater than those under NAA in the Sacramento River at Hamilton City. The increases and decreases in egg cohort exposure under NAA would not have a biologically meaningful effect due to their small absolute values relative to total egg cohort sizes.

Table 11-4-117. Differences (Percent Differences) between Model Scenarios in Pacific Lamprey Egg Cohort Temperature Exposure[a]

Location	EXISTING CONDITIONS vs. H3	NAA vs. H3
Sacramento River at Keswick	0 (NA)	-51 (-100%)
Sacramento River at Hamilton City	1,186 (NA)	118 (11%)
Trinity River at Lewiston	4 (200%)	-83 (-93%)
Trinity River at North Fork	14 (NA)	-3 (-18%)
Feather River at Fish Barrier Dam	0 (NA)	-1 (-100%)
Feather River below Thermalito Afterbay	117 (488%)	49 (53%)
American River at Nimbus	74 (673%)	0 (0%)
American River at Sacramento River Confluence	158 (282%)	-2 (-1%)
Stanislaus River at Knights Ferry	2 (NA)	0 (0%)
Stanislaus River at Riverbank	87 (4,350%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey egg cohorts experiencing water temperatures above 71.6°F during January to August on at least one day during a 49-day incubation period in the Sacramento River or for at least one month during a 2-month incubation period for in other rivers each model scenario. Positive values indicate a higher value in H3 than in EXISTING CONDITIONS or NAA.

H1/LOS

Flows during January through August under H1 would generally be similar to or greater than flows under H3 in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H1 in these rivers and results for H1 would be the same as those for H3.

In the Feather River at Thermalito Afterbay, there would be 41 more cohorts (38%) exposed to a 50% month over month drop in flow rate under H1 relative to NAA (Table 11-4-118). Although relatively large, this value represents 6% of the population of ammocoetes. Therefore, it is not expected that this increase in exposure would have a biologically meaningful effect to the population.

Table 11-4-118. Differences between Model Scenarios in Dewatering Risk of Pacific Lamprey Redd Cohorts in the Feather River at Thermalito Afterbay[a]

Measurement	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
Difference (Percent Difference)	-1 (-1%)	41 (38%)	-30 (-20%)	12 (11%)

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%. Positive values indicate a higher value in H1 or H4 than in Existing Conditions or NAA.

Water temperatures would not differ between H1 and H3 and, therefore, no egg cohort temperature analyses were conducted. Overall, results for H1 would be similar to those for H3.

H4/HOS

Flows during January through August under H4 would generally be similar to or greater than flows under H3 in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H4 in these rivers and results for H4 would be the same as those for H3.

In the Feather River at Thermalito Afterbay, there would be 12 more cohorts (11%) exposed to a 50% month over month drop in flow rate under H4 relative to NAA (Table 11-4-118). Although relatively large, this value represents <2% of the population of ammocoetes. Therefore, it is not expected that this increase in exposure would have a biologically meaningful effect to the population.

Water temperatures would not differ between H4 and H3 and, therefore, no egg cohort temperature analyses were conducted. Overall, results for H4 would be similar to those for H3.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because Alternative 4 would not have substantial effects on spawning and egg incubation habitat for Pacific lamprey. Flows reductions that increase redd dewatering risk would not differ between the NEPA point of comparison and H3 in all locations except the in Feather River at Thermalito Afterbay. This result in the Feather River would be similar for H4 but dewatering risk would be higher under H1. There would be increases and decreases in exposure risk of eggs to elevated temperatures but would not have a biologically meaningful effect due to their small absolute values relative to total egg cohort sizes.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of spawning and egg incubation habitat for Pacific lamprey would not be affected relative to the CEQA baseline.

H3/ESO

Effects of H3 on month-over-month flow reduction compared to Existing Conditions consist of negligible effects (<5% difference) in the Trinity River, a decrease in egg cohorts exposed to flow reductions (-20%) in the Feather River, and moderate to substantial increases in exposures in the Sacramento River and American River (Table 11-4-116). Changes would be most substantial for the American River (increased risk of dewatering exposure to 40 cohorts or 48% at Nimbus Dam, and 44 cohorts or 46% at the confluence). For the Sacramento River, there would be increased exposure to flow reductions for 12 cohorts or 22% at Keswick, and to 8 cohorts or 15% at Red Bluff. These results indicate that effects of Alternative 4 on flow would not affect Pacific lamprey redd dewatering risk in the Feather River and Trinity River; Alternative 4 would affect dewatering risk in the Sacramento River (increases to 22%) and the American River (increase of 48% at Nimbus Dam and 46% at the confluence).

The number of egg cohorts exposed to 22°C (71.6°F) under H3 would be greater than that under Existing Conditions in all the river locations, except the Trinity River (Table 11-4-117).

H1/LOS

Flows during January through August under H1 would generally be similar to or greater than flows under H3 in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H1 in these rivers and results for H1 would be the same as those for H3.

In the Feather River at Thermalito Afterbay, there would be no difference between H1 and Existing Conditions in the number of cohorts exposed to a 50% month over month drop in flow rate (Table 11-4-118).

Water temperatures under H1 would be similar to those under H3 for all rivers examined. Therefore, no additional cohort temperature exposure analyses were conducted for H1. Overall, results for H1 would be similar to those for H3 except for redd dewatering risk in the Feather River.

H4/HOS

Flows during January through August under H4 would generally be similar to or greater than flows under H3 in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H4 in these rivers and results for H4 would be the same as those for H3.

In the Feather River at Thermalito Afterbay, there would be 30 fewer cohorts (20%) exposed to a 50% month over month drop in flow rate under H1 relative to NAA (Table 11-4-118). Although relatively large, this value represents <5% of the population of ammocoetes. Therefore, it is not expected that this decrease in exposure would have a biologically meaningful effect to the population.

Water temperatures under H4 would be similar to those under H3 for all rivers examined. Therefore, no additional cohort temperature exposure analyses were conducted for H4. Overall, results for H4 would be similar to those for H3.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-166 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality, contrary to the NEPA conclusion set forth above. There would be moderate increases in redd dewatering in the Sacramento River (up to 22%) and substantial increases in the American River (up to 48%) that would increase the risk of desiccation of eggs. There would be a substantial increase (up to 4,350%) in exposure of egg cohorts to elevated water temperatures in all rivers except the Trinity River that would increase stress and the risk of mortality.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for Pacific lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

In general, the effect of Alternative 4 on Pacific lamprey rearing habitat would be negligible relative to the NAA.

H3/ESO

Flow-related impacts to Pacific lamprey rearing habitat were evaluated by estimating of the frequency of rapid flow reductions in ammocoete rearing areas. Rapid reductions in flow can strand ammocoetes, leading to mortality. Comparisons of effects were made for ammocoete cohorts in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River. An ammocoete remains relatively immobile in the sediment in the same location for 5 to 7 years, after which it migrates downstream. During the upstream rearing period there is potential for ammocoete stranding from rapid reductions in flow.

The analysis of ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (January through August) and spend 7 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than a given flow reduction (50%–90% in 5% increments)at any time during the seven-year period.

Comparisons of month-over-month flow reductions for the Sacramento River at Keswick (Table 11-4-119) indicate that H3 would have either no effect (0%) or negligible effects (<5%) on cohort exposures to all flow reductions. These results indicate that there would be no difference in Pacific lamprey stranding risk between H3 and NAA in the Sacramento River at Keswick.

Table 11-4-119. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3	NAA vs. H3
-50%	0	0
-55%	0	0
-60%	4	0
-65%	3	3
-70%	-2	-2
-75%	-3	0
-80%	7	0
-85%	47	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of H3.

Results of comparisons for the Sacramento River at Red Bluff (Table 11-4-120) indicate that there would be no or negligible changes in most flow reductions and a moderate decrease (-16%) in exposure at the 80% flow reduction, which would be a beneficial effect on rearing conditions. These results indicate that there would generally be no or beneficial effects of H3 on Pacific lamprey ammocoete in the Sacramento River at Red Bluff.

Table 11-4-120. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Red Bluff

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3	NAA vs. H3
-50%	0	0
-55%	4	0
-60%	6	4
-65%	-2	-3
-70%	9	-2
-75%	0	-9
-80%	6	-16
-85%	100	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of H3.

Comparisons for the Trinity River indicate that there would be no differences in cohort exposure between NAA and H3 at any flow reduction (Table 11-4-121). These results indicate that there would be no effects of H3 on Pacific lamprey stranding risk in the Trinity River.

Table 11-4-121. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Trinity River at Lewiston

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3	NAA vs. H3
-50%	0	0
-55%	0	0
-60%	0	0
-65%	0	0
-70%	0	0
-75%	21	-3
-80%	27	0
-85%	18	0
-90%	41	3

[a] Negative values indicate reduced cohort exposure, a benefit of H3.

In the Feather River at Thermalito Afterbay, there would be no difference in ammocoete cohort exposure at the 50% through 75% flow reductions (Table 11-4-122). For the 80% through 90% flow reductions, ammocoete exposure would be 6% to 35% lower, which would have a beneficial effect on ammocoete rearing. These results indicate that there will be beneficial effects of H3 on Pacific lamprey ammocoete rearing in the Feather River.

Table 11-4-122. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Feather River at Thermalito Afterbay

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3	NAA vs. H3
-50%	0	0
-55%	0	0
-60%	0	0
-65%	0	0
-70%	0	0
-75%	0	0
-80%	-12	-10
-85%	-15	-35
-90%	-53	-6

[a] Negative values indicate reduced cohort exposure, a benefit of H3.

Comparisons for the American River at Nimbus Dam (Table 11-4-123) and at the confluence with the Sacramento River (Table 11-4-124) have similar results. There would be no or negligible differences in cohort exposure between NAA and H3 for the 50% to 70% flow reductions range, There would be higher cohort exposure under H3 relative to NAA at Nimbus Dam at the 75% flow reduction (7% higher) and at the confluence with the Sacramento River at the 75% (7% higher) and 80% (17% higher) flow reductions. There would be up to 25% lower cohort exposures under H3 relative to NAA at the remaining flow reductions at both locations. These results indicate that there would generally be no effect of H3 on stranding risk in the American River with few small exceptions that would not be common enough to have biologically meaningful effects.

Table 11-4-123. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, American River at Nimbus Dam

-65%	1	0
-70%	7	-1
-75%	45	7
-80%	246	17
-85%	186	-18
-90%	268	-12

[a] Negative values indicate reduced cohort exposure, a benefit of H3.

To evaluate water temperature-related effects of H3 on Pacific lamprey ammocoetes, we examined the predicted number of ammocoete "cohorts" that experience water temperatures greater than 71.6°F for at least one day in the Sacramento River (because daily water temperature data are available) or for at least one month in the Feather, American, Stanislaus, and Trinity rivers over a 7 year period, the maximum likely duration of the ammocoete life stage (Moyle 2002). Each individual day or month starts a new "cohort" such that there are 18,244 cohorts for the Sacramento River, corresponding to 82 years of ammocoetes being "born" every day each year from January 1 through August 31, and 593 cohorts for the other rivers using monthly data over the same period.

There would be differences in the number of ammocoete cohorts exposed to temperatures greater than 71.6°F in most of the rivers (Table 11-1A-125). However, each river with an increase in exposure would also have a site with a decrease in exposure. Overall, the increases and decreases are expected to balance out within rivers such that there would be no overall effect on Pacific lamprey ammocoetes.

Table 11-4-125. Differences (Percent Differences) between Model Scenarios in Pacific Lamprey Ammocoete Cohorts Exposed to Temperatures Greater than 71.6°F in at Least One Day or Month

Location	EXISTING CONDITIONS vs. H3	NAA vs. H3
Sacramento River at Keswick[b]	0 (NA)	-1,705 (-100%)
Sacramento River at Hamilton City[b]	13,236 (NA)	1,981 (18%)
Trinity River at Lewiston	136 (NA)	23 (20%)
Trinity River at North Fork	283 (NA)	-22 (-7%)
Feather River at Fish Barrier Dam	0 (NA)	-56 (-100%)
Feather River below Thermalito Afterbay	211 (55%)	72 (14%)
American River at Nimbus	359 (185%)	-8 (-1%)
American River at Sacramento River Confluence	159 (37%)	0 (0%)
Stanislaus River at Knights Ferry	56 (NA)	0 (0%)
Stanislaus River at Riverbank	530 (946%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Positive values indicate a higher value in H3 than in EXISTING CONDITIONS or NAA.

[b] Based on daily data; all other locations use monthly data; 1922–2003.

H1/LOS

There would be generally no differences in mean flows year-round between H1 and H3 in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between NAA and H1at the 50% through 80% flow reductions (Table 11-4-126). For the 85% and 90% flow reductions, ammocoete exposure under H1 would be 6% and 5% lower, respectively, than that under NAA. These results indicate that there will be very small beneficial effects of H1 on Pacific lamprey ammocoete rearing in the Feather River.

Table 11-4-126. Percent Difference between Baselines and H1 and H4 Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Feather River at Thermalito Afterbay

Percent Flow Reduction	Percent Difference[a] EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
-50%	0	0	0	0
-55%	0	0	0	0
-60%	0	0	0	0
-65%	0	0	0	0
-70%	0	0	0	0
-75%	0	0	0	0
-80%	0	2	-2	0.2
-85%	23	-6	14	-13
-90%	-53	-5	7	114

[a] Negative values indicate reduced cohort exposure under H1 or H4.

There would generally be no differences in mean water temperatures year-round between H1 and H3 in any river examined. As a result, no additional ammocoete temperature cohort exposure analyses were conducted for H1. Results of these analyses for H1 would be the same as those for H3.

Overall, these results indicate that results for H1 would generally be similar to those under H3.

H4/HOS

There would be generally no differences in mean flows year-round between H4 and H3 in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between NAA and H4 at the 50% through 80% flow reductions (Table 11-4-126). For the 85% and 90% flow reductions, ammocoete exposure under H4 would be 13% lower and 114% higher, respectively.

There would generally be no differences in mean water temperatures year-round between H4 and H3 in any river examined. As a result, no additional ammocoete cohort exposure analyses were conducted for H4. Results of these analyses for H4 would be the same as those for H3.

Overall, these results indicate that results for H4 would generally be similar to those under H3 except for an increase in ammocoete stranding risk exposure in the Feather River at 90% flow reduction under H4 if water operations were to move to this end of the operational range.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. There would generally be negligible effects or beneficial effects of H3 on Pacific lamprey ammocoete stranding risk in all rivers evaluated. Stranding risk under both H1 and H4 in the Feather River at Thermalito Afterbay would be higher than those under H3, such that benefits to stranding risk predicted for H3 would not be as large under these limits of the operational range. There would be increase and decreases in exposure risk of ammocoetes to elevated temperatures within each river evaluated that would balance out such that there would be no net effect on Pacific lamprey ammocoetes.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of rearing habitat for Pacific lamprey would not be affected relative to the CEQA baseline.

H3/ESO

Comparisons of H3 to Existing Conditions for the Sacramento River at Keswick indicate negligible changes (<5%) in occurrence of flow reductions for all flow reduction categories, with the exception of a small increase (7%) in occurrence of month-over-month flow reductions of 80% and a more substantial increase (161 to 236 cohorts or 47%) for 85% flow reductions (Table 11-4-119). Comparisons for the Sacramento River at Red Bluff indicate no effect (0%) or negligible effects (<5%) for all flow reduction categories with the exception of a small increase in exposure (6%) for 80% flow reduction events and a more substantial increase in exposure (56 to 112 cohorts or a 100% increase for 85% flow reduction events) (Table 11-4-120). Based on the fact that increases in exposure would only be substantial for a single flow reduction category, H3 would not be expected to have biologically meaningful negative effects on spawning success in the Sacramento River but would contribute incrementally to regional effects.

Increases of 18–41% are predicted for flow reductions from 75% to 90% for the Trinity River (Table 11-4-121); the percentages correspond generally to increased occurrences from approximately 400 events for Existing Conditions to approximately 500 events for H3. Despite the prevalence of increased exposure risk to the higher flow reduction events, the percentage of cohorts exposed to stranding risk is relatively small compared to the total number of cohorts and therefore effects on spawning success in the Trinity River would not be biologically meaningful but would contribute incrementally to regional effects.

Comparisons for the American River at Nimbus Dam (Table 11-4-123) and at the confluence with the Sacramento River (Table 11-4-124) indicate increased chance of occurrence of flow reductions between 65% or 70% and 90% for H3 compared to Existing Conditions; predicted increases ranged from 39 to 352% for Nimbus Dam and from 7 to 268% for the confluence. These persistent and substantial increases in exposures to larger flow reduction events would have biologically meaningful effects on Pacific lamprey ammocoete cohort stranding and therefore spawning success in the American River.

The number of ammocoete cohorts exposed to 71.6°F under H3 would be higher than those under Existing Conditions in most locations examined, except in the Sacramento River at Keswick and in the Feather River at the Fish Barrier Dam (Table 11-4-125).

H1/LOS

There would be generally no differences in mean flows year-round between H1 and H3 in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between Existing Conditions and H1at the 50% through 80% flow reductions (Table 11-4-126). For the 85% and 90% flow reductions, ammocoete exposure under H1 would be 23% higher and 53% lower, respectively.

There would generally be no differences in mean water temperatures year-round between H1 and H3 in any river examined. As a result, no additional ammocoete cohort exposure analyses were conducted for H1. Results of these analyses for H1 would be the same as those for H3.

Overall, these results indicate that results for H1 would generally be similar to those under H3 except for an increase in ammocoete stranding risk exposure in the Feather River at Thermalito Afterbay for the 80% flow reduction under H1 if water operations were to move to this end of the operational range.

H4/HOS

There would be generally no differences in mean flows year-round between H4 and H3 in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between Existing Conditions and H4 at the 50% through 80% flow reductions (Table 11-4-126). For the 85% and 90% flow reductions, ammocoete exposure under H4 would be 14% and 7% higher, respectively.

There would generally be no differences in mean water temperatures year-round between H4 and H3 in any river examined. As a result, no additional ammocoete cohort exposure analyses were conducted for H4. Results of these analyses for H4 would be the same as those for H3.

Overall, these results indicate that results for H4 would generally be similar to those under H3.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-167 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of ammocoete mortality, contrary to the NEPA conclusion set forth above. Risk of redd dewatering would increase to some degree under higher flow reductions in the Sacramento River at Red Bluff (56 to 112 cohorts or a 100% increase for 85% flow reduction events) and the Trinity River (increases of 18–41% for flow reductions from 75% to 90%), and substantially in the American River at Nimbus Dam (increases from 39% to 352%) and at the confluence with the Sacramento (39% to 356%). Flow reductions would increase the risk of ammocoete stranding and desiccation in these rivers. There would be a beneficial effect from decreased occurrence of flow reduction events (=reduced ammocoete stranding risk) in the Feather River (-12% to -53% for the three largest flow reduction categories) but this effect would not offset the more substantial reductions in the other locations. Stranding risk under both H1 and H4 in the Feather River would be higher than those under H3, such that benefits under H3 would not occur under these limits of the operational range. There would be an increase in exposure to critical water temperatures in all locations examined except the Sacramento River at Keswick, and the Feather River at the Fish Barrier Dam. Increased exposure to higher water temperatures would increase stress and mortality of ammocoetes.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for Pacific lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

In general, the effect of Alternative 4 on Pacific lamprey migration conditions would be negligible relative to the NAA.

H3/ESO

After 5 to7 years, Pacific lamprey ammocoetes migrate downstream and become macropthalmia (juveniles) once they reach the Delta. Migration generally is associated with large flow pulses in winter months (December through March) (USFWS unpublished data) meaning alterations in flow have the potential to affect downstream migration conditions. The effects of H3 water operations on seasonal migration flows for Pacific lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the likely migration pathways of Pacific lamprey during the likely macropthalmia migration period (December through May) were examined for the Sacramento River at Rio Vista and Red Bluff, the Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

The adult Pacific lamprey upstream migration period occurs between January and June. CALSIM II flow outputs were examined during these periods for each model scenario.

Sacramento River

Macropthalmia

Flows the Sacramento River at Rio Vista (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the December to May macropthalmia migration period. Flows under H3 would generally be lower by up to 25% under H3 relative to NAA. Based on the prevalence of moderate decreases in flow in drier water years for much of migration period, H3 would affect

Pacific lamprey macropthalmia migration conditions at this location. In the Sacramento River upstream of Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), flows under H3 during December through May would be similar to or greater than flows under NAA.

Adults

Flows in the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the January to June adult migration period. Flows under H3 would be similar to flows under NAA during January through April and slightly greater (by up to 12%) during May and June. These results indicate that H3 would generally not affect adult migration conditions in the Sacramento River.

Feather River

Juveniles

Flows in the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the December to May macropthalmia migration period. Flows under H3 during would generally be similar to or greater (up to 23% greater) than flows under NAA. These results indicate that effects of H3 on macropthalmia migration flows in the Feather River would generally be negligible.

Adults

Flows in the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the January through June adult migration period. Flows under H3 would generally be similar to flows under NAA during January through April and greater by up to 65% during May and June. Increases in flow would have a beneficial effect on migration conditions. These results indicate that H3 would not have negative effects on adult migration conditions in the Feather River.

American River

Juveniles

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the December through March macropthalmia migration period. Flows under H3 would generally be similar to flows under NAA with few small exceptions. These results indicate that H3 would not have negative effects on macropthalmia migration conditions in the American River.

Adults

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the January to June adult migration period. Flows under H3 during January through April would generally be similar to flows under NAA with few small exceptions. Flows under H3 during May and June would generally be greater by up to 25% than flows under NAA. Increases in flow would have a beneficial effect on migration conditions. These results indicate that H3 would not have negative effects on adult migration conditions in the American River.

H1/LOS

Flows in the Sacramento River at Rio Vista and upstream of Red Bluff under H1 during the December through May macropthalmia migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Sacramento River at Red Bluff under H1 during the January through June migration period would generally be similar to or greater than flows under H3.

Flows in the Feather River at the confluence with the Sacramento River under H1 during the December through May macropthalmia migration period and the January through June adult migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in the American River at the confluence with the Sacramento River under H1 during the December through May macropthalmia migration period and the January through June adult migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

These results indicate that the effects of H1 on Pacific lamprey migration conditions would generally be the same as those under H3.

H4/HOS

Flows in the Sacramento River at Rio Vista and upstream of Red Bluff under H4 during the December through May macropthalmia migration period would generally be similar to or greater than (up to 35% greater) flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), indicating that migration conditions for macropthalmia would be improved under H4 relative to H3. Flows in the Sacramento River at Red Bluff under H4 during the January through June migration period would generally be similar to or greater than (up to 35% greater) flows under H3, except during June in which flows under H4 would be up to 21% lower. Overall, due to infrequent differences, flows would not be different under H4 than those under H3.

Flows in the Feather River at the confluence with the Sacramento River under H4 during the December through May macropthalmia migration period would generally be similar to or greater than (up to 100% greater) flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), indicating that migration conditions for macropthalmia would be improved under H4 relative to H3. Flows in the Feather River at the confluence with the Sacramento River under H4 during the January through June migration period would generally be similar to or greater than (up to 100% greater) flows under H3, except during June in which flows under H4 would be up to 29% lower. Overall, due to infrequent differences, flows would not be different under H4 than those under H3.

Flows in the American River at the confluence with the Sacramento River under H4 during the December through May macropthalmia migration period and the January through June adult migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

These results indicate that the effects of H4 on Pacific lamprey migration conditions would generally be the same as those under H3.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce or degrade migration habitat or substantially reduce the number of fish as a result of mortality. Effects of Alternative 4 on mean monthly flow for the macropthalmia and adult migration periods consist primarily of negligible effects (<5%) in all locations analyzed, with infrequent and small decreases in flow for some months/water years that would not have biologically meaningful effects on migration conditions, with the exception of small to moderate flow reductions (to -29%) for some months and water year types during the migration periods in the Sacramento River at Rio Vista. The degree to which this reduction would affect lamprey is unknown, but given the predominance of negligible effects in other locations, it is not likely that reduced flows at this location would affect the Pacific lamprey population.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of migration habitat for Pacific lamprey would not be reduced relative to the CEQA baseline.

H3/ESO

Sacramento River

Macropthalmia

Comparisons of mean monthly flow rates for H3 to Existing Conditions in the Sacramento River at Rio Vista (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate negligible effects (<5% difference) from H3 or reductions in flow ranging from -5% to -47% in most water years for each of these months, with only a single occurrence of a small increase in flow during May in dry years (11%). There would be negligible effects or small (to approximately -11%) to moderate (to -26%) reductions in flow during drier water years under H3, when flow reductions would be more critical for migration conditions.

Comparisons for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate negligible effects (<5%) or small increases or decreases in flow (to 12%) under H3 that would not have biologically meaningful effects on migration conditions. Exceptions include a decrease in flow of -17% during May in wet years under H3 when flow reductions would not be as critical for migration conditions. Overall, the effects of H3 would primarily consist of negligible effects (<5%), and small increases or decreases that would not have biologically meaningful effects on macropthalmia migration conditions.

Adults

Comparisons of mean monthly flow for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January through June for H3 relative to Existing Conditions indicate that for most months and water year types, flows under H3 would be similar to (<5% difference) or greater than flows under Existing Conditions, with increases in mean monthly flow to 20% that would have a beneficial effect on migration conditions, and a small decrease in flow during March in below normal years (-10%) and a moderate decrease (-17%) during May in wet years when flow reductions would be less critical for migration conditions. Increases in mean monthly flow, particularly those that would occur in drier water years during January, March, May and June, would have beneficial effects on migration conditions. These results indicate that the effects of H3 on flow consist predominantly of negligible effects (<5%) or increases in flow (to 20%)

that would be beneficial for migration, and infrequent and small reductions in flow that would not have biologically meaningful negative effects on migration conditions.

Feather River

Juveniles

Comparisons for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate variable effects of H3 relative to Existing Conditions by month and water year type, with negligible effects (<5%), moderate increases in flow (to 20%) that would be beneficial for migration conditions, with occasional occurrences of moderate decreases in flow to -26%. Decreases in flow would occur in below normal years during January (-15%), February (-11%) and March (-20%), but otherwise effects of H3 in drier water years consist of negligible effects or increases in flow that would have beneficial effects. These results indicate that the effects of H3 on flows would not have negative effects on macropthalmia migration in the Feather River.

Adults

Comparisons of mean monthly flow for the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January to June indicate variable effects of H3 relative to Existing Conditions depending on the month and water year type, with primarily negligible effects (<5%), small to substantial increases in flow (to 59%) that would have a beneficial effect on migration conditions, and occasional small to moderate decreases in flow, including during January through March in below normal years (to -20%), during May in wet years (-26%) when effects on migration conditions would be less critical, and during June in wet (-8%) and critical (-10%) years. Based on the prevalence of negligible effects and increases in flow which would have a beneficial effect on migration conditions, and only occasional reductions in flow of small to moderate magnitude, these results indicate that effects of H3 on flow would not have biologically meaningful negative effects on adult migration conditions in the Feather River.

American River

Juveniles

Comparisons for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for December to May indicate variable effects of H3 relative to Existing Conditions, with negligible effects (<5%) or decreases in flow during December, increases in flow during January through March for some wetter water year types (to 27%) and decreases for some drier water year types (to -19%), negligible effects or small increases or decreases (to 9%) during April, and decreases to -31% during May in all water year types except dry (increase of 12%). Decreases in drier water years for December and January, and in critical years during February and March encompass much of the migration period and would affect macropthalmia migration conditions for that time-frame, particularly in critical years. These results indicate that there would be moderate to substantial decreases in mean monthly flow for much of the migration period (to -31%), including in drier water years, that would affect Pacific lamprey migration conditions.

Adults

Comparisons of mean monthly flow for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for January to June indicate variable effects of H3 relative to Existing Conditions depending on the month and water year type, with primarily increases in mean monthly flow (to 27%) during January through March in wetter years, and decreases (to -19%) in drier years. There would be primarily negligible effects (<5%) or small increases or decreases (to 9%) during April. There would be decreases (to -31%) in all but critical years (increase of 12%) during May, and decreases during June in wet (-29%) and critical (-39%) years with increases (to 23%) in the remaining water years. Effects during dry and critical years when changes in flow would be more important for migration include negligible effects and increases and decreases in mean monthly flows throughout the migration period. The largest flow reductions in drier water years would not occur until late in the migration period (May and June). These results indicate that effects of H3 consist of variable effects on flow and flow reductions in some months would be offset by increases in other months and would not have biologically meaningful effects on adult migration conditions.

H1/LOS

Flows in the Sacramento River at Rio Vista and upstream of Red Bluff under H1 during the December through May macropthalmia migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows in the Sacramento River at Red Bluff under H1 during the January through June migration period would generally be similar to or greater than flows under H3.

Flows in the Feather River at the confluence with the Sacramento River under H1 during the December through May macropthalmia migration period and the January through June adult migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flows in the American River at the confluence with the Sacramento River under H1 during the December through May macropthalmia migration period and the January through June adult migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

These results indicate that the effects of H1 on Pacific lamprey migration conditions would generally be the same as those under H3.

H4/HOS

Flows in the Sacramento River at Rio Vista and upstream of Red Bluff under H4 during the December through May macropthalmia migration period would generally be similar to or greater than (up to 35% greater) flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), indicating that migration conditions for macropthalmia would be improved under H4 relative to H3. Flows in the Sacramento River at Red Bluff under H4 during the January through June migration period would generally be similar to or greater than (up to 35% greater) flows under H3, except during June in which flows under H4 would be up to 21% lower. Overall, due to infrequent differences, flows would not be different under H4 than those under H3.

Flows in the Feather River at the confluence with the Sacramento River under H4 during the December through May macropthalmia migration period would generally be similar to or greater than (up to 100% greater) flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*), indicating that migration conditions for macropthalmia would be improved under H4 relative to H3. Flows in the Feather River at the confluence with the Sacramento River under H4 during the January through June migration period would generally be similar to or greater than (up to 100% greater) flows under H3, except during June in which flows under H4 would be up to 29% lower. Overall, due to infrequent differences, flows would not be different under H4 than those under H3.

Flows in the American River at the confluence with the Sacramento River under H4 during the December through May macropthalmia migration period and the January through June adult migration period would generally be similar to or greater than flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

These results indicate that the effects of H4 on Pacific lamprey migration conditions would generally be the same as those under H3.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-168 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish. Alternative 4 would cause decreases in mean monthly flow to -31% in the American River during a substantial portion of the macropthalmia migration period, including in drier water year types. A prevalence of flow reductions in the Sacramento River at Rio Vista (to -47%, including moderate reductions, to -26%, in drier water year types) would contribute incrementally to negative effects. Flow reductions during the macropthalmia life stage would increase migration delays to the ocean life stage and straying and increase the risk of mortality. Effects of Alternative 4 in the other locations analyzed would consist of negligible effects and/or increases or decreases in mean monthly flow that would generally balance out throughout the macropthalmia and adult migration periods, with the exception of greater magnitude and occurrence of beneficial increases in flow in the Feather River that would enhance migration conditions at that location. These results are consistent among scenarios.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration conditions for Pacific lamprey. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for Pacific lamprey under Alternative 1A (Impacts AQUA-169 through AQUA-171) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on Pacific lamprey are the same for Alternative 4, as those described under Alternative 1A (Impacts AQUA 169-through AQUA-171). The effects would not be adverse, and would generally be beneficial.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for Pacific lamprey under Alternative 1A (Impacts AQUA-172 through AQUA-180) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (CM12)

Impact AQUA-173: Effects of Invasive Aquatic Vegetation Management on Pacific Lamprey (CM13)

Impact AQUA-174: Effects of Dissolved Oxygen Level Management on Pacific Lamprey (CM14)

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (CM15)

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (CM16)

Impact AQUA-177: Effects of Illegal Harvest Reduction on Pacific Lamprey (CM17)

Impact AQUA-178: Effects of Conservation Hatcheries on Pacific Lamprey (CM18)

Impact AQUA-179: Effects of Urban Stormwater Treatment on Pacific Lamprey (CM19)

Impact AQUA-180: Effects of Removal/Relocation of Nonproject Diversions on Pacific Lamprey (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on Pacific lamprey are the same as those described under Alternative 1A (Impacts AQUA-172 through AQUA-180). The effects range from no effect, to not adverse, to beneficial.

CEQA Conclusion: The effects of the nine impact mechanisms listed above range from no impact, to less than significant, to beneficial, and no mitigation is required.

River Lamprey

Construction and Maintenance of CM1

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

The potential effects of construction of water conveyance facilities on river lamprey would be similar to those described for Alternative 1A, Impact AQUA-181, except that Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Alternative 4 would use five barge locations rather than six as under Alternative 1A so those effects would also be proportionally less. Additionally, construction and excavation at Clifton Court Forebay would be done in the dry via installation of cofferdams for isolation and dewatering of work areas. Implementation of Appendix 3B, *Environmental Commitments*, including construction BMPs and 3B.8–*Fish Rescue and Salvage Plan*, would minimize adverse effects as described for Alternative 1A. Mitigation measures would also be available to avoid and minimize potential effects.

NEPA Effects: As concluded for Alternative 1A, Impact AQUA-181, the effect would not be adverse for river lamprey.

CEQA Conclusion: As described in Alternative 1A, Impact AQUA-181, the impact of the construction of water conveyance facilities on river lamprey would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

The potential effects of the maintenance of water conveyance facilities under Alternative 4 would be the same as those described for Alternative 1A (see Impact AQUA-182) except that only three intakes would need to be maintained under Alternative 4 rather than five under Alternative 1A. As concluded in Alternative 1A, Impact AQUA-182, the impact would not be adverse for river lamprey.

CEQA Conclusion: As described in Alternative 1A,Impact AQUA-182, the impact of the maintenance of water conveyance facilities on river lamprey would be less than significant and no mitigation is required.

Water Operations of CM1

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

Water Exports

The impact on entrainment of river lamprey at water operations facilities in the south and north Delta is expected to be the same as described for Pacific lamprey (see Impact AQUA-165). Entrainment losses at the south Delta facilities would be reduced for all flow scenarios under Alternative 4 compared to NAA. The potential impacts at the proposed new north Delta intakes are unknown since little is known about the river lamprey life history in the Delta.

Predation Associated with Entrainment

Entrainment-related predation loss of lamprey at the south Delta facilities would not be greater under this Alternative and may be lower due to a reduction in entrainment loss. Conditions under Scenario H4 would decrease predation loss relative to NAA and Scenario H3, while conditions would be similar between Scenario H1 and Scenario H3. Predation at the north Delta would be increased due to the installation of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta facilities is unknown because of the lack of knowledge about their distribution and population abundances in the Delta.

NEPA Effects: Overall, it is expected that the effect of predation loss on lamprey under Alternative 4 may be moderate, but would not be adverse.

CEQA Conclusion: As described above, annual entrainment losses of lamprey would be substantially reduced under all flow scenarios for Alternative 4 relative to existing biological conditions. The impact of predation loss at the north Delta is unknown, since there is little available knowledge on the distribution and abundance in the Delta, especially in the vicinity of the proposed new north Delta intakes. Overall the impact on River lamprey from water operations is expected to be less than significant. No mitigation would be required.

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

In general, the effect of Alternative 4 would be negligible relative to the NAA.

H3/ESO

Flow-related impacts to river lamprey spawning habitat were evaluated by estimating effects of flow alterations on redd dewatering risk as described for Pacific lamprey with appropriate time-frames for river lamprey incorporated into the analysis. The same locations were analyzed as for Pacific lamprey: the Sacramento River at Keswick and Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and the American River at Nimbus Dam and at the confluence with the Sacramento River. River lamprey spawn in these rivers between February and June so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage).

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, and substrate) of river lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, as described for Pacific lamprey, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, February to June.

There would be negligible differences between H3 and NAA in exposure to flow reductions in all rivers except for a small decrease (8% lower) in the Trinity River at Lewiston Dam and a small (6% greater) increase in the American River at Nimbus Dam (Table 11-4-127). These results indicate that H3 would not have biologically meaningful effects on river lamprey redd cohorts predicted to experience a month-over-month change in flow of greater than 50% in all locations analyzed.

Table 11-4-127. Differences between Model Scenarios in Dewatering Risk of River Lamprey Redd Cohorts[a]

Location	EXISTING CONDITIONS vs. H3	NAA vs. H3
Sacramento River at Keswick	3 (9%)	0 (0%)
Sacramento River at Red Bluff	-1 (-3%)	-3 (-8%)
Trinity River downstream of Lewiston	-4 (-6%)	-2 (-3%)
Feather River below Thermalito Afterbay	-8 (-12%)	2 (3%)
American River at Nimbus	13 (24%)	4 (6%)
American River at Sacramento River confluence	19 (32%)	2 (3%)

[a] Difference and percent difference between model scenarios in the number of river lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%. Positive values indicate a higher value in H3 than in Existing Conditions or NAA.

River lamprey generally spawn between February and June (Beamish 1980; Moyle 2002). Using Pacific lamprey as a surrogate, eggs are assumed to hatch in 18-49 days depending on water temperature (Brumo 2006) and are, therefore, assumed to be present during roughly the same period and locations as spawners. Moyle et al. (1995) indicate that river lamprey "adults need… temperatures [that] do not exceed 25°C," although there is no mention of thermal requirements for eggs in this or any existing literature. Meeuwig et al. (2005) reported that, for Pacific lamprey eggs, significant reductions in survival were observed at 22°C (71.6°F). Therefore, for this analysis, both temperatures, 22°C (71.6°F) and 25°C (77°F), were used as upper thresholds of river lamprey eggs. The analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) or 25°C (77°F) using daily data from USRWQM. For other rivers, the analysis predicted the number of consecutive two-month periods during which at least one month exceeds 22°C (71.6°F) or 25°C (77°F) using monthly averaged data from the Bureau's temperature model. Each individual day or month starts a new "egg cohort" such that there are 12.320 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from February 1 through June 30, and 405 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Spawning locations of river lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

For both thresholds, there would be few differences in egg cohort exposure between NAA and H3 among all sites (Table 11-4-128). In all cases, absolute differences account for <5% of the total number of cohorts; thus, none of these differences would have biologically meaningful effects.

Table 11-4-128. Differences (Percent Differences) between Model Scenarios in River Lamprey Egg Cohort Temperature Exposure[a]

Location	EXISTING CONDITIONS vs. H3	NAA vs. H3
Temperatures above 71.6°F		
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	291 (NA)	-32 (-10%)
Trinity River at Lewiston	0 (NA)	-1 (-100%)
Trinity River at North Fork	4 (NA)	-1 (-20%)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	39 (433%)	10 (26%)
American River at Nimbus	23 (460%)	-2 (-7%)
American River at Sacramento River Confluence	43 (154%)	-11 (-13%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	34 (3,400%)	0 (0%)
Temperatures above 77°F		
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	39 (NA)	3 (8%)
Trinity River at Lewiston	0 (NA)	0 (NA)
Trinity River at North Fork	0 (NA)	0 (NA)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	3 (NA)	1 (50%)
American River at Nimbus	4 (NA)	0 (0%)
American River at Sacramento River Confluence	8 (NA)	2 (33%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Difference and percent difference between model scenarios in the number of river lamprey egg cohorts experiencing water temperatures above 71.6°F and 77°F during February through June on at least one day during a 49-day incubation period in the Sacramento River or for at least one month during a 2-month incubation period in other rivers for each model scenario. Positive values indicate a higher value in H3 than in EXISTING CONDITIONS or NAA.

H1/LOS

Flows during February through June under H1 would generally be similar to or greater than flows under H3 in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H1 in these rivers and results for H1 would be the same as those for H3.

In the Feather River at Thermalito Afterbay, there would be 5 more cohorts (9%) exposed to a 50% month over month drop in flow rate under H1 relative to NAA (Table 11-4-129). This change of 5 cohorts out of 410 cohorts would be negligible to the population.

Table 11-4-129. Differences between Model Scenarios in Dewatering Risk of River Lamprey Redd Cohorts[a]

Location	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
Feather River at Thermalito Afterbay	-5 (-7%)	5 (9%)	4 (6%)	14 (24%)

[a] Difference and percent difference between model scenarios in the number of river lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%. Positive values indicate a higher value in H1 or H4 than in Existing Conditions or NAA.

Water temperatures would not differ between H1 and H3 and, therefore, no egg cohort temperature analyses were conducted. Overall, results for H1 would be similar to those for H3.

H4/HOS

Flows during January through August under H4 would generally be similar to or greater than flows under H3 in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H4 in these rivers and results for H4 would be the same as those for H3.

In the Feather River at Thermalito Afterbay, there would be 14 more cohorts (24%) exposed to a 50% month over month drop in flow rate under H4 relative to NAA (Table 11-4-129). This change of 14 cohorts out of 410 cohorts would be negligible to the population.

Water temperatures would not differ between H4 and H3 and, therefore, no egg cohort temperature analyses were conducted. Overall, results for H4 would be similar to those for H3.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. Effects of Alternative 4 on river lamprey redd dewatering risk would be negligible for all locations analyzed. Exposure risk of eggs to elevated water temperatures under Alternative 4 would be similar to or lower than that of NAA at all locations. These results are consistent among scenarios.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of spawning and egg incubation habitat for river lamprey would not be affected relative to the CEQA baseline.

H3/ESO

Effects of H3 relative to Existing Conditions on flow reductions during the river lamprey spawning period from February to June in the Sacramento River and American River consist of small to substantial increases in dewatering risk in the Sacramento River at Keswick (9%) and the American River (to 32%), and negligible effects (<5%) or small decreases in redd cohort dewatering risk in the Sacramento River at Red Bluff <5%), the Trinity River (-6%) and the Feather River (-12%) (Table 11-4-127). Effects of Alternative 4 on river lamprey redd dewatering in the American River consist of a substantial increase in risk that would affect river lamprey spawning success in that location (increases of 24% at Nimbus Dam and 32% at the confluence with the Sacramento River).

Egg cohort temperature exposure results are reported in Table 11-4-128. There would be increased exposure of egg cohorts (23 to 43 cohorts, or 154% to 3,400%) under H3 relative to Existing

Conditions to temperatures above 71.6°F in the Feather River, American River, and Stanislaus River. There would be 39 more cohorts exposed to temperatures above 77°F under H3 relative to Existing Conditions, although this absolute value, would not be biologically meaningful because it is a small proportion of the 12,320 total cohorts, There would be no differences in the number of cohorts exposed to the 77°F threshold.

H1/LOS

Flows during February through June under H1 would generally be similar to or greater than flows under H3 in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H1 in these rivers and results for H1 would be the same as those for H3.

In the Feather River at Thermalito Afterbay, there would be 5 fewer cohorts (7%) under H1 that would be exposed to a 50% flow reduction than under Existing Conditions (Table 11-4-129). This increase would be too small to have a biologically meaningful effect on river lamprey.

Water temperatures under H1 would be similar to those under H3 for all rivers examined. Therefore, no additional cohort temperature exposure analyses were conducted for H1.

Overall, results for H1 would be similar to those for H3.

H4/HOS

Flows during February through June under H4 would generally be similar to or greater than flows under H3 in all rivers except the Feather River. As a result, the redd dewatering risk analysis was not conducted for H4 in these rivers and results for H4 would be the same as those for H3.

In the Feather River at Thermalito Afterbay, there would be 4 more cohorts (236 under H4 that would be exposed to a 50% flow reduction than under H3 (Table 11-4-129). This increase would be too small to have a biologically meaningful effect on river lamprey.

Water temperatures under H4 would be similar to those under H3 for all rivers examined. Therefore, no additional cohort temperature exposure analyses were conducted for H1.

Overall, results for H4 would be similar to those for H3.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-184 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. Increased risk of redd dewatering in the American River (to 32%) would increase the risk of desiccation and mortality of eggs, contrary to the NEPA conclusion set forth above. The increase in exposure of egg cohorts to critical water temperatures in the Feather River would increase stress and egg mortality. Flow reductions in the Sacramento, Feather, American, and Stanislaus Rivers would cause increased risk of redd dewatering for river lamprey under H4 if operations were changed to this limit.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on spawning habitat for river lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

In general, the effect of Alternative 4 would be negligible relative to the NAA.

H3/ESO

Flow-related impacts to river lamprey rearing habitat were evaluated by estimating of the frequency of rapid flow reductions in ammocoete rearing areas. Rapid reductions in flow can strand ammocoetes, leading to mortality. Comparisons of effects were made for ammocoete cohorts, as described for Pacific lamprey, in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River.

As for Pacific lamprey, the analysis of river lamprey ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (February through June) and spend 5 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than the flow reduction at any time during the period.

Comparisons of H3 to NAA for the Sacramento River at Keswick (Table 11-4-130) indicate that there would be no effect (0%) or negligible effects (<5%) attributable to H3 in all flow reduction categories.

Table 11-4-130. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3	NAA vs. H3
-50%	0	0
-55%	2	0
-60%	6	2
-65%	3	3
-70%	-2	-2
-75%	-6	0
-80%	11	0
-85%	44	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of H3.

Results of comparisons for the Sacramento River at Red Bluff indicates that H3 would have negligible effects (<5%) or small to moderate decreases in cohort exposure (to -16%) that would have a beneficial effect, attributable to the project for different flow reduction categories (Table 11-4-131).

Table 11-4-131. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Red Bluff

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3	NAA vs. H3
-50%	0	0
-55%	6	3
-60%	12	5
-65%	-2	-3
-70%	10	1
-75%	10	-10
-80%	8	-16
-85%	100	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of H3.

Comparisons for the Trinity River indicate that there would be no or negligible differences in ammocoete cohorts exposed flow reductions between H3 and NAA (Table 11-4-132).

Table 11-4-132. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Trinity River at Lewiston

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3	NAA vs. H3
-50%	0	0
-55%	0	0
-60%	0	0
-65%	0	0
-70%	0	0
-75%	26	-5
-80%	39	0
-85%	31	0
-90%	59	4

[a] Negative values indicate reduced cohort exposure, a benefit of H3.

In the Feather River at Thermalito Afterbay, there would be no difference in ammocoete cohort exposure at the 50% through 75% flow reductions (Table 11-4-133). For the 80% through 90% flow reductions, ammocoete exposure would be 7% to 41% lower, which would have a beneficial effect on ammocoete rearing. These results indicate that there will be beneficial effects of H3 on river lamprey ammocoete rearing in the Feather River.

Table 11-4-133. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Feather River at Thermalito Afterbay

	Percent Difference[a]	
Percent Flow Reduction	EXISTING CONDITIONS vs. H3	NAA vs. H3

-70%	0	0
-75%	-1	-1
-80%	-17	-11
-85%	-23	-41
-90%	-48	-7

[a] Negative values indicate reduced cohort exposure, a benefit of H3.

Comparisons for the American River at Nimbus Dam (Table 11-4-134) and at the confluence with the Sacramento River (Table 11-4-135) have similar results. There would be no or negligible differences in cohort exposure between NAA and H3 for the 50% to 70% flow reductions range, There would be higher cohort exposure under H3 relative to NAA at Nimbus Dam at the 75% flow reduction (9% higher) and at the confluence with the Sacramento River at the 75% (11% higher) and 80% (25% higher) flow reductions. There would be up to 24% lower cohort exposures under

H3 relative to NAA at the remaining flow reductions at both locations. These results indicate that there would generally be no effect of H3 on stranding risk in the American River with few small exceptions that would not be common enough to have biologically meaningful effects.

Table 11-4-134. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, American River at Nimbus Dam

[a] Negative values indicate reduced cohort exposure, a benefit of H3.

Because the thermal tolerance of river lamprey ammocoetes is unknown, the thermal tolerance of Pacific lamprey ammocoetes of 22°C (71.6°F) and of river lamprey adults of 25°C (77°F) (Moyle et al. 1995) was used. River lamprey ammocoetes rear upstream for 3–5 years (Moyle 2002). To be conservative, this analysis assumed a maximum ammocoete duration of 5 years. Each individual day or month starts a new "cohort" such that there are 18,730 cohorts for the Sacramento River, corresponding to 82 years of ammocoetes being "born" every day each year from January 1 through August 31, and 380 cohorts for the other rivers using monthly data over the same period.

There would be differences in the number of ammocoete cohorts exposed to temperatures greater than the thresholds in most of the rivers, particularly for the 77°F threshold (Table 11-4-136). However, each river with an increase in exposure would also have a site with a decrease in exposure of similar magnitude, except in the Feather River for the 77°F threshold. Overall, the increases and decreases are expected to balance out within rivers such that there would be no overall effect on river lamprey ammocoetes.

Table 11-4-136. Differences (Percent Differences) between Model Scenarios in River Lamprey Ammocoete Cohorts Exposed to Temperatures in the Feather River Greater than 71.6°F and 77°F in at Least One Month

Location	EXISTING CONDITIONS vs. H3	NAA vs. H3
71.6°F Threshold		
Sacramento River at Keswick[b]	0 (NA)	-1,218 (-100%)
Sacramento River at Hamilton City[b]	10,951 (NA)	1,456 (15%)
Trinity River at Lewiston	65 (NA)	15 (30%)
Trinity River at North Fork	135 (NA)	-25 (-16%)
Feather River at Fish Barrier Dam	0 (NA)	-25 (-100%)
Feather River below Thermalito Afterbay	180 (95%)	50 (16%)
American River at Nimbus	240 (267%)	-5 (-1%)
American River at Sacramento River Confluence	135 (55%)	0 (0%)
Stanislaus River at Knights Ferry	25 (NA)	0 (0%)
Stanislaus River at Riverbank	335 (1,340%)	0 (0%)
77°F Threshold		
Sacramento River at Keswick[b]	0 (NA)	0 (NA)
Sacramento River at Hamilton City[b]	0 (NA)	0 (NA)
Trinity River at Lewiston	0 (NA)	0 (NA)
Trinity River at North Fork	25 (NA)	25 (NA)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	65 (NA)	25 (63%)
American River at Nimbus	200 (NA)	-20 (-9%)
American River at Sacramento River Confluence	265 (530%)	35 (15%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] Positive values indicate a higher value in H3 than in EXISTING CONDITIONS or NAA.
[b] Based on daily data; all other locations use monthly data; 1922–2003.

H1/LOS

There would be generally no differences in mean flows year-round between H1 and H3 in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between NAA and H1 at the 50% through 75% flow reductions (Table

11-4-137). For the 85% flow reductions, ammocoete exposure under H1 would be 9% higher than that under NAA, respectively. For the 90% and 95% flow reductions, ammocoete exposure under H1 would be7% lower than that under NAA. Overall, these results indicate that there would generally be no biologically meaningful effect of H1 on river lamprey ammocoete rearing in the Feather River.

Table 11-4-137. Percent Difference between Baselines and H1 and H4 Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Feather River at Thermalito Afterbay

	Percent Difference[a]			
Percent Flow Reduction	EXISTING CONDITIONS vs. H1	NAA vs. H1	EXISTING CONDITIONS vs. H4	NAA vs. H4
-50%	0	0	0	0
-55%	0	0	0	0
-60%	0	0	0	0
-65%	0	0	0	0
-70%	0	0	0	0
-75%	0	0	0	0
-80%	2	9	-2	4
-85%	23	-7	17	-11
-90%	-48	-7	15	103

[a] Negative values indicate reduced cohort exposure under H1 or H4.

There would generally be no differences in mean water temperatures year-round between H1 and H3 in any river examined. As a result, no additional ammocoete temperature cohort exposure analyses were conducted for H1. Results of these analyses for H1 would be the same as those for H3.

Overall, these results indicate that results for H1 would generally be similar to those under H3.

H4/HOS

There would be generally no differences in mean flows year-round between H4 and H3 in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between NAA and H4 at the 50% through 80% flow reductions (Table 11-4-137). For the 85% and 90% flow reductions, ammocoete exposure under H4 would be 11% lower and 103% higher, respectively.

There would generally be no differences in mean water temperatures year-round between H4 and H3 in any river examined. As a result, no additional ammocoete cohort exposure analyses were conducted for H4. Results of these analyses for H4 would be the same as those for H3.

Overall, these results indicate that results for H4 would generally be similar to those under H3 except for an increase in ammocoete stranding risk exposure in the Feather River at 90% flow reduction under H4 if water operations were to move to this end of the operational range.

NEPA Effects: These results indicate the effect would not be adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish through ammocoete mortality. Project-related effects on flow reductions and effects on water temperatures in all locations analyzed would be negligible and would not affect river lamprey ammocoete stranding risk and rearing success. There would be small to substantial beneficial effects from decreased stranding risk in the Sacramento River at Red Bluff (to -16%), the Feather River (to -41%), and the American River at Nimbus Dam (to -24%). However, stranding risk under both H1 and H4 in the Feather River would be higher than those under H3, such that benefits under H3 would not occur under these limits of the operational range.

There would be increases and decreases in ammocoete exposure to elevated temperatures that are expected to balance out within rivers such that there would be no overall effect.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of rearing habitat for river lamprey would not be affected relative to the CEQA baseline.

H3/ESO

Comparisons of H3 to Existing Conditions for the Sacramento River at Keswick indicate negligible effects (<5%) or small increases (to 11%) for ammocoete cohort exposures to flow reductions from 50% to 80%, and a more substantial increase in exposure (44%) to 85% flow reduction events (Table 11-4-130). Comparisons for the Sacramento River at Red Bluff indicate similar results with negligible effects (<5%) or small increases in exposure (to 12%) for 50% to 80% flow reduction categories, and a more substantial increases in exposure (from 25 to 50 cohorts or 100%) in the 85% flow reduction category (Table 11-4-131). Based on the prevalence of negligible effects (<5%), or relatively small increased occurrence of flow reductions for most of the flow reduction categories, the effects of a more substantial increase in flow reductions in a single flow reduction category would not be considered biologically meaningful to river lamprey in the Sacramento River.

Comparisons for the Trinity River between H3 and Existing Conditions indicated no effect (0%) for the lower flow reduction categories, up to 70%, and increases in occurrence ranging from 26% to 59% for the 75% through 90% flow reduction categories (Table 11-4-132). The prevalence of increased occurrence of higher-magnitude flow reductions would affect river lamprey ammocoete stranding in the Trinity River.

Comparisons for the Feather River between H3 and Existing Conditions indicated no effect (0%) or reductions in frequency of occurrence for all flow reduction categories, with 17% to 48% reductions in cohorts exposed to80% to 90% flow reduction events (Table 11-4-133). Decreased occurrences of flow reductions would have a beneficial effect.

Comparisons for the American River at Nimbus Dam (Table 11-4-134) and at the confluence with the Sacramento River (Table 11-4-135) between H3 and Existing Conditions indicate increased chance of occurrence of flow reductions between 70 and 90% for Alternative 4 compared to NAA; meaningful (>5%) predicted increases are from 59 to 416% (increase in cohorts exposed from 25 to 129) for Nimbus Dam and from 20 to 300% (increase in cohorts exposed from 25 to 100) for the confluence. The prevalence of increased occurrence of higher-magnitude flow reductions would constitute a biologically meaningful effect on river lamprey ammocoete stranding in the American River.

The number of ammocoete cohorts exposed to 71.6°F under H3 would be higher than those under Existing Conditions in most locations examined, except in the Sacramento River at Keswick and in the Feather River at the Fish Barrier Dam (Table 11-A1-132). The number of ammocoete cohorts exposed to 77°F would be similar between Existing Conditions and H3 in the Sacramento, Trinity, and Stanislaus Rivers, but higher in the Feather and American Rivers.

H1/LOS

There would be generally no differences in mean flows year-round between H1 and H3 in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between Existing Conditions and H1 at the 50% through 80% flow reductions (Table 11-4-137). There would be 23% more and 48% fewer cohorts exposed to 85% and 90% flow reductions, respectively, under H3 relative to Existing Conditions.

There would generally be no differences in mean water temperatures year-round between H1 and H3 in any river examined. As a result, no additional ammocoete temperature cohort exposure analyses were conducted for H1. Results of these analyses for H1 would be the same as those for H3.

Overall, these results indicate that results for H1 would generally be similar to those under H3.

H4/HOS

There would be generally no differences in mean flows year-round between H4 and H3 in the Sacramento, Trinity, and American rivers. Therefore, ammocoete stranding risk analysis was conducted only for the Feather River.

In the Feather River at Thermalito Afterbay, there would be no or a negligible difference in ammocoete cohort exposure between Existing Conditions and H4 at the 50% through 80% flow reductions (Table 11-4-137). There would be 17% and 15% more cohorts exposed to 85% and 90% flow reductions, respectively, under H3 relative to Existing Conditions.

There would generally be no differences in mean water temperatures year-round between H4 and H3 in any river examined. As a result, no additional ammocoete temperature cohort exposure analyses were conducted for H4. Results of these analyses for H4 would be the same as those for H3.

Overall, these results indicate that results for H4 would generally be similar to those under H3.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-185 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of ammocoete mortality, contrary to the NEPA conclusion set forth above. There would be moderate to substantial increases in occurrence of flow reduction events for Alternative 4 with respect to Existing Conditions for the Trinity River (26% to 59%) and the American River at Nimbus Dam (59% to 416%) and at the confluence with the Sacramento River (20% to 300%) that would affect river lamprey ammocoete stranding risk and therefore rearing success for these locations. There would be a beneficial effect from reduced occurrence of flow reductions in the Feather River (-17% to 48%) but this effect would not be sufficient to offset the negative effects from increased occurrence of flow reductions at the other locations. Further, stranding risk under both H1 and H4 in the Feather River would be higher than those under H3, such that benefits under H3 would not occur under these limits of the operational range. There would also be increases under Alternative 4 in ammocoete cohort exposure to critical water temperatures in all rivers evaluated that would have biologically meaningful effects on rearing success through ammocoete mortality. These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on rearing habitat for river lamprey. This impact is found to be less than significant and no mitigation is required.

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

In general, the effect of Alternative 4 on river lamprey migration conditions would be negligible relative to the NAA.

H3/ESO

After 3 to 5 years, river lamprey ammocoetes migrate downstream and become macropthalmia once they reach the Delta. River lamprey migration generally occurs September through November (USFWS unpublished data). The effects of H3 on seasonal migration flows for river lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the likely migration pathways of river lamprey during the likely migration period (September through November) were examined to predict how H3 may affect migration flows for outmigrating macropthalmia. Analyses were conducted for the Sacramento River at Red Bluff, Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

The adult river lamprey upstream migration period also occurs between September and June. Therefore, results presented below represent effects to the migration of both macropthalmia and adult river lamprey. CALSIM II flow outputs were examined during these periods for each model scenario.

Sacramento River

Mean monthly flow rates for the Sacramento River at Red Bluff (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the September to November river lamprey macropthalmia and adult migration periods. Flows under H3 would generally be similar to flows under NAA during September and October, but up to 18% lower during November depending on water year type. Because of the relatively small magnitude, reduced flows during November are not likely to cause biologically meaningful effects on river lamprey migration.

Feather River

Flows in the Feather River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the September to November river lamprey macropthalmia and adult migration periods. Flows under H3 would generally be lower than flows under NAA during September, higher than flows under NAA during October, and similar to flows under NAA during November. Based on occurrence of negligible effects or increases in flow that would have a beneficial effect on migration conditions, with decreases predicted for wetter water years when effects on migration conditions would not be as critical, these results indicate that effects of NAA on flows would not have biologically meaningful negative effects on migration conditions in the Feather River.

American River

Flows in the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) were examined during the September through November macropthalmia and adult migration periods. Flows under H3 would be lower than flows under NAA during September and November and similar to flows during October. However, flows during September would only be negative during wetter water years, when reduced flows are less critical to lamprey migration. Further, flows during November would be only marginally lower (6% to 8%). Overall, these results indicate that project-related effects would include small decreases in flow for some months and water year types, but that overall effects throughout the migration period would not have biologically meaningful effects on river lamprey migration.

H1/LOS

Flows under H1 in the Sacramento River at Red Bluff would be lower than flows under H3 (up to 44% lower) during September and November and similar during October (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 in the Feather River at the confluence with the Sacramento River would generally be similar to flows under H3, except in wet and above normal water years during September, in which flows would be 65% and 40% lower, respectively. Flows under H1 in the American River at the confluence with the Sacramento River would generally be similar to flows under H3, except in wet and above normal water years during September, in which flows would be 65% and 40% lower, respectively. Overall, migration conditions for river lamprey under H1 would be less favorable than conditions under H3.

H4/HOS

Flows under H4 in the Sacramento River at Red Bluff would be similar to or greater than flows under H3 during September through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at the confluence with the Sacramento River would generally be up to 24% lower than flows under H3 in September and October but similar during November. Flows under H4 in the American River at the confluence with the Sacramento River would generally be up to 20% greater than flows under H3 during September, up to 13%

lower than flows under H3 during October, and similar to flows under H3 during November. Overall, migration conditions for river lamprey under H4 would be less favorable than conditions under H3.

NEPA Effects: Collectively, these results indicate that the effect is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. H3 would primarily have negligible effects (<5%), small increases or decreases in flow, or decreases in wetter water year types and/or during a limited portion of the migration period that would not have negative effects on migration conditions. There would be beneficial effects from moderate increases in flow for some months and water year types in all locations, including the Sacramento River (to 18%), the Feather River (to 22%) and the American River (to 16%); however, the beneficial effect would be partially offset by flow reductions during other months of the migration periods. Flows under H1 and H4 would be less favorable than those under H3 if water operations, although neither would cause adverse impacts.

CEQA Conclusion: In general, under all the Alternative 4 water operations scenarios, the quantity and quality of migration habitat for river lamprey would not be reduced relative to the CEQA baseline.

H3/ESO

For the Sacramento River at Red Bluff, comparisons of mean monthly flow rate for H3 to Existing Conditions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate variable effects of H3 during September, with increases in mean monthly flow for wetter water year types (39 to 55%) and decreases for drier water year types (-11 and -14% for below normal and dry years, respectively). H3 would have negligible effects (<5%) for October in all water years, and would have negligible effects (<5%) or cause small decreases in mean monthly flows for all water year types in November (-7 to -14%). Based on small decreases in drier water year types during September and November, these results indicate that H3 would not have biologically meaningful negative effects on macropthalmia migration conditions in the Sacramento River.

Comparisons for the Feather River at the confluence with the Sacramento River indicate (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) indicate variable effects of H3 relative to Existing Conditions based on month and water year type. There would be substantial increases for wetter years (to 108%) and decreases in drier years (to -28%) during September, variable results during October with increases to 30% in above normal, dry, and critical years and small decreases (to -9%) in wet and below normal years, and negligible effects (<5%) or decreases (-20% in wet years, -8% in below normal years) during November. There would be small to moderate decreases during all three months in below normal years, however, effects during dry and critical years are more variable. These results indicate that despite variable effects by month and water year type, effects of H3 on flow would not have biologically meaningful negative effects on macropthalmia migration in the Feather River.

Comparisons for the American River at the confluence with the Sacramento River (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) for September through November indicate reductions in flow for most months and most water year types, ranging from -16 to -51%, with the exception of increases in mean monthly flow during October in below normal (26%) and critical (13%) water years, and negligible decreases (<5%) in above normal and dry years. The predominance of decreased flows for H3 compared to Existing Conditions would have adverse effects on migration, with substantial decreases for dry and critical years in September (-39 and -51%, respectively) and November (-33 and -28%, respectively).

H1/LOS

Flows under H1 in the Sacramento River at Red Bluff would be lower than flows under H3 (up to 44% lower) during September and November and similar during October (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 in the Feather River at the confluence with the Sacramento River would generally be similar to flows under H3, except in wet and above normal water years during September, in which flows would be 65% and 40% lower, respectively. Flows under H1 in the American River at the confluence with the Sacramento River would generally be similar to flows under H3, except in wet and above normal water years during September, in which flows would be 65% and 40% lower, respectively. Overall, migration conditions for river lamprey under H1 would be less favorable than conditions under H3.

H4/HOS

Flows under H4 in the Sacramento River at Red Bluff would be similar to or greater than flows under H3 during September through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at the confluence with the Sacramento River would generally be up to 24% lower than flows under H3 in September and October but similar during November. Flows under H4 in the American River at the confluence with the Sacramento River would generally be up to 20% greater than flows under H3 during September, up to 13% lower than flows under H3 during October, and similar to flows under H3 during November. Overall, migration conditions for river lamprey under H4 would be less favorable than conditions under H3.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-186 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 4 could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish, contrary to the NEPA conclusion set forth above. There would be moderate and persistent flow reductions for substantial portions of the river lamprey macropthalmia migration period in the American River, and less persistent and smaller magnitude flow reductions in the Sacramento River and Feather River. These flow reductions would affect juvenile migration success, increase straying, and delay access to the ocean. These flow reductions would also affect adult migration success, including a reduction in the ability for adults to sense olfactory cues if they use these cues to find natal spawning grounds. There would be beneficial effects from increases in flow for some months and water year types in each location including in the Sacramento River (to 55% in wetter water years), the Feather River (to 108% in wetter water years and to 30% for drier water years in October), and the American River (to 26% in October). However, this effect would not be sufficient to offset the negative effects of flow reductions for the remainder of the migration period and/or in other water year types, particularly drier water year types when effects of flow reductions would be more critical. Flows under H1 and H4 would be less favorable than those under H3.

These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to H3 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. In addition, CALSIM modeling has been conducted for Existing Conditions in the LLT implementation period, which does include future sea level rise, climate change, and water demands. Therefore, the comparison of results between the alternative and Existing Conditions in the LLT, both of which include sea level rise, climate change, and future water demands, isolates the effect of the alternative from those of sea level rise, climate change, and water demands.

The additional comparison of CALSIM flow outputs between Existing Conditions in the late long-term implementation period and H3 indicates that flows in the locations and during the months analyzed above would generally be similar between Existing Conditions during the LLT and H3. This indicates that the differences between Existing Conditions and Alternative 4 found above would generally be due to climate change, sea level rise, and future demand, and not the alternative. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on migration conditions for river lamprey. This impact is found to be less than significant and no mitigation is required.

Restoration Measures (CM2, CM4–CM7, and CM10)

Alternative 4 has the same Restoration Measures as Alternative 1A. Because no substantial differences in restoration-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of restoration measures described for river lamprey under Alternative 1A (Impacts AQUA-187 through AQUA-189) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

NEPA Effects: Detailed discussions regarding the potential effects of these three impact mechanisms on river lamprey are the same for Alternative 4, as those described under Alternative 1A (Impacts AQUA 187-through AQUA-189). The effects would not be adverse, and would generally be beneficial.

CEQA Conclusion: All of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Other Conservation Measures (CM12–CM19 and CM21)

Alternative 4 has the same other conservation measures as Alternative 1A. Because no substantial differences in other conservation-related fish effects are anticipated anywhere in the affected environment under Alternative 4 compared to those described in detail for Alternative 1A, the fish effects of other conservation measures described for river lamprey under Alternative 1A (Impacts AQUA-190 through AQUA-198) also appropriately characterize effects under Alternative 4.

The following impacts are those presented under Alternative 1A that are identical for Alternative 4.

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (CM12)

Impact AQUA-191: Effects of Invasive Aquatic Vegetation Management on River Lamprey (CM13)

Impact AQUA-192: Effects of Dissolved Oxygen Level Management on River Lamprey (CM14)

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (CM15)

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (CM16)

Impact AQUA-195: Effects of Illegal Harvest Reduction on River Lamprey (CM17)

Impact AQUA-196: Effects of Conservation Hatcheries on River Lamprey (CM18)

Impact AQUA-197: Effects of Urban Stormwater Treatment on River Lamprey (CM19)

Impact AQUA-198: Effects of Removal/Relocation of Nonproject Diversions on River Lamprey (CM21)

NEPA Effects: Detailed discussions regarding the potential effects of these nine impact mechanisms on river lamprey are the same as those described under Alternative 1A, Impacts AQUA-190 through AQUA-198). The effects would not be adverse, and would generally be beneficial.

CEQA Conclusion: All nine of the impact mechanisms listed above would be at least slightly beneficial, or less than significant, and no mitigation is required.

Non-Covered Aquatic Species of Primary Management Concern

Construction and Maintenance of CM1

The effects of construction and maintenance of CM1 under Alternative 4 would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-1 under delta smelt for a discussion of the effects of construction of water conveyance facilities on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of water conveyance facilities under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-1) except that Alternative 4 would include three intakes compared to five intakes under Alternative 1A, so the effects would be proportionally less under this alternative. This would convert about 6,360 lineal feet of existing shoreline habitat into intake facility structures and would require about 17.1 acres of dredge and channel reshaping. In contrast, Alternative 1A would convert 11,900 lineal feet of shoreline and would require 27.3 acres of dredging. Additionally, California bay shrimp would not be affected because they do not occur in the vicinity and Sacramento-San Joaquin roach and hardhead are unlikely to be affected because their primary distributions are upstream.

Similar to the conclusion for Alternative 1A, Impact AQUA-1, environmental commitments and mitigation measures would be available to avoid and minimize potential effects, and the effect would not be adverse for non-covered aquatic species of primary management concern.

CEQA Conclusion: Similar to the conclusion for Alternative 1A, Impact AQUA-1, the impact of the construction of the water conveyance facilities on non-covered aquatic species of primary management concern would not be significant except for construction noise associated with pile driving. Potential pile driving impacts would be less than Alternative 1A because only three intakes would be constructed rather than five. Implementation of Mitigation Measure AQUA-1a and Mitigation Measure AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Impact AQUA-1 in the discussion of Alternative 1A.

Mitigation Measure AQUA-1b: Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Impact AQUA-1 in the discussion of Alternative 1A.

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-2 under delta smelt for a discussion of the effects of maintenance of water conveyance facilities on non-covered species of primary management concern. That discussion under delta smelt addresses the type, magnitude and range of impact mechanisms that are relevant to the aquatic environment and aquatic species. The potential effects of the construction of water conveyance facilities under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-2). California bay shrimp would not be affected because they do not occur in the vicinity and Sacramento-San Joaquin roach and hardhead are unlikely to be affected because their primary distributions are upstream. Consequently, the effects would not be adverse.

CEQA Conclusion: Similar to the conclusion for Alternative 1A, Impact AQUA-2, the impact of the maintenance of water conveyance facilities on non-covered species of primary management concern would be less than significant and no mitigation is required.

Water Operations of CM1

The effects of water operations of CM1 under Alternative 4 include a detailed analysis of the following species:

- Striped Bass
- American Shad
- Threadfin Shad
- Largemouth Bass

- Sacramento tule perch
- Sacramento-San Joaquin roach – California species of special concern
- Hardhead – California species of special concern

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

Striped Bass

NEPA Effects: Under Existing Conditions, striped bass are observed in salvage operations of the south Delta facilities throughout the year, with the majority of juvenile striped bass entrainment occurring during the summer (May through July). Entrainment losses under Scenario H3 to the SWP/CVP south Delta intakes would be reduced moderately compared to baseline conditions (NAA) since exports from the south Delta facilities would be reduced in the summer. Entrainment loss at the south Delta facilities under Scenario H1 would be similar to conditions under Scenario H3, while entrainment would be further reduced under Scenario H4. Entrainment of juvenile and adult striped bass would be limited at the proposed north Delta intakes and the alternate NBA intake by screens designed to exclude fish larger than 15 mm. Eggs and larvae would be vulnerable as they are passively transported downstream from spawning areas on the Sacramento River. Agricultural diversions are potential sources of entrainment for small fish such as larval and juvenile striped bass. Reduction or consolidation of up to 12% of agricultural diversions in ROAs would not increase entrainment and may provide a minor benefit for the species. Also larval entrainment is not thought to have population consequences due to the large fecundity of individual females and the fact that population levels do not correspond to numbers of larvae (Moyle 2002). In addition, restoration activities as part of the conservation measures should increase the amount of habitat for young striped bass (e.g. inshore rearing habitat), and increase their food supply. The expectation is that these habitat changes would result in at least a minor improvement in production of juvenile striped bass. Overall, the effect of Alternative 4 on striped bass entrainment would not be adverse and may benefit the species due to reductions in south Delta entrainment and increases in habitat and food supply.

CEQA Conclusion: The impact of water operations on entrainment of striped bass would be the same as described immediately above. The changes in entrainment under Alternative 4 would not substantially reduce the striped bass population when other conservation measures are taken into consideration. The impact would be less than significant and no mitigation would be required.

American Shad

American shad eggs and larvae would be vulnerable to entrainment at the proposed north SWP/CVP Delta intakes and the alternate NBA intake as these life stages are passively transported downstream to the north Delta. Most American shad spawning though takes place well upstream of the Delta. State-of-the-art fish screens on these north Delta intakes though would exclude juvenile and adult American shad.

NEPA Effects: American shad entrainment losses would be reduced at the SWP/CVP south Delta facilities under the flow scenarios for Alternative 4 compared to baseline conditions due to moderately reduced south delta exports in the summer. Entrainment losses would be further reduced under Scenario H4 compared to the other flow scenarios. Reduction or consolidation of up to 12% of agricultural diversions in ROAs would not increase entrainment and may provide a modest benefit to the species. Overall, the effect on American shad would not be adverse, and would be slightly beneficial.

CEQA Conclusion: The impact of water operations on entrainment of American shad would be the same as described immediately above. The changes in entrainment under Alternative 4 would not substantially reduce the American shad population. The impact would be less than significant and no mitigation would be required.

Threadfin Shad

NEPA Effects: The impact and conclusion would be the same as discussed for Alternative 1A (Impact AQUA-201 for Threadfin Shad). Entrainment at the south delta would be reduced due to overall decreased exports from the SWP/CVP south Delta facilities. Entrainment losses would be further reduced under Scenario H4 compared to the other flow scenarios for Alternative 4. There would be potential entrainment of threadfin shad eggs and larvae to the north Delta intakes, although this risk is minimal because threadfin shad are most abundant in the south Delta (Baxter et al. 2010). Decommissioning or consolidation of agricultural diversions in Delta ROAs would potentially reduce threadfin shad entrainment loss. Overall, threadfin shad entrainment would be reduced because they are most abundant in the southern Delta and would particularly benefit from reduced south Delta exports. The effect would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of threadfin shad would be the same as described immediately above. The changes in entrainment under Alternative 4 would not substantially reduce and may benefit the threadfin shad population. The impact would be less than significant and no mitigation would be required.

Largemouth Bass

NEPA Effects: Since largemouth bass are predominantly found in the south and central portions of the Delta, largemouth bass would be most vulnerable to entrainment to south Delta facilities. Entrainment to the south Delta would be reduced under all flow scenarios for Alternative 4 because of reductions in south Delta exports in the summer. Entrainment loss would be further reduced under Scenario H4 compared to other Alternative 4 flow scenarios, because of lower south Delta exports. As discussed for Alternative 1A (Impact AQUA-201for Largemouth Bass) few larval largemouth bass would be vulnerable to entrainment to north Delta and alternative NBA intake since they are not expected to readily occur in the vicinity. Largemouth bass are nest builders and typically build their nests in quiet, low flow backwaters. Decommissioning or consolidation of up to 12% of Delta agricultural diversions would potentially reduce entrainment of largemouth bass. Overall entrainment would be reduced under Alternative 4.

CEQA Conclusion: The impact of water operation on largemouth bass would be as described immediately above. The changes in entrainment under Alternative 4 could benefit the largemouth bass population. The impact would be less than significant and no mitigation would be required.

Sacramento Tule Perch

NEPA Effects: The effects and conclusion for this impact would be the same as Alternative 1A (Impact AQUA-201 for Sacramento tule perch). Entrainment of Sacramento tule perch is documented in small numbers at the SWP/CVP south Delta. Entrainment at the south Delta intakes would be further minimized under all flow scenarios for Alternative 4, especially Scenario H4. Under Alternative 4, entrainment would be reduced because north Delta intakes would be screened and south Delta exports would be reduced compared to baseline conditions (NAA). Because Sacramento tule perch are viviparous, newly born Sacramento tule perch would be large enough to be effectively screened at the proposed north delta facilities. Reduction or consolidation of agricultural diversions under the Plan would potentially reduce entrainment of Sacramento tule perch. Overall the reduction in entrainment of Sacramento tule perch under Alternative 4 would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of Sacramento tule perch would be the same as described immediately above. The changes in entrainment under Alternative 4 would not substantially reduce the Sacramento tule perch population. The impact would be less than significant and no mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: The effect of water operations on entrainment of Sacramento-San Joaquin roach under Alternative 4 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-201). Also, Sacramento-San Joaquin roach distribution is primarily upstream of the intakes and south Delta facilities. For a detailed discussion, please see Alternative 1A, Impact AQUA-201. The effects would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of Sacramento-San Joaquin roach would be the same as described immediately above and would be less than significant and no mitigation would be required.

Hardhead

NEPA Effects: The effect of water operations on entrainment of hardhead under Alternative 4 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-201). Also, hardhead distribution is primarily upstream of the intakes and south Delta facilities. For a detailed discussion, please see Alternative 1A, Impact AQUA-201. The effects would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of hardhead would be the same as described immediately above and would be less than significant and no mitigation would be required.

California Bay Shrimp

NEPA Effects: California bay shrimp do not occur in the vicinity of the intakes so there would be no entrainment effect on them.

CEQA Conclusion: California bay shrimp do not occur in the vicinity of the intakes so there would no entrainment impact on them.

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-202 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

In general, Alternative 4 would slightly improve the quality and quantity of upstream habitat conditions for striped bass relative to the NAA.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under NAA during April through June except in above normal years during April (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA during April through June except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be moderately to substantially greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during April through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside the range would be similar to or lower than the percentage under NAA in all water year types (Table 11-4-138).

Table 11-4-138. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 59°F to 68°F Water Temperature Range for Striped Bass Spawning, Embryo Incubation, and Initial Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-3 (-7%)	-8 (-16%)
Above Normal	-18 (-40%)	-15 (-36%)
Below Normal	-17 (-40%)	-19 (-42%)
Dry	-2 (-4%)	1 (2%)
Critical	11 (28%)	-3 (-6%)
All	-5 (-11%)	-8 (-17%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the April through June striped bass spawning, embryo incubation, and initial rearing period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. The percentage of months under H1 with mean water temperatures outside the 59°F to 68°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to or lower than the percentage under H3 in all water year types (Table 11-4-139).

Table 11-4-139. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 59°F to 68°F Water Temperature Range for Striped Bass Spawning, Embryo Incubation, and Initial Rearing[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (0%)	10 (24%)
Above Normal	-3 (-11%)	18 (67%)
Below Normal	0 (0%)	17 (65%)
Dry	-3 (-7%)	-5 (-11%)
Critical	0 (0%)	-3 (-6%)
All	-2 (-5%)	7 (18%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through June striped bass spawning, embryo incubation, and initial rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during April and May and generally up to 20% lower than flows under H3 during June. Flows under H4 in the

American River below Nimbus Dam would generally be similar to flows under H3 during April and May and generally up to 39% lower than flows under H3 during June. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures outside the 59°F to 68°F suitable water temperature range in the Feather River below Thermalito Afterbay would be 10% to 18% higher than the percentage under H3 in wet, above normal, and below normal water years and 3% to 5% lower in dry and critical water years (Table 11-4-139).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in striped bass spawning, incubation, or initial rearing habitat. Flows in all rivers examined during the April through June spawning, incubation, and initial rearing period under Alternative 4 would generally be similar to or greater than flows under the NAA. The percentage of months outside the 59°F to 68°F water temperature range would generally be lower under Alternative 4 than under the NAA. Flow and water temperature conditions under H4 would be less favorable than those under H3 if water operations were to shift towards this end of the adaptive range.

CEQA Conclusion: In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for striped bass relative to Existing Conditions.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions during April through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during April through June, except in wet years during May (33% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal and below normal years during April (7% and 6% lower, respectively) and wet and critical years during June (27% and 33% lower, respectively), but generally lower, by up to 29%, during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The most persistent flow reductions in drier water year types, when effects would be most critical for habitat conditions, consist of reductions in critical years during May (15% lower) and June (33% lower).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June would be lower than the percentage under Existing Conditions in all water years except critical years (28% higher) (Table 11-4-138). This is a relatively small effect that would not have biologically meaningful negative effects on the striped bass population.

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the April through June striped bass spawning, embryo incubation, and initial rearing period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. The percentage of months under H1 with mean water temperatures outside the 59°F to 68°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to or lower than the percentage under H3 in all water year types (Table 11-4-139).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through June striped bass spawning, embryo incubation, and initial rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during April and May and generally up to 20% lower than flows under H3 during June. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 during April and May and generally up to 39% lower than flows under H3 during June. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures outside the 59°F to 68°F suitable water temperature range in the Feather River below Thermalito Afterbay would be 10% to 18% higher than the percentage under H3 in wet, above normal, and below normal water years and 3% to 5% lower in dry and critical water years (Table 11-4-139).

Collectively, these results indicate that the impact would not be significant because Alternative 4 would not cause a substantial reduction in spawning, incubation, and initial rearing habitat of striped bass. Therefore, no mitigation is necessary. Flows in all rivers except the San Joaquin and Stanislaus rivers during the April through June spawning, incubation, or initial rearing period under Alternative 4 would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types that would not have biologically meaningful negative effects. The most persistent flow reductions would be small to moderate reductions for two of the three months in the spawning period in the American River, which would not have biologically meaningful negative effects on the striped bass population. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 4, although this effect would not be biologically meaningful to striped bass. The percentage of months outside the 59°F to 68°F water temperature range would generally be lower under Alternative 4 than under Existing Conditions. Flow and water temperature conditions under H4 would be less favorable than those under H3 if water operations were to shift towards this end of the adaptive range.

American Shad

In general, Alternative 4 would slightly improve the quality and quantity of upstream habitat conditions for American shad relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under NAA during April through June except in above normal years during April (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA during April through June except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be moderately to substantially greater than flows under NAA during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during April through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside the 60°F to 70°F water temperature range would generally be lower than the percentage under NAA depending on water year type (Table 11-4-140).

Table 11-4-140. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 60°F to 70°F Water Temperature Range for American Shad Adult Migration and Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-6 (-13%)	-1 (-2%)
Above Normal	-6 (-17%)	-15 (-33%)
Below Normal	0 (0%)	-7 (-18%)
Dry	0 (0%)	-5 (-11%)
Critical	3 (8%)	-3 (-7%)
All	-2 (-5%)	-5 (-12%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the April through June American Shad migration and spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. The percentage of months under H1 with mean water temperatures outside the 60°F to 70°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to or lower than the percentage under H3 in all water year types (Table 11-4-141).

Table 11-4-141. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 60°F to 70°F Water Temperature Range for American Shad Adult Migration and Spawning[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (0%)	11 (28%)
Above Normal	-3 (-10%)	18 (60%)
Below Normal	0 (0%)	14 (45%)
Dry	-6 (-15%)	-6 (-15%)
Critical	0 (0%)	0 (0%)
All	-2 (-5%)	7 (19%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through June American Shad migration and spawning period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during April and May and generally up to 20% lower than flows under H3 during June. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 during April and May and generally up to 39% lower than flows under H3 during June. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures outside the 60°F to 70°F suitable water temperature range in the Feather River below Thermalito Afterbay would be 11% to 18% higher than the percentage under H3 in wet, above normal, and below normal water years, 6% lower in dry water years, and identical in critical water years (Table 11-4-141).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in American shad spawning or adult migration. Flows in all rivers examined during the April through June adult migration and spawning period under Alternative 4 would generally be similar to or greater than flows under the NAA. The percentage of months outside the 60°F to 70°F water temperature range would generally be lower under Alternative 4 than under the NAA. Flow and water temperature conditions under H4 would be less favorable than those under H3 if water operations were to shift towards this end of the adaptive range.

CEQA Conclusion: In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for American shad relative to Existing Conditions.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions during April through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during April through June, except in wet years during May (33% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal and below normal years during April (7% and 6% lower, respectively) and wet and critical years during June (27% and 33% lower, respectively), but generally lower, by up to 29%, during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The most persistent flow reductions in drier water year types, when effects would be most critical for habitat conditions, consist of reductions in critical years during May (15% lower) and June (33% lower).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature related effects in these rivers during the April through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside of the 60°F to 70°F water temperature range would be similar to or lower than the percentage under Existing Conditions in all water years except critical years (8% higher) (Table 11-4-140).

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the April through June American Shad migration and spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the*

Fish Analysis). The percentage of months under H1 with mean water temperatures outside the 60°F to 70°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to or lower than the percentage under H3 in all water year types (Table 11-4-141).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through June American Shad migration and spawning period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. Flows under H4 in the Trinity River below Lewiston Reservoir and in Clear Creek at Whiskeytown Dam would be similar to flows under H3 throughout the period. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during April and May and generally up to 20% lower than flows under H3 during June. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 during April and May and generally up to 39% lower than flows under H3 during June. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures outside the 60°F to 70°F suitable water temperature range in the Feather River below Thermalito Afterbay would be 11% to 18% higher than the percentage under H3 in wet, above normal, and below normal water years, 6% lower in dry water years, and identical in critical water years (Table 11-4-141).

Collectively, these results indicate that the impact would not be significant because Alternative 4 would not cause a substantial reduction in American shad adult migration and spawning habitat, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus rivers during the April through June adult migration and spawning period under Alternative 4 would generally be similar to or greater than flows under Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 4, although this effect would be biologically meaningful to American shad. The percentage of months outside the 60°F to 70°F water temperature range would generally be similar to or lower under Alternative 4 than under Existing Conditions. Flow and water temperature conditions under H4 would be less favorable than those under H3 if water operations were to shift towards this end of the adaptive range.

Threadfin Shad

In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to the NAA.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during April through August threadfin shad spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA during April through August except in dry years during July (7% lower) and in dry and critical years during August (to 14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under NAA during April through August except in above normal years during April and in critical years during August (both 11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA during April through August except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would be moderately to substantially greater than flows under NAA during April through June, and lower than flows under NAA during July and August (to 50% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Based on occurrence late in the spawning period, and the fact that they would be partially offset by flow increases in the prior months, these flow reductions are not expected to have biologically meaningful effects.

In the American River below Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during April through August regardless of water year type except in dry years during July (12% lower) and in drier water year types during August (to 24%) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These flow reductions are small to moderate magnitude and limited to late in the spawning period and, therefore, would not have biologically meaningful negative effects.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 below 68°F would be greater than those under NAA (11% to 22% greater) in all but dry and critical years (Table 11-4-142). These are relatively small increases that would not have biologically meaningful effects.

Table 11-4-142. Difference and Percent Difference in the Percentage of Months during April–August in Which Water Temperatures in the Feather River below Thermalito Afterbay fall below the 68°F Water Temperature Threshold for Threadfin Shad Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-8 (-12%)	5 (11%)
Above Normal	-20 (-26%)	9 (19%)
Below Normal	-14 (-20%)	10 (22%)
Dry	-36 (-48%)	-6 (-12%)
Critical	-28 (-44%)	0 (0%)
All	-20 (-29%)	3 (7%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the April through August threadfin shad spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. The percentage of months under H1 with mean water temperatures outside the 59°F to 68°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water year types (Table 11-4-143).

Table 11-4-143. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay fall below the 68°F Water Temperature Threshold for Threadfin Shad Spawning[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (0%)	-6 (-11%)
Above Normal	-2 (-3%)	-9 (-16%)
Below Normal	-1 (-3%)	-4 (-8%)
Dry	1 (3%)	2 (6%)
Critical	0 (0%)	0 (0%)
All	0 (0%)	-3 (-7%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through August threadfin shad spawning period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4, and during August, in which flows would be up to 13% greater under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during April and May and generally up to 39% lower than flows under H3 during June through August. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 except during June in which flows would be up to 39% lower than flows under H3, and during August, in which flows would be up to 32% greater than flows under H3. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures below the 68°F temperature threshold in the Feather River below Thermalito Afterbay would be similar to or lower than the percentage under H3 in all water years (Table 11-4-143).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in threadfin shad spawning habitat. Flows in all rivers examined during the April through August spawning period under Alternative 4 would generally be similar to or greater than flows under the NAA. Small to substantial flow reductions would occur in the Feather River during July and August, but would be offset by increases in flows during the preceding months. In all other locations the occurrence of flow reductions would not be of sufficient magnitude or frequency to have a biologically meaningful effect on threadfin shad. The percentage of years below the spawning temperature threshold would be moderately higher under Alternative 4 relative to the NAA, but this increase is not expected to have a biologically meaningful effect on the threadfin shad population because there are no temperature-related effects in any other rivers. Flow conditions in the Feather River under H4 would be less favorable than those under H3 if water operations were to shift towards this end of the adaptive range.

CEQA Conclusion: In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to Existing Conditions.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during April through August spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through August, except in wet years during May (17% lower), in critical years during July (8% lower), and in wet, dry and critical years during August (5%, 11%, and 26% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). These are relatively small-magnitude and infrequent flow reductions and would not have biologically meaningful effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through August, except in critical years during May and August (6% and 33% lower, respectively) and in wet years during July (14% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions during April through August regardless of water year type except in critical years during August (25% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during April through June, except in wet years during May (33% lower), and in wetter years during July and August, and would be lower than flows under Existing Conditions in drier water years during July (to 61% lower) and August (to 47% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal and below normal years during April (7% and 6% lower, respectively) and wet and critical years during June (27% and 33% lower, respectively), but generally lower, by up to 48%, during May, July, and August (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The most persistent flow reductions in drier water year types, when effects would be most critical for habitat conditions, would be inconsistent and of relatively small magnitude, and/or would occur for two months in a row during July and August at the end of the spawning period, and therefore would not have biologically meaningful negative effects.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, the percentage of months below the 68°F water temperature threshold for threadfin shad spawning under H3 would be 12% to 48% lower than the percentage under Existing Conditions, depending on water year type (Table 11-4-142).

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the April through August threadfin shad spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis)*. The percentage of months under H1 with mean water temperatures outside the 59°F to 68°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water year types (Table 11-4-143).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through August threadfin shad spawning period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4, and during August, in which flows would be up to 13% greater under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during April and May and generally up to 39% lower than flows under H3 during June through August. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 except during June in which flows would be up to 39% lower than flows under H3, and during August, in which flows would be up to 32% greater than flows under H3. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures below the 68°F temperature threshold in the Feather River below Thermalito Afterbay would be similar to or lower than the percentage under H3 in all water years (Table 11-4-143). Collectively, these results indicate that the impact would not be significant because Alternative 4 would not cause a substantial reduction in threadfin shad spawning habitat, and no mitigation is necessary. Flows in most rivers examined during the April through August spawning period under Alternative 4 would generally be similar to or greater than flows under Existing Conditions. There would be substantial flow reductions during July and August in drier water years in the Feather River that would have a localized effect late in the spawning season. There would be flow reductions for some months and some of the drier water year types from May through August in the American River, but the flow reductions would be offset by increases in adjoining months and/or would not be of sufficient magnitude or frequency to cause a biologically meaningful effect on threadfin shad. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 4, although these reductions would not have population-level effects on American shad. The percentage of months outside all temperature thresholds are lower under Alternative 4 than under Existing Conditions, indicating that there would be a net temperature-related benefit of Alternative 4 to threadfin shad. Flow conditions in the Feather River under H4 would be less favorable than those under H3 if water operations were to shift towards this end of the adaptive range.

Largemouth Bass

In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for largemouth bass relative to the NAA.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under NAA during March through June except in above normal years during April (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA during March through June except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be moderately to substantially greater than flows under NAA during March through June except in below normal years during March (20% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during March through June regardless of water year type except in dry and critical years during March (5% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside the 59°F to 75°F water temperature range would be similar to or lower than the percentage under NAA in all water years except dry years (7% higher) (Table 11-4-144).

Table 11-4-144. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Be outside the 59°F to 75°F Water Temperature Range for Largemouth Bass Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-9 (-16%)	0 (0%)
Above Normal	-16 (-32%)	-2 (-6%)
Below Normal	-11 (-24%)	0 (0%)
Dry	-16 (-34%)	2 (7%)
Critical	-15 (-34%)	-4 (-12%)
All	-13 (-27%)	-1 (-3%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the March through June largemouth bass spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The percentage of months under H1 outside the 59°F to 75°F water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water year types (Table 11-4-145).

Table 11-4-145. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Be outside the 59°F to 75°F Water Temperature Range for Largemouth Bass Spawning[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (0%)	4 (9%)
Above Normal	-2 (-6%)	9 (26%)
Below Normal	-2 (-6%)	5 (15%)
Dry	-2 (-6%)	-3 (-10%)
Critical	0 (0%)	-4 (-14%)
All	-1 (-3%)	3 (8%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the March through June largemouth bass spawning period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at Thermalito Afterbay would generally be similar to flows under H3 during March, up to 330% greater than flows under H3 during April and May, and generally up to 39% lower than flows under H3 during June. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 except during June in which flows would be up to 39% lower than flows under H3. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures below outside the 59°F to 75°F water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water years except above and below normal water years in which the percentages under H4 would be 9% and 5% higher than those under H3 (Table 11-4-143). These small increases would not cause biologically meaningful effects to largemouth bass spawning habitat conditions.

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in largemouth bass spawning habitat. Flows in all rivers examined during the March through June spawning period under Alternative 4 would generally be similar to or greater than flows under the NAA. The occurrence of flow reductions would not be of sufficient magnitude or frequency to have a biologically meaningful effect on largemouth bass. The percentage of years outside the suitable spawning temperature range under Alternative 4 would be similar to the NAA and there are no differences in water temperatures between the NAA and Alternative 4 in all other rivers and creeks examined.

CEQA Conclusion: In general, Alternative 4 would not reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to Existing Conditions.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (10% lower) and in wet years during May (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (6% lower) and in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions during March through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during March through June, except in below normal years during March (53% lower) and in wet years during May (33% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions during March, April and June, except in critical years during March (7% lower), above and below normal years during April (7% and 6% lower, respectively), and in wet and critical years during June (27% and 33% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to or lower than flows under Existing Conditions during May (to 29% lower) except in dry years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water year types, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude throughout the spawning period and would not have biologically meaningful negative effects.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside of the 59°F to 75°F water temperature range for largemouth bass spawning would be lower than the percentage under Existing Conditions in all water years (Table 11-4-144).

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the March through June largemouth bass spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The percentage of months under H1 outside the 59°F to 75°F water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water year types (Table 11-4-145).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the March through June largemouth bass spawning period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at Thermalito Afterbay would generally be similar to flows under H3 during March, up to 330% greater than flows under H3 during April and May, and generally up to 39% lower than flows under H3 during June. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 except during June in which flows would be up to 39% lower than flows under H3. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures below outside the 59°F to 75°F water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water years except above and below normal water years in which the percentages under H4 would be 9% and 5% higher than those under H3 (Table 11-4-143). These small increases would not cause biologically meaningful effects to largemouth bass spawning habitat conditions.

Collectively, these results indicate that the impact would not be significant because Alternative 4 would not cause a substantial reduction in largemouth bass spawning habitat, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus rivers during the March through June spawning period under Alternative 4 would generally be similar to or greater than flows under Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 4, although these reductions would not have population-level effects on largemouth bass. The percentage of months outside the 59°F to 75°F water temperature range would generally be lower under Alternative 4 than under Existing Conditions.

Sacramento Tule Perch

NEPA Effects: The effects of water operations on spawning habitat for Sacramento tule perch under Alternative 4 would be similar to that described for Alternative 1A. For a detailed discussion, please see Alternative 1A, Impact AQUA-202. The effects would not be adverse.

CEQA Conclusion: As described under Alternative 1A, Impact AQUA-202 the impacts on Sacramento tule perch spawning would be not be significant and no mitigation is required.

Sacramento-San Joaquin Roach – California species of special concern

In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the NAA.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA during March through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under NAA during March through June except in above normal years during April (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA during March through June except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be moderately to substantially greater than flows under NAA during March through June except in below normal years during March (20% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during March through June regardless of water year type except in dry and critical years during March (5% and 7% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

In the Feather River below Thermalito Afterbay, the percentage of months in which temperatures would be below the 60.8°F water temperature threshold for roach spawning initiation under H3 would be similar to or lower than the percentage under NAA in all water years (Table 11-4-146).

Table 11-4-146. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Fall below the 60.8°F Water Temperature Threshold for the Initiation of Sacramento-San Joaquin Roach Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-13 (-19%)	0 (0%)
Above Normal	-7 (-12%)	0 (0%)
Below Normal	-4 (-7%)	2 (4%)
Dry	-11 (-20%)	0 (0%)
Critical	-17 (-30%)	-2 (-5%)
All	-11 (-18%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the March through June Sacramento-San Joaquin roach spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The percentage of months under H1 below the 60.8°F water temperature threshold in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water year types (Table 11-4-147).

Table 11-4-147. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Fall below the 60.8°F Water Temperature Threshold for Sacramento-San Joaquin Roach Spawning[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (0%)	4 (7%)
Above Normal	0 (0%)	2 (5%)
Below Normal	0 (0%)	2 (4%)
Dry	-1 (-3%)	0 (0%)
Critical	0 (0%)	0 (0%)
All	0 (-1%)	2 (4%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the March through June Sacramento-San Joaquin roach spawning period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at Thermalito Afterbay would generally be similar to flows under H3 during March, up to 330% greater than flows under H3 during April and May, and generally up to 39% lower than flows under H3 during June. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 except during June in which flows would be up to 39% lower than flows under H3. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures below the 60.8°F water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water years (Table 11-4-147).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in roach spawning habitat. Flows in all rivers examined during the March through June spawning period under Alternative 4 would generally be similar to or greater than flows under the NAA. The occurrence of flow reductions would not be of sufficient magnitude or frequency to have a biologically meaningful effect on roach. The percentage of years below the spawning temperature threshold under Alternative 4 would be similar to the NAA and there are no differences in water temperatures between the NAA and Alternative 4 in all other rivers and creeks examined.

CEQA Conclusion: In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin Roach relative to Existing Conditions.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (10% lower) and in wet years during May (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (6% lower) and in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions during March through June regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during March through June, except in below normal years during March (53% lower) and in wet years during May (33% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions during March, April and June, except in critical years during March (7% lower), above and below normal years during April (7% and 6% lower, respectively), and in wet and critical years during June (27% and 33% lower, respectively) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be similar to or lower than flows under Existing Conditions during May (to 29% lower) except in dry years (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water year types, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude throughout the spawning period and would not have biologically meaningful negative effects.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the March through June period.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 in which temperatures would be below the 60.8°F water temperature threshold for roach spawning initiation would be lower than the percentage under Existing Conditions in all water years (Table 11-4-146).

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the March through June Sacramento-San Joaquin roach spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The percentage of months under H1 below the 60.8°F water temperature threshold in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water year types (Table 11-4-147).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the March through June Sacramento-San Joaquin roach spawning period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower under H4 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at Thermalito

Afterbay would generally be similar to flows under H3 during March, up to 330% greater than flows under H3 during April and May, and generally up to 39% lower than flows under H3 during June. Flows under H4 in the American River below Nimbus Dam would generally be similar to flows under H3 except during June in which flows would be up to 39% lower than flows under H3. Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures below the 60.8°F water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water years (Table 11-4-147).

Collectively, these results indicate that the impact would not be significant because Alternative 4 would not cause a substantial reduction in Sacramento-San Joaquin roach spawning habitat, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus rivers during the March through June spawning period under Alternative 4 would generally be similar to or greater than flows under Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 4, although these reductions would not have population-level effects on roach. The percentage of months below the 60.8°F water temperature threshold would generally be lower under Alternative 4 than under Existing Conditions.

Hardhead – California species of special concern

In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the NAA.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA during April and May) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under NAA during April and May except during April compared to NAA (11% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA during April and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be moderately to substantially greater than flows under NAA during April and May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during April and May regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows relative to the NAA.

Water Temperature

The percentage of years outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, the percentage of years under H3 outside the 59°F to 64°F suitable water temperature range would be similar to or lower than the percentage under NAA in all water year types (Table 11-4-148).

Table 11-4-148. Difference and Percent Difference in the Percentage of Months during April–May in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Be outside the 59°F to 64°F Water Temperature Range for Hardhead Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-2 (-3%)	-3 (-5%)
Above Normal	-19 (-30%)	-10 (-18%)
Below Normal	18 (42%)	-3 (-5%)
Dry	-9 (-16%)	-3 (-6%)
Critical	-4 (-7%)	-4 (-7%)
All	-2 (-4%)	-4 (-7%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the April through May hardhead spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The percentage of months under H1 outside the 59°F to 64°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water year types (Table 11-4-149).

Table 11-4-149. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months during April–May in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Fall outside the 59°F to 64°F Water Temperature Range for Hardhead Spawning[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (0%)	5 (8%)
Above Normal	-4 (-9%)	10 (22%)
Below Normal	0 (0%)	0 (0%)
Dry	-3 (-6%)	-3 (-6%)
Critical	4 (8%)	0 (0%)
All	-1 (-2%)	2 (4%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through May period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Feather River at Thermalito Afterbay would up to 330% greater than flows under H3 during April and May. Flows under H4 in the Trinity, American, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures outside the 59°F to 64°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water years (Table 11-4-149).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in roach spawning habitat. Flows in all rivers examined during the April through May spawning period under Alternative 4 would generally be similar to or greater than flows under the NAA. The percentage of years below the spawning temperature threshold under Alternative 4 would be similar to the NAA and there are no differences in water temperatures between the NAA and Alternative 4 in all other rivers and creeks examined.

CEQA Conclusion: In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for hardhead relative to Existing Conditions.

H3/ESO

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through May, except in wet years during May (17% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through May, except in critical years during May (6% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions during April through May regardless of water year type (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during April through May, except in wet years during May (33% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April except in above normal and below normal years (7% and 6% lower, respectively), but generally lower, by up to 29%, during May (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water year types, when effects would be most critical for habitat conditions, consist of reductions in below normal years in both months (6% and 19% lower, respectively) and in critical years during May (15% lower, following a 10% increase in flows during April), which are relatively small-magnitude flow reductions that would not have biologically meaningful negative effects.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. For a discussion of the topic see the analysis for Alternative 1A.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside of the 59°F to 64°F water temperature range for hardhead spawning would be lower than the percentage under Existing Conditions in all water years except below normal years (18% higher) (Table 11-4-148).

H1/LOS

Flows under H1 in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek during the April through May hardhead spawning period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The percentage of months under H1 outside the 59°F to 64°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water year types (Table 11-4-149).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through May period would generally be similar to flows under H3 (Appendix 11C, *CALSIM II Model Results utilized in the*

Fish Analysis). Flows under H4 in the Feather River at Thermalito Afterbay would up to 330% greater than flows under H3 during April and May. Flows under H4 in the Trinity, American, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 throughout the period. The percentage of months under H4 with mean water temperatures outside the 59°F to 64°F suitable water temperature range in the Feather River below Thermalito Afterbay would be similar to the percentage under H3 in all water years (Table 11-4-149).

Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in roach spawning habitat, and no mitigation is necessary. Flows in most rivers examined during the April through May spawning period under Alternative 4 would generally be similar to or greater than flows under Existing Conditions. Flows in the San Joaquin and Stanislaus rivers would be lower under Alternative 4, although these reductions would not have population-level effects on hardhead. The percentage of years below the spawning temperature threshold under Alternative 4 would be similar to Existing Conditions and there are no differences in water temperatures between Existing Conditions and Alternative 4 in all other rivers and creeks examined.

California Bay Shrimp

NEPA Effects: The effect of water operations on spawning habitat of California bay shrimp under Alternative 4 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-202). For a detailed discussion, please see Alternative 1A, Impact AQUA-202. The effects would not be adverse.

CEQA Conclusion: The impact of water operations on spawning habitat of California bay shrimp would be the same as described immediately above. The impacts would be less than significant and no mitigation would be required.

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-203 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

NEPA Effects: The discussion under Alternative 4, Impact AQUA-202 for striped bass also addressed the embryo incubation and initial rearing period. That analysis indicates that there is no adverse effect on striped bass rearing during that period. Other effects of water operations on rearing habitat for striped bass under Alternative 4 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203). For a detailed discussion, please see Alternative 1A, Impact AQUA-203. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on striped bass rearing habitat would be less than significant and no mitigation would be required.

American Shad

The effects of water operations on rearing habitat for American shad under Alternative 4 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203). For a detailed discussion, please see Alternative 1A, Impact AQUA-203. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on American shad rearing habitat would be less than significant and no mitigation would be required.

Threadfin Shad

NEPA Effects: The effects of water operations on rearing habitat for threadfin shad under Alternative 4 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203). For a detailed discussion, please see Alternative 1A, Impact AQUA-203. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on threadfin shad rearing habitat would be less than significant and no mitigation would be required.

Largemouth Bass

H3/ESO

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA during April through October with some exceptions (to 14% lower), and would be lower in all water year types during November (to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to flows under NAA with isolated exceptions, including small flow reductions in critical years during August through October (to 11%) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA during April through November except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be greater than flows under NAA during April through June, drier water years during September, in all water years during October, and in dry years during November; flows would be lower (to 50% lower) during July, August, wetter water years during September, and above normal years during November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects would be more critical for habitat conditions, range from moderate to substantial in drier water years during July, August, and below normal years during September. These would be partially offset by increases in flow in the adjoining months (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during April through July except in dry years during July (12% lower), and would be similar to or lower than flows under NAA (to 40% lower) during August through November with a few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years when effects would be more critical for habitat conditions consist of small to moderate reductions for some months and water year types from July through November, which would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows between H3 and NAA.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 88°F under NAA or H3. As a result, there would be no difference between NAA and H3 in the percentage of months in which the 88°F water temperature threshold is exceeded (Table 11-4-150).

Table 11-4-150. Difference and Percent Difference in the Percentage of Months during April–November in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 88°F Water Temperature Threshold for Juvenile Largemouth Bass Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round adult largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for adult rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA throughout the year with some exceptions (up to 14% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to flows under NAA during the period with isolated exceptions (up to 11% lower), including small flow reductions in critical years during August through October (up to 12% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA throughout the year except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be similar to or greater than flows under NAA during January through June with a few isolated exceptions in drier water years during September, and during October through December with a few relatively isolated, small-magnitude reductions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would be more persistently lower under H3 relative to NAA (up to 50% lower) during July, August, and in wetter water years during September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects would be more critical for habitat conditions, range from moderate to substantial in drier water years during July, August, and below normal years during September. These would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during January through July and December, with a few isolated, small-magnitude exceptions (up to 12% lower), and would be similar to or lower than flows under NAA (up to 40% lower) during August through November with a few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years when effects would be more critical for habitat conditions consist of small to moderate reductions for some months and water year types from July through November, which would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows between H3 and NAA.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the year-round period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F under NAA and H3 (Table 11-4-151). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between NAA and H3.

Table 11-4-151. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Adult Largemouth Bass Survival[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Juveniles

Flows under H1 in the Sacramento River upstream of Red Bluff during the April through November juvenile largemouth bass rearing period would generally be similar to flows under H3 except in wetter water years during September, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers, and Clear Creek would generally be similar to flows under H3 throughout the period. Flows under H1 in the Feather River at Thermalito Afterbay would generally be similar to those under H3 except in wetter years during September, in which flows would be up to 83% lower. Flows under H1 in the American River below Nimbus Dam would generally be similar to those under H3 except in wetter years during September, in which flows would be up to 35% lower. Flow reductions in wetter water years are less critical to largemouth bass than in drier water years and, therefore, these flow reductions would not have biologically meaningful effects on largemouth bass rearing habitat.

Water temperatures in the Feather River below Thermalito Afterbay during the April through November juvenile largemouth bass rearing period would not exceed the 88°F water temperature threshold in H1 or H3. As a result, there would be no difference between H1 and H3 in the percentage of months in which the 88°F water temperature threshold is exceeded (Table 11-4-152).

Table 11-4-152. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months during April–November in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 88°F Water Temperature Threshold for Juvenile Largemouth Bass Rearing[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

Adults

Flows under H1 in the Sacramento River upstream of Red Bluff during the year-round adult largemouth bass rearing period would generally be similar to flows under H3 except in wetter water years during September and December, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H1 in the Feather River at Thermalito Afterbay would be up to 29% greater than flows under H3 during January and December, up to 83% lower during September, and generally similar during the remainder of months. Flows under H1 in the American River at Nimbus Dam would be up to 8% greater than flows under H3 during December, up to 35% lower during September, and generally similar during the remainder of months. Flow reductions would not be frequent enough to have biologically meaningful effects on adult largemouth bass rearing habitat.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass rearing period would not exceed the 86°F water temperature threshold in H1 or H3. As a result, there would be no difference between H1 and H3 in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4-153).

Table 11-4-153. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Adult Largemouth Bass Survival[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Juveniles

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through November juvenile largemouth bass rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers, and Clear Creek would generally be similar to flows under H3 throughout the period. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during April and May, up to 39% lower during June through October, and similar to flows under H3 during November. Based on these flow reductions, adult rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during April, May, July, and November.

Water temperatures in the Feather River below Thermalito Afterbay during the April through November juvenile largemouth bass rearing period would not exceed the 88°F water temperature threshold in H4 or H3. As a result, there would be no difference between H4 and H3 in the percentage of months in which the 88°F water temperature threshold is exceeded (Table 11-4-152).

Adults

Flows under H4 in the Sacramento River upstream of Red Bluff during the year-round adult largemouth bass rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during January, April, and May, up to 39% lower during June through October, and similar to flows under H3 during February, March, November, and December. Based on these flow reductions, adult rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during the remaining eight months.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass rearing period would not exceed the 86°F water temperature threshold in H4 or H3. As a result, there would be no difference between H4 and H3 in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4-153).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in juvenile and adult rearing or spawning habitat. Flows in all rivers examined during the year under Alternative 4 are generally similar to or greater than flows under the NAA in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the largemouth bass population. Flow-related habitat conditions in the Feather River for both juvenile and adult largemouth bass under H4 would be less favorable than those under H3 if water operations were to shift to this end of the adaptive limits. The percentage of months outside all temperature thresholds examined in the Feather River under Alternative 4 are the same as those under the NAA. Also, there are no temperature-related effects in any other rivers examined.

CEQA Conclusion: In general, Alternative 4 would reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to Existing Conditions.

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through July and October, except in wet years during May (17% lower) and in critical years during July (9% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during August, September, and November (to 26% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April through November, except in critical years during May (6% lower), in wet years during July (14% lower), in critical years during August through November (to 45% lower), and in most of the remaining water year types during October and November (to 25% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions in critical years during August through November would have a localized effect on rearing conditions in that water year type. Flow reductions in the other drier water year types are inconsistent and of small magnitude and would not have biologically meaningful negative effects.

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions during April through November regardless of water year type except in critical years during August through October (6% to 28% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively small, isolated effect limited to a single water year type and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during April through June and October, with a few isolated exceptions (to 33% lower), and in wetter water year types during July, August, and September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be moderately to substantially lower than flows under Existing Conditions in drier water years during July through September (to 61% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). However, these would be offset by substantial increases in flow that would occur in drier water year types during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) and therefore are not expected to have biologically meaningful negative effects.

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions during April and June, except in above normal and below normal years during April (7% and 6% lower, respectively) and wet and critical years during June (27% and 33% lower, respectively), but generally lower, by up to 48%, during May and July through November (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be moderate flow reductions in drier water year types, when effects would be most critical for habitat conditions, for some months/water year types from May through November that would affect rearing conditions at this location (to 42% lower in below normal, to 48% lower in dry and to 43% lower in critical water years).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 88°F water temperature threshold for year-round juvenile largemouth bass occurrence under Existing Conditions or H3 (Table 11-4-150). As a result, there would be no difference in the percentage of months in which the 88°F water temperature threshold is exceeded between H3 and Existing Conditions.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round adult largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for adult rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during January through July, October, and December, except in below normal years during March (10% lower), in wet years during May (17% lower), in critical years during July (9% lower), and in wet years during December (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during August, September, and November (to 26% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions throughout the year, except in below normal and critical years during January (16% and 8% lower, respectively), in below normal years during March (6% lower), in critical years during May (6% lower), in wet years during July (14% lower), in critical years during August through December (to 45% lower), and in most of the remaining water year types during October and November (to 25% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions in critical years during August through December would have a localized effect on rearing conditions in that water year type. Flow reductions in the other drier water year types are inconsistent and of small magnitude and would not have biologically meaningful negative effects.

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions throughout the year regardless of water year type except in critical years during August through October (6% to 28% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively small, isolated effect limited to a single water year type and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during March through June and October, with a few isolated exceptions (to 53% lower), and in wetter water year types during July, August, and September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be moderately to substantially lower than flows under Existing Conditions in drier water years during July through September (to 61% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). However, these would be offset by substantial increases in flow that would occur in drier water year types during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) and therefore are not expected to have biologically meaningful negative effects.

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions in wetter years during January, and most water years during February through April, with isolated exceptions of relatively small flow reductions (to 13% lower), but generally lower, by up to 48%, in drier years during January, most water years during May, wet and critical years during June, and in most water years during July through December (Appendix

11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be small to substantial flow reductions in drier water year types, when effects would be most critical for habitat conditions, for some months/water year types during each month of the year, with the most consistent flow reductions in critical water years and the greatest magnitude of flow reductions occurring during June through December. These persistent flow reductions would affect rearing conditions at this location (to 42% lower in below normal, to 48% lower in dry and to 43% lower in critical water years).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 86°F water temperature range for year-round adult largemouth bass occurrence under Existing Conditions or H3 (Table 11-4-151). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between H3 and Existing Conditions.

H1/LOS

Juveniles

Flows under H1 in the Sacramento River upstream of Red Bluff during the April through November juvenile largemouth bass rearing period would generally be similar to flows under H3 except in wetter water years during September, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers, and Clear Creek would generally be similar to flows under H3 throughout the period. Flows under H1 in the Feather River at Thermalito Afterbay would generally be similar to those under H3 except in wetter years during September, in which flows would be up to 83% lower. Flows under H1 in the American River below Nimbus Dam would generally be similar to those under H3 except in wetter years during September, in which flows would be up to 35% lower. Flow reductions in wetter water years are less critical to largemouth bass than in drier water years and, therefore, these flow reductions would not have biologically meaningful effects on largemouth bass rearing habitat.

Water temperatures in the Feather River below Thermalito Afterbay during the April through November juvenile largemouth bass rearing period would not exceed the 88°F water temperature threshold in H1 or H3. As a result, there would be no difference between H1 and H3 in the percentage of months in which the 88°F water temperature threshold is exceeded (Table 11-4-152).

Adults

Flows under H1 in the Sacramento River upstream of Red Bluff during the year-round adult largemouth bass rearing period would generally be similar to flows under H3 except in wetter water years during September and December, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H1 in the Feather River at Thermalito Afterbay would be up to 29% greater than flows under H3 during January and December, up to 83% lower during September, and generally similar during the remainder of months. Flows under H1 in the American River at Nimbus Dam would be up to 8% greater than flows under H3 during December, up to 35% lower during September, and generally similar during the remainder of months. Flow reductions would not be frequent enough to have biologically meaningful effects on adult largemouth bass rearing habitat.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass rearing period would not exceed the 86°F water temperature threshold in H1 or H3. As a result, there would be no difference between H1 and H3 in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4-153).

H4/HOS

Juveniles

Flows under H4 in the Sacramento River upstream of Red Bluff during the April through November juvenile largemouth bass rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers, and Clear Creek would generally be similar to flows under H3 throughout the period. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during April and May, up to 39% lower during June through October, and similar to flows under H3 during November. Based on these flow reductions, adult rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during April, May, July, and November.

Water temperatures in the Feather River below Thermalito Afterbay during the April through November juvenile largemouth bass rearing period would not exceed the 88°F water temperature threshold in H4 or H3. As a result, there would be no difference between H4 and H3 in the percentage of months in which the 88°F water temperature threshold is exceeded (Table 11-4-152).

Adults

Flows under H4 in the Sacramento River upstream of Red Bluff during the year-round adult largemouth bass rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during January, April, and May, up to 39%

lower during June through October, and similar to flows under H3 during February, March, November, and December. Based on these flow reductions, adult rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during the remaining eight months.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass rearing period would not exceed the 86°F water temperature threshold in H4 or H3. As a result, there would be no difference between H4 and H3 in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4-153).

Collectively, these results indicate that the impact is not significant because Alternative 4 would not cause a substantial reduction in largemouth bass habitat and no mitigation is necessary. Flows would be substantially lower during the majority of the year-round adult rearing period in the American River, but based on the fact that this persistent effect occurs at only one location, it would not be expected to have biologically meaningful negative effects on the largemouth bass population. Flow reductions would occur throughout roughly half of the rearing period in the Feather River, but would be partially offset by substantial increases in flow during the preceding months. There would also be small to moderate flow reductions in the Trinity River in critical water years for roughly half the year that would have a localized effect juvenile and adult rearing in that water year type. Reduced flows in other rivers including the San Joaquin and Stanislaus rivers would not have biologically meaningful effects on largemouth bass. Flow-related habitat conditions in the Feather River for both juvenile and adult largemouth bass under H4 would be less favorable than those under H3 if water operations were to shift to this end of the adaptive limits. The percentages of months outside all temperature thresholds under Alternative 4 are the same as those under Existing Conditions. Also, there are no temperature-related effects in any other rivers examined.

Sacramento Tule Perch

In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round Sacramento tule perch presence. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA throughout the year with some exceptions (up to 14% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to flows under NAA during the period with isolated exceptions (up to 11% lower), including small flow reductions in critical years during August through October (up to 12% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA throughout the year except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be similar to or greater than flows under NAA during January through June with a few isolated exceptions, in drier water years during September, and during October through December with a few relatively isolated, small-magnitude reductions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would be more persistently lower under H3 relative to NAA (up to 50% lower) during July, August, and in wetter water years during September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects would be more critical for habitat conditions, range from moderate to substantial in drier water years during July, August, and below normal years during September. These would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during January through July and December, with a few isolated, small-magnitude exceptions (up to 12% lower), and would be similar to or lower than flows under NAA (up to 40% lower) during August through November with a few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years when effects would be more critical for habitat conditions consist of small to moderate reductions for some months and water year types from July through November, which would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows between H3 and NAA.

Water Temperature

The percentage of months exceeding water temperature thresholds of 72°F and 75°F for the year-round occurrence of all life stages of Sacramento tule perch was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quantity and quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, the percentage of years under H3 exceeding the 72°F threshold would be higher than the percentage under NAA by 16% to 65% depending on water year type (Table 11-4-154). Although relative differences in above normal, below normal, and critical years are large due to small values, the absolute differenced in percent exceedance are only 2% to 6%, and do not represent biologically meaningful effects to Sacramento tule perch.

The percentage of months under H3 exceeding the 75°F threshold would be similar to or slightly greater than the percentage under NAA (up to 9% greater) (Table 11-4-154). The maximum increase corresponds to an absolute increase of 1%, which would not represent a biologically meaningful effect to Sacramento tule perch.

Table 11-4-154. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed 72°F and 75°F Water Temperature Thresholds for Sacramento Tule Perch Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
72°F Threshold		
Wet	3 (145%)	4 (184%)
Above Normal	2 (NA)	2 (188%)
Below Normal	7 (NA)	4 (137%)
Dry	11 (NA)	6 (118%)
Critical	13 (314%)	3 (19%)
All	7 (538%)	4 (84%)
75°F Threshold		
Wet	0.3 (NA)	0.3 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	1 (NA)	0 (0%)
Critical	6 (986%)	1 (10%)
All	1 (1,300%)	0.2 (17%)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento River upstream of Red Bluff during the year-round adult Sacramento tule perch rearing period would generally be similar to flows under H3 except in wetter water years during September and December, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H1 in the Feather River at Thermalito Afterbay would be up to 29% greater than flows under H3 during January and December, up to 83% lower during September, and generally similar during the remainder of months. Flows under H1 in the American River at Nimbus Dam would be up to 8% greater than flows under H3 during December, up to 35% lower during September, and generally similar during the remainder of months. Flow reductions would not be frequent enough to have biologically meaningful effects on Sacramento tule perch upstream rearing habitat.

The percentage of months under H1 exceeding the 72°F and 75°F water temperature thresholds in the Feather River below Thermalito Afterbay during the year-round Sacramento tule perch rearing period would be similar to the percentage under H3 in all water year types (Table 11-4-155).

Table 11-4-155. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed 72°F and 75°F Water Temperature Thresholds for Sacramento Tule Perch Occurrence[a]

Water Year Type	H3 vs. H1	H3 vs. H4
72°F Threshold		
Wet	0 (0%)	3 (54%)
Above Normal	0 (0%)	6 (261%)
Below Normal	-1 (-8%)	2 (25%)
Dry	-1 (-8%)	0 (0%)
Critical	-1 (-8%)	0 (0%)
All	-1 (-6%)	2 (25%)
75°F Threshold		
Wet	0 (0%)	1 (433%)
Above Normal	0 (NA)	1 (NA)
Below Normal	0 (NA)	3 (NA)
Dry	0 (0%)	1 (156%)
Critical	0 (0%)	0 (0%)
All	0 (0%)	1 (100%)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a reduction in percentage of months outside suitable range under H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the year-round Sacramento tule perch rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during January, April, and May, up to 39% lower during June through October, and similar to flows under H3 during February, March, November, and December. Based on these flow reductions, rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during the remaining eight months.

The percentage of months under H4 exceeding the 72°F and 75°F water temperature thresholds in the Feather River below Thermalito Afterbay during the year-round Sacramento tule perch rearing period would generally be similar to the percentage under H3, except in above normal water years under the 72°F threshold (6% higher)(Table 11-4-155).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in Sacramento tule perch habitat. Flows in all rivers examined during the year under Alternative 4 are generally similar to or greater than flows under the NAA in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the Sacramento tule perch population. The percentages of months outside all temperature thresholds under Alternative 4 are generally similar to or only slightly greater than the percentages under the NAA.

CEQA Conclusion: In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during year-round Sacramento tule perch presence. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during January through July, October, and December, except in below normal years during March (10% lower), in wet years during May (17% lower), in critical years during July (9% lower), and in wet years during December (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during August, September, and November (to 26% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions throughout the year, except in below normal and critical years during January (16% and 8% lower, respectively), in below normal years during March (6% lower), in critical years during May (6% lower), in wet years during July (14% lower), in critical years during August through December (to 45% lower), and in most of the remaining water year types during October and November (to 25% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions in critical years during August through December would have a localized effect on rearing conditions in that water year type. Flow reductions in the other drier water year types are inconsistent and of small magnitude and would not have biologically meaningful negative effects.

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions throughout the year regardless of water year type except in critical years during August through October (6% to 28% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively small, isolated effect limited to a single water year type and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during March through June and October, with a few isolated exceptions (to 53% lower), and in wetter water year types during July, August, and September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be moderately to substantially lower than flows under Existing Conditions in drier water years during July through September (to 61% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

However, these would be offset by substantial increases in flow that would occur in drier water year types during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) and therefore are not expected to have biologically meaningful negative effects.

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions in wetter years during January, and most water years during February through April, with isolated exceptions of relatively small flow reductions (to 13% lower), but generally lower, by up to 48%, in drier years during January, most water years during May, wet and critical years during June, and in most water years during July through December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be small to substantial flow reductions in drier water year types, when effects would be most critical for habitat conditions, for some months/water year types during each month of the year, with the most consistent flow reductions in critical water years and the greatest magnitude of flow reductions occurring during June through December. These persistent flow reductions would affect rearing conditions at this location (to 42% lower in below normal, to 48% lower in dry and to 43% lower in critical water years).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months exceeding water temperatures of 72°F and 75°F for the year-round occurrence of all life stages of Sacramento tule perch was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in Clear Creek or the San Joaquin River.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the year.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 exceeding 72°F relative to the percentage under Existing Conditions would be similar to or higher, by up to 314% (Table 11-4-154). The increases correspond to relatively small absolute increases, up to 13%, and are not expected to have biologically meaningful negative effects.

The percentage of years under H3 exceeding 75°F would be similar to the percentage under Existing Conditions in all water years except critical years (986% higher) (Table 11-4-154). The increase corresponds to a small absolute increase (6%) and would not have biologically meaningful negative effects.

H1/LOS

Flows under H1 in the Sacramento River upstream of Red Bluff during the year-round adult Sacramento tule perch rearing period would generally be similar to flows under H3 except in wetter water years during September and December, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H1 in the Feather River at Thermalito Afterbay would be up to 29% greater than flows under H3 during January and December, up to 83% lower during September, and generally similar during the remainder of months. Flows under H1 in the American River at Nimbus Dam would be up to 8% greater than flows under H3 during December, up to 35% lower during September, and generally similar during the remainder of months. Flow reductions would not be frequent enough to have biologically meaningful effects on Sacramento tule perch upstream rearing habitat.

The percentage of months under H1 exceeding the 72°F and 75°F water temperature thresholds in the Feather River below Thermalito Afterbay during the year-round Sacramento tule perch rearing period would be similar to the percentage under H3 in all water year types (Table 11-4-155).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the year-round Sacramento tule perch rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during January, April, and May, up to 39% lower during June through October, and similar to flows under H3 during February, March, November, and December. Based on these flow reductions, rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during the remaining eight months.

The percentage of months under H4 exceeding the 72°F and 75°F water temperature thresholds in the Feather River below Thermalito Afterbay during the year-round Sacramento tule perch rearing period would generally be similar to the percentage under H3, except in above normal water years under the 72°F threshold (6% higher)(Table 11-4-155).

Collectively, these results indicate that the impact is not significant because Alternative 4 would not cause a substantial reduction in Sacramento tule perch habitat, and no mitigation is necessary. Flows would be substantially lower during the majority of the year-round adult rearing period in the American River, but based on the fact that this persistent effect occurs at only one location, it would not be expected to have biologically meaningful negative effects on the Sacramento tule perch population. Flow reductions would occur throughout roughly half of the rearing period in the Feather River, but would be partially offset by substantial increases in flow during the preceding months. There would also be small to moderate flow reductions in the Trinity River in critical water years for roughly half the year that would have a localized effect juvenile and adult rearing in that water year type. Reduced flows in other rivers including the San Joaquin and Stanislaus rivers would not have biologically meaningful effects. The percentages of months outside both temperature thresholds are generally lower under Alternative 4 than under Existing Conditions.

Sacramento-San Joaquin Roach

In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach rearing period. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA throughout the year with some exceptions (up to 14% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to flows under NAA during the period with isolated exceptions (up to 11% lower), including small flow reductions in critical years during August through October (up to 12% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA throughout the year except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be similar to or greater than flows under NAA during January through June with a few isolated exceptions, in drier water years during September, and during October through December with a few relatively isolated, small-magnitude reductions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would be more persistently lower under H3 relative to NAA (up to 50% lower) during July, August, and in wetter water years during September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects would be more critical for habitat conditions, range from moderate to substantial in drier water years during July, August, and below normal years during September. These would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during January through July and December, with a few isolated, small-magnitude exceptions (up to 12% lower), and would be similar to or lower than flows under NAA (up to 40% lower) during August through November with a few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years when effects would be more critical for habitat conditions consist of small to moderate reductions for some months and water year types from July through November, which would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows between H3 and NAA.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F under NAA or H3(Table 11-4-156). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between NAA and H3.

Table 11-4-156. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Sacramento-San Joaquin Roach Survival[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento River upstream of Red Bluff during the year-round Sacramento-San Joaquin roach rearing period would generally be similar to flows under H3 except in wetter water years during September and December, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H1 in the Feather River at Thermalito Afterbay would be up to 29% greater than flows under H3 during January and December, up to 83% lower during September, and generally similar during the remainder of months. Flows under H1 in the American River at Nimbus Dam would be up to 8% greater than flows under H3 during December, up to 35% lower during September, and generally similar during the remainder of months. Flow reductions would not be frequent enough to have biologically meaningful effects on roach upstream rearing habitat.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass rearing period would not exceed the 86°F water temperature threshold in H1 or H3. As a result, there would be no difference between H1 and H3 in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4-157).

Table 11-4-157. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Sacramento-San Joaquin Roach Survival[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the year-round Sacramento-San Joaquin roach rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during January, April, and May, up to 39% lower during June through October, and similar to flows under H3 during February, March, November, and December. Based on these flow reductions, rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during the remaining eight months.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass rearing period would not exceed the 86°F water temperature threshold in H4 or H3. As a result, there would be no difference between H4 and H3 in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4-157).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in spawning and juvenile and adult Sacramento-San Joaquin roach rearing habitat. Flows in all rivers examined during the year under Alternative 4 are generally similar to or greater than flows under the NAA in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the largemouth bass population. The percentage of months outside temperature thresholds are generally similar to or lower under Alternative 4 than under the NAA.

CEQA Conclusion: In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach rearing period. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during January through July, October, and December, except in below normal years during March (10% lower), in wet years during May (17% lower), in critical years during July (9% lower), and in wet years during December (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during August, September, and November (to 26% lower). There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions throughout the year, except in below normal and critical years during January (16% and 8% lower, respectively), in below normal years during March (6% lower), in critical years during May (6% lower), in wet years during July (14% lower), in critical years during August through December (to 45% lower), and in most of the remaining water year types during October and November (to 25% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions in critical years during August through December would have a localized effect on rearing conditions in that water year type. Flow reductions in the other drier water year types are inconsistent and of small magnitude and would not have biologically meaningful negative effects.

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions throughout the year regardless of water year type except in critical years during August through October (6% to 28% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively small, isolated effect limited to a single water year type and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during March through June and October, with a few isolated exceptions (to 53% lower), and in wetter water year types during July, August, and September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be moderately to substantially lower than flows under Existing Conditions in drier water years during July through September (to 61% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). However, these would be offset by substantial increases in flow that would occur in drier water year types during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) and therefore are not expected to have biologically meaningful negative effects.

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions in wetter years during January, and most water years during February through April, with isolated exceptions of relatively small flow reductions (to 13% lower), but generally lower, by up to 48%, in drier years during January, most water years during May, wet and critical years during June, and in most water years during July through December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be small to substantial flow reductions in drier water year types, when effects would be most critical for habitat conditions, for some months/water year types during each month of the year, with the most consistent flow reductions in critical water years and the greatest magnitude of flow reductions occurring during June through December. These persistent flow reductions would affect rearing conditions at this location (to 42% lower in below normal, to 48% lower in dry and to 43% lower in critical water years).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach rearing period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Elevated water temperatures could lead to reduced quantity and quality of adult rearing habitat and increased stress and mortality of rearing adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F water temperature threshold for Sacramento-San Joaquin roach occurrence under Existing Conditions or H3 (Table 11-4-156). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between H3 and Existing Conditions.

H1/LOS

Flows under H1 in the Sacramento River upstream of Red Bluff during the year-round Sacramento-San Joaquin roach rearing period would generally be similar to flows under H3 except in wetter water years during September and December, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H1 in the Feather River at Thermalito Afterbay would be up to 29% greater than flows under H3 during January and December, up to 83% lower during September, and generally similar during the remainder of months. Flows under H1 in the American River at Nimbus Dam would be up to 8% greater than flows under H3 during December, up to 35% lower during September, and generally similar during the remainder of months. Flow reductions would not be frequent enough to have biologically meaningful effects on roach upstream rearing habitat.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass rearing period would not exceed the 86°F water temperature threshold in H1 or H3. As a result, there would be no difference between H1 and H3 in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4-157).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the year-round Sacramento-San Joaquin roach rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during January, April, and May, up to 39% lower during June through October, and similar to flows under H3 during February, March, November, and December. Based on these flow reductions, rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during the remaining eight months.

Water temperatures in the Feather River below Thermalito Afterbay during the year-round adult largemouth bass rearing period would not exceed the 86°F water temperature threshold in H4 or H3. As a result, there would be no difference between H4 and H3 in the percentage of months in which the 86°F water temperature threshold is exceeded (Table 11-4-157).

Collectively, these results indicate that the impact would not be significant because Alternative 4 would not cause a substantial reduction in Sacramento-San Joaquin roach habitat, and no mitigation is necessary. Flows would be substantially lower during the majority of the year-round adult rearing period in the American River, but based on the fact that this persistent effect occurs at only one location, it would not be expected to have biologically meaningful negative effects on the largemouth bass population. Flow reductions would occur throughout roughly half of the rearing period in the Feather River, but would be partially offset by substantial increases in flow during the preceding months. There would also be small to moderate flow reductions in the Trinity River in critical water years for roughly half the year that would have a localized effect juvenile and adult rearing in that water year type. Reduced flows in other rivers including the San Joaquin and Stanislaus rivers would not have biologically meaningful effects on largemouth bass. The percentages of months outside both temperature thresholds would generally be lower under Alternative 4 than under Existing Conditions.

Hardhead

In general, H4 would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the NAA.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under NAA throughout the year with some exceptions (up to 14% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to flows under NAA during the period with isolated exceptions (up to 11% lower), including small flow reductions in critical years during August through October (up to 12% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to flows under NAA throughout the year except in critical years during June (8% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*).

In the Feather River at Thermalito Afterbay, flows under H3 would generally be similar to or greater than flows under NAA during January through June with a few isolated exceptions, in drier water years during September, and during October through December with a few relatively isolated, small-magnitude reductions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would be more persistently lower under H3 relative to NAA (up to 50% lower) during July, August, and in wetter water years during September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years, when effects would be more critical for habitat conditions, range from moderate to substantial in drier water years during July, August, and below normal years during September. These would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under H3 would be similar to or greater than flows under NAA during January through July and December, with a few isolated, small-magnitude exceptions (up to 12% lower), and would be similar to or lower than flows under NAA (up to 40% lower) during August through November with a few exceptions (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flow reductions in drier water years when effects would be more critical for habitat conditions consist of small to moderate reductions for some months and water year types from July through November, which would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no differences in flows between H3 and NAA.

Water Temperature

The percentage of months outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead rearing was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers throughout the year.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside the range would be similar to or lower than the percentage under NAA in all water year except below normal years (5% higher) (Table 11-4-158).

Table 11-4-158. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 65°F to 82.4°F Water Temperature Range for Juvenile and Adult Hardhead Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. H3	NAA vs. H3
Wet	-2 (-3%)	2 (3%)
Above Normal	-9 (-12%)	-4 (-6%)
Below Normal	-5 (-7%)	5 (8%)
Dry	-7 (-10%)	0 (0%)
Critical	-7 (-10%)	-1 (-2%)
All	-5 (-7%)	1 (2%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

H1/LOS

Flows under H1 in the Sacramento River upstream of Red Bluff during the year-round hardhead rearing period would generally be similar to flows under H3 except in wetter water years during September and December, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H1 in the Feather River at Thermalito Afterbay would be up to 29% greater than flows under H3 during January and December, up to 83% lower during September, and generally similar during the remainder of months. Flows under H1 in the American River at Nimbus Dam would be up to 8% greater than flows under H3 during December, up to 35% lower during September, and generally similar during the remainder of months. Flow reductions would not be frequent enough to have biologically meaningful effects on hardhead upstream rearing habitat.

The percentage of months under H1 outside the 65°F to 82.4°F water temperature range in the Feather River below Thermalito Afterbay during the year-round hardhead rearing period would be similar to the percentage under H3 in all water year types (Table 11-4-159).

Table 11-4-159. Difference and Percent Difference between the H3 Model Scenario and H1 and H4 Model Scenarios in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 65°F to 82.4°F Water Temperature Range for Juvenile and Adult Hardhead Occurrence[a]

Water Year Type	H3 vs. H1	H3 vs. H4
Wet	-4 (-5%)	-4 (-5%)
Above Normal	2 (3%)	0 (0%)
Below Normal	-2 (-3%)	-1 (-2%)
Dry	0 (0%)	0 (0%)
Critical	0 (0%)	1 (2%)
All	-1 (-1%)	-1 (-1%)

[a] A negative value indicates a reduction in percentage of months outside suitable range for H1 or H4.

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the year-round juvenile and adult hardhead rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13% greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during January, April, and May, up to 39% lower during June through October, and similar to flows under H3 during February, March, November, and December. Based on these flow reductions, rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during the remaining eight months.

The percentage of months under H4 outside the 65°F to 82.4°F water temperature range in the Feather River below Thermalito Afterbay during the year-round hardhead rearing period would be similar to the percentage under H3 in all water year types (Table 11-4-159).

NEPA Effects: Collectively, these results indicate that the effect would not be adverse because Alternative 4 would not cause a substantial reduction in spawning and juvenile and adult hardhead rearing. Flows in all rivers examined during the year under Alternative 4 are generally similar to or greater than flows under the NAA in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on hardhead. The percentages of months outside all temperature thresholds are generally lower under Alternative 4 than under the NAA.

CEQA Conclusion: In general, Alternative 4 would not affect the quality and quantity of upstream habitat conditions for hardhead relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult rearing.

In the Sacramento River upstream of Red Bluff, flows under H3 would generally be similar to or greater than flows under Existing Conditions during January through July, October, and December, except in below normal years during March (10% lower), in wet years during May (17% lower), in critical years during July (9% lower), and in wet years during December (7% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows would generally be similar to or lower than flows under Existing Conditions during August, September, and November (to 26% lower). There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under H3 would generally be similar to or greater than flows under Existing Conditions throughout the year, except in below normal and critical years during January (16% and 8% lower, respectively), in below normal years during March (6% lower), in critical years during May (6% lower), in wet years during July (14% lower), in critical years during August through December (to 45% lower), and in most of the remaining water year types during October and November (to 25% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). The persistent, small to moderate flow reductions in critical years during August through December would have a localized effect on rearing conditions in that water year type. Flow reductions in the other drier water year types are inconsistent and of small magnitude and would not have biologically meaningful negative effects.

In Clear Creek at Whiskeytown Dam, flows under H3 would be similar to or greater than flows under Existing Conditions throughout the year regardless of water year type except in critical years during August through October (6% to 28% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). This flow reduction is a relatively small, isolated effect limited to a single water year type and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under H3 would be greater than flows under Existing Conditions during March through June and October, with a few isolated exceptions (to 53% lower), and in wetter water year types during July, August, and September (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Flows under H3 would generally be moderately to substantially lower than flows under Existing Conditions in drier water years during July through September (to 61% lower) (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). However, these would be offset by substantial increases in flow that would occur in drier water year types during April through June (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*) and therefore are not expected to have biologically meaningful negative effects.

In the American River at Nimbus Dam, flows under H3 would generally be similar to or greater than flows under Existing Conditions in wetter years during January, and most water years during February through April, with isolated exceptions of relatively small flow reductions (to 13% lower), but generally lower, by up to 48%, in drier years during January, most water years during May, wet and critical years during June, and in most water years during July through December (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). There would be small to substantial flow reductions in drier water year types, when effects would be most critical for habitat conditions, for some months/water year types during each month of the year, with the most consistent flow reductions in critical water years and the greatest magnitude of flow reductions occurring during June through December. These persistent flow reductions would affect rearing conditions at this location (to 42% lower in below normal, to 48% lower in dry and to 43% lower in critical water years).

Flow rates in the San Joaquin and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be small to moderate reductions in flows during the period relative to Existing Conditions.

Water Temperature

The percentage of months in which year-round in-stream temperatures would be outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead rearing was examined in the Sacramento, Trinity, Feather, American, and Stanislaus rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus rivers under H3 would be the same as those under Alternative 1A. The analysis for Alternative 1A indicates that there would be no temperature-related effects in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, the percentage of months under H3 outside of the 65°F to 82.4°F water temperature range for juvenile and adult hardhead occurrence would be similar to or lower than the percentage under Existing Conditions in all water years (Table 11-4-158).

H1/LOS

Flows under H1 in the Sacramento River upstream of Red Bluff during the year-round hardhead rearing period would generally be similar to flows under H3 except in wetter water years during September and December, in which flows would be up to 45% lower (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H1 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H1 in the Feather River at Thermalito Afterbay would be up to 29% greater than flows under H3 during January and December, up to 83% lower during September, and generally similar during the remainder of months. Flows under H1 in the American River at Nimbus Dam would be up to 8% greater than flows under H3 during December, up to 35% lower during September, and generally similar during the remainder of months. Flow reductions would not be frequent enough to have biologically meaningful effects on hardhead upstream rearing habitat.

The percentage of months under H1 outside the 65°F to 82.4°F water temperature range in the Feather River below Thermalito Afterbay during the year-round hardhead rearing period would be similar to the percentage under H3 in all water year types (Table 11-4-159).

H4/HOS

Flows under H4 in the Sacramento River upstream of Red Bluff during the year-round juvenile and adult hardhead rearing period would generally be similar to flows under H3 except during June, in which flows would be up to 12% lower, and during September, in which flows would be up to 13%

greater (Appendix 11C, *CALSIM II Model Results utilized in the Fish Analysis*). Year-round flows under H4 in the Trinity, San Joaquin, and Stanislaus rivers and in Clear Creek would be similar to flows under H3 with few exceptions. Flows under H4 in the Feather River at Thermalito Afterbay would generally be up to 330% greater than flows under H3 during January, April, and May, up to 39% lower during June through October, and similar to flows under H3 during February, March, November, and December. Based on these flow reductions, rearing habitat conditions would generally be less favorable under H4 relative to H3 in the Feather River. Flows under H4 in the American River below Nimbus Dam would generally be up to 32% greater than flows under H3 during August and September, up to 20% lower during June and October, and similar to flows under H3 during the remaining eight months.

The percentage of months under H4 outside the 65°F to 82.4°F water temperature range in the Feather River below Thermalito Afterbay during the year-round hardhead rearing period would be similar to the percentage under H3 in all water year types (Table 11-4-159).

Collectively, these results indicate that the impact is not significant because Alternative 4 would not cause a substantial reduction in hardhead habitat, and no mitigation is necessary. Flows would be substantially lower during the majority of the year-round adult rearing period in the American River, but based on the fact that this persistent effect occurs at only one location, it would not be expected to have biologically meaningful negative effects on the largemouth bass population. Flow reductions would occur throughout roughly half of the rearing period in the Feather River, but would be partially offset by substantial increases in flow during the preceding months. There would also be small to moderate flow reductions in the Trinity River in critical water years for roughly half the year that would have a localized effect juvenile and adult rearing in that water year type. Reduced flows in other rivers including the San Joaquin and Stanislaus rivers would not have biologically meaningful effects on hardhead. The percentages of months outside both temperature thresholds are generally lower under Alternative 4 than under Existing Conditions.

California Bay Shrimp

NEPA Effects: The effect of water operations on rearing habitat of California bay shrimp under Alternative 4 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203). For a detailed discussion, please see Alternative 1A, Impact AQUA-203. These effects would not be adverse.

CEQA Conclusion: As described above the impacts on California bay shrimp rearing habitat would be less than significant and no mitigation would be required.

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-204 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

NEPA Effects: Under Alternative 4 Scenario H3, average monthly flows in the Sacramento River downstream of the north Delta intake would be reduced 12–21% during the adult striped bass migration compared to baseline (NAA). Migration conditions for striped bass would be similar under all flow scenarios for Alternative 4. Sacramento River flows are highly variable inter-annually, but striped bass are still able to migrate upstream the Sacramento River during years of lower flows. The effect of reduced Sacramento flows under Alternative 4 would not be adverse.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because the changes in flow under Scenario H3 (21–27% lower compared to Existing Conditions) would not interfere substantially with movement of pre-spawning striped bass through the Delta. Conditions would also be similar under the other flow scenarios for Alternative 4. No mitigation would be required.

American Shad

NEPA Effects: Flows in the Sacramento River below the north Delta diversion facilities under Scenario H3 would be reduced relative to the NEPA point of comparison (NAA) during March–May. Monthly flows on average under Scenario H3 would be reduced 14–21% relative to baseline (NAA). Conditions would be similar between Scenarios H1 and H3, while flows downstream of the north Delta intakes would be decreased less under Scenarios H4 relative to Scenario H3. Flows from the San Joaquin River at Vernalis would be unchanged under Alternative 4 flow scenarios. Sacramento River flows are highly variable inter-annually, and American shad are still able to migrate upstream the Sacramento River during lower flow years. Overall, the impact to American shad migration habitat conditions would not be adverse under Alternative 4.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because the changes in flow under Scenario H3 (21–27% lower compared to Existing Conditions) would not interfere substantially with movement of American shad from the Delta to upstream spawning habitat. Flows would be less reduced under Scenario H4 because of reduced exports at the north Delta intakes compared to the other flow scenarios. No mitigation would be required.

Threadfin Shad

NEPA Effects: Threadfin shad are semi-anadromous, moving between freshwater and brackish water habitats. Threadfin shad found in the Delta do not actively migrate upstream to spawn. Therefore there is no effect on migration habitat conditions.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because flow changes in the Delta under Alternative 4 would not alter movement patterns for threadfin shad. No mitigation would be required.

Largemouth Bass

NEPA Effects: Largemouth bass are non-migratory fish within the Delta. Therefore they do not use the Delta as a migration habitat corridor. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes under Alternative 4 would not affect largemouth movements within the Delta. No mitigation would be required.

Sacramento Tule Perch

NEPA Effects: Similar with largemouth bass, Sacramento tule perch are a non-migratory species and do not use the Delta as a migration corridor as they are a resident Delta species. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes would not affect Sacramento tule perch movements within the Delta. No mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: For Sacramento-San Joaquin roach, the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 4, Impact AQUA-202 for spawning. As described there, the flows would slightly improve the upstream conditions relative to the NEPA point of comparison. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for Sacramento-San Joaquin roach would be less than significant and no mitigation would be required.

Hardhead

NEPA Effects: For hardhead the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 4, Impact AQUA-202 for spawning. As described there, the flows would slightly improve the upstream conditions relative to the NEPA point of comparison. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for hardhead would be less than significant and no mitigation would be required.

California Bay Shrimp

NEPA Effects: The effect of water operations on migration conditions of California bay shrimp under Alternative 4 would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-204). For a detailed discussion, please see Alternative 1A, Impact AQUA-204. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on California bay shrimp rearing habitat would be less than significant and no mitigation would be required.

Restoration Measures (CM2, CM4–CM7, and CM10)

The effects of restoration measures under Alternative 4would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-7 under delta smelt for a discussion of the effects of construction of restoration measures on non-covered species of primary management concern. The potential effects of the construction of restoration measures under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-7). For a detailed discussion, please see Alternative 1A, Impact AQUA-7. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of the construction of restoration measures would be less than significant and no mitigation would be required.

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-8 under delta smelt for a discussion of the effects of contaminants associated with restoration measures on non-covered species of primary management concern. The potential effects of the construction of contaminants associated with restoration measures under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-8). For a detailed discussion, please see Alternative 1A, Impact AQUA-8. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of the contaminants associated with restoration measures would be less than significant and no mitigation would be required.

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: Refer to Impact AQUA-9 under delta smelt for a general discussion of the effects of restored habitat conditions on non-covered species of primary management concern. Although there are minor differences the effects are similar. The potential effects of restored habitat conditions under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-8 and AQUA-9). For a detailed discussion, please see Alternative 1A, Impact AQUA-8. In addition, see Alternative 1A, Impact AQUA-207 for a discussion of the different effects on non-covered species of primary management concern. The effects range from slightly beneficial to beneficial.

CEQA Conclusion: As described immediately above, the impacts of restored habitat conditions would range from slightly beneficial to beneficial and no mitigation would be required.

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (CM12)

NEPA Effects: Refer to Impact AQUA-10 under delta smelt for a discussion of the effects of methylmercury management on non-covered species of primary management concern. The potential effects of methylmercury management under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-10). For a detailed discussion, please see Alternative 1A, Impact AQUA-10. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of methylmercury management would be less than significant and no mitigation would be required.

Impact AQUA-209: Effects of Invasive Aquatic Vegetation Management on Non-Covered Aquatic Species of Primary Management Concern (CM13)

NEPA Effects: Refer to Impact AQUA-11 under delta smelt for a discussion of the effects of invasive aquatic vegetation management on non-covered species of primary management concern. The potential effects of invasive aquatic vegetation management under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-11) except for predatory species (striped bass and largemouth bass) and Sacramento tule perch. Invasive aquatic vegetation provides hiding habitat for predatory fish which improves their hunting success. Sacramento tule perch also use the cover of aquatic plants in the Sacramento and San Joaquin rivers and in Suisun marsh. Consequently, reducing the amount of invasive aquatic habitat will negatively affect these predatory species and Sacramento tule perch. However, this control will not substantially reduce the ability of the predatory species to hunt and there will still be many other habitats in which the predatory species can successfully hunt and in which Sacramento tule perch will thrive. The effect on them will not be adverse.

CEQA Conclusion: Refer to Impact AQUA-11 under delta smelt for a discussion of the effects of invasive aquatic vegetation management on non-covered species of primary management concern. There are minor differences and the effects are similar except for predatory species (striped bass and largemouth bass) and Sacramento tule perch. Invasive aquatic vegetation provides hiding habitat for predatory fish which improves their hunting success. Sacramento tule perch use the cover of aquatic plants in the Sacramento and San Joaquin rivers and in Suisun marsh. Consequently, reducing the amount of invasive aquatic habitat will negatively affect the predatory species and Sacramento tule perch. However, this control will not substantially reduce the ability of the predatory species to hunt and there will still be many other habitats in which the predatory species can successfully hunt and in which Sacramento tule perch will thrive. Therefore the effect on them will not be significant and no mitigation would be required.

Other Conservation Measures (CM12–CM19 and CM21)

The effects of other conservation measure under Alternative 4would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-210: Effects of Dissolved Oxygen Level Management on Non-Covered Aquatic Species of Primary Management Concern (CM14)

NEPA Effects: Refer to Impact AQUA-12 under delta smelt for a discussion of the effects of dissolved oxygen management on non-covered species of primary management concern. The potential effects of dissolved oxygen management under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-12). For a detailed discussion, please see Alternative 1A, Impact AQUA-12. These effects would be beneficial.

CEQA Conclusion: As described immediately above, the impacts of oxygen level management would be beneficial and no mitigation would be required.

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (CM15)

NEPA Effects: Refer to Alternative 1A, Impact AQUA-13 under delta smelt for a discussion of the effects of predatory fish (striped bass and largemouth bass) and predator management on non-predatory fish. The purpose of predatory fish management is to reduce the numbers of predatory fish and to reduce their hunting success. This management will have negative effects on predatory fish. However, the numbers of predatory fish are high and the extent of the habitats in which they hunt is extensive. Therefore the effects of this management will not be adverse.

CEQA Conclusion: Refer to Alternative 1A, Impact AQUA-13 under delta smelt for a discussion of the effects of predatory fish and predator management on non-predatory fish. The purpose of predatory fish management is to reduce the numbers of predatory fish and to reduce their hunting success. This management will have negative effects on predatory fish. However, the numbers of predatory fish are high and the extent of the habitats in which they hunt is extensive. Therefore the effects of this management will not be significant. No mitigation is required.

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (CM16)

NEPA Effects: Refer to Impact AQUA-14 under delta smelt for a discussion of the effects of nonphysical fish barriers on non-covered species of primary management concern. The potential effects of nonphysical fish barriers under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-14). For a detailed discussion, please see Alternative 1A, Impact AQUA-14. The effects would be similar except for Sacramento-San Joaquin roach and hardhead which are unlikely to be present in their vicinity. California bay shrimp do not occur in these habitats and there would be no effect on them. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of nonphysical fish barriers would be less than significant and no mitigation would be required.

Impact AQUA-213: Effects of Illegal Harvest Reduction on Non-Covered Aquatic Species of Primary Management Concern (CM17)

NEPA Effects: Refer to Impact AQUA-15 under delta smelt for a discussion of the effects of illegal harvest reduction on non-covered species of primary management concern. The potential effects of illegal harvest reduction under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-15). For a detailed discussion, please see Alternative 1A, Impact AQUA-15. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of illegal harvest reduction would be less than significant and no mitigation would be required.

Impact AQUA-214: Effects of Conservation Hatcheries on Non-Covered Aquatic Species of Primary Management Concern (CM18)

NEPA Effects: Refer to Impact AQUA-16 under delta smelt for a discussion of the effects of conservation hatcheries on non-covered species of primary management concern. The potential effects of conservation hatcheries under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-16). For a detailed discussion, please see Alternative 1A, Impact AQUA-16. There would be no effect.

CEQA Conclusion: As described immediately above, conservation hatcheries would have no impact and no mitigation would be required.

Impact AQUA-215: Effects of Urban Stormwater Treatment on Non-Covered Aquatic Species of Primary Management Concern (CM19)

NEPA Effects: Refer to Impact AQUA-17 under delta smelt for a discussion of the effects of stormwater treatment on non-covered species of primary management concern. The potential effects of stormwater treatment under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-17). For a detailed discussion, please see Alternative 1A, Impact AQUA-17. The effects would be beneficial.

CEQA Conclusion: As described immediately above, the impacts of stormwater management would be beneficial and no mitigation would be required.

Impact AQUA-216: Effects of Removal/Relocation of Nonproject Diversions on Non-Covered Aquatic Species of Primary Management Concern (CM21)

NEPA Effects: Refer to Impact AQUA-18 under delta smelt for a discussion of the effects of removal/relocation of nonproject diversions on non-covered species of primary management concern. The potential effects of removal/relocation of nonproject diversions under Alternative 4 would be similar to those described for Alternative 1A (see Alternative 1A, Impact AQUA-18). For a detailed discussion, please see Alternative 1A, Impact AQUA-18. The effects would be similar except for Sacramento-San Joaquin roach, hardhead and Sacramento tule perch which are unlikely to be present near these diversions. The effects would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of removal/relocation of nonproject diversions would be less than significant and no mitigation would be required.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: Similar to the description for Alternative 1A, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 4 would not be substantially reduced when compared to the No Action Alternative.

CEQA Conclusion: Similar to the description for Alternative 1A, Alternative 4 would reduce the quantity of coldwater fish habitat in the CVP and SWP as shown in Table 11-1A-102. There would be a greater than 5% increase (5 years) for several of the reservoirs, which could result in a significant impact. These results are primarily caused by four factors: differences in sea level rise, differences in climate change, future water demands, and implementation of the alternative. The analysis described above comparing Existing Conditions to Alternative 4 does not partition the effect of implementation of the alternative from those of sea level rise, climate change and future water demands using the model simulation results presented in this chapter. However, the increment of change attributable to the alternative is well informed by the results from the NEPA analysis, which found this effect to be not adverse. As a result, the CEQA conclusion regarding Alternative 4, if adjusted to exclude sea level rise and climate change, is similar to the NEPA conclusion, and therefore would not in itself result in a significant impact on coldwater habitat in upstream reservoirs. This impact is found to be less than significant and no mitigation is required.
