As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, *AMM18 Swainson's Hawk and White-Tailed Kite*, and Mitigation Measure BIO-75, impacts on cormorants, herons, and egrets would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-45. Changes in Cormorant, Heron and Egret Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5
CM1	Nesting (Rookeries)	61	61	248	248	NA	NA
Total Impacts CM1		**61**	**61**	**248**	**248**	NA	NA
CM2–CM18	Nesting (Rookeries)	387	684	88	123	51–92	266
Total Impacts CM2–CM18		**387**	**684**	**88**	**123**	**51–92**	**266**
TOTAL IMPACTS		**448**	**745**	**336**	**371**	**51–92**	**266**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-117: Loss or Conversion of Nesting Habitat for and Direct Mortality of Cormorants, Herons and Egrets

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 1,116 acres of modeled habitat (745 acres of permanent loss, 371 acres of temporary loss) for double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron (Table 12-9-45). Conservation measures that would result in these losses are *CM1 Water Facilities and Operation* (which would involve conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas), *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate cormorant, heron, and egret modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Conveyance Facilities and Operation:* Construction of Alternative 9 water conveyance facilities would result in the combined permanent and temporary loss of up to 309 acres of modeled Cormorant, heron, and egret habitat (Table 12-9-45). Of the 309 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 61 acres would be a permanent loss and 248 acres would be a temporary loss of habitat. Permanent losses would primarily consist of channel enlargement at the Sacramento River and Meadows Slough. Temporary losses would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. The riparian habitat in these areas is composed of very small patches or stringers bordering waterways, which are composed of valley oak and scrub vegetation. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

The primary impact of concern regarding double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron is the loss of existing known nest trees, and other large trees associated with known nest sites. The CM1 footprint overlaps with one great blue heron rookery on an instream island northeast of Woodward Island. This rookery occurrence was recorded in 2000 by the CNDDB and was recorded again during DHCCP surveys in 2009. The CM1 footprint includes dredging of Middle River and inchannel island dredging that would remove the island on which the rookery is located. In addition, the rookery could be indirectly affected by the barge facility work area and dredging work area to the west on Woodward Island. Because the species is highly traditional in their use of rookeries, the establishment of new nest sites is unpredictable. Therefore to avoid adverse effects on great blue herons (and cormorants, herons, and egrets, should future surveys detect additional rookeries), this rookery would have to be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries,* would be available to address this adverse effect on great blue herons. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 177 acres of nesting habitat (89 acres of permanent loss, 88 acres of temporary loss) in the Yolo Bypass in CZ 2. Activities through CM2 could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Most of the riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. Excavation to improve water movement in the Toe Drain and in the Sacramento Weir would also remove potential nesting habitat. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated552 acres of nesting habitat for cormorants, herons and egrets. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated. Depending on the extent and value of remaining habitat, this could reduce use of these habitats by these species. There is one CNDDB occurrence of a great blue heron rookery that overlaps with the hypothetical restoration footprint for tidal restoration. The occurrence is on Decker Island and tidal restoration could potentially impact the nest trees from inundation. This potential effect would need to be addressed within the project-specific analysis for tidal restoration projects.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently remove approximately 43 acres and temporarily remove approximately 35 acres of potential cormorants, heron, and egret nesting habitat. These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb cormorant, heron, and egret nests if they were present near work sites. A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of cormorant, heron, and egret habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available habitat for these species and are expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- Permanent and temporary habitat losses from the above conservation measures would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities. Although the effects are considered temporary, the restored riparian habitat would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure for established rookeries. *AMM18 Swainson's Hawk and White-Tailed Kite* contains actions described below to reduce the effect of temporal loss of mature riparian habitat, including the transplanting of mature trees.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect use of the surrounding habitat by cormorants, herons or egrets. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- The primary impact of concern regarding double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron is the loss of existing known nest trees, and other large trees associated with known nest sites. Because these species are highly traditional in their use of rookeries, the establishment of new nest sites is unpredictable. To avoid adverse effects on these species, existing known nest sites would have to be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these potential effects on cormorants, herons, and egrets.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If birds were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects on cormorants, herons, and egrets.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 784 acres of nesting habitat for cormorants, herons, and egrets in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 309 acres of nesting habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancemen*t, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—475 acres of nesting habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for breeding habitat. Using these ratios would indicate that 309 acres of breeding habitat should be restored/created and 309 acres should be protected to compensate for the CM1 losses of modeled cormorant, heron, and egret habitat. In addition, the near-term effects of other conservation actions would remove 475 acres of modeled breeding habitat, and therefore require 475 acres of restoration and 475 acres of protection of modeled cormorant, heron, and egret habitat using the same typical NEPA and CEQA ratios.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for these species. In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on cormorant, heron, and egret nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of potential nesting habitat, but would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for established rookeries. This time lag between the removal and restoration of nesting habitat could have a substantial impact on cormorants, herons and egrets in the near-term time period.

AMM18 Swainson's Hawk and White-Tailed Kite would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller anticipated to be removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout protected lands.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. For the BDCP to avoid adverse effects on individuals, existing nests and rookeries would have to be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting cormorants, herons, and egrets.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 17,966 acres of modeled nesting habitat for cormorants, herons, and egrets. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,116 acres of potential breeding habitat (6% of the potential breeding habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration,* and *CM7 Riparian Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3, *Description of Alternatives*). The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit cormorants, herons, and egrets by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences(Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. These species are highly traditional in their use of nest sites, and, in order for the BDCP to avoid a significant impact on individuals, preconstruction surveys would be required to ensure that nests are detected and any direct and indirect impacts on rookeries are avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and*

Avoid Disturbance of Nesting Birds and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would be available to address adverse effects on nesting cormorants, herons, and egrets.

NEPA Effects: The loss of cormorant, heron, and egret habitat and potential direct mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM5, CM7, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7 and AMM18 Swainson's Hawk and White-Tailed Kite, which would be in place throughout the construction period, the effects of habitat loss and potential mortality on cormorants, herons, and egrets under Alternative 9 would not be adverse. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. Preconstruction surveys for noncovered species would be required for the BDCP to avoid an adverse effect on individuals. Mitigation Measure BIO-75 and Mitigation Measure BIO-117 would be available to address effects on nesting cormorants, herons, and egrets.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under NEPA. Alternative 9 would remove 784 acres of nesting habitat for cormorants, herons, and egrets in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 309 acres of nesting habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancemen*t, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—475 acres of nesting habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for breeding habitat. Using these ratios would indicate that 309 acres of breeding habitat should be restored/created and 309 acres should be protected to compensate for the CM1 losses of modeled cormorant, heron, and egret habitat. In addition, the near-term effects of other conservation actions would remove 475 acres of modeled breeding habitat, and therefore require 475 acres of restoration and 475 acres of protection of modeled cormorant, heron, and egret habitat using the same typical NEPA and CEQA ratios.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for these species. In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on cormorant, heron, and egret nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of potential nesting habitat, but would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for established rookeries. This time lag between the removal and restoration of nesting habitat could have a substantial impact on cormorants, herons and egrets in the near-term time period.

AMM18 Swainson's Hawk and White-Tailed Kite would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller anticipated to be removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout protected lands.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. For the BDCP to avoid a significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries,* would reduce this potential impact to a less-than-significant level.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 17,966 acres of modeled nesting habitat for cormorants, herons, and egrets. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 1,116 acres of potential breeding habitat (5% of the potential breeding habitat in the study area).

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration,* and *CM7 Riparian Natural Community Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3, *Description of Alternatives*). The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit cormorants, herons, and egrets by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. These species are highly traditional in their use of nest sites and, for the BDCP to avoid a significant impact on individuals, preconstruction surveys would be required to ensure that nests are detected and any direct and indirect impacts on rookeries are avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would reduce this potential impact to a less-than-significant level.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts sufficient to compensate for the loss of riparian habitats lost to construction and restoration activities, and considering implementation of AMM1–AMM7, Mitigation Measure BIO-75, and Mitigation Measure BIO-117, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of cormorants, herons, and egrets. Therefore, the loss of habitat and potential mortality under this alternative would have a less-than-significant impact on cormorants, herons, and egrets.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries): therefore, DWR will avoid all direct and indirect impacts on rookeries.

Impact BIO-118: Effects Associated with Electrical Transmission Facilities on Cormorants, Herons and Egrets

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons and egrets. *AMM20 Greater Sandhill Crane* would minimize the risk for bird-power line strikes, for these species. This measure would ensure that conductor and ground lines are fitted with flight diverters in compliance with the best available practices, such as those specified in the USFWS Avian Protection Guidelines and would minimize the potential for an adverse effect.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. *AMM20 Greater Sandhill Crane* would reduce the potential for collisions on new and select existing powerlines in the study area.

The construction of new transmission lines would not result in an adverse effect on cormorants, herons, and egrets.

***CEQA Conclusion*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. *AMM20 Greater Sandhill Crane* would reduce birdstrike on new transmission lines and select existing transmission lines with the installation of flight diverters. With these in place, new transmission lines would have a less-than-significant impact on cormorants, herons and egrets.

Impact BIO-119: Indirect Effects of Plan Implementation on Cormorants, Herons and Egrets

Indirect construction- and operation-related effects: Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect cormorants, herons, or egrets. If cormorants, herons or egrets were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting cormorants, herons or egrets. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect cormorants, herons or egrets in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including cormorants, herons or egrets. Future operational impacts under CM1 were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability resulting from proposed flows. Subsequently, a regression model was used to estimate fish-tissue concentrations under these future operational conditions (evaluated starting operations or ESO). Results indicated that changes in total mercury levels in water and fish tissues due to ESO were insignificant (see BDCP Appendix 5.D, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly effect on cormorants, herons or egrets, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury*

Management contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on cormorants, herons or egrets.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including cormorants, herons, and egrets. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on cormorants, herons, and egrets.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on cormorants, herons, and egrets from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce cormorant, heron, and egret use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect cormorant, heron, and egret use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. Tidal habitat restoration could result in increased exposure of cormorants, herons, and egrets to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of cormorants, herons or egrets to methylmercury through the ingestion of fish in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12, would address the uncertainty of methylmercury levels in restored tidal marsh in the study area and better inform potential impacts on cormorants, herons, and egrets. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for cormorants, herons, and egrets once site specific sampling and other information could be developed.

***CEQA Conclusion*:** Impacts of noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would be less than significant with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, and AMM1–AMM7. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of cormorants, herons or egrets to methylmercury, through the ingestion of fish in tidally restored areas. However, it is unknown what concentrations of methylmercury are harmful to these species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would address the potential impacts of methylmercury levels in restored tidal marsh in the study area on cormorants, herons, and egrets. Tidal habitat restoration could result in increased exposure of cormorants, herons, and egrets to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 9 implementation would not have an adverse effect on cormorants, herons, and egrets.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries); therefore, DWR will avoid all direct and indirect impacts on rookeries.

Impact BIO-120: Periodic Effects of Inundation on Cormorants, Herons and Egrets as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and duration of inundation of approximately 51–92 acres of modeled breeding habitat for cormorants, herons and egrets. However, increased periodic flooding is not expected to cause any adverse effect on breeding habitat because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic inundation of up to 266 acres of breeding habitat for cormorants, herons and egrets. The overall effect of seasonal inundation in existing riparian natural communities is likely to be beneficial for these species, because, historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants.

NEPA Effects: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration of periodic inundation from CM2 and CM5 would not result in an adverse effect on cormorants, herons and egrets.

CEQA Conclusion: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration of periodic inundation from CM2 and CM5 would have a less-than-significant impact on cormorants, herons and egrets.

Short-Eared Owl and Northern Harrier

Modeled habitat for short-eared owl and northern harrier consists of tidal brackish and freshwater emergent wetland, nontidal freshwater perennial emergent wetland, other natural seasonal wetland, grassland, and selected cultivated lands.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for short-eared owl and northern harrier as indicated in Table 12-9-46. Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP that would benefit short-eared owl and northern harrier (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11 including at least 1,500 acres of middle and high marsh (Objectives TBEWNC1.1 and TBEWNC1.2, associated with CM4).

- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.2, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4,VPNC2.5, and GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species and implementation of AMM1–AMM7, *AMM27 Selenium Management* and Mitigation Measure BIO-75, impacts on short-eared owl and northern harrier would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-46. Changes in Short-Eared Owl and Northern Harrier Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5
CM1	Nesting and Foraging	419	419	1,468	1,468	NA	NA
Total Impacts CM1		**419**	**419**	**1,468**	**1,468**	**NA**	**NA**
CM2–CM18	Nesting and Foraging	12,281	46,700	471	1,224	2,926–8,060	5,978
Total Impacts CM2–CM18		**12,281**	**46,700**	**471**	**1,224**	**2,926–8,060**	**5,978**
TOTAL IMPACTS		**12,700**	**47,119**	**1,939**	**2,692**	**2,926–8,060**	**5,978**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-121: Loss or Conversion of Habitat for and Direct Mortality of Short-Eared Owl and Northern Harrier

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 34,689 acres of modeled habitat for short-eared owl and northern harrier (of which 32,369 acres would be a permanent loss and 2,320 acres would be a temporary loss of habitat, Table 12-9-46). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), grassland restoration (CM8), vernal pool and wetland restoration (CM9), marsh restoration (CM10) and construction of conservation hatcheries (CM18). The majority of habitat loss would result from CM4. Habitat enhancement and management activities (CM11), which would include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate short-eared owl and northern harrier modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,887 acres of modeled short-eared owl and northern harrier habitat (419 acres of permanent loss, 1,468 acres of temporary loss) from CZs 4, 5, 6, 7, and 8. The majority of habitat removed would be grassland and cultivated lands. However, fringes of tidal freshwater emergent wetland along channels and island edges would also be impacted from construction activities. There are no occurrences of nesting short-eared owl and northern harrier that overlap with the construction footprint of CM1. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on short-eared owls and northern harriers if they were to nest in or adjacent to construction activities. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would permanently remove 1,021 acres of modeled short-eared owl and northern harrier habitat in the Yolo Bypass in CZ 2. In addition, 471 acres of habitat would be temporarily removed. The impact would primarily consist of loss of acreages of pastures. The conversion is expected to occur during the first 10 years of Alternative 1C implementation.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 39,017 acres of modeled short-eared owl and northern harrier habitat. The majority of the losses would be managed wetlands and cultivated lands in CZs 1, 2, 4, 5, 6, 7, 8, 10, and 11. Tidal restoration actions through CM4 would restore an estimated 55,000 acres of tidal natural communities. These restored wetland areas could provide suitable nesting habitat for short-eared owl and northern harrier. Consequently, although existing nesting habitat for short-eared owl and northern harrier would be removed, restoration of wetland habitats is expected to benefit marsh associated ground nesting birds by increasing the extent and value of their nesting habitat. Grizzley Island supports the only known resident population of short-eared owls in the Suisun Marsh and Sacramento-San Joaquin River

Delta (Roberson 2008). Grizzley Island does not overlap with the hypothetical footprint for CM4. However, this is an important breeding area for short-eared owl and if restoration footprints were changed during the implementation process of BDCP to overlap with this area, the effects on breeding short-eared owls could likely be adverse. Future NEPA and CEQA analysis would be conducted for restoration projects under BDCP and if restoration was proposed to occur outside of the hypothetical footprints used for this programmatic analysis, potential impacts on these species would be captured in the project-level analysis (Appendix 3B, Section 3.2.5).

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 2,086 acres of modeled short-eared owl and northern harrier habitat (1,332 permanent, 754 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7.
- *CM7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 623 acres of short-eared owl and northern harrier habitat as part of tidal restoration and 2,479 acres of habitat as part of seasonal floodplain restoration.
- *CM8 Grassland Natural Community Restoration*: Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 1,066 acres of cultivated lands to grassland in CZs 1, 2, 4, 5, 7, 8, and 11. The resulting 2,000 acres of grassland would provide habitat for short-eared owl and northern harrier.
- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP.

  Habitat management- and enhancement-related activities could short-eared owl and northern harrier nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to minimize these effects.
- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of short-eared owl and northern harrier habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1. The loss is expected to occur during the first 10 years of Alternative 9 implementation.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect short-eared owl and northern harrier use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged short-eared owl and northern harrier if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to minimize these effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 14,639 acres of modeled habitat (12,700 permanent, 1,939 temporary) for short-eared owl and northern harrier in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,887 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7, Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM18 Conservation Hatcheries*—12,752 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these typical ratios would indicate that 1,887 acres of habitat should be restored and 1,887 acres should be protected to compensate for the CM1 losses of short-eared owl and northern harrier habitat. The near-term effects of other conservation actions would remove 12,752 acres of modeled habitat, and therefore require 12,752 acres of restoration and 12,752 acres of protection of short-eared owl and northern harrier habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, and CM8 and would occur in the same timeframe as the construction and early restoration losses. The acres of protection and restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and the effects from other near-term restoration actions.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would

provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which currently supports a high concentration of nesting short-eared owls on Grizzley Island.

The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). A minimum of 87% of cultivated lands protected by the late long-term time period would be in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2). This biological objective provides an estimate for the proportion of cultivated lands protected in the near-term time period which would provide suitable nesting and foraging habitat for short-eared owl and northern harrier. These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

The short-eared owl and the northern harrier are not covered species under the BDCP. For the BDCP to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 406,784 acres of modeled nesting and foraging habitat for short-eared owl and northern harrier. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 49,811 acres of modeled short-eared owl and northern harrier habitat during the term of the Plan (12% of the modeled habitat in the study area).

The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration*, and *CM8 Grassland Natural Community Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzley Island. At least 1,500 acres of the managed wetlands would be protected and enhanced on Grizzley Island by the late long-term time period. The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. A minimum of 87% of the 48,625 acres of cultivated lands protected by the late long-term time period (Objective CLNC1.1) would be managed in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2) which are compatible crop types for these species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Short-eared owl and northern harrier are not species that are covered under the BDCP. In order for the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

NEPA Effects: The loss of short-eared owl and northern harrier habitat and potential direct mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM8, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of short-eared owl and northern harrier habitat loss resulting from Alternative 9 would not be adverse. Short-eared owl and northern harrier are not covered species under the BDCP, and preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address the adverse effect of direct mortality on short-eared owl and northern harrier.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 14,639 acres of modeled habitat (12,700 permanent, 1,939 temporary) for short-eared owl and northern harrier in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,887 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7, Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM18 Conservation Hatcheries*—12,752 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these typical ratios would indicate that 1,887 acres of habitat should be restored and 1,887 acres should be protected to compensate for the CM1 losses of short-eared owl and northern harrier habitat. The near-term effects of other conservation actions would remove 12,752 acres of modeled habitat, and therefore require 12,752 acres of restoration and 12,752 acres of protection of short-eared owl and northern harrier habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, and CM8 and would occur in the same timeframe as the construction and early restoration losses. The acres of protection and restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM and the effects from other near-term restoration actions.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzley Island.

The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). A minimum of 87% of cultivated lands protected by the late long-term time period would be in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2). This biological objective provides an estimate for the proportion of cultivated lands protected in the near-term time period which would provide suitable nesting and foraging habitat for short-eared owl and northern harrier. These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

The short-eared owl and the northern harrier are not covered species under the BDCP. For the BDCP to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. The implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this potential impact to a less-than–significant level.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 406,784 acres of modeled nesting and foraging habitat for short-eared owl and northern harrier. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 49,811 acres of modeled short-eared owl and northern harrier habitat during the term of the Plan (12% of the modeled habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, and CM8 Grassland Natural Community Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzley Island. At least 1,500 acres of the managed wetlands would be protected and enhanced on Grizzley Island by the late long-term time period. The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. A minimum of 87% of the 48,625 acres of cultivated lands protected by the late long-term time period (Objective CLNC1.1) would be managed in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2) which are compatible crop types for these species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Short-eared owl and northern harrier are not species that are covered under the BDCP. In order for the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be reduce the impact to a less-than-significant level.

Considering these protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, and Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of short-eared owl and northern harrier. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on short-eared owl and northern harrier.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-122: Effects on Short-Eared Owl and Northern Harrier Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that short-eared owl and northern harrier could be subject to power line strikes, which could result in injury or mortality of these species. Short-eared owl and northern harrier would be at low risk of bird strike mortality based on factors assessed in the bird strike vulnerability analysis (BDCP Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Factors analyzed include the height of the new transmission lines and the flight behavior of species. The existing network of transmission lines in the Plan Area currently poses the same small risk for these species, and any incremental risk associated with the new power line corridors would also be expected to be low. *AMM20 Greater Sandhill Crane* would further reduce any potential effects.

NEPA Effects: New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. With the implementation of *AMM20 Greater Sandhill Crane*, the potential effect of the construction of new transmission lines on short-eared owl and northern harrier would not be adverse.

CEQA Conclusion: New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. *AMM20 Greater Sandhill Crane* would reduce the potential impact of the construction of new transmission lines on short-eared owl and northern harrier to a less-than-significant level.

Impact BIO-123: Indirect Effects of Plan Implementation on Short-Eared Owl and Northern Harrier

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect short-eared owl and northern harrier use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect short-eared owl or northern harrier. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to short-eared owl and northern harrier could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect short-eared owl and northern harrier, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on short-eared owl and northern harrier.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on short-eared owl and northern harrier.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on short-eared owl and northern harrier from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances from the construction of water conveyance facilities could reduce short-eared owl and northern harrier use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect short-eared owl and northern harrier use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Tidal habitat restoration is unlikely to have an adverse effect on short-eared owl and northern harrier through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in CM12 *Methylmercury Management,* would address the uncertainty of methylmercury levels in restored tidal marsh. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for California least tern, once site specific sampling and other information could be developed.

CEQA Conclusion**:** Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would have a less-than-significant impact on short-eared owl and northern harrier with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. Tidal habitat restoration is unlikely to have a significant impact on short-eared owl and northern harrier through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to these species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 9 implementation would not have a significant impact on short-eared owl and northern harrier.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-124: Periodic Effects of Inundation on Short-Eared Owl and Northern Harrier as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 2,926–8,060 acres of modeled short-eared owl and northern harrier habitat (Table 12-9-46).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 5,978 acres of modeled habitat (Table 12-9-46), the majority of which would be pasture and other cultivated lands.

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, inundation would occur during the nonbreeding season and would not be expected to have an adverse effect on either species.

NEPA Effects: Periodic inundation of floodplains would not result in an adverse effect on short-eared owl and northern harrier because inundation is expected to occur prior to the breeding season.

CEQA Conclusion: Periodic inundation of floodplains would not have a significant impact on short-eared owl and northern harrier because inundation is expected to occur prior to the breeding season.

Redhead and Tule Greater White-Fronted Goose

Impacts, relevant protection and restoration actions, and mitigation requirements under CEQA are discussed for these species in the *General Terrestrial Biology Effects* section under Impacts BIO-178 through BIO-183. Further details of the methods of analysis for waterfowl and shorebirds can be found in the *BDCP Waterfowl and Shorebird Effects Analysis* (Ducks Unlimited 2013).

Mountain Plover

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on mountain plover. Modeled habitat for mountain plover consists of grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for mountain plover as indicated in Table 12-9-47. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit the mountain plover (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4,VPNC2.5, GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Within the 48,625 acres of protected cultivated lands, protect at least 42,275 acres of cultivated lands as Swainson's hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species, impacts on mountain plover would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-47. Changes in Mountain Plover Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Wintering	318	318	1,281	1,281	NA	NA
Total Impacts CM1		**318**	**318**	**1,281**	**1,281**	**NA**	**NA**
CM2–CM18	Wintering	5,450	26,198	376	893	1,158-3,650	3,823
Total Impacts CM2–CM18		**5,450**	**26,198**	**376**	**893**	**1,158-3,650**	**3,823**
TOTAL IMPACTS		**5,768**	**26,516**	**1,657**	**2,174**	**1,158-3,650**	**3,823**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-125: Loss or Conversion of Habitat for and Direct Mortality of Mountain Plover

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 28,690 acres of modeled habitat for mountain plover (25,516 acres of permanent loss and 2,174 of temporary loss, Table 12-9-47). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss (20,880 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate mountain plover modeled wintering habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,559 acres of modeled mountain plover habitat (318 acres of permanent loss, 1,281 acres of temporary loss) from CZ 4, 5, 6, and 8. These losses would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. Other impacts would occur from potential borrow and spoil sites, access roads, barge unloading facilities, and intake and fish screen construction areas. There are no CNDDB occurrences of mountain plover that intersect with the CM1 footprint. However, the study area does overlap with the species' winter range, and there are occurrences west and north of the study area. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of modeled mountain plover wintering habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. Impacted habitat would consist primarily of grassland and pasture. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels. Realignment of Putah Creek could also involve excavation and grading in alkali seasonal wetland complex habitat as a new channel is constructed. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of modeled mountain plover habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.

- *CM5 Seasonally Inundated Floodplain Restoration:* Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of modeled mountain plover habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 370 acres of mountain plover wintering habitat as part of tidal restoration and 1,489 acres of habitat as part of seasonal floodplain restoration.

- *CM8 Grassland Natural Community Restoration* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide wintering habitat for mountain plover and would result in the conversion of 837 acres of cultivated lands to grassland.

- *CM10 Nontidal Marsh Restoration*: Implementation of CM10 would result in the permanent removal of 705 acres of mountain plover habitat.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of mountain plover habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available mountain plover habitat. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

- *CM18 Conservation Hatcheries:* Implementation of CM18 would remove up to 35 acres of modeled mountain plover habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect mountain plover use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7and conservation actions as described below.
- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of mountain plover because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled mountain plover wintering habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of mountain plover wintering habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of mountain plover habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding adverse effects of habitat loss on mountain plover wintering in the study area. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand mountain plover wintering habitat and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which are also modeled habitat for wintering mountain plover. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would be suitable for mountain plover.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on mountain plover, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. Mitigation Measure BIO-125, *Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat*, would be available to address the adverse effect of habitat loss in the near-term.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 269,411 acres of potential habitat for mountain plover. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of modeled mountain plover wintering habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for mountain plover and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which would also provide potential wintering habitat for mountain plover. The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

NEPA Effects: The loss of mountain plover habitat and potential mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, and with implementation of Mitigation Measure BIO-125, *Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat,* the effects of habitat loss and potential for direct mortality on mountain plover under Alternative 9 would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled mountain plover wintering habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of mountain plover wintering habitat.

The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of mountain plover habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding significant impacts of habitat loss on mountain plover. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand wintering habitat for mountain plover and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which would also provide potential habitat for mountain plover wintering in the study area. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would provide habitat for mountain plover.

These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on mountain plover, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. The implementation of Mitigation Measure BIO-125, *Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat*, would reduce the impact of habitat loss in the near-term to a less-than-significant level.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of mountain plover habitat during the term of the Plan (11% of the total habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities*

Protection and Restoration, CM8 Grassland Natural Community Restoration, and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand wintering habitat for mountain plover and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential habitat for mountain plover (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which would also provide habitat for mountain plover.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-125, *Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of mountain plover. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on mountain plover.

Mitigation Measure BIO-125: Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat

DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa to provide habitat for mountain plover such that the total acres of high-value habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1. Additional grassland protection, enhancement, and management may be substituted for the protection of high-value cultivated lands.

Impact BIO-126: Effects on Mountain Plover Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of mountain plover. Mountain plovers congregate in flocks during the winter and travel between grasslands and cultivated lands that provide foraging habitat for the species. This flocking behavior puts them at risk of collisions with powerlines. Existing transmission lines in the study area currently pose this risk. Plovers are primarily visual foragers and therefore, the risk for collision would be reduced by *AMM20 Greater Sandhill Crane*, which would require the installation of bird flight diverters on new and selected existing transmission lines in the study area.

NEPA Effects: New transmission lines are not expected to have an adverse effect on mountain plover because mortality from powerline strikes would be minimized with the implementation of *AMM20 Greater Sandhill Crane* which would require the installation of bird flight diverters on new and selected existing transmission lines in the study area. The risk for bird-power line strikes is, therefore, not expected to have an adverse effect on mountain plover.

CEQA Conclusion: New transmission lines would have a less-than-significant impact on mountain plover because mortality from powerline strikes would be minimized with the implementation of *AMM20 Greater Sandhill Crane* which would require the installation of bird flight diverters on new and selected existing transmission lines in the study area.

Impact BIO-127: Indirect Effects of Operations and Maintenance of Water Conveyance Facilities on Mountain Plover

Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for mountain plover. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect mountain plover. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to mountain plover grassland habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on mountain plover as a result of Alternative 9 implementation could have adverse effects on the species through the modification of habitat. With the With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 9 implementation would not have an adverse effect mountain plover.

CEQA Conclusion: Indirect effects on mountain plover as a result of Alternative 9 implementation could have a significant impact on the species from modification of habitat. With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 9 implementation would have a less-than-significant impact on mountain plover.

Impact BIO-128: Periodic Effects of Inundation on Mountain Plover as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled mountain plover wintering habitat (Table 12-9-47). Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration*, could result in the periodic inundation of up to approximately 3,823 acres of modeled mountain plover habitat (Table 12-9-47).

NEPA Effects: Implementation of CM2 and CM5 would periodically inundate suitable mountain plover foraging habitat. However, effects of periodic inundation would not have an adverse effect on mountain plover because birds would be expected to move to adjacent foraging habitat.

CEQA Conclusion: Implementation of CM2 and CM5 would periodically inundate suitable mountain plover foraging habitat. However, effects of periodic inundation would have a less-than-significant impact on mountain plover because birds would be expected to move to adjacent foraging habitat.

Black Tern

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on black tern. Modeled nesting habitat for black tern in the study area is currently limited to rice in CZ 2.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for black tern as indicated in Table 12-9-48. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit the black tern (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect 700 acres of cultivated lands, with at least 500 acres consisting of rice land, to expand upon and buffer newly restored/created nontidal perennial habitat in CZ 2, (Objective GGS2.3, associated with CM3).
- Protect up to 1,700 acres of rice land or equivalent habitat (e.g. perennial wetland) in the Yolo Bypass if this portion meets the criteria specified in CM3, *Reserve Design Requirements by Species*, for giant garter snake. Any remaining acreage (from a total 2,740-acre commitment) will consist of rice land or equivalent-value habitat outside the Yolo Bypass in CZs 1, 2, 4, or 5 (Objective GGS3.1, associated with CM3).

As explained below, with the restoration and protection of these amounts of habitat, in addition to management activities that would enhance this habitat for the species and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on black tern would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-48. Changes in Black Tern Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5
CM1	Nesting	0	0	0	0	NA	NA
Total Impacts CM1		**0**	**0**	**0**	**0**	NA	NA
CM2–CM18	Nesting	76	260	0	0	791–1,582	0
Total Impacts CM2–CM18		**76**	**260**	**0**	**0**	**791–1,582**	**0**
TOTAL IMPACTS		**76**	**260**	**0**	**0**	**791–1,582**	**0**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-129a: Loss or Conversion of Habitat for and Direct Mortality of Black Tern

Alternative 9 conservation measures would result in the permanent loss of up to 260 acres of modeled nesting habitat for black tern, consisting of rice in CZ 2 (Table 12-9-48). Conservation measures that would result in these losses are grassland restoration (CM8) and nontidal marsh restoration (CM10). Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- *CM8 Grassland Natural Community Restoration:* Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 52 acres of rice lands to grassland in CZ 2 by the late-long time period. An estimated 30 acres of impact would occur in the first 10 years.
- *CM10 Nontidal Marsh Restoration:* Implementation of *CM10* would result in the permanent removal of 208 acres of black tern nesting habitat in in CZ 2. An estimated 46 acres would be removed in the first 10 years.

  CM11 Natural Communities Enhancement and Management: A variety of habitat management actions that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. Habitat management- and enhancement-related activities could disturb nesting black terns if they were to nest in the vicinity of a worksite. Equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in direct mortality of black tern would be minimized with the implementation of and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*.

- Operations and Maintenance: Postconstruction operation and maintenance of the restoration infrastructure could result in ongoing but periodic disturbances that could affect black tern nesting adjacent to maintenance areas. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged black tern individuals if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. If black tern were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the implementation of Mitigation Measure BIO-75.
- Late season flooding in the Yolo Bypass could result in the loss of rice (nesting habitat for black tern) by precluding the preparation and planting of rice fields. The methods for estimating loss of rice in the bypass and results are provided in BDCP Appendix 5.J, Attachment 5J.E, *Estimation of BDCP Impact on Giant Garter Snake Summer Foraging Habitat in the Yolo Bypass.* This analysis concludes that the estimated loss of rice could be up to 1,662 acres by the late long-term timeframe. This potential impact is further described under Impact BIO-129c below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. There would be no impacts on black tern nesting habitat resulting from the construction of the water conveyance facilities (CM1). However, there would be a loss of 76 acres of modeled nesting habitat for black tern in the study area in the near-term. These effects would result from implementing *CM8 Grassland Natural Community Restoration* and *CM10 Nontidal Marsh Restoration.*

The typical NEPA and CEQA project-level mitigation ratio would be 1:1 protection for the loss of cultivated lands including rice. Using this ratio would indicate that 76 acres of rice lands should be protected in CZ 2 to compensate for the losses of black tern nesting habitat.

The BDCP has committed to near-term goals of protecting 200 acres of rice and 700 acres of rice or equivalent habitat (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3 and would occur in the same timeframe as the early restoration losses. The BDCP also contains objectives for the giant garter snake to protect at least 500 acres of rice in CZ 2 and to protect up to 1,700 acres of rice land or equivalent habitat in the Yolo Bypass (if this portion meets the criteria specified in CM3, *Reserve Design Requirements by Species* for giant garter snake, Objectives GGS2.3 and GGS 3.1) by the late long-term time period. These objectives would inform the near-term protection actions, and therefore some portion of the 200 acres of rice and 700 acres of rice or equivalent habitat would be expected to be restored in CZ 2. However, there is no near-term acreage commitment in the plan that is specific to CZ 2. In order to avoid an adverse effect on black tern from habitat loss, protection of 76 acres of rice would need to occur in CZ 2 in the near-term timeframe. Mitigation Measure BIO-129a, *Compensate for Loss of Black Tern Nesting Habitat*, would be available to address this adverse effect.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Black tern is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of 260 acres of modeled black tern nesting habitat during the term of the Plan. This impact would result from the removal of rice in CZ 2. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration* to protect 500 acres of rice lands (Table 3-4 in Chapter 3) and up to 1,700 acres of rice lands or equivalent habitat for the giant garter snake (Objective GGS3.1) in CZ 2. The nesting habitat for black tern in the northern part of the study area has largely been reduced to rice lands, and these acres would provide protected nesting habitat for the species.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Black tern is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

NEPA Effects: The loss of black tern nesting habitat and potential for mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection associated with CM3, guided by biological goals and objectives and AMM1–AMM6, which would be in place throughout the construction period, the effects of habitat loss under Alternative 9 would not be adverse under NEPA. Black tern is not a covered species under the BDCP and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

***CEQA Conclusion*:**

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. There would be no impacts on black tern nesting habitat resulting from the construction of the water conveyance facilities (CM1). However, there would be a loss of 76 acres of modeled nesting habitat for black tern in the study area in the near-term. These effects would result from implementing *CM8 Grassland Natural Community Restoration* and *CM10 Nontidal Marsh Restoration.*

The typical NEPA and CEQA project-level mitigation ratio would be 1:1 protection for the loss of cultivated lands including rice. Using this ratio would indicate that 76 acres of rice lands should be protected in CZ 2 to mitigate the losses of black tern nesting habitat.

The BDCP has committed to near-term goals of protecting 200 acres of rice and 700 acres of rice or equivalent habitat (Table 3-4 in Chapter 3). These conservation actions are associated with CM3 and would occur in the same timeframe as the early restoration losses. The BDCP also contains objectives for the giant garter snake to protect at least 500 acres of rice in CZ 2 and to protect up to 1,700 acres of rice land or equivalent habitat in the Yolo Bypass (if this portion meets the criteria specified in CM3, *Reserve Design Requirements by Species* for giant garter snake, Objectives GGS2.3 and GGS 3.1) by the late long-term time period. These objectives would inform the near-term protection actions, and therefore some portion of the 200 acres of rice and 700 acres of rice or equivalent habitat would be expected to be restored in CZ 2. However, there is no near-term acreage commitment in the plan that is specific to CZ 2. Implementation of Mitigation Measure BIO-129a, *Compensate for Loss of Black Tern Nesting Habitat,* which would require 1:1 protection of habitat in CZ 2 in the near-term timeframe, would reduce this potential impact to a less-than-significant level.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Black tern is not a covered species under the BDCP. For the BDCP to have a less-than-significant impact on individuals, preconstruction would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce the potential impact on nesting black tern to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of 260 acres of modeled black tern nesting habitat during the term of the Plan. This impact would result from the removal of rice in CZ

2. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration* to protect 500 acres of rice lands (Table 3-4 in Chapter 3) and up to 1,700 acres of rice lands or equivalent habitat for the giant garter snake (Objective GGS3.1) in CZ 2.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Black tern is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce the potential impact on nesting black tern to a less-than-significant level.

Considering these protection provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on black tern.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-129a: Compensate for loss of black tern nesting habitat

Because there is no near-term acreage commitment associated with the protection of rice in CZ 2, BDCP proponents must protect rice at a 1:1 ratio for each acre of rice impacted in CZ 2.

Impact BIO-129b: Indirect Effects of Plan Implementation on Black Tern

Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect black tern. If black terns were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting black terns. The use of mechanical equipment during restoration activities could cause the accidental release of petroleum or other contaminants that could affect black terns in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including black tern. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy,* for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on black tern.

Because of the uncertainty that exists at this programmatic level of review, there could be an effect on black tern from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances from the construction of conservation components could black tern use of modeled habitat adjacent to work areas. Moreover, the use of mechanical equipment for the construction of conservation components could cause the accidental release of petroleum or other contaminants, or the inadvertent discharge of sediment or excess dust adjacent to suitable habitat. AMM1–AMM7, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals. Tidal habitat restoration could result in increased exposure of black tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management,* which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

CEQA Conclusion: Noise and visual disturbances from the construction of conservation components could black tern use of modeled habitat adjacent to work areas. Moreover, the use of mechanical equipment for the construction of conservation components could cause the accidental release of petroleum or other contaminants, or the inadvertent discharge of sediment or excess dust adjacent to suitable habitat. AMM1–AMM7, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce these impacts to a less-than–significant level. Tidal habitat restoration could result in increased exposure of black tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Impact BIO-129c: Periodic Effects of Inundation on Black Tern Nesting Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass would inundate 791–1,582 acres of suitable black tern nesting habitat (land currently managed as rice in CZ 2). Inundation would occur during the nonbreeding season but could reduce the availability of nesting habitat during years that flooding extends into the nesting season (past March). Extended inundation of the Yolo Bypass would not be expected to affect black tern nesting habitat. However, if periodic inundation took land out of rice production, this could have an adverse effect on black tern nesting habitat. Late season flooding in the Yolo Bypass could result in the loss of rice (nesting habitat for black tern) by precluding the preparation and planting of rice fields. The methods for estimating loss of rice in the bypass and results are provided in BDCP Appendix 5.J, Attachment 5J.E, *Estimation of BDCP Impact on Giant Garter Snake Summer Foraging Habitat in the Yolo Bypass.* This analysis concludes that the estimated loss of rice could be up to 1,662 acres by the late long-term timeframe. The BDCP has committed to protect, restore and/or create up to 1,700 acres of rice in the Yolo Bypass (Objective GGS3.1). These acres of rice would be protected in areas that are less susceptible to inundation, which would benefit the black tern during years in which the magnitude and duration of inundation were increased.

NEPA Effects: Flooding of the Yolo Bypass is not expected to adversely affect nesting habitat for black tern. However, if flooding were to extend into the nesting season or were to significantly reduce rice production it could also reduce suitable black tern nesting habitat. This potential effect would not be adverse with the creation and/or protection of 1,700 acres of rice in CZ 2 under Objective GGS3.1 in the BDCP.

CEQA Conclusion: Flooding of the Yolo Bypass is not expected to have a significant impact on nesting habitat for black tern. However, if flooding were to extend into the nesting season or were to significantly reduce rice production it could also reduce suitable black tern nesting habitat. This potential impact would be reduced to less than significant by the creation and/or protection of 1,700 acres of rice in CZ 2 under Objective GGS3.1 in the BDCP.

California Horned Lark and Grasshopper Sparrow

The primary impact of concern for grasshopper sparrow and California horned lark would be the loss of breeding habitat in the study area, which consists of grassland, vernal pool complex, and alkali seasonal wetland natural communities and selected cultivated lands including grain and hay crops and pasture. Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled breeding habitat for California horned lark and grasshopper sparrow as indicated in Table 12-9-49. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit the California horned lark and the grasshopper sparrow (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Within the 48,625 acres of protected cultivated lands, protect at least 42,275 acres of cultivated lands as Swainson's hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4,VPNC2.5, and GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species, and implementation of AMMs1–AMM7 and Mitigation Measure BIO-75, impacts on California horned lark and grasshopper sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-49. Changes in California Horned Lark and Grasshopper Sparrow Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Breeding	318	318	1,281	1,281	NA	NA
Total Impacts CM1		**318**	**318**	**1,281**	**1,281**	NA	NA
CM2–CM18	Breeding	5,450	26,198	376	893	777–2,423	3,823
Total Impacts CM2–CM18		5,450	26,198	376	893	777–2,423	3,823
TOTAL IMPACTS		**5,768**	**26,516**	**1,657**	**2,174**	**777–2,423**	**3,823**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-130: Loss or Conversion of Habitat for and Direct Mortality of California Horned Lark and Grasshopper Sparrow

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 28,690 acres of modeled breeding habitat for California horned lark and grasshopper sparrow (26,516 acres of permanent loss, 2,174 acres of temporary loss, Table 12-9-49). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss (20,880 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate California horned lark and grasshopper sparrow modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,599 acres of potential California horned lark and grasshopper sparrow habitat (318 acres of permanent loss, 1,281 acres of temporary loss) from CZ 4, 5, 6, 7, and 8. These losses would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. Other impacts would occur from potential borrow and spoil sites, access roads, barge unloading facilities, and intake and fish screen construction areas. Grasshopper sparrows were detected in DHCCP surveys south of Byron Highway in CZ 8 (1 occurrence) and in the Stone Lakes NWR (6 occurrences). However, the CM1 footprint does not overlap with any grasshopper sparrow or California horned lark occurrences. However, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on California horned larks and grasshopper sparrows if they were to nest in or adjacent to construction areas. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of modeled California horned lark and grasshopper sparrow habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. Impacted habitat would consist primarily of grassland and pasture. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels. Realignment of Putah Creek could also involve excavation and grading in alkali seasonal wetland complex habitat as a new channel is constructed. The loss is expected to occur during the first 10 years of Alternative 9 implementation.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of modeled California horned lark and grasshopper sparrow habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.
- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of modeled California horned lark and grasshopper sparrow nesting habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.
- *CM7 Riparian Natural Community Restoration*: Riparian restoration would permanently remove approximately 370 acres of California horned lark and grasshopper sparrow nesting habitat as part of tidal restoration and 1,489 acres as part of seasonal floodplain restoration.
- *CM8 Grassland Natural Community Restoration* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide nesting habitat for California horned lark and

grasshopper sparrow and would result in the conversion of 837 acres of cultivated lands to grassland.

- *CM10 Nontidal Marsh Restoration*: Implementation of CM10 would result in the permanent removal of 705 acres of California horned lark and grasshopper sparrow nesting habitat.
- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

  Habitat management- and enhancement-related activities could disturb California horned lark and grasshopper sparrow nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects.
- *CM18 Conservation Hatcheries:* Implementation of CM18 would remove up to 35 acres of modeled California horned lark and grasshopper sparrow habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect California horned lark and grasshopper sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.
- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged California horned lark and grasshopper sparrow if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled breeding habitat for California horned lark and grasshopper sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of California horned lark and grasshopper sparrow habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of California horned lark and grasshopper sparrow nesting habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding adverse effects of habitat loss on California horned lark and grasshopper sparrow. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would provide nesting habitat for California horned lark and grasshopper sparrow.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on California horned lark and grasshopper sparrow, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the

15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. Mitigation Measure BIO-130, *Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat*, would be available to address the adverse effect of habitat loss in the near-term.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of modeled California horned lark and grasshopper sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types. These are very high- and high-value crop types for Swainson's hawk (Objective SH1.2) and would provide potential nesting habitat for California horned lark and grasshopper sparrow.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or

minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of California horned lark and grasshopper sparrow habitat and potential mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and AMM1–AMM7, which would be in place throughout the construction period, and with Mitigation Measure BIO-130, *Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat*, the effects of habitat loss under Alternative 9 on California horned lark and grasshopper sparrow would not be adverse under NEPA. California horned lark and grasshopper sparrow are not covered species under the BDCP, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of modeled breeding habitat for California horned lark and grasshopper sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the CM1 losses of 1,599 acres of California horned lark and grasshopper sparrow habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of California horned lark and grasshopper sparrow nesting habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding significant impacts on California horned lark and grasshopper sparrow. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would provide nesting habitat for California horned lark and grasshopper sparrow.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on California horned lark and grasshopper sparrow, as well as mitigate the near-term effects of the other conservation measures with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would be managed in suitable crop types to compensate for the loss of habitat at a ratio of 2:1. Implementation of Mitigation Measure BIO-130, *Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat*, would reduce the impact of habitat loss in the near-term to a less-than-significant level.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this potential impact to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 28,690 acres of modeled California horned lark and grasshopper sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and*

Alkali Seasonal Wetland Complex Restoration to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid significant impacts on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, Mitigation Measure BIO-75, and Mitigation Measure BIO-130, *Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of California horned lark and grasshopper sparrow. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on California horned lark and grasshopper sparrow.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-130: Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat

DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa to provide California horned lark and grasshopper sparrow habitat such that the total acres of habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1 protection. Additional grassland protection, enhancement, and management may be substituted for the protection of cultivated lands.

Impact BIO-131: Effects on California Horned Lark and Grasshopper Sparrow Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes and/or electrocution, which could result in injury or mortality of grasshopper sparrow and California horned lark. The potential for this risk, is considered minimal based on the flight behaviors of each species. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure. However, this would be expected to have few adverse effects on the grasshopper sparrow and California horned lark local populations.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the implementation of *AMM20 Greater Sandhill Crane* the effect of new transmission lines on California horned lark and grasshopper sparrow would not be adverse.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the incorporation of *AMM20 Greater Sandhill Crane*, new transmission lines would have a less-than-significant impact on grasshopper sparrow and California horned lark.

Impact BIO-132: Indirect Effects of Plan Implementation on Grasshopper Sparrow and California Horned Lark

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect California horned lark and grasshopper sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect California horned lark or grasshopper sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to grasshopper sparrow and California horned lark habitat could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on California horned lark and grasshopper sparrow as a result of Alternative 9 implementation could have adverse effects on these species through the modification of habitat and potential direct mortality. California horned lark and grasshopper sparrow are not covered species under the BDCP, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75 *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

CEQA Conclusion: Indirect effects on grasshopper sparrow and California horned lark as a result of constructing the water conveyance facilities could have a significant impact on these species. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75a: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75a under Impact BIO-75.

Impact BIO-133: Periodic Effects of Inundation on Grasshopper Sparrow and California Horned Lark as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled California horned lark and grasshopper sparrow habitat (Table 12-9-49).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 3,823 acres of modeled habitat (Table 12-9-49).

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, inundation would occur during the nonbreeding season and would not be expected to have an adverse effect on either species.

NEPA Effects: Periodic inundation of floodplains would not have adverse effects on grasshopper sparrow or California horned lark because inundation is expected to occur prior to the breeding season.

CEQA Conclusion: Periodic inundation of floodplains would not have a significant impact on grasshopper sparrow or California horned lark because inundation is expected to occur prior to the breeding season.

Least Bittern and White-Faced Ibis

This section describes the effects of Alternative 9, including water conveyance facilities construction and implementation of other conservation components, on least bittern and white-faced ibis. Modeled breeding habitat for least bittern and white-faced ibis consists of tidal freshwater and nontidal freshwater emergent wetlands, managed wetlands, and other natural seasonal wetlands in CZs 2, 4, and 11. Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for least bittern and white-faced ibis as indicated in Table 12-9-50. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit least bittern and white-faced ibis (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species, and implementation of AMM1–AMM7, *AMM27 Selenium Management*, and Mitigation Measure BIO-75, impacts on least bittern and white-faced ibis would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-50. Changes in Least Bittern and White-Faced Ibis Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5
CM1	Nesting	1	1	0	0	NA	NA
Total Impacts CM1		**1**	**1**	**0**	**0**	NA	NA
CM2–CM18	Nesting	5,134	13,063	45	45	961–2,672	NA
Total Impacts CM2–CM18		**5,134**	**13,063**	**45**	**45**	**961–2,672**	**NA**
TOTAL IMPACTS		**5,135**	**13,064**	**45**	**45**	**961–2,672**	**NA**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-134: Loss or Conversion of Habitat for and Direct Mortality of Least Bittern and White-Faced Ibis

Alternative 9 conservation measures would result in the combined permanent and temporary loss and conversion of up to 13,109 acres of modeled habitat for least bittern and white-faced ibis (13,064 acres of permanent loss and conversion and 45 of temporary loss, Table 12-9-50). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), *CM2 Yolo Bypass Fisheries Enhancement*, and *CM4 Tidal Natural Communities Restoration*. Habitat enhancement and management activities (CM11), which would include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate least bittern and white-faced ibis habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the permanent loss of 1 acre of modeled least bittern and white-faced ibis habitat from CZ 4. This loss would occur from the fringes of tidal freshwater emergent wetland along channels and island edges that would be impacted from channel dredging activities. The construction footprint for CM1 does not overlap with any occurrences of least bittern or white-faced ibis. The Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would permanently remove 55 acres of modeled least bittern and white-faced ibis habitat in the Yolo Bypass in CZ 2. In addition, 45 acres of habitat would be temporarily removed. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 13,008 acres of modeled least bittern and white-faced ibis habitat in CZ 2, 4, and 11 by the late long-term time period.

- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of least bittern and white-faced ibis habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available least bittern and white-faced ibis habitat.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least bittern and white-faced ibis use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7described below and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to further reduce potential effects.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of least bittern and white-faced ibis because adults and fledged young would be expected to avoid contact with construction and other equipment. However, if either species were to nest in the construction area, equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 5,180 acres of modeled habitat for least bittern and white-faced ibis in the study area in the near-term (5,135 acres of permanent loss, and 45 acres of temporary loss). These effects would result from the construction of the water conveyance facilities (CM1, 1 acre), and the implementation of other conservation measures (Yolo Bypass fisheries enhancement [CM2], and tidal restoration [CM4] 5,179 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of least bittern and white-faced ibis habitat. Using these ratios would indicate that 1 acre of habitat should be restored and 1 acre of habitat should be protected to compensate for the CM1 losses of 1 acre of least bittern and white-faced ibis habitat. The near-term effects of other conservation actions would remove 5,179 acres of modeled habitat, and therefore require 5,179 acres of restoration and 5,179 acres of protection of least bittern and white-faced ibis habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland and protecting and enhancing 4,800 acres of managed wetland in the Plan Area (Table 3-4 in Chapter 3, *Biological Goals and Objectives*). These conservation actions are associated with CM4 and CM3 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on least bittern and white-faced ibis. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit these species through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 400 acres of nontidal marsh would be created, some of which would provide nesting habitat for least bittern and white-faced ibis. These Plan objectives represent performance standards for considering the effectiveness of restoration and protection actions. The acres of restoration and protection contained in the near-term Plan goals satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 13,109 acres (13,064 acres of permanent loss, 45 acres of temporary loss) of least bittern and white-faced ibis habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM4 Tidal Natural Communities Restoration* to restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1). In addition, 1,200 acres of nontidal marsh would be created through *CM10 Nontidal Marsh Restoration* and 8,100 acres of managed wetland would be protected and enhanced in CZ 11.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided.

***NEPA Effects*:** The loss of least bittern and white-faced ibis habitat and potential mortality of these special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. However, with the habitat protection and restoration associated with CM3, CM4, CM6, CM7, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of habitat loss on least bittern and white-faced ibis would not be adverse under Alternative 9. Least bittern and white-faced ibis are not covered species under the BDCP, and the potential for mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

***CEQA Conclusion*:**

Near-Term Timeframe

Because the water conveyance facilities construction (CM1)is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant under CEQA. Alternative 9 would remove 1,580 acres of modeled habitat for least bittern and white-faced ibis in the study area in the near-term (5,135 acres of permanent loss, and 45 acres of temporary loss). These effects would result from the construction of the water conveyance facilities (CM1, 1 acre), and the implementation of other conservation measures (Yolo Bypass fisheries enhancement [CM2], and tidal restoration [CM4] 5,179 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of least bittern and white-faced ibis habitat. Using these ratios would indicate that 1 acre of habitat should be restored and 1 acre of habitat should be protected to compensate for the CM1 losses of 1 acre of least bittern and white-faced ibis habitat. The near-term effects of other conservation actions would remove 5,179 acres of modeled habitat, and therefore require 5,179 acres of restoration and 5,179 acres of protection of least bittern and white-faced ibis habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal freshwater emergent wetland and 4,800 acres of managed wetland in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM4 and CM3 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on least bittern and white-faced ibis. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit these species through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 400 acres of nontidal marsh would be created, some of which would provide nesting habitat for least bittern and white-faced ibis. These Plan objectives represent performance standards for considering the effectiveness of restoration and protection actions. The acres of restoration and protection contained in the near-term Plan goals satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material,* and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to have a less-than-significant impact on individuals, preconstruction surveys would be required to ensure that nests were detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce the potential impact on nesting least bittern and white-faced ibis to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 13,109 acres (13,064 acres of permanent loss, 45 acres of temporary loss) of least bittern and white-faced ibis habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM4 Tidal Natural Communities Restoration* to restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1). In addition, 1,200 acres of nontidal marsh would be created through *CM10 Nontidal Marsh Restoration* and 8,100 acres of managed wetland would be protected and enhanced in CZ 11.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests were detected and avoided. Implementation of Mitigation Measure BIO-75 would reduce the potential impact on nesting least bittern and white-faced ibis and to a less-than-significant level.

Considering these protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of least bittern and white-faced ibis. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on least bittern and white-faced ibis.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-135: Effects on Least Bittern and White-Faced Ibis Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. The risk for bird-power line strikes, would be minimized with the incorporation of *AMM20 Greater Sandhill Crane* into the BDCP. This measure would ensure that conductor and ground lines are fitted with flight diverters in compliance with the best available practices, such as those specified in the USFWS Avian Protection Guidelines.

***NEPA Effects*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. With the incorporation of *AMM20 Greater Sandhill Crane* into the BDCP, new transmission lines would not have an adverse effect on least bittern and white-faced ibis.

***CEQA Conclusion*:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. With the incorporation of *AMM20 Greater Sandhill Crane* into the BDCP, new transmission lines would have a less-than-significant impact on least bittern and white-faced ibis.

Impact BIO-136: Indirect Effects of Plan Implementation on Least Bittern and White-Faced Ibis

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect least bittern and white-faced ibis use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect least bittern or white-faced ibis. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to least bittern and white-faced ibis could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on least bittern and white-faced ibis.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including least bittern and white-faced ibis. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on least bittern and white-faced ibis.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on least bittern and white-faced ibis from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Indirect effects on least bittern and white-faced ibis as a result of constructing the water conveyance facilities could have adverse effects on these species in the absence of other conservation actions. However, the implementation of AMM1–AMM7 would help to reduce this effect. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would also be available to address the adverse indirect effects of construction on active nests. Tidal habitat restoration could result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*). However, it is unknown what concentrations of methylmercury are harmful to the species, and the potential for increased exposure varies substantially within the study area. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would better inform potential adverse effects and address the uncertainty of methylmercury levels in restored tidal marsh in the study area. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for least bittern and white-faced ibis, once site specific sampling and other information could be developed.

CEQA Conclusion: Indirect effects on least bittern and white-faced ibis as a result of constructing the water conveyance facilities could have a significant impact on these species. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*). In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Tidal habitat restoration could result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 9 implementation would not have an significant impact on least bittern and white-faced ibis.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-137: Periodic Effects of Inundation on Least Bittern and White-Faced Ibis as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 961-2,672 acres of modeled least bittern and white-faced ibis habitat (Table 12-9-50). However, no adverse effects of increased inundation frequency on nesting habitat would be expected because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types. Inundation would occur in the nonbreeding season and wetlands supporting habitat would not be expected to be affected by flood flows.

NEPA Effects: Periodic inundation of Yolo Bypass would not be expected to have adverse effects on least bittern or white-faced ibis because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types.

CEQA Conclusion: Periodic inundation of Yolo Bypass would not be expected to have a significant impact on least bittern or white-faced ibis because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types.

Loggerhead Shrike

Modeled habitat for loggerhead shrike includes both high-value and low-value modeled habitat. High-value habitat includes grassland, vernal pool complex and alkali seasonal wetland natural communities in addition to cultivated lands, including pasture and grain and hay crops. Low-value habitat includes row crops such as truck and berry crops and field crops that are not considered to be valuable habitat for the species but which were included in the model because they may provide foraging opportunities.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of modeled habitat for loggerhead shrike as indicated in Table 12-9-51. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit loggerhead shrike (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4,VPNC2.5, and GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).

- Maintain and protect the small patches of important wildlife habitats that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3 and CM11).
- Establish 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands at a minimum rate of 400 linear feet per 100 acres (Objective SH2.2, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species, and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on loggerhead shrike would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-51. Changes in Loggerhead Shrike Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	High-value	318	318	1,281	1,281	NA	NA
	Low-value	55	55	1,231	1,231	NA	NA
Total Impacts CM1		**373**	**373**	**2,512**	**2,512**	**NA**	**NA**
CM2–CM18	High-value	5,450	26,198	376	893	777-2,423	3,823
	Low-value	1,801	17,575	97	624	672-1,996	4,315
Total Impacts CM2–CM18		**7,251**	**43,723**	**474**	**1,517**	**1,830-5,646**	**8,138**

Total Low-value		**1,856**	**17,630**	**1,328**	**1,855**		
TOTAL IMPACTS		**7,624**	**44,096**	**2,986**	**4,029**		

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-138: Loss or Conversion of Modeled Habitat for and Direct Mortality of Loggerhead Shrike

Alternative 9 conservation measures would result in the combined permanent loss or conversion and temporary loss of up to 48,125 acres of modeled habitat for loggerhead shrike (28,690 acres of which would be high-value habitat, Table 12-9-51). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), channel margin enhancement (CM6), riparian restoration, (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), natural communities enhancement and management (CM11) and construction of conservation hatcheries (CM18). The majority of habitat loss (33,244 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate loggerhead shrike modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 1,599 acres of high-value loggerhead shrike habitat (318 acres of permanent loss, 1,281 acres of temporary loss). In addition, 1,286 acres of low-value habitat would be removed (55 acres of permanent loss or conversion, 1,231 acres of temporary loss or conversion, Table 12-9-51). These losses would occur at numerous locations where dredging, construction of operable barriers and canals, and channel enlargement would be undertaken. Other impacts would occur from potential borrow and spoil sites, access roads, barge unloading facilities, and intake and fish screen construction areas. The CM1 construction footprint for the canal that would be constructed south of the Clifton Court Forebay overlaps with two loggerhead shrike occurrences. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on nesting loggerhead shrikes. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Construction of the water conveyance facilities would occur in the near-term timeframe.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of high-value loggerhead shrike habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. In addition, 182 acres of low-value habitat would be removed (85 acres of permanent loss, 97 acres of temporary loss). The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of high-value loggerhead shrike habitat and 12,364 acres of low-value habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of high-value loggerhead shrike habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 9 implementation along the San Joaquin River and other major waterways in CZ 7.

- *CM7 Riparian Natural Community Restoration:* Riparian restoration would permanently remove approximately 370 acres of high-value loggerhead shrike habitat as part of tidal restoration and 1,489 acres as part of seasonal floodplain restoration. In addition, 503 acres of low-value habitat would be removed as a part of tidal restoration and 1,971 acres would be removed as part of seasonal floodplain restoration through CM7.

- *CM8 Grassland Natural Community Restoration* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide habitat for loggerhead shrike and would result in the conversion of 1,849 acres of cultivated lands to high-value grassland.

- *CM10 Nontidal Marsh Restoration*: Implementation of CM10 would result in the permanent removal of 705 acres of high-value loggerhead shrike habitat and 735 acres of low-value loggerhead shrike habitat.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

  Habitat management- and enhancement-related activities could disturb loggerhead shrike nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects.

- *CM18 Conservation Hatcheries*: Implementation of CM18 would remove up to 35 acres of high-value loggerhead shrike habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1. Hatchery construction is expected to occur within the first 10 years of Plan implementation.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect loggerhead shrike use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged loggerhead shrike if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these potential effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of high-value habitat for loggerhead shrike in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres). In addition, 3,184 acres of low-value habitat would be removed or converted in the near-term (CM1, 1,286 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—1,898 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 protection of high-value habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the loss of high-value habitat from CM1. The near-term effects of other conservation actions would require 11,652 acres of protection to compensate for the loss of high-value shrike habitat using the same typical NEPA and CEQA ratio (2:1 protection for the loss of high-value habitat). The loss of low-value habitat would not require mitigation because a large proportion of the low-value habitat would result from the conversion and enhancement to high-value habitats. In addition, temporary impacts on cultivated lands would be restored relatively quickly after completion of construction.

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2). These Plan objectives represent performance standards for considering the effectiveness of conservation actions.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 and other near-term effects on loggerhead shrike high-value habitat with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would include suitable high-value crop types for loggerhead shrike. Sufficient acreage of the protected cultivated lands would need to be managed in pasture, alfalfa, or grain and hay crops such that the near-term impacts on high-value habitat were compensated for at a ratio of 2:1. Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, would be available to address the adverse effect of near-term high-value habitat loss. With the management and enhancement of cultivated lands including insect prey enhancement through CM3 and CM11, the protection of shrubs and establishment of hedgerows within protected cultivated lands would compensate for any potential effect from the loss of low-value loggerhead shrike foraging habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the combined permanent of and temporary effects on 28,690 acres of high-value habitat and 19,485 acres of low-value loggerhead shrike habitat over the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 48,625 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

NEPA Effects: The loss of loggerhead shrike habitat and potential mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7, and with implementation of Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, which would be available to guide the near-term protection and management of cultivated lands, the effects of habitat loss on loggerhead shrike under Alternative 9 would not be adverse. Loggerhead shrike is not a covered species under the BDCP, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure

BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 7,425 acres (5,768 permanent, 1,657 temporary) of high-value habitat for loggerhead shrike in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 1,599 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—5,826 acres). In addition, 3,184 acres of low-value habitat would be removed or converted in the near-term (CM1, 1,286 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management* and *CM18 Conservation Hatcheries*—1,898 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 protection of high-value habitat. Using this ratio would indicate that 3,198 acres should be protected to compensate for the loss of high-value habitat from CM1. The near-term effects of other conservation actions would require 11,652 acres of protection to compensate for the loss of high-value shrike habitat using the same typical NEPA and CEQA ratio (2:1 protection for the loss of high-value habitat). The loss of low-value habitat would not require mitigation because a large proportion of the low-value habitat would result from the conversion and enhancement to high-value habitats. In addition, temporary impacts on cultivated lands would be restored relatively quickly after completion of construction.

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2). These Plan objectives represent performance standards for considering the effectiveness of conservation actions.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 and other near-term effects on loggerhead shrike high-value habitat with the consideration that some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would include suitable high-value crop types for loggerhead shrike. Sufficient acreage of the protected cultivated lands would need to be managed in pasture, alfalfa, or grain and hay crops such that the near-term impacts on high-value habitat were compensated for at a ratio of 2:1. The implementation of Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, would reduce the impact of near-term high-value habitat loss to a less-than-significant level. With the management and enhancement of cultivated lands including insect prey enhancement through CM3 and CM11, the protection of shrubs and establishment of hedgerows within protected cultivated lands would compensate for any potential impact from the loss of low-value loggerhead shrike foraging habitat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

The loggerhead shrike is not a covered species under the BDCP and in order to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this potential impact to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the combined permanent of and temporary effects on 28,690 acres of high-value habitat and 19,485 acres of low-value loggerhead shrike habitat over the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration,* and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 48,625 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this potential impact to a less-than–significant level.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of loggerhead shrike. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on loggerhead shrike.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-138: Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat

Because the BDCP does not include acreage commitments for the protection of crop types in the near-term time period, DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa as high-value loggerhead shrike habitat such that the total acres of high-value habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1. Additional grassland protection, enhancement, and management may be substituted for the protection of high-value cultivated lands.

Impact BIO-139: Effects on Loggerhead Shrike Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of loggerhead shrike. The risk for bird-power line strikes would be minimized with the incorporation of *AMM20 Greater Sandhill Crane* into the BDCP. This measure would ensure that conductor and ground lines are fitted with flight diverters in compliance with the best available practices, such as those specified in the USFWS Avian Protection Guidelines and would further ensure no adverse effect from electrical transmission facilities.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of loggerhead shrike. With the implementation of *AMM20 Greater Sandhill Crane* the effect of new transmission lines on loggerhead shrike would not be adverse.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of loggerhead shrike. With the incorporation of *AMM20 Greater Sandhill Crane* into the BDCP, new transmission lines would have a less-than-significant impact on loggerhead shrike.

Impact BIO-140: Indirect Effects of Plan Implementation on Loggerhead Shrike

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect loggerhead shrike use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect loggerhead shrike. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Indirect effects from construction of the new forebay in CZ 8 could result in substantial effects on active loggerhead shrike nests. DHCCP surveys in 2009 detected 10 nest sites south-west of the Clifton Court Forebay (Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report*) and the large expanses of grassland in CZ 8 provide high-value nesting habitat for the species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills. The inadvertent discharge of sediment or excessive dust adjacent to loggerhead shrike nesting habitat could also have a negative effect on these species. AMM1–AMM7would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on loggerhead shrike as a result of Alternative 9 implementation could have adverse effects on the species through the modification of habitat and potential for direct mortality. The loggerhead shrike is not a covered species under the BDCP, and the potential for mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

CEQA Conclusion: Indirect effects on loggerhead shrike as a result of Alternative 1A implementation could have a significant impact on the species. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-141: Periodic Effects of Inundation on Loggerhead Shrike as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on 1,830–5,646 acres of modeled loggerhead shrike habitat (consisting of approximately 777–2,423 acres of high-value habitat; Table 12-9-51).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 8,138 acres of modeled habitat (Table 12-9-51), consisting of 3,823 acres of high-value and 4,315 acres of low-value habitat.

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, increased frequency and duration of inundation would occur during the nonbreeding season.

NEPA Effects: Periodic inundation of floodplains would not result in an adverse effect on loggerhead shrike from the modification of habitat. Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, increased frequency and duration of inundation would occur during the nonbreeding season.

CEQA Conclusion: Periodic inundation of floodplains would result in a less-than-significant impact on loggerhead shrike from the modification of habitat. Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, increased frequency and duration of inundation would occur during the nonbreeding season.

Song Sparrow "Modesto" Population

The Modesto song sparrow is common and ubiquitous throughout the study area, excluding CZ 11, and modeled habitat for the species includes managed wetlands, tidal freshwater emergent, nontidal freshwater emergent, and valley/foothill riparian vegetation communities.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent removal of Modesto song sparrow habitat in the quantities indicated in Table 12-9-52. However, BDCP activities are expected to have little impact on the population. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit Modesto song sparrow (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Create 500 acres of managed wetlands in CZs 3, 4, 5, or 6 (Objectives GSHC1.3 and GSHC1.4, associated with CM10).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4,VPNC2.5, and GNC2.4, associated with CM11).
- Maintain and protect the small patches of important wildlife habitats that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).
- Establish 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands at a minimum rate of 400 linear feet per 100 acres (Objective SH2.2, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to implementation of AMMs and Mitigation Measure BIO-75, impacts on Modesto song sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-52. Changes in Modesto Song Sparrow Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Nesting	133	133	418	418	NA	NA
Total Impacts CM1		**133**	**133**	**418**	**418**	**NA**	**NA**
CM2–CM18	Nesting	2,444	3,253	133	169	81-158	284
Total Impacts CM2–CM18		**2,444**	**3,253**	**133**	**169**	**81-158**	**284**
TOTAL IMPACTS		**2,2,577**	**3,386**	**551**	**587**	**81-158**	**284**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-142: Loss or Conversion of Habitat for and Direct Mortality of Modesto Song Sparrow

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 3,973 acres of modeled habitat for Modesto song sparrow (of which 3,386 acres would be a permanent loss and 587 acres would be a temporary loss of habitat, Table 12-9-52). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). Habitat enhancement and management activities (CM11), which would include ground disturbance and removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate Modesto song sparrow modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 551 acres of modeled Modesto song sparrow habitat (133 acres of permanent loss, 418 acres of temporary loss) from CZ 4, 5, 6, 7, and 8. Most of the permanent loss would occur as wider and deeper channels are dredged in Middle River and Victoria Canal, and as operable barriers and new Sacramento River diversions are constructed in various waterways across the Delta. Temporary losses of habitat would occur primarily along Middle River between Victoria Canal and Mildred Island, where large dredging work areas and operable barrier work areas would be placed. Some of this vegetation may be temporarily removed as dredging progresses, while other areas could remain in place but be temporarily affected by sedimentation and equipment movement associated with dredging. The Modesto song sparrow is ubiquitous throughout the study area. The CM1 construction footprint of permanent impacts overlaps with 63 occurrences of Modesto song sparrow. Permanent impacts include the construction of the canal south of Clifton Court Forebay, channel dredging, instream island dredging, and channel enlargement in Middle River and Victoria Canal, an operable barrier, and a fish screen area. The CM1 footprint of temporary impacts overlaps with 102 occurrences of Modesto song sparrow and the majority of these impacts would be a result of dredging work areas. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on nesting Modesto song sparrows. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Construction of the water conveyance facilities would occur in the near-term timeframe.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement would permanently remove 143 acres of modeled Modesto song sparrow habitat in the Yolo Bypass in CZ 2. In addition, 133 acres of habitat would be temporarily removed. These losses would occur in the near-term timeframe and primarily consist of valley/foothill riparian natural community and managed wetland. The loss is expected to occur during the first 10 years of Alternative 9 implementation.

- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration site preparation and inundation would result in the conversion of an estimated loss of 3,066 acres of modeled Modesto song sparrow habitat by the late long-term timeframe.

- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 80 acres of modeled Modesto song sparrow habitat (44 permanent, 36 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7. The BDCP is expected to restore approximately 5,000 acres of valley/foothill riparian natural community. These lands would be managed as a mosaic of seral stages, age classes, and plant heights, some of which would provide suitable nesting habitat for Modesto song sparrow.

- *CM6 Channel Margin Enhancement:* Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs. Some of the restored riparian habitat in the channel margin would be expected to support nesting habitat for Modesto song sparrow.

- *CM11 Natural Communities Enhancement and Management:* A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP.

Habitat management- and enhancement-related activities could affect Modesto song sparrow nests. If the individuals were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these effects.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Modesto song sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs, and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Modesto song sparrow if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 3,128 acres of modeled habitat (2,557 permanent, 551 temporary) for Modesto song sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 551 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—2,577 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these ratios would indicate that 551 acres of suitable habitat should be restored/created and 551 acres should be protected to compensate for the CM1 losses of 551 acres of Modesto song sparrow habitat. The near-term effects of other conservation actions would remove 2,577 acres of modeled habitat, and therefore require 2,577 acres of restoration/creation and 2,577 acres of protection of Modesto song sparrow habitat using the same typical NEPA and CEQA ratios (1:1 for restoration/creation and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community, restoring 2,000 acres of tidal freshwater emergent wetland, restoring 500 acres of managed wetland, and restoring 400 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM7, and CM10 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on Modesto song sparrow. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*) and would provide suitable Modesto song sparrow nesting habitat. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan also includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5,and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material* and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Modesto song sparrow is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 3,973 acres (3,386 acres of permanent loss, 587 acres of temporary loss) of modeled Modesto song sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration,* and *CM10 Nontidal Marsh Restoration* to protect 750 acres and restore 5,000 acres of the valley/foothill riparian natural community, restore 24,000 acres of tidal freshwater emergent wetland, restore 500 acres of managed wetland, and restore 1,200 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Additional acres of valley/foothill riparian habitat would be restored as a component of channel margin enhancement actions (CM6) along 20 miles of river and slough channels in the Delta, some of which would be expected to support nesting habitat for Modesto song sparrow. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable nesting habitat for Modesto song sparrow.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5,and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Modesto song sparrow is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of Modesto song sparrow habitat and potential mortality of this special-status species under Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM4, CM6, CM7, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of habitat loss on Modesto song sparrow under Alternative 9 would not be adverse. The Modesto song sparrow is not a covered species under the

BDCP, and potential mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

***CEQA Conclusion*:**

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 3,128 acres of modeled habitat (2,557 permanent, 551 temporary) for Modesto song sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 551 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—2,577 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these ratios would indicate that 551acres of suitable habitat should be restored/created and 551 acres should be protected to compensate for the CM1 losses of 551 acres of Modesto song sparrow habitat. The near-term effects of other conservation actions would remove 2,577 acres of modeled habitat, and therefore require 2,577 acres of restoration/creation and 2,577 acres of protection of Modesto song sparrow habitat using the same typical NEPA and CEQA ratios (1:1 for restoration/creation and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community, restoring 2,000 acres of tidal freshwater emergent wetland, restoring 500 acres of managed wetland, and restoring 400 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM7, and CM10 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding a significant impact of habitat loss on Modesto song sparrow. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, *Conservation Strategy*) and would provide suitable Modesto song sparrow nesting habitat. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan also includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5,and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Modesto song sparrow is not a covered species under the BDCP. For the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests were detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Late Long-Term Timeframe

Alternative 9 as a whole would result in the permanent loss of and temporary effects on 3,973 acres (3,386 acres of permanent loss, 587 acres of temporary loss) of modeled Modesto song sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration,* and *CM10 Nontidal Marsh Restoration* to protect 750 acres and restore 5,000 acres of the valley/foothill riparian natural community, restore 24,000 acres of tidal freshwater emergent wetland, restore 500 acres of managed wetland, and restore 1,200 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). Additional acres of valley/foothill riparian habitat would be restored as a component of channel margin enhancement actions (CM6) along 20 miles of river and slough channels in the Delta, some of which would be expected to support nesting habitat for Modesto song sparrow. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable nesting habitat for Modesto song sparrow.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective

CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5,and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Modesto song sparrow is not a covered species under the BDCP. For the BDCP to minimize direct mortality of individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of Modesto song sparrow. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on Modesto song sparrow.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-143: Effects on Modesto Song Sparrow Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Modesto song sparrow. Existing lines currently pose this risk for Modesto song sparrow and the incremental increased risk from the construction of new transmission lines is not expected to adversely affect the population.

NEPA Effects: The incremental increased risk of bird-powerline strikes from the construction of new transmission lines would not adversely affect the Modesto song sparrow population.

CEQA Conclusion: The incremental increased risk of bird-powerline strikes from the construction of new transmission lines would have a less-than-significant impact on the Modesto song sparrow population.

Impact BIO-144: Indirect Effects of Plan Implementation on Modesto Song Sparrow

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect Modesto song sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect Modesto song sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 including *AMM2 Construction Best Management Practices and Monitoring* would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to Modesto song sparrow could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect Modesto song sparrow, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on Modesto song sparrow.

***NEPA Effects*:** Indirect effects on Modesto song sparrow as a result of constructing the Alternative 9 water conveyance facilities could adversely affect individuals in the absence of other conservation actions. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would minimize this adverse effect. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of Modesto song sparrow to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in *CM12 Methylmercury Management* would address the potential impacts of methylmercury levels in restored tidal marsh in the study area. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for Modesto song sparrow, once site specific sampling and other information could be developed.

CEQA Conclusion: Indirect effects on Modesto song sparrow as a result of constructing the water conveyance facilities could have a significant impact on these species. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of Modesto song sparrow to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to the species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in *CM12 Methylmercury Management* would address the potential impacts of methylmercury levels in restored tidal marsh in the study area.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-145: Periodic Effects of Inundation on Modesto Song Sparrow as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass (CM2) would inundate 81-158 acres of modeled Modesto song sparrow habitat. However, inundation would occur during the nonbreeding season. Reduced foraging habitat availability would be expected during the fledgling period of the nesting season due to periodic inundation.

Based on hypothetical floodplain restoration, construction of setback levees from seasonally inundated floodplain restoration (CM5) could result in periodic inundation of up to approximately 284 acres of Modesto song sparrow modeled habitat (Table 12-9-52).

The periodic inundation of the Yolo Bypass (CM2) and of seasonal floodplains (CM5) is expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support Modesto song sparrow habitat, but may reduce the availability of nesting habitat during years when flooding extends into the nesting season (past March).

NEPA Effects: Periodic effects of inundation would not result in an adverse effect on Modesto song sparrow because increased frequency and duration of inundation would be expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support Modesto song sparrow habitat.

CEQA Conclusion: Periodic effects of inundation would have a less-than-significant impact on Modesto song sparrow because increased frequency and duration of inundation would be expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support Modesto song sparrow habitat.

Bank Swallow

Bank swallows nest in colonies along rivers, streams, or other water and require fine textured sandy soils in vertical banks to create their burrows. There is little suitable habitat for bank swallow in the study area because most of the erodible banks have been stabilized with of levee revetment. The placement of rock revetment prevents the lateral migration of rivers, removing the natural river process that creates vertical banks through erosion (Bank Swallow Technical Advisory Committee 2013, Stillwater Sciences 2007). An estimated 70–90% of the bank swallow population in California nests along the Sacramento and Feather Rivers upstream of the study area (Bank Swallow Technical Advisory Committee 2013). However, there are three CNDDB records of bank swallow colonies in the study area: two in CZ 2 north of Fremont Weir, and one in CZ 5 on Brannan Island, just west of Twitchell Island.

Construction and restoration associated with Alternative 9 conservation measures would not result in any direct loss of modeled habitat for bank swallow (Table 12-9-53). However, indirect effects of noise and visual disturbance from *CM2 Yolo Bypass Fisheries Enhancement* and *CM4 Tidal Natural Communities Restoration* could impact bank swallow colonies if they are present near work areas. In addition, there is uncertainty with respect to how water flows upstream of the study area would affect bank swallow habitat. As explained below, impacts on bank swallow under Alternative 9 would not be adverse for NEPA purposes and would be less than significant for CEQA purposes with the implementation of mitigation measures to monitor colonies and address the uncertainty of upstream operations on the species.

Table 12-9-53. Changes in Bank Swallow Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Breeding	0	0	0	0	NA	NA
Total Impacts CM1		**0**	**0**	**0**	**0**	**NA**	**NA**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-146: Indirect Effects of Implementation of Conservation Components on Bank Swallow

Noise and visual disturbances during restoration activities from *CM2 Yolo Bypass Fisheries Enhancement*, and *CM4 Tidal Natural Communities Restoration* including operation of earthmoving equipment and human activities at work sites, could result in temporary disturbances that cause bank swallow to abandon active nest burrows adjacent to construction areas. Bank swallow colonies with occupied burrows have been recorded in CZ 2 and CZ 5 and construction-related disturbances could result in an adverse effect on individuals. Various activities related to *CM11 Natural Communities Enhancement and Management* could also have indirect impacts on bank swallow.

NEPA Effects: Construction activities associated with habitat restoration could adversely affect bank swallow colonies in the absence of other measures. Noise and visual disturbances could result in adverse effects on bank swallows if active colonies were present within 500 feet of work areas. Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would be available to address this effect.

CEQA Conclusion: Construction activities associated with habitat restoration could result in a significant impact on bank swallow colonies in the absence of other measures. Noise and visual disturbances could result in significant impacts on bank swallows if active colonies were present within 500 feet of work areas. Implementation of Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized

To the extent practicable, BDCP proponents will not construct conservation components during the bank swallow nesting season (April 1 through August 31). If construction activities cannot be avoided during nesting season, a qualified biologist will conduct preconstruction surveys to determine if active bank swallow nesting colonies are present within 500 feet of work areas. If no active nesting colonies are present, no further mitigation is required.

If active colonies are detected, BDCP proponents will establish a nondisturbance buffer (determined in coordination with CDFW and the Bank Swallow Technical Advisory Committee) around the colony during the breeding season. In addition, a qualified biologist will monitor any active colony within 500 feet of construction to ensure that construction activities do not affect nest success.

Impact BIO-147: Effects of Upstream Reservoir and Water Conveyance Facilities Operations on Bank Swallow

Bank swallows are a riparian species that have evolved to deal with a dynamic system that changes with annual variation in variables such as rainfall, or late snowpack runoff. The primary threat to the species is loss of nesting habitat from the placement of rock revetment for levee stabilization. Because of this limited available habitat, and the reduction of natural river process, the species is highly sensitive to 1) reductions in winter flows which are necessary to erode banks for habitat creation, and 2) high flows during the breading season. The potential impacts of changes in upstream flows during the breeding season on bank swallows are the flooding of active burrows and destruction of burrows from increased bank sloughing. Bank swallows arrive in California and begin to excavate their burrows in March, and the peak egg-laying occurs during April and May (Bank Swallow Technical Advisory Committee 2013). Therefore, increases in flows after March when the swallows have nested and layed eggs in the burrows could result in the loss of nests. On the Sacramento River, breeding season flows between 14,000 and 30,000 cfs have been associated with localized bank collapses, which resulted in partial or complete colony failure (Stillwater Sciences 2007).

The CALSIM II modeling results of mean monthly flow were analyzed for three flow gauge stations on the Sacramento River (Sacramento River at Keswick, Sacramento River upstream of Red Bluff, Sacramento River at Verona) and two flow gauge stations on the Feather River (Feather River high-flow channel at Thermalito Dam, and Feather River at the confluence with the Sacramento River). Flows were estimated for wet years, above normal years, below normal years, dry years, and critical years. An average also was estimated (see Chapter 5, Section 5.3.1, *Methods for Analysis*, for a description of the model).

On the Sacramento River at the Keswick and Red Bluff gauges, mean monthly flows under Alternative 9 would increase between April and August in average water years (Table 1 in Section 11C.9.1.1 and Table 3 Section 11C.9.1.2 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*) which could lead to inundation of active colonies. However, the flows under Existing Conditions and the predicted flows in the late long-term without the project (NAA) show increases in flows during the breeding season (April through August) in these water year types. Similar trends are shown for the Feather River (Table 15 in Section 11C.9.1.8 and Table 17 in Section 11C.9.1.9 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*). In addition, at the Keswick flow gauge on the Sacramento River in above normal water years (Table 1 in Section 11C.9.1.1 of Appendix 11C, *CALSIM II Model Results Utilized in the Fish Analysis*) flows are predicted to be greater than 14,000 cfs during the breeding season, which could lead to bank collapse. However, flows of this height are recorded under Existing Conditions at this flow gauge and are also predicted for the late long-term without the project (NAA).

NEPA Effects: High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternative 9 would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of effects on bank swallow from changes in upstream operations. Soil type, high winter flows, and low spring flows all contribute to successful nesting of bank swallow, and even moderate changes in seasonal flows could have an adverse effect on breeding success for the species. Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would be available to address the uncertainty of potential adverse effects of upstream operations on bank swallow.

CEQA Conclusion: High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies the breeding season, and predicted flows under Alternative 9 would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. There are many variables that dictate suitable habitat for the species that cannot be clearly quantified, and seasonal changes in flow could increase or decrease suitable habitat for bank swallow depending on soil type and location of current colonies. Implementation of Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of* *the Study Area*, would address this potential significant impact and further determine if additional mitigation is required for bank swallow.

Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area

To address the uncertainty of the impact of upstream spring flows on existing bank swallow habitat, DWR will monitor existing colonies upstream of the study area and collect habitat suitability data including soil type, number of active burrows per colony, and height of average burrows. In addition, to determine the degree to which reduced winter flows are contributing to habitat loss, DWR will quantify the winter flows required for river meander to create suitable habitat through lateral channel migration and bank resurfacing. If impacts of upstream flows on bank swallow are identified, further mitigation may be required after consultation with CDFW and the Bank Swallow Technical Advisory Committee. Recommended mitigation for changes in flow regimes associated with water conveyance includes conservation easements on currently occupied habitat or revetment removal projects to create habitat for bank swallow (Bank Swallow Technical Advisory Committee 2013).

Yellow-Headed Blackbird

The habitat model used to assess impacts on yellow-headed blackbird consists of nesting habitat and foraging habitat. Modeled nesting habitat includes tidal freshwater emergent wetland, other natural seasonal wetland, nontidal freshwater perennial emergent wetland, and managed wetland. Modeled foraging habitat for yellow-headed blackbird consists of cultivated lands and noncultivated land cover types known to support abundant insect populations, including corn, pasture, and feedlots.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of yellow-headed blackbird modeled habitat as indicated in Table 12-9-54. Full implementation of Alternative 9 would include the following biological objectives over the term of the BDCP that would benefit yellow-headed blackbird (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Protect at least 8,000 acres of grassland, with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objective ASWNC1.1, Objective VPNC1.1, associated with CM3).

- Maintain and protect the small patches of important wildlife habitats that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).
- Protect at least 11,050 acres of high- to very high-value breeding-foraging habitat (Table 12-9-38) in CZs 1, 2, 3, 4, 7, 8, or 11 (Objective TRBL1.3, associated with CM3).
- Increase prey abundance and accessibility for grassland-foraging species (Objective GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance habitats for the species, and implementation of AMM1–AMM7, *AMM27 Selenium Management*, and Mitigation Measure BIO-75, impacts on yellow-headed blackbird would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-54. Changes in Yellow-Headed Blackbird Modeled Habitat Associated with Alternative 9

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Nesting	72	72	169	169	NA	NA
	Foraging	327	327	1,288	1,288	NA	NA
Total Impacts CM1		**399**	**399**	**1,457**	**1,457**	**NA**	**NA**
CM2–CM18	Nesting	5,814	13,902	45	46	961–2,678	18
	Foraging	5,612	26,673	376	905	368–1,476	2,701
Total Impacts CM2–CM18		**11,426**	**40,575**	**421**	**951**	**1,495-4,394**	**2,719**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-148: Loss of Habitat for and Direct Mortality of Yellow-Headed Blackbird

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 43,382 acres of suitable habitat for yellow-headed blackbird (14,189 acres of nesting habitat and 29,193 acres foraging habitat; Table 12-9-54). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), marsh restoration (CM10), and construction of conservation hatcheries (CM18). Habitat enhancement and management activities (CM11) which include ground disturbance or removal of nonnative vegetation could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate yellow-headed blackbird suitable habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Conveyance Facilities and Operation:* Construction of Alternative 9 water conveyance facilities would result in the combined permanent and temporary loss of up to 241 acres of yellow-headed blackbird nesting habitat (72 acres of permanent loss and 169 acres of temporary loss). In addition, 1,615 acres of foraging habitat would be removed (327 acres of permanent loss, 1,288 acres of temporary loss, Table 12-9-54). Impacts from CM1 would occur in the central delta in CZ 4, 5, 6, 7, and 8. Most of the loss of nesting habitat would occur at the channel dredging sites within the Middle River and Victoria Canal. Middle River dredging would occur from Victoria Canal north to Mildred Island, while Victoria Canal dredging would extend from Middle River westward to Old River. Smaller areas would be permanently lost at operable barrier sites adjacent to Middle River and San Joaquin River. impacts on foraging habitat would occur from the construction of the canals in CZ 8 east and south of Clifton Court Forebay and other conveyance structures in CZ 4, 5, 6, 7, and 8. Temporary impacts would primarily occur from borrow and spoil areas and temporary work areas. There are no occurrences of yellow-headed blackbird that overlap with the construction footprint for CM1. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds,* would be available to address potential effects on yellow-headed blackbirds if they were to nest in or adjacent to construction areas. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations. Impacts from CM1 would occur within the first 10 years of Alternative 9 implementation.

- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement (CM2) would result in the permanent removal of 29 acres of breeding habitat and 113 acres of nonbreeding habitat for yellow-headed blackbird. In addition, CM2 would result in the temporary loss of 43 acres of breeding habitat for the species. Impacts from CM2 would primarily occur in the near-term timeframe.

- *CM4 Tidal Natural Communities Restoration*: Site preparation and inundation from CM4 would permanently remove or convert an estimated 4,801 acres of breeding habitat. In addition, 3,282 acres of non-breeding habitat would be lost or converted as a result of tidal restoration. However, the resulting 65,000 acres of tidal natural communities would also provide habitat for the species, 24,000 acres of which would be tidal freshwater natural communities providing breeding habitat for yellow-headed blackbird.

- *CM5 Seasonally Inundated Floodplain Restoration/CM7: Riparian Natural Community Restoration:* Construction of setback levees to restore seasonally inundated floodplain and riparian restoration actions (CM5) would permanently and temporarily remove approximately 2,477 acres of suitable yellow-headed blackbird habitat consisting of 2 acres of breeding habitat and 2,475 acres of nonbreeding habitat.

- *CM8 Grassland Natural Community Restoration:* Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 230 acres of yellow-headed blackbird agricultural foraging habitat to grassland foraging habitat in CZs 1, 8, and/or 11. If agricultural lands supporting higher value foraging habitat than the restored grassland were removed, there would be a loss of yellow-headed blackbird foraging habitat value. CM8 would result in the restoration of 2,000 acres of grassland foraging habitat in the Plan Area.

- *CM10 Nontidal Marsh Restoration*: Restoration and creation of nontidal freshwater marsh would result in the permanent conversion of 133 acres of cultivated lands foraging habitat to nontidal marsh in CZ 2 and CZ 4. Yellow-headed blackbird nesting habitat may develop along the margins of restored nontidal marsh and restoration would also provide foraging habitat for the species.

- *CM11 Natural Communities Enhancement and Management:* Habitat management- and enhancement-related activities could disturb yellow-headed blackbird nests if they were present near work sites. A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of yellow-headed blackbird habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, would be expected to have minor effects on available yellow-headed blackbird habitat. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged yellow-headed blackbird if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment.

- If yellow-headed blackbird were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects on yellow-headed blackbird.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 6,100 acres (5,886 acres of permanent loss, 214 acres of temporary loss) of yellow-headed blackbird nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 241 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Seasonally Inundated Floodplain Restoration*—5,859 acres). In addition, 7,603 acres (5,939 acres of permanent loss, 1,664 acres of temporary loss) of yellow-headed blackbird foraging habitat would be removed or converted in the near-term (CM1, 1,615acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM18 Conservation Hatcheries*—5,988 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of nesting habitat, and 1:1 protection of foraging habitat. Using these ratios would indicate that 241 acres of nesting habitat should be restored/created and 241 acres should be protected to compensate for the CM1 losses of yellow-headed blackbird nesting habitat. In addition, 1,615 acres of foraging habitat should be protected to compensate for the CM1 losses of yellow-headed blackbird foraging habitat. The near-term effects of other conservation actions would require 5,859 acres each of restoration and protection of breeding habitat and 5,988 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting and 1: protection of foraging habitat).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland, protecting 4,800 acres of managed wetland, protecting 25 acres and restoring 900 acres of nontidal marsh, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM8, and CM10 and would occur in the same timeframe as the construction and early restoration losses.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 900 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3).

At least 15,600 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1), much of which would provide foraging habitat for yellow-headed blackbird. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on yellow-headed blackbird habitat, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

Late Long-Term Timeframe

The study area supports approximately 82,005 acres of modeled nesting habitat and 333,956 acres of modeled foraging habitat for yellow-headed blackbird. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 14,189 acres of potential nesting habitat (17% of the potential nesting habitat in the study area) and the loss or conversion of 29,193 acres of foraging habitat (9% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration*, *CM8 Grassland Natural Community Restoration,* and *CM10 Nontidal Marsh Restoration* to protect and enhance at least 8,100 acres of managed wetland, restore or create at least 24,000 acres of tidal freshwater emergent wetland, create or restore at least 1,200 acres of nontidal marsh, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*).

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations

(Objective MWNC1.1). In addition, at least 1,200 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3). Of the 48,625 acres of cultivated lands that would be protected and enhanced by the late long-term time period (Objective CLNC1.1), 26,300 acres would be managed in moderate to high-value crop types for tricolored blackbird (BDCP Chapter 3, Table 3.3-6). These crop types include pasture, sunflower, alfalfa, and other crop types that would provide high-value foraging habitat for yellow-headed blackbird.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

NEPA Effects: The loss of yellow-headed blackbird habitat and potential direct mortality of this special-status species associated with Alternative 9 would represent an adverse effect in the absence of other conservation actions. With habitat protection and restoration associated with CM3, CM4, CM8, CM10, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction phase, the effects of habitat loss would not be adverse under Alternative 9. The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. Alternative 9 would remove 6,100 acres (5,886 acres of permanent loss, 214 acres of temporary loss) of yellow-headed blackbird nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 241 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, and *CM5 Floodplain Restoration*—5,859 acres). In addition, 7,603 acres (5,939 acres of permanent loss, 1,664 acres of temporary loss) of yellow-headed blackbird foraging habitat would be removed or converted in the near-term (CM1, 1,615 acres; *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM18 Conservation Hatcheries*—,988,985 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of nesting habitat, and 1:1 protection of foraging habitat. Using these ratios would indicate that 241 acres of nesting habitat should be restored/created and 241 acres should be protected to compensate for the CM1 losses of yellow-headed blackbird nesting habitat. In addition, 1,615 acres of foraging habitat should be protected to compensate for the CM1 losses of yellow-headed blackbird foraging habitat. The near-term effects of other conservation actions would require 5,859 acres each of restoration and protection of breeding habitat and 5,988 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting and 1: protection of foraging habitat).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland, protecting 4,800 acres of managed wetland, protecting 25 acres and restoring 900 acres of nontidal marsh, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3, *Description of Alternatives*). These conservation actions are associated with CM3, CM4, CM8, and CM10 and would occur in the same timeframe as the construction and early restoration losses.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 900 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would

provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3).

At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1), much of which would provide foraging habitat for yellow-headed blackbird. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on yellow-headed blackbird habitat, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. The implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce potential impacts on nesting yellow-headed blackbird to a less-than-significant level.

Late Long-Term Timeframe

The study area supports approximately 82,005 acres of modeled nesting habitat and 333,956 acres of modeled foraging habitat for yellow-headed blackbird. Alternative 9 as a whole would result in the permanent loss of and temporary effects on 14,189 acres of potential nesting habitat (17% of the potential nesting habitat in the study area) and the loss or conversion of 29,193 acres of foraging habitat (9% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM8 Grassland Natural Community Restoration,* and *CM10 Nontidal Marsh Restoration* to protect and enhance at least 8,100 acres of managed wetland, restore or create at least 24,000 acres of tidal freshwater emergent wetland, create or restore at least 1,200 acres of nontidal marsh, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, *Description of Alternatives*).

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, *Conservation Strategy*) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 1,200 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3). Of the 48,625 acres of cultivated lands that would be protected and enhanced by the late long-term time period (Objective CLNC1.1), 26,300 acres would be managed in moderate to high-value crop types for tricolored blackbird (BDCP Chapter 3, Table 3.3-6). These crop types include pasture, sunflower, alfalfa, and other crop types that would provide high-value foraging habitat for yellow-headed blackbird.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan.* All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

Considering Alternative 9's protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts necessary to compensate for habitat lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on yellow-headed blackbird.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-149: Effects on Yellow-Headed Blackbird Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbirds. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on yellow-headed blackbirds. The existing network of transmission lines in the study area currently poses this risk for yellow-headed blackbirds, and any incremental risk associated with the new transmission line corridors would be expected to be low. *AMM20 Greater Sandhill Crane* would further minimize the risk for bird-power line strikes with the installation of flight diverters on new and selected existing transmission lines.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on yellow-headed blackbirds. The existing network of transmission lines in the study area currently poses this risk for yellow-headed blackbirds, and any incremental risk associated with the new transmission line corridors would not be expected to have an adverse effect on yellow-headed blackbirds. *AMM20 Greater Sandhill Crane* would further minimize the risk for bird-power line strikes.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on yellow-headed blackbirds. The existing network of transmission lines in the study area currently poses this risk for yellow-headed blackbirds, and any incremental risk associated with the new transmission line corridors would have a less-than-significant impact on yellow-headed blackbird. *AMM20 Greater Sandhill Crane* would further minimize the risk for bird-power line strikes.

Impact BIO-150: Indirect Effects of Plan Implementation on Yellow-Headed Blackbird

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-headed blackbird use of suitable habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect yellow-headed blackbird. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect the species in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to yellow-headed blackbird habitat could also have a negative effect on the species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including yellow-headed blackbird. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect yellow-headed blackbird, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on yellow-headed blackbird.

***NEPA Effects*:** Noise and visual disturbances from the construction of water conveyance facilities could reduce yellow-headed blackbird use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of yellow-headed blackbird to methylmercury, in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12, would address the uncertainty of methylmercury levels in restored tidal marsh in the study area and better inform potential impacts on yellow-headed blackbird. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for yellow-headed blackbird, once site specific sampling and other information could be developed.

***CEQA Conclusion*:** Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 9 would have a less-than-significant impact on yellow-headed blackbird with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of yellow-headed blackbird to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to this species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12, would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-151: Periodic Effects of Inundation of Yellow-Headed Blackbird Nesting Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass (CM2) would inundate 961–2,678 acres of nesting habitat and 368–2,678 acres of foraging habitat (Table 12-9-54). Based on hypothetical floodplain restoration, construction of setback levees for *CM5 Seasonally Inundated Floodplain Restoration* could result in periodic inundation of approximately 18 acres of nesting habitat and 2,701 acres of nonbreeding habitat (Table 12-9-54) resulting in the temporary loss of these habitats. Foraging yellow-headed blackbirds would be expected to move to adjacent suitable foraging habitat when the bypass is inundated, as they do under the current flooding regime. However, this inundation could reduce the availability of nesting habitat during years when flooding extends into the nesting season (past March). The periodic inundation of the Yolo Bypass (CM2) and of other floodplains (CM5) is expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support nesting habitat.

NEPA Effects: Implementation of CM2 and CM5 would result in periodic inundation of nesting and foraging habitat for yellow-headed blackbird. Periodic inundation would have a less-than-significant impact on yellow-headed blackbird because inundation is expected to take place outside of the breeding season, and although foraging habitat may be temporarily unavailable, birds would be expected to move to adjacent foraging habitat.

CEQA Conclusion: Implementation of CM2 and CM5 would result in periodic inundation of nesting and foraging habitat for yellow-headed blackbird. Periodic inundation would have a less-than-significant impact on yellow-headed blackbird because inundation is expected to take place outside of the breeding season, and although foraging habitat would be temporarily unavailable, birds would be expected to move to adjacent foraging habitat.

Riparian Brush Rabbit

The habitat model used to assess effects on the riparian brush rabbit consists of 38 vegetation associations within the valley/foothill riparian natural community and adjacent grasslands. The vegetation associations were selected based on a review of understory and overstory composition from Hickson and Keeler-Wolf (2007) and species habitat requirements.

Just until recently, the only known naturally occurring populations of riparian brush rabbits were confined to Caswell Memorial State Park (MSP), a 258-acre park supporting riparian oak woodland on the Stanislaus River immediately southeast of the study area, and in the south Delta southwest of Lathrop, which is within the study area (Williams and Basey 1986; Williams et al. 2002) (Figure 12-46). On October 11, 2012 a single female riparian brush rabbit was captured near Durham Ferry

Road in riparian habitat along the San Joaquin River between Caswell MSP and Lathrop (Bradbury pers. comm.). The is only the second naturally occurring population documented outside of Caswell MSP. Factors considered in assessing the value of adversely affected habitat for riparian brush rabbit, to the extent information was available, included size and degree of isolation of habitat patches, proximity to recorded species occurrences, and adjacency to conserved lands.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of riparian brush rabbit modeled habitat as indicated in Table 12-9-55. Full implementation of Alternative 9 would also include biological objectives over the term of the BDCP to benefit the riparian brush rabbit (BDCP Chapter 3, *Conservation Strategy*). The conservation strategy for the riparian brush rabbit, with conservation principles involves protecting, restoring or creating, and maintaining habitat and corridors near the largest remaining fragments of habitat and extant populations; providing high-water refugia from flooding; and managing feral predators (dogs and cats) in areas occupied by the species. The conservation measures that would be implemented to achieve the biological goals and objectives are summarized below.

- Provide a range of elevations in restored floodplains that transition from frequently flooded (e.g., every 1 to 2 years) to infrequently flooded (e.g., every 10 years or more) areas to provide a range of habitat conditions, upland habitat values, and refugia from flooding during most flood events (Objective L1.5, associated with CM3, CM5, and CM8).
- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Objective L1.6, associated with CM3).
- Allow floods to promote fluvial processes, such that bare mineral soils are available for natural recolonization of vegetation, desirable natural community vegetation is regenerated, and structural diversity is promoted, or implement management actions that mimic those natural disturbances (Objective L2.1, associated with CM3, CM5, and CM11).
- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3–CM8, and CM11).
- Restore or create 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM3 and CM7).
- Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Maintain 1,000 acres of early- to mid-successional vegetation with a well-developed understory of dense shrubs on restored seasonally inundated floodplain (Objective VFRNC2.2, associated with CM5, CM7, and CM11).
- Of the 750 acres of protected valley/foothill riparian natural community protected under Objective VFRNC1.2, protect at least 200 acres of suitable riparian brush rabbit habitat (defined in CM7 Riparian Natural Community Restoration) that is occupied by the species or contiguous with occupied habitat (Objective RBR1.1, associated with 3).
- Of the 1,000 acres of early- to midsuccessional riparian habitat maintained under VFRNC2.2, maintain at least 800 acres within the range of the riparian brush rabbit (CZ 7), in areas that are

adjacent to or that facilitate connectivity with occupied or potentially occupied habitat (Objective RBR1.2, associated with CM3, CM7, and CM11).

- Of the 5,000 acres of valley/foothill riparian natural community restored under Objective VFRNC1.1, restore/create and maintain at least 300 acres of early- to mid-successional riparian habitat that meets the ecological requirements of the riparian brush rabbit and that is within or adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat (Objective 1.3, associated with CM3, CM7, and CM11).
- Create and maintain high-water refugia in the 300 acres of restored riparian brush rabbit habitat and the 200 acres of protected riparian brush rabbit habitat, through the retention, construction and/or restoration of high-ground habitat on mounds, berms, or levees, so that refugia are no further apart than 66 feet (Objective RBR1.4, associated with CM7 and CM11).
- In protected riparian areas that are occupied by riparian brush rabbit, monitor for and control nonnative predators that are known to prey on riparian brush rabbit (Objective RBR1.5, associated with CM11).
- Of the 8,000 acres of grasslands protected under Objective GNC1.1 and the 2,000 acres of grasslands restored under Objective GNC1.2, protect or restore grasslands on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6m, associated with CM3 and CM8).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of the AMMs to reduce potential effects, impacts on riparian brush rabbit would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-152: Loss or Conversion of Habitat for and Direct Mortality of Riparian Brush Rabbit

- Alternative 9 conservation measures would result in the permanent loss of up to 111 acres of riparian habitat and 261 acres of associated grassland habitat for the riparian brush rabbit in the study area (Table 12-9-55). The hypothetical footprint for levee construction overlaps with one occurrence record for riparian brush rabbit, south of the Interstate 5/Interstate 205 interchange. Conservation measures resulting in permanent habitat loss include conveyance facilities construction (CM1), tidal natural communities restoration (CM4), and floodplain restoration (CM5). Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Development of Alternative 9 water conveyance facilities would result in the permanent removal of approximately 8 acres of riparian habitat and 58 acres of associated grassland habitat and in the temporary removal of 6 acres of riparian habitat and 139 acres of grassland habitat for riparian brush rabbit in CZ 8 (Table 12-9-55). The riparian habitat that would be removed is of low value for the riparian brush rabbit as is consists of several small, isolated patches surrounded by agricultural lands northeast of Clifton Court Forebay. The associated grasslands are also of low-quality for the species: They consist of long, linear strips that abut riparian habitat, but extend several miles from the riparian habitat and, therefore, provide few if any opportunities for adjacent cover. Trapping efforts conducted for the riparian brush rabbit in this area were negative (BDCP Appendix 3.E, *Conservation Principles* *for the Riparian Brush Rabbit and Riparian Woodrat*). Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove approximately 19 acres of riparian habitat and 18 acres of associated grassland habitat for the riparian brush rabbit in CZ 7 in the late long-term. The riparian habitat that would be removed consists of relatively small and isolated patches along canals and irrigation ditches surrounded by agricultural lands in the Union Island and Roberts Island areas, and several small patches along the San Joaquin River. The habitat that would be removed is not adjacent to any existing conserved lands, and is several miles north and northeast of the northernmost riparian brush rabbit record located northeast of Paradise Cut (Williams et al. 2002). Although the final footprint for tidal natural communities restoration would differ from the hypothetical footprint, compliance monitoring would be implemented to ensure that acreage limits are not exceeded, and the measures described in *AMM25 Riparian Woodrat and Riparian Brush Rabbit* require that tidal natural communities restoration avoid removal of any habitat occupied by the riparian brush rabbit.

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration would result in the permanent removal of approximately 43 acres of riparian habitat and 26 acres of associated grassland habitat for the riparian brush rabbit in CZ 7 in the late long-term. Levee construction would also result in the temporary removal of 35 acre riparian habitat and 20 acres of grassland habitat for the riparian brush rabbit. Although the effects are considered temporary, 5 years to several decades may be required for ecological succession to occur and for restored riparian habitat to replace the function of habitat that has been affected.

  The value of this habitat for riparian brush rabbit is high: although it consists of small patches and narrow bands of riparian vegetation, these areas are in proximity to, or contiguous with, habitat with recorded occurrences of riparian brush rabbit. The hypothetical footprint for levee construction overlaps with one occurrence record for riparian brush rabbit, south of the Interstate 5/Interstate 205 interchange.

  Although the final floodplain restoration design would differ from the hypothetical footprint used for this effects analysis, restoration of the river floodplain in CZ 7 would be targeted in the general area of the riparian brush rabbit population. Implementation of adaptive management described in *AMM25* would ensure that riparian brush rabbit habitat permanently removed as a result of floodplain restoration does not exceed the maximum allowable habitat loss for this species.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP protected habitats may result in localized ground disturbances that could temporarily remove small amounts of riparian brush rabbit habitat. Enhancement and management actions in riparian brush rabbit habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities are expected to have minor adverse effects on available riparian brush rabbit habitat and are expected to result in overall improvements to and maintenance of riparian brush rabbit habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below.

Passive recreation in the reserve system could result in disturbance of individual riparian brush rabbits foraging in the ecotone between riparian and adjacent open habitats. However, *AMM37 Recreation* limits trail development adjacent to riparian corridors within the range of the riparian brush rabbit. With this minimization measure in place, recreation-related effects on the riparian brush rabbit are expected to be minimal.

- Operations and maintenance: Ongoing maintenance of BDCP facilities are not expected to adversely affect the riparian brush rabbit because the species is not expected to occur in the vicinity of proposed facilities.
- Injury and direct mortality: Water conveyance facility construction is not is not likely to result in injury or mortality of individual riparian brush rabbit because the species is not likely to be present in the areas that would be affected by this activity, based on live trapping results (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Tidal natural communities restoration would not result in injury or mortality of the riparian brush rabbit because tidal natural communities restoration projects would be designed to avoid occupied riparian brush rabbit habitat and, if that is not possible, rabbits would be trapped and relocated as described in AMM25 (see BDCP Appendix 3.C). Activities associated with construction of setback levees for floodplain restoration could result in injury or mortality of riparian brush rabbits: however, preconstruction surveys, construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during construction (AMM25).

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA.

Alternative 9 would result in permanent and temporary effects combined on 14 acres of riparian habitat and 197 acres of grassland habitat for riparian brush rabbit in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian and grassland natural communities. Most of the near-term loss of riparian brush rabbit habitat would be in an area the species is unlikely to occupy in CZ 8. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term timeframes. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical NEPA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for riparian brush rabbit in Chapter 3 of the BDCP would be 1:1 for restoration and protection of the valley/foothill riparian natural community, and 2:1 for protection of grassland. Using these ratios would indicate that 14 acres of riparian habitat should be restored, 14 acres of riparian habitat should protected, and 394 acres of grassland should be protected for riparian brush rabbit to mitigate near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian(Objective VFRNC1.1and an unknown number of associated acres of grassland and protection of 750 acres of riparian (Objective VFRNC1.2)with an unknown number of associated acres of grassland (Table 3-4 in Chapter 3, *Description of Alternatives*). In addition, the species-specific biological goals and objectives (RBR1.1-RBR1.6) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be not be adverse under NEPA, because the number of acres required to meet the typical ratios described above would be 14 acres of riparian habitat restored, 14 acres protected, and 394 acres of grassland protected.

The plan also contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM25 RiparianWoodrat and Riparian Brush Rabbit, and AMM37 Recreation*. These AMMs contain elements that avoid or minimize the risk of BDCP activities affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Late Long-Term Timeframe

There are 6,012 acres of modeled riparian brush rabbit habitat in the Plan Area, consisting of 2,909 acres of riparian habitat and 3,103 acres of associated grassland habitat. Alternative 9 a whole would result in permanent and temporary effects combined on 111 acres of modeled riparian habitat and 261 acres of modeled grassland habitat for riparian brush rabbit, representing 4% and 8% of the riparian and grassland modeled habitat. The BDCP would restore 5,000 acres and protect 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RBR1.2 requires that at least 800 acres of early- to midsuccessional riparian natural community be conserved in CZ 7, in areas that are adjacent to or that facilitate connectivity with existing occupied or potentially occupied habitat. This would consist of 200 acres of protected habitat (Objective RBR1.1) and 600 acres of restored habitat. The 800 acres to be conserved would consist of early successional riparian vegetation suitable for riparian brush rabbit. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian brush rabbit habitat. The species-specific objectives further require that the 200 acres of protected riparian habitat (Objective RBR1.4) and at least 300 acres of the restored riparian habitat (Objective RBR1.3) meet more specific ecological requirements of riparian brush rabbit, including large patches of dense riparian brush; ecotonal edges that transition from brush species to grasses and forbs, scaffolding plants to support vines that grow above flood levels; a tree canopy that is open, if present; and high-ground refugia from flooding. In protected riparian areas that are occupied by riparian brush rabbit, nonnative predators that are known to prey on riparian brush rabbit would be monitored and controlled (Objective RBR1.5).

In addition to restoration and protection of riparian habitat for the riparian brush rabbit, the BDCP would protect, and, if necessary, create or restore grasslands adjacent to suitable riparian vegetation in areas outside the floodplain levees (Objective RBR1.6). These grasslands are expected to provide additional foraging opportunities for the riparian brush rabbit and upland refugia during flood events. The actual acreage of grassland to be restored or protected for riparian brush rabbit would depend on site-specific needs adjacent to restored and protected riparian habitat (CM3). Grasslands on the landward side of levees adjacent to restored floodplain would be restored or protected as needed to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6).

In addition to grasslands protected and restored outside the levees for riparian brush rabbit as needed, the floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian brush rabbit during most years. The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RBR1.4) that are designed specifically to provide flood refugia for the riparian brush rabbit (BDCP Appendix 3.F, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Additionally, nonnative predators that are known to prey on riparian brush rabbit (e.g., feral dogs and cats) would be monitored in protected and restored riparian areas that are occupied by riparian brush rabbit (Objective RBR1.5), and controlled as needed (CM11).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian and grassland that could overlap with the species model, would result in the restoration of 800 acres of riparian and 79 acres of grassland modeled habitat for riparian brush rabbit. In addition, protection of valley/foothill riparian and grassland could overlap with the species model and would result in the protection of 200 acres of riparian and 317 acres of grassland riparian brush rabbit modeled habitat.

NEPA Effects: In the near-term, the loss of riparian brush rabbit habitat under Alternative 9 would not be adverse because there is little likelihood of riparian brush rabbits being present and the BDCP has committed to protecting and restoring the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of riparian brush rabbit riparian and grassland habitat associated with Alternative 9, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, AMM10, AMM25, and AMM37, the effects of Alternative 9 as a whole on riparian brush rabbit would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA.

Alternative 9 would result in permanent and temporary effects combined on 14 acres of riparian habitat and 197 acres of grassland habitat for riparian brush rabbit in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian and grassland natural communities. Most of the near-term loss of riparian brush rabbit habitat would be in an area unlikely to be occupied by the species in CZ 8. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term timeframes. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses resulting from CM2–CM18.

Typical CEQA project-level mitigation ratios for those natural communities that would be affected and that are identified in the biological goals and objectives for riparian brush rabbit in Chapter 3 of the BDCP would be 1:1 for restoration and protection of the valley/foothill riparian natural community, and 2:1 for protection of grassland. Using these ratios would indicate that 14 acres of riparian habitat should be restored, 14 acres of riparian habitat should protected, and 394 acres of grassland should be protected for riparian brush rabbit to mitigate CM1 losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1and an unknown number of associated acres of grassland and protection of 750 acres of riparian (Objective VFRNC1.2) with an unknown number of associated acres of grassland (Table 3-4 in Chapter 3, *Description of Alternatives*). In addition, the species-specific biological goals and objectives (RBR1.1-RBR1.6) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA, because the number of acres required to meet the typical ratios described above would be 14 acres or riparian habitat protected, 14 acres of riparian habitat restored, and 394 acres of grassland habitat protected.

The plan also contains commitments to implement AMM1–AMM7, AMM10, AMM25, and AMM37. These AMMs contain elements that avoid or minimize the risk of BDCP activities affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Late Long-Term Timeframe

There are 6,012 acres of modeled riparian brush rabbit habitat in the Plan Area, consisting of 2,909 acres of riparian habitat and 3,103 acres of associated grassland habitat. Alternative 9 would result in permanent and temporary effects combined on 111 acres of modeled riparian habitat and 261 acres of modeled grassland habitat for riparian brush rabbit, representing 4% and 8% of the riparian and grassland modeled habitat.

The BDCP would restore 5,000 acres and protect 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RBR1.2 requires that at least 800 acres of early- to midsuccessional riparian natural community be conserved in CZ 7, in areas that are adjacent to or that facilitate connectivity with existing occupied or potentially occupied habitat. This would consist of 200 acres of protected habitat (Objective RBR1.1) and 600 acres of restored habitat. The 800 acres to be conserved would consist of early successional riparian vegetation suitable for riparian brush rabbit. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in

CZ 7 and would be contiguous with existing modeled riparian brush rabbit habitat. The species-specific objectives further require that the 200 acres of protected riparian habitat (Objective RBR1.4) and at least 300 acres of the restored riparian habitat (Objective RBR1.3) meet more specific ecological requirements of riparian brush rabbit, including large patches of dense riparian brush; ecotonal edges that transition from brush species to grasses and forbs, scaffolding plants to support vines that grow above flood levels; a tree canopy that is open, if present; and high-ground refugia from flooding. In protected riparian areas that are occupied by riparian brush rabbit, nonnative predators that are known to prey on riparian brush rabbit would be monitored and controlled (Objective RBR1.5).

In addition to restoration and protection of riparian habitat for the riparian brush rabbit, the BDCP would protect, and, if necessary, create or restore grasslands adjacent to suitable riparian vegetation in areas outside the floodplain levees (Objective RBR1.6). These grasslands are expected to provide additional foraging opportunities for the riparian brush rabbit and upland refugia during flood events. The actual acreage of grassland to be restored or protected for riparian brush rabbit would depend on site-specific needs adjacent to restored and protected riparian habitat (CM3). Grasslands on the landward side of levees adjacent to restored floodplain would be restored or protected as needed to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6).

In addition to grasslands protected and restored outside the levees for riparian brush rabbit as needed, the floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian brush rabbit during most years. The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RBR1.4) that are designed specifically to provide flood refugia for the riparian brush rabbit (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Additionally, nonnative predators that are known to prey on riparian brush rabbit (e.g., feral dogs and cats) would be monitored in protected and restored riparian areas that are occupied by riparian brush rabbit (Objective RBR1.5), and controlled as needed (CM11).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian and grassland that could overlap with the species model, would result in the restoration of 800 acres of riparian and 79 acres of grassland modeled habitat for riparian brush rabbit. In addition, protection of valley/foothill riparian and grassland could overlap with the species model and would result in the protection of 200 acres of riparian and 317 acres of grassland riparian brush rabbit modeled habitat.

Only a small proportion of the lost habitat would be considered occupied and of high-value. Alternative 9 conservation measures provide for large acreages of riparian brush rabbit riparian and grassland habitat to be protected and restored, and the BDCP includes AMM1–AMM7, AMM10, AMM25, and AMM37, which are directed at minimizing or avoiding potential effects during construction and operation of the conservation measures. Overall, the BDCP would provide a substantial net benefit to the riparian brush rabbit through the increase in available habitat and habitat in protected status. These protected areas would be managed to support the species.

Considering the habitat restoration and protection associated with CM3, CM7, CM8 and CM11, guided by species-specific goals and objectives and by AMM1–AMM7, AMM10, AMM25, and AMM37, the temporary and permanent losses of riparian and grassland habitat and potential direct mortality of riparian brush rabbit as a result of implementing Alternative 9 would not represent a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. The loss of habitat and potential mortality of riparian brush rabbits would be a less-than-significant impact under CEQA.

Impact BIO-153: Indirect Effects of Plan Implementation on Riparian Brush Rabbit

Noise and visual disturbance adjacent to construction activities could indirectly affect the use of modeled riparian brush rabbit riparian habitat and of associated grassland habitat in the study area. These construction activities would include water conveyance (including transmission line) construction in CZ 8, tidal natural communities restoration construction, and construction of setback levees. Water conveyance construction would potentially affect acres of adjacent riparian habitat and of associated grassland habitat: this construction would occur in CZ 8 where there is suitable habitat for the species but surveys by ESRP did not indicate the species is present in this area;; therefore, the potential for adverse noise and visual effects from conveyance facility construction would be minimal. Tidal natural communities restoration construction would also potentially affect adjacent riparian habitat and associated grassland habitat for this species: however, adverse effects on the species are unlikely because tidal natural communities restoration projects would be sited to avoid areas occupied by riparian brush rabbit. The activity most likely to result in noise and visual disturbance to riparian brush rabbit is the construction of setback levees for floodplain restoration, which would take place in CZ 7, where the species is known to occur. The use of mechanical equipment during construction might cause the accidental release of petroleum or other contaminants that would affect the riparian brush rabbit in adjacent habitat, if the species is present.

NEPA Effects**:** Implementation of AMM1–AMM7, AMM10, AMM25, and AMM37 as part of implementing BDCP Alternative 9 would avoid the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications or result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Therefore, indirect effects of Alternative 9 would not have an adverse effect on riparian brush rabbit.

CEQA Conclusion**:** Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could affect riparian brush rabbit in riparian and grassland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could affect riparian brush rabbit. The inadvertent discharge of sediment or excessive dust adjacent to riparian brush rabbit habitat could also have a negative effect on the species. With implementation of AMM1–AMM7, AMM10, AMM25, and AMM37 as part of Alternative 9, the BDCP would avoid the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Indirect effects of Alternative 9 would have a less-than-significant impact on riparian brush rabbit.

Impact BIO-154: Periodic Effects of Inundation of Riparian Brush Rabbit Habitat as a Result of Implementation of Conservation Components

CM5 Seasonally Inundated Floodplain Restoration is the only covered activity expected to result in periodic inundation of riparian brush rabbit habitat. This activity would periodically inundate approximately 264 acres of riparian habitat (9% of riparian habitat in the Plan Area) and 423 acres of associated grassland habitat (14% of associated grassland habitat in the Plan Area) for the riparian brush rabbit. The area between existing levees that would be breached and the newly constructed setback levees would be inundated through seasonal flooding. The potentially inundated areas consist of high-value habitat for the species: although they consist of small patches and narrow bands of riparian vegetation, many of these areas are in proximity to, or contiguous with, habitat with recorded occurrences of riparian brush rabbit. The restored floodplain would include a range of elevations from lower lying areas that flood frequently (e.g., every 1 to 2 years) to higher elevation areas that flood infrequently (e.g., every 10 years or more).

Seasonal flooding in restored floodplains can result in injury or mortality of individuals if riparian brush rabbits occupy these areas and cannot escape flood waters. One recorded occurrence of riparian brush rabbit (Williams et al. 2002), just west of Stewart Road in Mossdale, is in the area that would be seasonally flooded based on the hypothetical restoration footprint.

NEPA Effects: Floodplain restoration under CM5 would periodically affect only a small proportion of the modeled riparian brush rabbit habitat in the study area. The adverse effects of periodic inundation on the riparian brush rabbit would be minimized through construction and maintenance of flood refugia to allow riparian brush rabbits to escape inundation. Therefore, implementing Alternative 9, including AMM1–AMM7, AMM10, AMM25, and AMM37, would not be expected to result in substantial adverse effects on riparian brush rabbit, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Therefore, Alternative 9 would not adversely affect the species.

CEQA Conclusion: Floodplain restoration under CM5 would periodically affect only a small proportion of the modeled riparian brush rabbit habitat in the study area. The overall effect of seasonal inundation on existing riparian natural communities may instead be beneficial. Historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants. In the late long-term, seasonal inundation in areas currently occupied by riparian vegetation may contribute to the establishment of high-value habitat for covered riparian species, such as the riparian brush rabbit. Long-term management of riparian areas would ensure that refugia also exist along the edges of seasonally inundated habitat.

The adverse effects of periodic inundation on the riparian brush rabbit would be minimized through construction and maintenance of flood refugia to allow riparian brush rabbits to escape inundation. Therefore, implementing Alternative 9, including AMM1–AMM7, AMM10, AMM25, and AMM37, would not be expected to result in substantial adverse effects on riparian brush rabbit, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Periodic inundation of riparian and grassland habitat for riparian brush rabbit under Alternative 9 would have a less-than-significant impact on the species.

Riparian Woodrat

The habitat model used to assess effects for the riparian woodrat consists of selected plant alliances from the valley/foothill riparian natural community, geographically constrained to the south Delta portion of the BDCP area in CZ 7, south of State Route 4 and Old River Pipeline along the Stanislaus, San Joaquin, Old, and Middle Rivers. Valley/foothill riparian areas along smaller drainages (Paradise Cut, Tom Paine Slough), and some larger streams in the northern portion of CZ 7 were excluded from the riparian woodrat habitat model due to a lack of trees or riparian corridors that were too narrow. Factors considered in assessing the value of affected habitat for the riparian woodrat, to the extent that information is available, include habitat patch size and connectivity.

The riparian woodrat is not known to occur in the study area. The only verified extant population of riparian woodrats rangewide is 2 miles east of the southern end of the study area in Caswell Memorial State Park along the Stanislaus River (Williams 1986:1–112; 1993). Riparian woodrat may occur in small patches of valley oak riparian forest along the San Joaquin River from the southern tip of the study area north to approximately the Interstate 5 overcrossing near Lathrop (Figure 12-47). Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of riparian woodrat modeled habitat as indicated in Table 12-9-56. Tidal habitat restoration, floodplain restoration, and protection and management of natural communities could affect modeled riparian woodrat habitat. However, because the species is not known to occur in the study area it is not expected to be affected by BDCP actions unless the species were to establish in the study area over the term of the BDCP. Full implementation of Alternative 9 would also include biological objectives over the term of the BDCP to benefit the riparian woodrat (BDCP Chapter 3, *Conservation Strategy*). The conservation strategy for the riparian woodrat involves providing opportunities for population expansion into the Plan Area from adjacent lands to the south and southeast. The strategy focuses on restoring and maintaining suitable habitat at the southernmost end of CZ 7, providing connectivity with existing populations to the south and southeast, and creating and maintaining flood refugia. This conservation approach is consistent with the recovery plan (U.S. Fish and Wildlife Service 1998) and conservation principles (BDCP Appendix 3.E). The conservation measures that would be implemented to achieve the biological goals and objectives are summarized below.

- **P**rovide a range of elevations in restored floodplains that transition from frequently flooded (e.g., every 1 to 2 years) to infrequently flooded (e.g., every 10 years or more) areas to provide a range of habitat conditions, upland habitat values, and refugia from flooding during most flood events (Objective L1.5, associated with CM3, CM5, and CM8).
- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Objective L1.6, associated with CM3).
- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3-CM8, and CM11).
- Restore or create 5,000 acres of valley/foothill riparian natural community, with 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM3 and CM7).
- Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Restore, maintain and enhance structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1, associated with CM5, CM7, and CM11).
- Of the 5,000 acres of valley/foothill riparian natural community restored under Objective VFRNC1.1, restore/create and maintain 300 acres riparian habitat in CZ 7 that meets the ecological requirements of the riparian woodrat (i.e., dense willow understory and oak

overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat (Objective RW1.1, associated with CM3, CM7, CM11).

- Provide and maintain high-water refugia in the 300 acres of riparian woodrat habitat restored under Objective RW1.1 through the retention, construction, and/or restoration of high-ground habitat on mounds, berms, or levees, so that refugia are no further apart than 67 feet (Objective RW1.2, associated with CM7 and CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of the AMMs to reduce potential effects, impacts on riparian woodrat would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-56. Changes in Riparian Woodrat Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Riparian	2	2	1	1	NA	NA
Total Impacts CM1		**2**	**2**	**1**	**1**	**NA**	**NA**
CM2–CM18	Riparian	0	51	0	33	0	203
Total Impacts CM2–CM18		**0**	**51**	**0**	**33**	**0**	**203**
TOTAL IMPACTS		**2**	**53**	**1**	**34**	**0**	**203**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-155: Loss or Conversion of Habitat for and Direct Mortality of Riparian Woodrat

Alternative 9 conservation measures would result in the permanent loss of up to 53 acres of habitat and temporary loss of up to 34 acres of habitat for riparian woodrat (Table 12-9-56). Construction of Alternative 9 water conveyance facilities (CM1) would not affect modeled habitat; however, tidal natural communities restoration (CM4) and seasonally inundated floodplain restoration (CM5) would remove habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Development of Alternative 9 water conveyance facilities would result in the permanent and temporary removal of approximately 3 acres of modeled habitat for riparian woodrat in CZ 8 (Table 12-9-56). The modeled habitat that would be removed is of low value for the riparian woodrat as it consists of several small, isolated patches surrounded by agricultural lands northeast of Clifton Court Forebay in CZ 8. Trapping efforts conducted for the riparian woodrat in this area were negative (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 9 construction locations.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would permanently remove approximately 10 acres of modeled habitat for the riparian woodrat in CZ 7. This habitat is of low value, consisting of a small, isolated patch surrounded by agricultural lands, and the species has a relatively low likelihood of being present in these areas. The measures described in *AMM25 Riparian Woodrat and Riparian Brush Rabbit*, require that tidal natural communities restoration avoid removal of any habitat occupied by the riparian woodrat as determined by presence/absence surveys. Because the estimates of habitat loss due to tidal inundation are based on projections of where restoration may occur, actual habitat loss is expected to be lower because sites would be selected to minimize effects on riparian woodrat.

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration would result in the permanent removal of approximately 41 acres of modeled habitat for the riparian woodrat in CZ 7. The value of this habitat for riparian woodrat is moderate. Although the habitat consists of small patches and narrow bands of riparian vegetation and no riparian woodrats have detected in CZ 7, the riparian patches are in proximity to each other along the San Joaquin River. There are two species occurrences immediately south of CZ 7, one of which is less than 1.5 mile from the southernmost patch of riparian habitat potentially affected by levee construction.

  The final floodplain restoration design would differ from the hypothetical footprint used for this effects analysis. However, monitoring and adaptive management described in *CM11 Natural Communities Enhancement and Management a*nd AMM25 *Riparian Woodrat and Riparian Brush Rabbit* would ensure that riparian woodrat habitat permanently removed as a result of floodplain restoration does not exceed the amount estimated based on the hypothetical footprint. Habitat loss is expected to be lower than 41 acres because sites would be selected and restoration designed to minimize effects on the riparian woodrat. If natural flooding is insufficient to maintain appropriate riparian woodrat vegetation structure, the vegetation would be actively managed to provide suitable habitat structure as described in *CM11 Natural Communities Enhancement and Management.*

  Levee construction would also result in the temporary removal of 33 acres of modeled habitat for the riparian woodrat. Although the effects are considered temporary, 5 years to several decades may be required for ecological succession to occur and for restored riparian habitat to replace the function of habitat that has been affected.

- *CM11 Natural Communities Enhancement and Management*: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP protected habitats may result in localized ground disturbances that could temporarily remove small amounts of riparian woodrat habitat. Enhancement and management actions in riparian woodrat habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities are expected to have minor adverse effects on available riparian woodrat habitat and are expected to result in overall improvements to and maintenance of riparian woodrat habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below.

- Operations and maintenance: The only ongoing effects on the riparian woodrat are those potentially resulting from habitat enhancement and management activities. Enhancement and management actions in riparian woodrat habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities may result in harassment of riparian woodrats through noise and visual disturbance which would be minimized with implementation of AMM1–AMM7, AMM10, and AMM25.
- Injury and direct mortality: Construction vehicle activity is not likely to result in injury or mortality of individual riparian woodrats because the species is not likely to be present in the areas that would be affected by this activity, based on live trapping results (BDCP Appendix 3.E, *Conservation Principles for the Riparian Woodrat and Riparian Brush Rabbit*). Tidal natural communities restoration would not result in injury or mortality of the riparian woodrats because under AMM25 tidal natural communities restoration projects would be designed to avoid occupied riparian woodrat habitat and if that is not possible to trap and relocate the species. Activities associated with construction of setback levees for floodplain restoration could result in injury or mortality of riparian woodrats; however, preconstruction surveys, construction monitoring, and other measures would be implemented under AMM25 to avoid and minimize injury or mortality of this species during construction, as described in BDCP Appendix 3.C. If occupied riparian woodrat habitat cannot be avoided, mortality would be avoided through implementation of a trapping and relocation program. The program would be developed in coordination with USFWS, and relocation would be to a site approved by USFWS prior to construction activities.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA.

Alternative 9 would result in permanent and temporary effects on 3 acres of modeled habitat for riparian woodrat in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian. All the near-term loss of riparian woodrat habitat would result from CM1 conveyance facility construction in CZ 8, and would occur in an area not likely to be occupied by the species. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term implementation periods. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical NEPA project-level mitigation ratios for these natural communities that would be affected and that are identified in the biological goals and objectives for riparian woodrat in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of the valley/foothill riparian natural community. Using these ratios would indicate that 3 acres of riparian habitat should be restored and 3 acres of riparian habitat should be protected for riparian woodrat for near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian(Objective VFRNC1.1) and protection of 750 acres of riparian (Objective VFRNC1.2) (Table 3-4 in Chapter 3, *Description of Alternatives*). In addition, the species-specific biological goals and objectives (RW1.1 and RW1.2)would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be not be adverse under NEPA, because no riparian woodrat habitat would be lost and there is only limited potential for minor adverse effects on woodrats or its habitat from implementation of CM11.

These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the BDCP's commitment to *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, *AMM10 Restoration of Temporarily Affected Natural Communities*, and *AMM25 Riparian Woodrat and Riparian Brush Rabbit*. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Late Long-Term Timeframe

The study area supports approximately 2,166 acres of modeled riparian woodrat habitat. Alternative 9 as a whole would result in the permanent loss of and temporary removal of 87 acres of modeled habitat for riparian woodrat habitat. None of this habitat is considered occupied.

The BDCP would restore 5,000 acres and protect 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RW1.1 requires at least 300 acres of riparian habitat that meets the ecological requirements of the riparian woodrat (e.g., dense willow understory and oak overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat to be restored in CZ 7. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian woodrat habitat. The species-specific objective further requires that the 300 acres of restored riparian habitat meet more specific ecological requirements of riparian woodrat (e.g., dense willow understory and oak overstory). Additionally, assuming the protected riparian natural community would provide riparian woodrat habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (12% of the riparian natural community in the Plan Area is modeled riparian woodrat habitat), the protection of 750 acres of riparian natural community (CM3) would provide an estimated 90 acres of protected riparian woodrat habitat that is comparable to or of higher value than existing modeled grassland habitat. All riparian protection would occur during the near-term period, to offset early riparian losses.

The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RW1.2) that are designed specifically to provide flood refugia for the riparian woodrat (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). In addition, the restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian woodrat during most years.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian that could overlap with the species model, would result in the restoration of 300 acres of modeled habitat for riparian woodrat. In addition, protection of valley/foothill riparian could overlap with the species model and would result in the protection of 90 acres riparian woodrat modeled habitat.

Although there are no records of occurrences of the riparian woodrat in the study area, habitat restoration in CZ 7, in the vicinity of occurrences south of the study area, would increase opportunities for northward expansion of the species into the study area Implementation of Alternative 9 conservation measures is not expected to adversely affect the riparian woodrat for the following reasons.

- There are no riparian woodrat occurrences in the Plan Area.
- The habitat that would be removed consists of small patches that are of moderate value for the species.
- The habitat that would be removed permanently is a small proportion of the total habitat in the Plan Area (2%).
- Avoidance and minimization measures would be implemented to avoid injury or mortality of riparian woodrats, and to minimize loss of occupied habitat.
- Floodplain restoration would be designed to provide flood refugia so that flooding would not adversely affect any riparian woodrats that occupy restored floodplains.

NEPA Effects: Alternative 9 would provide a substantial benefit to the riparian woodrat through the net increase in available habitat and a net increase of habitat in protected status. These protected areas would be managed and monitored to support the species. The habitat that Alternative 9 would affect is currently unoccupied, and habitat removal is not expected to result in a discernible change in the abundance or distribution of riparian woodrats if they occupy study area habitats. Should the species be detected in the study area, implementation of AMM1–AMM7, AMM10, and AMM25 would avoid and minimize the effects of conservation component construction and implementation. Therefore, the loss of habitat and potential mortality of individuals would not have an adverse effect on riparian woodrat.

CEQA Conclusion:

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction impacts would be less than significant for CEQA purposes.

Alternative 9 would result in permanent and temporary effects on 3 acres of modeled habitat for riparian woodrat in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian. All the near-term loss of riparian woodrat habitat would result from CM1 conveyance facility construction in CZ 8, and would occur in an area not likely to be occupied by the species. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term implementation periods. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical CEQA project-level mitigation ratios for these natural communities that would be affected and that are identified in the biological goals and objectives for riparian woodrat in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of the valley/foothill riparian natural community. Using these ratios would indicate that 3 acres of riparian habitat should be restored and 3 acres of riparian habitat should be protected for riparian woodrat for near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1) and protection of 750 acres of riparian (Objective VFRNC1.2) (Table 3-4 in Chapter 3, *Description of Alternatives*). In addition, the species-specific biological goals and objectives (RW1.1 and RW1.2)would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. The Plan also contains commitments to implement AMM1–AMM7, AMM10, and AMM25, which contain elements that avoid or minimize the risk of affected habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA, because no riparian woodrat habitat would be lost and there is only limited potential for minor adverse effects on woodrats or its habitat from implementation of CM11.

Late Long-Term Timeframe

The study area supports approximately 2,166 acres of modeled riparian woodrat habitat. Alternative 9 as a whole would result in the permanent loss of and temporary removal of 87 acres of modeled habitat for riparian woodrat habitat. None of this habitat is considered occupied.

The BDCP would restore 5,000 acres and protect 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RW1.1 requires at least 300 acres of riparian habitat that meets the ecological requirements of the riparian woodrat (e.g., dense willow understory and oak overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat to be restored in CZ 7. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian woodrat habitat. The species-specific objective further requires that the 300 acres of restored riparian habitat meet more specific ecological requirements of riparian woodrat (e.g., dense willow understory and oak overstory). Additionally, assuming the protected riparian natural community would provide riparian woodrat habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (12% of the riparian natural community in the Plan Area is modeled riparian woodrat habitat), the protection of 750 acres of riparian natural community (CM3) would provide an estimated 90 acres of protected riparian woodrat habitat that is comparable to or of higher value than existing modeled grassland habitat. All riparian protection would occur during the near-term period, to offset early riparian losses.

The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RW1.2) that are designed specifically to provide flood refugia for the riparian woodrat (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). In addition, the restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian woodrat during most years.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian that could overlap with the species model, would result in the restoration of 300 acres of modeled habitat for riparian woodrat. In addition, protection of valley/foothill riparian could overlap with the species model and would result in the protection of 90 acres riparian woodrat modeled habitat.

Although there are no records of occurrences of the riparian woodrat in the study area, habitat restoration in CZ 7, in the vicinity of occurrences south of the study area, would increase opportunities for northward expansion of the species into the study area Implementation of Alternative 9 conservation measures is not expected to adversely affect the riparian woodrat for the following reasons.

- There are no riparian woodrat occurrences in the Plan Area.
- The habitat that would be removed consists of small patches that are of moderate value for the species.
- The habitat that would be removed permanently is a small proportion of the total habitat in the Plan Area (2%).
- Avoidance and minimization measures would be implemented to avoid injury or mortality of riparian woodrats, and to minimize loss of occupied habitat.
- Floodplain restoration would be designed to provide flood refugia so that flooding would not adversely affect any riparian woodrats that occupy restored floodplains.

Alternative 9 would provide a substantial benefit to the riparian woodrat through the net increase in available habitat and a net increase of habitat in protected status. These protected areas would be managed and monitored to support the species. The affected habitat is currently unoccupied and habitat removal is not expected to result in a discernible change in the abundance or distribution of riparian woodrats if they occupy study area habitats. Should the species be detected in the study area, implementation of AMM1–AMM7, AMM10, and AMM25 would avoid and minimize the effects of conservation component construction and implementation. Therefore, the loss of habitat and potential mortality of individuals under Alternative 9 would not have a significant impact on riparian woodrat.

Impact BIO-156: Indirect Effects of Plan Implementation on Riparian Woodrat

Noise and visual disturbance adjacent to construction activities could indirectly affect the use of modeled habitat for riparian woodrat. These effects are related construction activities associated with water conveyance construction, tidal natural communities restoration construction, and construction of setback levees. Indirect effects on the species from construction associated with tidal natural communities restoration are unlikely because tidal natural communities restoration projects would be sited to avoid areas occupied by riparian woodrat (AMM25) The activity most likely to result in noise and visual disturbance to riparian woodrat would be the construction of setback levees. These adverse effects would be minimized through implementation of AMM1–AMM7, AMM10, and AMM25.

NEPA Effects: Implementation of the AMMs listed above as part of implementing BDCP Alternative 9 would avoid the potential for substantial adverse effects on riparian woodrats, either indirectly or through habitat modifications or result in a substantial reduction in numbers or a restriction in the range of riparian woodrats. Therefore, indirect effects of Alternative 9 would not have an adverse effect on riparian woodrat.

CEQA Conclusion: Should the species be detected in the study area, indirect effects of conservation measure construction and implementation could impact riparian woodrat and its habitat. AMM1–AMM7, AMM10, and AMM25 would avoid and minimize the impact.

Impact BIO-157: Periodic Effects of Inundation of Riparian Woodrat Habitat as a Result of Implementation of Conservation Components

CM5 Seasonally inundated floodplain restoration is the only covered activity expected to result in periodic inundation of riparian woodrat habitat. Floodplain restoration would result in periodic inundation of up to 203 acres of riparian woodrat habitat (9% of the riparian woodrat habitat in the Plan Area). The area between existing levees that would be breached and the newly constructed setback levees would be inundated through seasonal flooding. The potentially inundated areas consist of moderate-value habitat for the species. Although the habitat consists of small patches and narrow bands of riparian vegetation and no riparian woodrats have detected in CZ 7, the riparian patches are in proximity to each other along the San Joaquin River and there are two species occurrences immediately south of CZ 7, one of which is less than 1 mile from the southernmost patch of riparian habitat potentially affected by levee construction. The restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more).

NEPA Effects**:** Alternative 9's periodic inundation of 203 acres of riparian habitat is not expected to result in substantial adverse effects on riparian woodrat, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian woodrat. The effects of periodic inundation on the riparian woodrat would be minimized through construction and maintenance of flood refugia to allow riparian woodrats to escape inundation. Therefore, the periodic inundation of riparian woodrat habitat would not adversely affect the species under Alternative 9.

CEQA Conclusion**:** Floodplain restoration under CM5 would periodically affect a total of 203 acres of riparian habitat for riparian woodrat, representing 9% of the 2,166 acres of modeled riparian woodrat habitat in the study area. The impact of periodic inundation on the riparian woodrat would be minimized through construction and maintenance of flood refugia to allow riparian woodrats to escape inundation, as described in AMM25. Implementation of CM5 would not be expected to result in significant impacts on riparian woodrat, either directly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of riparian woodrats. Periodic inundation of riparian woodrat habitat under Alternative 9 would have a less-than-significant impact.

Salt Marsh Harvest Mouse

The habitat model used to assess effects for the salt marsh harvest mouse includes six habitat types: primary tidal marsh habitat, secondary tidal marsh habitat (low marsh), secondary upland habitat adjacent to tidal marsh habitat, primary habitat within managed wetlands, secondary habitat within managed wetlands (dominated by plants characteristic of low marsh), and upland habitats within managed wetland boundaries. The tidal and managed wetland habitats were discriminated recognizing that regardless of habitat value, managed wetlands are at high risk of catastrophic flooding and have lower long-term conservation value than tidal wetlands.

Construction and restoration associated with Alternative 9 conservation measures would result in effects to modeled salt marsh harvest mouse habitat, which would include permanent losses and habitat conversions (i.e., existing habitat converted to greater or lesser valued habitat for the species post-restoration) as indicated in Table 12-9-57. All of the effects to the species would take place over an extended period of time as tidal marsh is restored in the Plan Area. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit salt marsh harvest mouse (BDCP Chapter 3, *Conservation Strategy*).

- Restore or create 6,000 acres of tidal brackish emergent wetland in CZ 11 to be consistent with the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective TBEWNC1.1, associated with CM4)
- Within the 6,000 acres of tidal brackish emergent wetland restored or created, distribute 1,500 acres of middle and high marsh (primary salt marsh harvest mouse habitat) to contribute to total (existing and restored) acreage targets for each complex as specified in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective TBEWNC1.2, associated with CM4).
- Limit perennial pepperweed to no more than 10% cover in the tidal brackish emergent wetland natural community within the reserve system (Objective TBEWNC2.1).
- Protect and enhance at least 1,500 acres of managed wetland in Grizzly Island Marsh Complex for the benefit of salt marsh harvest mouse (Objective MWNC1.1, associated with CM3).
- Protect or restore grasslands adjacent to restored tidal brackish emergent wetlands to provide at least 200 feet of adjacent grasslands beyond the sea level rise accommodation area (Objective GNC1.4, associated with CM3 and CM8).
- Provide viable habitat areas for salt marsh harvest mouse within the 1,500 acres of restored or created middle and high marsh as defined in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective SMHM1.1).
- Provide viable habitat areas for salt marsh harvest mouse within the 1,500 acres of managed wetland protected and enhanced in the Grizzly Island Marsh Complex as defined in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California, and increase population levels above the current baseline (Objective SMHM1.2).

As explained below, with the restoration or protection of these amounts of habitat, impacts on the salt marsh harvest mouse would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-57. Changes in Salt Marsh Harvest Mouse Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent		Temporary		Periodic[d]	
		NT	LLT[c]	NT	LLT[c]	CM2	CM5

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[d] Periodic effects were estimated for the late long-term only.
TBEW = tidal brackish emergent wetland
MW = managed wetland
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-158: Loss or Conversion of Habitat for and Direct Mortality of Salt Marsh Harvest Mouse

BDCP tidal restoration (CM4) would be the only conservation measure resulting in effects on salt marsh harvest mouse habitat. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these activities is described in detail below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration* would result in effects to 6,968 acres of salt marsh harvest mouse modeled habitat, which would include 5,376 acres of permanent losses and 1,592acres of habitat conversions. Salt marsh harvest mouse may be displaced temporarily from areas of converted habitat but these areas would ultimately provide suitable habitat for the species. However, 1,058 of these acres would be downgraded from primary habitat(67 acres of primary tidal brackish emergent wetland and 991 acres of primary managed wetland) to secondary tidal brackish emergent wetland. The hypothetical restoration footprints in Suisun Marsh overlap with 13 CNDDB records for salt marsh harvest mouse (California Department of Fish and Wildlife 2013); however, the BDCP's conservation actions assume that all suitable habitat in Suisun Marsh is occupied by the species.
- *CM11 Natural Communities Enhancement and Management:* As described in the BDCP, the restoration of at least 1,500 acres of tidal brackish emergent wetland would be managed to provide viable habitat for salt marsh harvest mouse and the protection of 1,500 acres of managed wetland specifically to be managed for salt marsh harvest mouse. A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance and manage these areas for salt marsh harvest mouse and may result in localized ground disturbances that could temporarily remove small amounts of salt marsh harvest mouse habitat. The restoration of tidal brackish emergent wetlands, the protection of managed wetlands, and the protection and/or restoration of grasslands within 200 feet of restored salt marsh harvest mouse habitat would also have enhancement and management actions that would include invasive species control, nonnative wildlife control, and vegetation management. Ground-disturbing activities, such as removal of nonnative vegetation are expected to have minor effects on habitat and are expected to result in overall improvements to and maintenance of salt marsh harvest mouse habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.
- Injury and Direct Mortality: The use of heavy equipment and handtools may result in injury or mortality to salt marsh harvest mouse during restoration, enhancement, and management activities. However, preconstruction surveys, construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during these activities, as required by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would not be adverse under NEPA. Alternative 9 would affect 2,465 acres of salt marsh harvest mouse modeled habitat in the study area in the near-term. These effects include 1,517 acres of permanent loss and 948 acres of converted habitat. Most of the habitat converted would be from primary habitats (599 acres consisting of 64 acres of tidal brackish emergent wetland and 534 acres of managed wetland) to secondary tidal brackish emergent wetland.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland, the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, and the protection and enhancement of 1,500 acres of managed wetlands for salt marsh harvest mouse. Though there would be a net loss of modeled habitat, nearly all of these losses (97%) are to managed wetlands, which according to the U.S. Fish and Wildlife Service are at high risk of catastrophic flooding (U.S. Fish and Wildlife Service 2010) and have lower long-term conservation value than tidal wetlands. The species-specific biological goals and objectives would inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects to salt marsh harvest mouse.

Other factors relevant to effects on salt marsh harvest mouse are listed here.

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the specie's draft recovery plan because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP would be consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan. Restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs. This phasing would ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4,), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).

- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

Because there would be no project-level impacts on salt marsh harvest mouse resulting from CM1, the analysis of the effects and conservation actions does not include a comparison with standard ratios used for project-level NEPA analyses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM26 Salt Marsh Harvest Mouse and Suisun Shrew*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 35,588 acres of salt marsh harvest mouse modeled habitat. Alternative 9 as a whole would result in effects to 6,968 acres of saltmarsh harvest mouse modeled habitat over the term of the Plan, which would include 5,376 acres of permanent losses and 1,592 acres of habitat conversions. These effects (loss and conversion) would be on 20% of the modeled habitat in the study area. Most of these effects (99%) would be to managed wetlands, which though are known to be occupied by salt marsh harvest mouse are at high risk of catastrophic flooding and have a lower long-term conservation value than tidal wetlands (U.S. Fish and Wildlife Service 2010). Effects on up to 20% of the species' habitat in the Plan Area may diminish the salt marsh harvest mouse population in the Plan Area and result in reduced genetic diversity, thereby putting the local population at risk of local extirpation due to random environmental fluctuations or catastrophic events. This effect is expected to be greatest if large amounts of habitat are removed at one time in Suisun Marsh and are not effectively restored for many years, and if there are no adjacent lands with salt marsh harvest mouse populations to recolonize restored areas.

The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for salt marsh harvest mouse) (TBEWNC1.1, TBEWNC1.2, SMHM1.1, associated with CM4), the protection of 6,500 acres of managed wetlands, 1,500 acres of which would be specifically managed for salt marsh harvest mouse (SMHM1.2 and MWNC1.1, associated with CM3), and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration) to provide upland refugia for salt marsh harvest mouse (GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on salt marsh harvest mouse include:

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the draft recovery plan for salt marsh harvest mouse because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP are consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- In order to ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).
- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4,), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).
- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value, which is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 6,046 acres and the protection of 1,550 acres of modeled habitat for salt marsh harvest mouse.

NEPA Effects: In the absence of other conservation actions, the effects on salt marsh harvest mouse habitat from Alternative 9 would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, the BDCP has committed to habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8, and CM11. This habitat protection, restoration, management, and enhancement would be guided by species-specific goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction period. Considering these commitments, losses and conversions of salt marsh harvest mouse habitat and potential mortality of individuals in the near-term and late long-term under Alternative 9 would not be an adverse effect.

CEQA Conclusion:

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would be less than significant under CEQA. Alternative 9 would affect 2,465 acres of salt marsh harvest mouse modeled habitat in the study area in the near-term. These effects include 1,517 acres of permanent loss and 948 acres of converted habitat. Most of the habitat converted would be to primary habitats (599 acres consisting of 64 acres of tidal brackish emergent wetland and 534 acres of managed wetland) to secondary tidal brackish emergent wetland.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland, the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, and the protection and enhancement of 3,200 acres of managed wetlands for salt marsh harvest mouse. Though there would be a net loss of modeled habitat, nearly all of these losses (97%) are to managed wetlands, which according to the U.S. Fish and Wildlife Service are at high risk of catastrophic flooding (U.S. Fish and Wildlife Service 2010) and have lower long-term conservation value than tidal wetlands. The species-specific biological goals and objectives would inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects to salt marsh harvest mouse habitat.

Other factors relevant to effects on salt marsh harvest mouse are listed here.

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the specie's draft recovery plan because the conversion of managed wetland to tidal marsh occurs be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP would be consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- To ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4,), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).

- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

Because there would be no project level impacts on salt marsh harvest mouse resulting from CM1, the analysis of the effects and conservation actions does not include a comparison with standard ratios used for project level CEQA analyses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM26 Salt Marsh Harvest Mouse and Suisun Shrew*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 35,588 acres of salt marsh harvest mouse modeled habitat. Alternative 9 as a whole would result in effects to 6,968 acres of saltmarsh harvest mouse modeled habitat over the term of the Plan, which would include 5,376 acres of permanent losses and 1,592 acres of habitat conversions. The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for salt marsh harvest mouse) (TBEWNC1.1, TBEWNC1.2, SMHM1.1, associate with CM4); the protection of 6,500 acres of managed wetlands, 1,500 acres of which would be specifically managed for salt marsh harvest mouse (SMHM1.2 and MWNC1.1, associated with CM3), and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration) to provide upland refugia for salt marsh harvest mouse (GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on salt marsh harvest mouse include:

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the draft recovery plan for salt marsh harvest mouse because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP are consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- In order to ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).
- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4,), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).
- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value, which is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 6,046 acres and the protection of 1,550 acres of modeled habitat for salt marsh harvest mouse.

Alternative 9 would result in substantial modifications to salt marsh harvest mouse habitat in the absence of other conservation actions. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8 and CM11, guided by species-specific goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction period, Alternative 9 over the term of the BDCP would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on salt marsh harvest mouse.

Impact BIO-159: Indirect Effects of Plan Implementation on Salt Marsh Harvest Mouse

Construction/disturbance activities associated tidal restoration (CM4), grassland restoration (CM8), and management and enhancement activities (CM11) could result in temporary noise and visual disturbances to salt marsh harvest mouse occurring within 100 feet of these areas over the term of the BDCP. These potential effects would be minimized or avoided through AMM1–AMM5, and AMM26, which would be in effect throughout the term of the Plan.

The use of mechanical equipment during the implementation of the conservation measures could cause the accidental release of petroleum or other contaminants that could affect salt marsh harvest mouse and its habitat. The inadvertent discharge of sediment could also have a negative effect on the species and its habitat. AMM1–AMM5 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment on salt marsh harvest mouse.

Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). High tidal marsh is considered to be primary habitat for salt marsh harvest mouse and thus the species could be exposed to methyl mercury in tidal restoration areas. Salt marsh harvest mouse may be exposed to elemental mercury by feeding on pickleweed, which is found concentrated in the distal tips of pickleweed leaves (Yee et. al., 2008). Though elemental mercury is less bioavailable than methylmercury, studies have shown that mercury can become methylated in the anaerobic portions of the intestinal tract (Rudd et al. 1980, Rieder et al. 2013) and could thus become a pathway for salt marsh harvest exposure to methylmercury. A study of small mammals residing in pickleweed around the San Francisco Bay showed an absence of salt marsh harvest mouse where mercury concentrations measured in house mice (*Mus musculus*) livers were ≥0.19 ug/g (dry weight) (Clark et al. 1992). Clark et al (1992) also report that the lack of salt marsh harvest mouse at these locations are not the result of undetected habitat differences or are by chance. Clarke et al (1992) suggest that the absence of salt marsh harvest mouse at certain locations may be associated with higher amounts of mercury and polychlorinated biphenyls (PCBs); however, because their study didn't analyze contaminants in salt marsh harvest mouse and because (at that time) there was no data in the literature on contaminants in harvest mice, they could not make conclusions on these associations. Currently, it is unknown what the exact exposure pathways are or what tissue concentrations are harmful to the salt marsh harvest mouse.

The Suisun Marsh Plan (Bureau of Reclamation et al. 2010) anticipates that tidal wetlands restored under the plan would generate less methylmercury than the existing managed wetlands. The potential for salt marsh harvest mouse exposure to methyl mercury in Suisun Marsh may decrease in the long term because the creation of tidal brackish emergent wetland would predominantly result from the conversion of managed wetlands.   *CM12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Along with avoidance and minimization measures and adaptive management and monitoring, CM12 could reduce the effects of methylmercury on salt marsh harvest mouse resulting from BDCP tidal restoration.

NEPA Effects: Implementation of the AMMs listed above as part of implementing BDCP Alternative 9 would avoid and minimize indirect effects on salt marsh harvest mouse. These AMMs would also avoid and minimize effects that could substantially reduce the number of salt marsh harvest mouse, or restrict the species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on salt marsh harvest mouse.

CEQA Conclusion: Indirect effects from construction-related noise and visual disturbances could impact salt marsh harvest mouse within 100 feet of these disturbances. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact salt marsh harvest mouse and its habitat. The inadvertent discharge of sediment adjacent to salt marsh harvest mouse habitat could also impact the species. With implementation of AMM1–AMM5 and AMM26 as part of Alternative 9 construction, operation and maintenance, the BDCP would avoid the potential for substantial adverse effects on salt marsh harvest mouse, either indirectly or through habitat modifications, in that the BDCP would not result in a substantial reduction in numbers or a restriction in the range of salt marsh harvest mouse. The indirect effects of BDCP Alternative 9 would have a less-than-significant impact on salt marsh harvest mouse.

Salt marsh harvest mouse could experience indirect effects from increased exposure to methylmercury as a result of tidal habitat restoration (CM4). With implementation of CM12, the potential indirect effects of methlymercury would not result in a substantial reduction in numbers or a restriction in the range of salt marsh harvest mouse, and, therefore, would have a less-than-significant impact on the species.

Suisun Shrew

Primary Suisun shrew habitat consists of all *Salicornia*-dominated natural seasonal wetlands and certain *Scirpus* and *Typha* communities found within Suisun Marsh only. Low marsh dominated by *Schoenoplectus acutus* and *S. californicus* and upland transitional zones within 150 feet of the tidal wetland edge were classified separately as secondary habitat because they are used seasonally (Hays and Lidicker 2000). All managed wetlands were excluded from the habitat model. Construction and restoration associated with Alternative 9 conservation measures would result in effects to modeled Suisun shrew habitat, which would include permanent losses and habitat conversions (i.e., existing habitat converted to greater or lesser valued habitat for the species post-restoration) as indicated in Table 12-9-58. All of the effects on the species would take place over an extended period of time as tidal marsh is restored in the Plan Area. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP to benefit Suisun shrew (BDCP Chapter 3, *Conservation Strategy*).

- Restore or create 6,000 acres of tidal brackish emergent wetland in CZ 11 to be consistent with the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (TBEWNC1.1, associated with CM4)
- Within the 6,000 acres of tidal brackish emergent wetland restored or created, distribute 1,500 acres of middle and high marsh (primary Suisun shrew habitat) to contribute to total (existing and restored) acreage targets for each complex as specified in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (TBEWNC1.2, associated with CM4).
- Limit perennial pepperweed to no more than 10% cover in the tidal brackish emergent wetland natural community within the reserve system (TBEWNC2.1).
- Protect or restore grasslands adjacent t restored tidal brackish emergent wetlands to provide at least 200 feet of adjacent grasslands beyond the sea level rise accommodation area, which provides refugia during high tides (GNC1.4, associated with CM3 and CM8).

As explained below, with the restoration or protection of these amounts of habitat, impacts on the Suisun shrew would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-58. Changes in Suisun Shrew Modeled Habitat Associated with Alternative 9 (acres)[a]

Conservation Measure[b]	Habitat Type	Permanent NT	Permanent LLT[c]	Temporary NT	Temporary LLT[c]	Periodic[d] CM2	Periodic[d] CM5

LLT = late long-term
NA = not applicable

Impact BIO-160: Loss or Conversion of Habitat for and Direct Mortality of Suisun shrew

BDCP tidal restoration (CM4) would be the only conservation measure resulting in loss of habitat to Suisun shrew. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these activities is described in detail below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM4 Tidal Natural Communities Restoration* would result in effects to 401 acres of Suisun shrew modeled habitat, which would include 377 acres of permanent losses and 24 acres of habitat conversions. Suisun shrew may be displaced temporarily from areas of converted habitat but would ultimately provide suitable habitat for the species. However, all 24 acres would be converted from secondary to primary habitat and therefore over would be a net benefit to the species. The hypothetical restoration footprints overlap with two CNDDB records for Suisun shrew (California Department of Fish and Wildlife 2013).

- *CM11 Natural Communities Enhancement and Management:* As described in the BDCP, the restoration of at least 6,000 acres of tidal brackish emergent wetland would be managed to provide habitat for covered species, including Suisun shrew. A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance and manage these areas may result in localized ground disturbances that could temporarily remove small amounts of Suisun shrew habitat. The areas of grasslands that would be protected and/or restored within 200 feet of restored tidal marsh would also have enhancement and management actions that would include invasive species control, nonnative wildlife control, and vegetation management. Ground-disturbing activities, such as removal of nonnative vegetation are expected to have minor effects on habitat and are expected to result in overall improvements to and maintenance of Suisun shrew habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- Injury and Direct Mortality: The use of heavy equipment and handtools may result in injury or mortality to Suisun shrew during restoration, enhancement, and management activities. However, preconstruction surveys, construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during these activities, as required by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would not be adverse under NEPA. Alternative 9 would affect 105 acres of Suisun shrew modeled habitat in the study area in the near-term. These effects include 90 acres of permanent loss and 15 acres of converted habitat, which is all secondary habitat being converted to primary habitat.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland and the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, of which approximately 150 feet of this area would benefit the species. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of tidal restoration and the commitment to protection of adjacent uplands contained in the near-term Plan goals would keep pace with the loss of habitat and effects to Suisun shrew.

Other factors relevant to effects on Suisun shrew are listed below.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored in the near term (2,000 acres) greatly exceeds the amount permanently lost (105 acres).

Because there would be no project level impacts on Suisun shrew from CM1, the analysis of the effects and conservation actions does not include a comparison to standard ratios used for project level NEPA analyses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention*

Plan, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, and *AMM26 Salt Marsh Harvest Mouse and Suisun Shrew*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 7,515 acres of Suisun shrew modeled habitat. Alternative 9 as a whole would result in effects on 401 acres of Suisun shrew modeled habitat over the term of the Plan, which would include 377 acres of permanent losses and 24 acres of habitat conversions (roughly 5% of the habitat in the study area).

The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for Suisun shrew) (Objectives TBEWNC1.1, TBEWNC1.2, SMHM1.1, associated with CM4) and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration, of which approximately 150 feet would likely benefit the species) to provide upland refugia for Suisun shrew (Objectives GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on Suisun shrew are listed below.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.

The amount of tidal habitat restored (6,000 acres) greatly exceeds the amount permanently lost and converted (401 acres). The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 6,006 acres and the protection of 232 acres of modeled habitat for Suisun shrew.

NEPA Effects: In the absence of other conservation actions, the effects on Suisun shrew habitat from Alternative 9 would represent an adverse effect as a result of habitat modification and potential for direct mortality of a special-status species. However, the BDCP has committed to habitat protection, restoration, management, and enhancement with CM3, CM4, CM8, and CM11. This habitat protection, restoration, management, and enhancement would be guided by biological goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction period. Considering these commitments, losses and conversions of Suisun shrew habitat and potential mortality of individuals in the near-term and late long-term under Alternative 9 would not be an adverse effect.

***CEQA Conclusion*:**

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would be less than significant under CEQA. Alternative 9 would affect 105 acres of Suisun shrew modeled habitat in the study area in the near-term. These effects include 90 acres of permanent loss and 15 acres of converted habitat, which is all secondary habitat being converted to primary habitat.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland and the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, of which approximately 150 feet of this area would benefit the species. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of tidal restoration and the commitment to protection of adjacent uplands contained in the near-term Plan goals would keep pace with the loss of habitat and effects to Suisun shrew.

Other factors relevant to effects on Suisun shrew are listed below.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored in the near term (2,000 acres) greatly exceeds the amount permanently lost (105 acres).

Because there are no project level impacts on Suisun shrew from CM1, the analysis of the effects and conservation actions does not include a comparison with standard ratios used for project level NEPA analyses.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM26 Salt Marsh Harvest Mouse and Suisun Shrew*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 7,515 acres of Suisun shrew modeled habitat. Alternative 9 as a whole would result in effects to 401 acres of Suisun shrew modeled habitat over the term of the Plan, which would include 377 acres of permanent losses and 24 acres of habitat conversions (roughly 5% of the habitat in the study area). The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for Suisun shrew) (Objectives TBEWNC1.1, TBEWNC1.2, and SMHM1.1, associated with CM4), and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration, of which approximately 150 feet of this area would benefit the species) to provide upland refugia for Suisun shrew (Objective GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on Suisun shrew are listed below.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored (6,000 acres) greatly exceeds the amount permanently lost and converted (401 acres).

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 6,006 acres and the protection of 232 acres of modeled habitat for Suisun shrew.

Alternative 9 would result in substantial modifications to Suisun shrew habitat in the absence of other conservation actions. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8, and CM11, guided by species-specific goals and objectives and by AMM1–AMM5, and AMM26, which would be in place throughout the construction period, Alternative 9 over the term of the BDCP would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on Suisun shrew.

Impact BIO-161: Indirect Effects of Plan Implementation on Suisun Shrew

Construction/disturbance activities associated tidal restoration (CM4), grassland restoration (CM8), and management and enhancement activities (CM11) could result in temporary noise and visual disturbances to Suisun shrew occurring within 100 feet of these areas over the term of the BDCP. These potential effects would be minimized or avoided through AMM1–AMM5, and AMM26, which would be in effect throughout the term of the Plan.

The use of mechanical equipment during the implementation of the conservation measures could cause the accidental release of petroleum or other contaminants that could affect Suisun shrew and its habitat. The inadvertent discharge of sediment could also have a negative effect on the species and its habitat. AMM1–AMM5 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment on Suisun shrew.

Tidal marsh restoration has the potential to increase Suisun shrew's exposure to mercury. Mercury is transformed into the more bioavailable form of methylmercury under anaerobic conditions, which in the environment typically occurs in sediments subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). High and mid tidal marsh is considered to be primary habitat for Suisun shrew and thus the species could be exposed to methylmercury in tidal restoration areas. Suisun shrew could be exposed to methylmercury by feeding on marsh invertebrates that may bioaccumulate methylmercury from marsh sediments. Toxic concentrations of methylmercury have been found in the kidneys of shrews that inhabit contaminated sites and forage on earthworms and other prey that live within contaminated sediments (Talmage and Walton 1993; Hinton and Veiga 2002).

The Suisun Marsh Plan (Bureau of Reclamation et al. 2010) anticipates that tidal wetlands restored under the plan would generate less methylmercury than the existing managed wetlands. The potential for Suisun shrew exposure to methyl mercury in Suisun Marsh may decrease in the long term because the creation of tidal brackish emergent wetland would predominantly result from the conversion of managed wetlands. *CM12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Along with avoidance and minimization measures and adaptive management and monitoring, CM12 could reduce the effects of methylmercury on Suisun shrew resulting from BDCP tidal restoration.

NEPA Effects: Implementation of the AMMs listed above as part of implementing BDCP Alternative 9 would avoid and minimize the potential for substantial adverse effects on Suisun shrew, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of Suisun shrew, or restrict the species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on Suisun shrew.

CEQA Conclusion: Indirect effects from construction-related noise and visual disturbances could impact Suisun shrew within 100 feet of these disturbances. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact Suisun shrew and its habitat. The inadvertent discharge of sediment adjacent to Suisun shrew habitat could also impact the species. With implementation of AMM1–AMM5, and AMM26 as part of Alternative 9 construction, operation and maintenance, the BDCP would avoid the potential for substantial adverse effects on Suisun shrew, either indirectly or through habitat modifications, in that the BDCP would not result in a substantial reduction in numbers or a restriction in the range of Suisun shrew. The indirect effects of BDCP Alternative 9 would have a less-than-significant impact on Suisun shrew.

Suisun shrew could experience indirect effects from increased exposure to methylmercury as a result of tidal habitat restoration (CM4). With implementation of CM12, the potential indirect effects of methlymercury would not result in a substantial reduction in numbers or a restriction in the range of Suisun shrew, and, therefore, would have a less-than-significant impact on the species.

San Joaquin Kit Fox and American Badger

Within the study area, the modeled habitat for the San Joaquin kit fox and potential habitat for the American badger is restricted to 5,327 acres of grassland habitat west of Clifton Court Forebay along the study area's southwestern edge, in CZ 7– CZ 10. The study area represents the extreme northeastern corner of the species' range in California, which extends westward and southward from the study area border. The northern range of the San Joaquin kit fox (including the study area) was most likely marginal habitat historically and has been further degraded due to development pressures, habitat loss, and fragmentation (Clark et al. 2007). CNDDB (California Department of Fish and Wildlife 2013) reports eight occurrences of San Joaquin kit foxes along the extreme western edge of the Plan Area within CZ 8, south of Brentwood (Figure 12-49). However, Clark et al. (2007) provide evidence that a number of CNDDB occurrences in the northern portion of the species' range may be coyote pups misidentified as San Joaquin kit foxes. Smith et al. (2006) suggest that the northern range may possibly be a population sink for the San Joaquin kit fox.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of San Joaquin kit and American badger habitat (Table 12-9-59). Grassland restoration, and protection and management of natural communities could affect modeled San Joaquin kit fox habitat and potential American badger habitat. Full implementation of Alternative 9 would also include biological objectives over the term of the BDCP to benefit the San Joaquin kit fox which would also benefit American badger which uses similar habitat (BDCP Chapter 3, *Conservation Strategy*). The conservation strategy for the San Joaquin kit fox involves protecting and enhancing habitat in the northern extent of the species' range to increase the likelihood that San Joaquin kit fox may reside and breed in the Plan Area; and providing connectivity to habitat outside the Plan Area. The conservation measures that would be implemented to achieve the biological goals and objectives are summarized below.

- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3-8, and CM11).
- Protect 150 acres of alkali seasonal wetland in CZ 1, CZ 8, and/or CZ 11 among a mosaic of protected grasslands and vernal pool complex (Objective ASWNC1.1, associated with CM3).
- Restore or create alkali seasonal wetlands in CZ 1, CZ 8, and/or CZ 11 (up to 72 acres of alkali seasonal wetland complex restoration) (Objective ASWNC1.2, associated with CM3 and CM9).
- Protect 600 acres of existing vernal pool complex in CZ 1, CZ 8, and/or CZ 11, primarily in core vernal pool recovery areas identified in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (U.S. Fish and Wildlife Service 2005) (Objective VPNC1.1, associated with CM3).
- Restore vernal pool complex in CZ 1, CZ 8, and/or CZ 11 to achieve no net loss of vernal pool acreage (up to 67 acres of vernal pool complex restoration) (Objective VPNC1.2, associated with CM3 and CM9).
- Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
- Restore 2,000 acres of grasslands to connect fragmented patches of protected grassland (Objective GNC1.2, associated with CM3 and CM8).
- Increase burrow availability for burrow-dependent species in grasslands surrounding alkali seasonal wetlands within restored and protected alkali seasonal wetland complex (Objective ASWNC2.3, associated with CM11).
- Increase prey, especially small mammals and insects, for grassland-foraging species in grasslands surrounding alkali seasonal wetlands within restored and protected alkali seasonal wetland complex (Objective ASWNC2.4, associated with CM11).

- Increase burrow availability for burrow-dependent species in grasslands surrounding vernal pools within restored and protected vernal pool complex (Objective VPNC2.4, associated with CM11).
- Increase prey, especially small mammals and insects, for grassland-foraging species in grasslands surrounding vernal pools within restored and protected vernal pool complex (Objective VPNC2.5, associated with CM11).
- Increase burrow availability for burrow-dependent species (Objective GNC2.3, associated with CM11).
- Increase prey abundance and accessibility, especially small mammals and insects, for grassland-foraging species (Objective GNC2.4, associated with CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of AMMs to reduce potential effects, impacts on San Joaquin kit fox and American badger would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Impact BIO-162: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Kit Fox and American Badger

Alternative 9 conservation measures would result in the permanent and temporary loss combined of 33 acres of modeled habitat for the San Joaquin kit fox (Table 12-9-59).   Because American badger uses grasslands for denning and foraging and shares the same geographic locations as the San Joaquin kit fox, effects on are anticipated to be the same as those described for San Joaquin kit fox. There are no San Joaquin kit fox and no American badger occurrences that overlap with the Plan footprint. Construction of Alternative 9 water conveyance facilities (CM1) and recreation facilities (CM11) would remove habitat. Habitat enhancement and management activities (CM11) could result in local adverse effects on species. In addition, construction vehicle activity could cause injury or mortality of San Joaquin kit foxes and badgers. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of the conveyance facilities would result in the permanent loss of approximately 15 acres and the temporary loss of 10 acres of modeled San Joaquin kit fox habitat and American badger habitat. This habitat is located in areas of naturalized grassland in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay, in CZ 8.

- *CM11 Natural Communities Enhancement and Managemen*t: The creation of recreational trails and recreational staging areas would result in the permanent removal of 8 acres of San Joaquin kit fox modeled habitat. *AMM24 San Joaquin Kit Fox,* would be implemented to ensure that San Joaquin kit fox dens are avoided, as described in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Passive recreation in the reserve system could result in disturbance of San Joaquin kit foxes at their den site. Natal and pupping dens would be particularly vulnerable to human disturbance. Additionally, disease could be transmitted from domestic dogs that enter the reserve system with recreational users. However, *AMM37 Recreation* would prohibit construction of new trails within 250 feet of active San Joaquin kit fox dens. Existing trails would be closed within 250 feet of active natal/pupping dens until young have vacated, and within 50 feet of other active dens. No dogs would be allowed on reserve units with active San Joaquin kit fox populations. Rodent control would be prohibited even on grazed or equestrian access areas with San Joaquin kit fox populations. With these restrictions, recreation-related effects on San Joaquin kit fox are expected to be minimal.

  The BDCP would require the protection of grasslands in large patch sizes connected to existing large areas of grassland, habitat corridors and transition habitat areas to improve the ecological functions of the grasslands necessary to support the San Joaquin kit fox. American badger is expected to benefit in a similar fashion.

  The BDCP would require the enhancement and management of these protected existing grasslands and restored grasslands to improve their function as a natural community of plants and wildlife and for associated covered species, including San Joaquin kit fox. The BDCP also includes actions to improve rodent prey availability.

  However, management activities could result in injury or mortality of San Joaquin kit fox or American badger if individuals were present in work sites or if dens were located in the vicinity of habitat management work sites. A variety of habitat management actions included in *CM11* that are designed to enhance wildlife values on protected lands may result in localized ground disturbances that could temporarily remove small amounts of San Joaquin kit fox and American badger habitat near Clifton Court Forebay, in CZ 8. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor effects on available habitat and are expected to result in overall improvements to and maintenance of San Joaquin kit fox and badger habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below. These AMMs would remain in effect throughout the BDCP's construction phase.

- Operations and maintenance: Ongoing maintenance of BDCP facilities would be expected to have little if any adverse effect on San Joaquin kit fox or American badger. Postconstruction operations and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect either species' use of the surrounding habitat near Clifton Court Forebay, in CZ 8. Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of AMM1–AMM6, AMM10, and AMM24 and with preconstruction surveys for the American badger, as required by Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*.

- Injury and direct mortality: Construction vehicle activity may cause injury to or mortality of either species. If San Joaquin kit fox or American badger reside where activities take place (most likely in the vicinity of Clifton Court Forebay, in CZ 8), the operation of equipment for land clearing, construction, operations and maintenance, and restoration, enhancement, and management activities could result in injury to or mortality of either species. Measures would be implemented to avoid and minimize injury to or mortality of these species as described in AMMs 1–6, 10, and 24 (see BDCP Appendix 3.C) and Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA.

Under Alternative 9 there would be a loss of 28 acres of San Joaquin kit fox modeled habitat and American badger habitat from CM1 (25 acres) and CM11 (3 acres).

Typical NEPA project-level mitigation ratio for the natural community that would be affected and that is identified in the biological goals and objectives for San Joaquin kit fox in Chapter 3 of the BDCP would be 2:1 for protection of grassland. Using this ratio would indicate that 56 acres of grassland should be protected for San Joaquin kit fox to mitigate near-term losses.

The BDCP has committed to near-term restoration of 58 acres of alkali seasonal wetland (Objective ASWNC1.2), 40 acres of vernal pool complex (Objective VPNC1.2), and 1,140 acres of grassland (Objective GNC1.2). In addition, there would be near-term protection of 120 acres of alkali seasonal wetland (Objective ASWNC1.1), 400 acres of vernal pool complex (Objective VPNC1.1), and 2,000 acres of grassland (Objective GNC1.1). The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be not be adverse under NEPA, because the number of acres required to meet the typical ratios described above would be only 56 acres of grassland protected.

The effects on San Joaquin kit fox and American badger habitat from Alternative 9 as a whole would represent an adverse effect as a result of habitat modification of a special-status species and potential for direct mortality in the absence of other conservation actions. However, the effects of Alternative 9 would be not be adverse with habitat protection, restoration, and management and enhancement in addition to implementation of *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM10 Restoration of Temporarily Affected Natural Communities*, *AMM24 San Joaquin Kit Fox*, and *AMM37 Recreation*. These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. Remaining effects would be addressed by implementation of Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*. BDCP Appendix 3.C describes the AMMs in detail.

Late Long-Term Timeframe

There are 5,327 acres of modeled San Joaquin kit fox habitat in the study area. Alternative 9 as a whole would result in the permanent loss of and temporary effects to 33 acres of modeled habitat for San Joaquin kit fox and potential habitat for American badger representing less than 1% of the modeled habitat. \

With full implementation of the BDCP, at least 1,000 acres of grassland would be protected in CZ 8, where the San Joaquin kit fox is most likely to occur if present in the Plan Area. Additionally, a portion of the 2,000 acres of grassland restoration would likely occur in CZ 8. Assuming the restored grasslands would provide suitable San Joaquin kit fox habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (6.8% of the grasslands in the Plan Area consist of modeled San Joaquin kit fox habitat), an estimated 132 acres of restored grasslands would be suitable for the species (6.6% of 2,000 acres).

Because San Joaquin kit fox home ranges are large (ranging from around 1 to 12 square miles; see BDCP Appendix 2.A, *Covered Species Accounts*), habitat connectivity is key to the conservation of the species. Grasslands would be acquired for protection in locations that provide connectivity to existing protected breeding habitats in CZ 8 (Objective L3.1)and to other adjoining San Joaquin kit fox habitat within and adjacent to the Plan Area. Connectivity to occupied habitat adjacent to the Plan Area would help ensure the movement of San Joaquin kit foxes, if present, to larger habitat patches outside of the Plan Area in Contra Costa County. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (BDCP Appendix 2.A). This area connects to over 620 acres of existing habitat that was protected under the East Contra Costa County HCP/NCCP.

Grasslands in CZ 8 would also be managed and enhanced to increase prey availability and to increase mammal burrows, which could benefit the San Joaquin kit fox by increasing potential den sites, which are a limiting factor for the San Joaquin kit fox in the northern portion of its range (Objectives ASWNC2.3, ASWNC2.4, VPNC2.4, Objective VPNC2.5, Objective GNC2.3, Objective GNC2.4). These management and enhancement actions are expected to benefit the San Joaquin kit fox as well as the American badger by increasing the habitat value of the protected and restoration grasslands.

CZ 8 supports 74% of the modeled San Joaquin kit fox grassland habitat in the study area, and the remainder of habitat consists of fragmented, isolated patches that are unlikely to support this species. The BDCP's commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 and to maintain connectivity with the remainder of the satellite population in Contra Costa County would sufficiently offset the impacts resulting from water conveyance facilities construction.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of grassland and vernal pool that could overlap with the species model, would result in the restoration of 131acres of modeled habitat for San Joaquin kit fox. In addition, protection of grassland and vernal pool complex could overlap with the species model and would result in the protection of 1,011 acres of modeled habitat for San Joaquin kit fox.

NEPA Effects: In the absence of other conservation actions, the effects on San Joaquin kit fox and American badger habitat from Alternative 9 would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM8, and CM11, and guided by AMM1–AMM6, AMM10, AMM24, and AMM37, which would be in effect during the construction period, and with implementation of Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*, the effects of Alternative 9 as a whole on San Joaquin kit fox and American badger would not be adverse under NEPA.

CEQA Conclusion:

Near-Term Timeframe

Because water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction impacts would be less than significant under CEQA.

Under Alternative 9 there would be a loss of 28 acres of San Joaquin kit fox modeled habitat and American badger habitat from CM1 (25 acres) and CM11 (3 acres).

Typical CEQA project-level mitigation ratio for the natural community that would be affected and that is identified in the biological goals and objectives for San Joaquin kit fox in Chapter 3 of the BDCP would be 2:1 for protection of grassland. Using this ratio would indicate that 56 acres of grassland should be protected for San Joaquin kit fox to mitigate near-term losses.

The BDCP has committed to near-term restoration of 58 acres of alkali seasonal wetland (Objective ASWNC1.2), 40 acres of vernal pool complex (Objective VPNC1.2), and 1,140 acres of grassland (Objective GNC1.2). In addition, there would be near-term protection of 120 acres of alkali seasonal wetland (Objective ASWNC1.1), 400 acres of vernal pool complex (Objective VPNC1.1), and 2,000 acres of grassland (Objective GNC1.1). The natural community restoration and protection activities are expected to be concluded during the first 10 years of Plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of

Alternative 9 would not be significant under CEQA, because the number of acres required to meet the typical ratios described above would be only 56 acres of grassland protected.

The BDCP also contains commitments to implement AMM1–AMM6, AMM10, AMM24, and AMM37 which include elements that avoid or minimize the risk of construction activity impacting habitat and species adjacent to work areas and storage sites. Remaining effects would be addressed by implementation of Mitigation Measure BIO-162. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 on San Joaquin kit fox and American badger would be less than significant under CEQA, because the number of acres required to meet the typical ratios described above would be only 56 acres of grassland protected

Late Long-Term Timeframe

There are 5,327 acres of modeled San Joaquin kit fox habitat in the study area. Alternative 9 as a whole would result in the permanent loss of and temporary effects to 33 acres of modeled habitat for San Joaquin kit fox and potential habitat for American badger representing less than 1% of the modeled habitat.

With full implementation of the BDCP, at least 1,000 acres of grassland would be protected in CZ 8, where the San Joaquin kit fox is most likely to occur if present in the Plan Area. Additionally, a portion of the 2,000 acres of grassland restoration would likely occur in CZ 8. Assuming the restored grasslands would provide suitable San Joaquin kit fox habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (6.8% of the grasslands in the Plan Area consist of modeled San Joaquin kit fox habitat), an estimated 132 acres of restored grasslands would be suitable for the species (6.6% of 2,000 acres).

Because San Joaquin kit fox home ranges are large (ranging from around 1 to 12 square miles; see BDCP Appendix 2.A, *Covered Species Accounts*), habitat connectivity is key to the conservation of the species. Grasslands would be acquired for protection in locations that provide connectivity to existing protected breeding habitats in CZ 8 (Objective L3.1)and to other adjoining San Joaquin kit fox habitat within and adjacent to the Plan Area. Connectivity to occupied habitat adjacent to the Plan Area would help ensure the movement of San Joaquin kit foxes, if present, to larger habitat patches outside of the Plan Area in Contra Costa County. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (BDCP Appendix 2.A). This area connects to over 620 acres of existing habitat that was protected under the East Contra Costa County HCP/NCCP.

Grasslands in CZ 8 would also be managed and enhanced to increase prey availability and to increase mammal burrows, which could benefit the San Joaquin kit fox by increasing potential den sites, which are a limiting factor for the San Joaquin kit fox in the northern portion of its range (Objectives ASWNC2.3, ASWNC2.4, VPNC2.4, Objective VPNC2.5, Objective GNC2.3, Objective GNC2.4). These management and enhancement actions are expected to benefit the San Joaquin kit fox as well as the American badger by increasing the habitat value of the protected and restoration grasslands.

CZ 8 supports 74% of the modeled San Joaquin kit fox grassland habitat in the study area, and the remainder of habitat consists of fragmented, isolated patches that are unlikely to support this species. The BDCP's commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 and to maintain connectivity with the remainder of the satellite population in Contra Costa County would sufficiently offset the impacts resulting from water conveyance facilities construction.

The BDCP's beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above, as well as the restoration of grassland and vernal pool that could overlap with the species model, would result in the restoration of 131acres of modeled habitat for San Joaquin kit fox. In addition, protection of grassland and vernal pool complex could overlap with the species model and would result in the protection of 1,011 acres of modeled habitat for San Joaquin kit fox.

In the absence of other conservation actions, the effects on San Joaquin kit fox and American badger habitat from Alternative 9 would represent a significant impact as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM8, and CM11, and guided by AMM1–AMM6, AMM10, AMM24, and AMM37, which would be in place throughout the time period of construction, and with implementation of Mitigation Measure BIO-162, the impact of Alternative 9 as a whole on San Joaquin kit fox and American badger would be less than significant. Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger

A qualified biologist provided by DWR will survey for American badger concurrent with the preconstruction survey for San Joaquin kit fox and burrowing owl. If badgers are detected, the biologist will passively relocate badgers out of the work area prior to construction if feasible. If an active den is detected within the work area, DWR will avoid the den until the qualified biologist determines the den is no longer active. Dens that are determined to be inactive by the qualified biologist will be collapsed by hand to prevent occupation of the den between the time of the survey and construction activities.

Impact BIO-163: Indirect Effects of Plan Implementation on San Joaquin Kit Fox and American Badger

Noise and visual disturbances outside the project footprint but within 250 feet of construction activities could temporarily affect modeled San Joaquin kit fox habitat and potential American badger. Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove San Joaquin kit fox and badger habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual foxes and badgers, if present. Given the remote likelihood of active San Joaquin kit fox or badger dens in the vicinity of the conveyance facility, the potential for this effect is small and would further be minimized with the implementation of seasonal no-disturbance buffers around occupied dens, if any, and other measures as described in AMM24 and Mitigation Measure BIO-162.

NEPA Effects: Implementation of the AMMs listed above and Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger,* would avoid the potential for substantial adverse effects on San Joaquin kit fox or American badger, either indirectly or through habitat modifications.

These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin kit fox or American badger, or restrict either species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on San Joaquin kit fox or American badger.

CEQA Conclusion: Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin kit fox and American badger. With implementation of AMM1–AMM6, AMM10, AMM24, and AMM37 as part of Alternative 9 construction, operation, and maintenance, the BDCP would avoid the potential for significant adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of either species. In addition, Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger,* would reduce the impact of indirect effects of Alternative 9 on American badger to a less-than-significant level.

Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger

Please see Mitigation Measure BIO-162 under Impact BIO-162.

San Joaquin Pocket Mouse

Habitat for this species consists of the grassland natural community throughout the Plan Area. The species requires friable soils for burrowing. Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of San Joaquin pocket mouse habitat as indicated in Table 12-9-60. Full implementation of Alternative 9 would also include the following conservation actions over the term of the BDCP that would likely benefit San Joaquin pocket mouse.

- Protect 8,000 acres of grasslands (GNC1.1, associated with CM3).
- Restore 2,000 acres of grasslands to connect fragmented patches of protected grasslands (GNC1.2, associated with CM8).
- Restore and sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states (GNC2.1).

As explained below, with the restoration or protection of these amounts of habitat, impacts on San Joaquin pocket mouse would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-60. Changes in San Joaquin Pocket Mouse Habitat Associated with Alternative 9 (acres)[a]

Conservation		Permanent		Temporary		Periodic[d]	
Measure[b]	Habitat Type	NT	LLT[c]	NT	LLT[c]	CM2	CM5
CM1	Grassland	82	82	344	344	NA	NA
Total Impacts CM1		**82**	**82**	**344**	**344**		
CM2–CM18	Grassland	889	2,057	239	273	385–1,277	514
Total Impacts CM2–CM18		**889**	**2,057**	**239**	**273**	**385–1,277**	**514**
TOTAL IMPACTS		**971**	**2,139**	**583**	**617**	**385–1,277**	**514**

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

[b] See discussion below for a description of applicable CMs.

[c] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

[d] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-164: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Pocket Mouse

Alternative 9 conservation measures would result in the combined permanent and temporary loss of up to 2,756 acres of habitat for San Joaquin pocket mouse (of which 2,139 acres would be a permanent loss and 617 acres would be a temporary loss of habitat, Table 12-9-60). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), *CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM10 Nontidal Marsh Restoration*, *CM11 Natural Communities Enhancement and Management*, and *CM18 Conservation Hatcheries*. The majority of habitat loss would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate San Joaquin pocket mouse habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation:* Construction of Alternative 9 conveyance facilities would result in the combined permanent and temporary loss of up to 426 acres of potential San Joaquin pocket mouse habitat (82 acres of permanent loss, 344 acres of temporary loss) in CZ 5, CZ 6, and CZ 8. The majority of grassland that would be removed would on the existing levees along the conveyance route. These areas represent poor-value habitat for the species because most of these areas consists of narrow strips of grass that are often managed to remove burrowing species.
- *CM2 Yolo Bypass Fisheries Enhancement:* Construction of the Yolo bypass fisheries enhancement (CM2) would permanently remove 388 acres of potential San Joaquin pocket mouse habitat in the Yolo Bypass in CZ 2. In addition, 239 acres would be temporarily removed. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels.
- *CM4 Tidal Natural Communities Restoration:* Tidal habitat restoration (CM4) site preparation and inundation would permanently remove an estimated 1,122acres of potential San Joaquin pocket mouse habitat. The majority of the losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and

along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment remaining grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough.

- *CM5 Seasonally Inundated Floodplain Restoration:* Construction of setback levees to restore seasonally inundated floodplain (CM5) would permanently and temporarily remove approximately 85 acres of San Joaquin pocket mouse habitat (51 permanent, 34 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7.
- *CM7 Riparian Natural Community Restoration*: Riparian restoration would impact 410 acres of grasslands, primarily in CZ 7, as part of tidal natural communities restoration (11 acres) and seasonal floodplain restoration (399 acres).
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:* Up to 10 acres of grassland would be permanently converted to vernal pool complex. The vernal pool and alkali seasonal wetland restoration would leave intact the grasslands surrounding the vernal pools. Temporary construction-related disturbance of grassland habitat would result from implementation of *CM9* in CZ 1, CZ 8, and CZ 11. However, all areas would be restored to their original or higher value habitat after the construction periods.
- *CM11 Natural Communities Enhancement and Management:* The creation of recreational trails and recreational staging areas would result in the permanent removal of 50 acres of grassland. The protection of 8,000 acres of grassland for covered species is also expected to benefit San Joaquin pocket mouse by protecting existing habitats from potential loss or degradation that otherwise could occur with future changes in existing land use. Habitat management and enhancement-related activities could cause disturbance to or direct mortality of San Joaquin pocket mouse if the species is present near work areas.

  A variety of habitat management actions included in *CM11 Natural Communities Enhancement and Management* that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of San Joaquin pocket mouse habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. Noise and visual disturbance from management-related equipment operation could temporarily displace individuals or alter the behavior of the species if adjacent to work areas. With full implementation of the BDCP, enhancement and management actions designed for western burrowing owl would also be expected to benefit these species. San Joaquin pocket mouse would benefit particularly from protection of grassland habitat against potential loss or degradation that otherwise could occur with future changes in existing land use.
- *CM18 Conservation Hatcheries:* Implementation of CM18 would remove up to 35 acres of San Joaquin pocket mouse habitat.
- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect San Joaquin pocket mouse use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and

re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and Direct Mortality: Construction could result in direct mortality of San Joaquin pocket mouse if present in construction areas.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. Alternative 9 would remove 1,554 acres of San Joaquin pocket mouse habitat (971 permanent, 583 temporary) in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 426 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management*, and *CM18 Conservation Hatcheries*—1,128 acres).

Typical NEPA project-level mitigation ratios for those natural communities affected by CM1 would be 2:1 protection of grassland habitat. Using these typical ratios would indicate that 852 acres of grassland natural communities should be protected to mitigate the CM1 losses of 426 acres of San Joaquin pocket mouse habitat. The near-term effects of other conservation actions would remove 1,128 acres of modeled habitat, and therefore require 2,256 acres of protection of San Joaquin pocket mouse habitat using the same typical NEPA and CEQA ratios (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community in CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11. The protection and restoration of grasslands, would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for San Joaquin pocket mouse and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, San Joaquin pocket mouse would likely benefit from the management of the grasslands for general wildlife benefit.

These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions for the species. The acres of protection and restoration contained in the near-term Plan goals would satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites. The AMMs are described in detail in BDCP Appendix 3.C.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 78,047 acres of potential habitat for San Joaquin pocket mouse. Alternative 9 as a whole would result in the permanent loss of and temporary effects to 2,756 acres of grasslands that could be suitable for San Joaquin pocket mouse (4% of the habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes a commitment to restore or create 2,000 acres of grassland in CZ 1, 8 and 11(Objective GNC1.2) and to protect 8,000 acres of grassland (with at least 2,000 acres protected in CZ 1, at least 1,000 acres in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed throughout CZ 1, 2, 4, 5, 7, 8, and 11 in the study area) (Objective GNC1.1). The Plan's commitment to restore grasslands such that they connect fragmented patches of already protected grasslands (Objective GNC1.2) would improve habitat connectivity and dispersal abilities of San Joaquin pocket mouse within and outside of the plan area. All protected habitat would be managed under *CM11 Natural Communities Enhancement and Management*.

NEPA Effects: In the near-term, the loss of San Joaquin pocket mouse habitat and potential for direct mortality would not be adverse because the BDCP has committed to protecting and restoring an acreage that would meet the typical mitigation ratios described above. In the absence of other conservation actions, the effects on San Joaquin pocket mouse habitat and potential mortality of a special-status species resulting from Alternative 9 would represent an adverse effect in the late long-term. However, the BDCP has committed to habitat protection and restoration associated with CM3, CM8, and CM11. This habitat protection and restoration would be guided by biological goals and objectives and by AMM1–AMM6 and AMM10, which would be in place throughout the construction period. Considering these commitments, losses of San Joaquin pocket mouse habitat and potential mortality under Alternative 9 would not be an adverse effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant. Alternative 9 would remove 1,554 acres of modeled (971 permanent, 583 temporary) habitat for San Joaquin pocket mouse in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 426 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM7 Riparian Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM11 Natural Communities Enhancement and Management*, and *CM18 Conservation Hatcheries*—1,128 acres).

The typical CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 2:1 protection of grassland habitat. Using this ratio would indicate that 852 acres of grassland natural communities should be protected to mitigate the CM1 losses of 426 acres of San Joaquin pocket mouse habitat. The near-term effects of other conservation actions would remove

1,128 acres of modeled habitat, and therefore require 2,256 acres of protection of San Joaquin pocket mouse habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community in CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11. The protection and restoration of grasslands, would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for San Joaquin pocket mouse and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, San Joaquin pocket mouse would likely benefit from the management of the grasslands for general wildlife benefit.

These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions for the species. The acres of protection and restoration contained in the near-term Plan goals would satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM10 Restoration of Temporarily Affected Natural Communities*. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and RTM storage sites. The AMMs are described in detail in BDCP Appendix 3.C.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 9 would be less than significant under CEQA.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 78,047 acres of potential habitat for San Joaquin pocket mouse. Alternative 9 as a whole would result in the permanent loss of and temporary impacts on 2,756 acres of grasslands that could be suitable for San Joaquin pocket mouse (4% of the habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes a commitment to restore or create 2,000 acres of grassland in CZ 1, 8 and 11 (Objective GNC1.2) and to protect 8,000 acres of grassland (with at least 2,000 acres protected in CZ 1, at least 1,000 acres in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed throughout CZ 1, 2, 4, 5, 7, 8, and 11 in the study area) (Objective GNC1.1). The Plan's commitment to restore grasslands such that they connect fragmented patches of already protected grasslands (Objective GNC1.2) would improve habitat connectivity and dispersal abilities of San Joaquin pocket mouse within and outside of the plan area. All protected habitat would be managed under *CM11 Natural Communities Enhancement and Management*.

Considering these protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with implementation of AMM1–AMM6 and AMM10, the loss of habitat or direct mortality through implementation of Alternative 9 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of San Joaquin pocket mouse. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on San Joaquin pocket mouse.

Impact BIO-165: Indirect Effects of Plan Implementation on San Joaquin Pocket Mouse

Construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on San Joaquin kit pocket mouse and its habitat over the term of the BDCP. These potential effects would be minimized and avoided through AMM1–AMM6, and AMM10, which would be in effect throughout the plan's construction phase.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove pocket mouse habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual pocket mice, if present.

NEPA Effects: Implementation of the AMMs listed above would avoid the potential for substantial adverse effects on San Joaquin pocket mouse, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin pocket mouse, or restrict the species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on San Joaquin pocket mouse.

CEQA Conclusion: Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin pocket mouse. With implementation of AMM1–AMM6 and AMM10, as part of Alternative 9 construction, operation, and maintenance, the BDCP would avoid the potential for significant adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of the species. Therefore, the indirect effects under this alternative would have a less-than-significant impact on San Joaquin pocket mouse.

Special-Status Bat Species

Special-status bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as tunnels, buildings, and bridges. Various roost strategies could include night roosts, maternity roosts, migration stopover, or hibernation. The habitat types used to assess effects for special-status bats roosting habitat includes valley/foothill riparian natural community, developed lands and landscaped trees, including eucalyptus, palms and orchards. Potential foraging habitat includes all riparian habitat types, cultivated lands, developed lands, grasslands, and wetlands.

There is potential for at least thirteen different bat species to be present in the study area (Figure 12-51), including four California species of special concern and nine species ranked from low to moderate priority by the Western Bat Working Group (Table 12A-2 in Appendix 12A, *Special-Status Species with Potential to Occur in the Study Area*). In 2009, DHCCP conducted a large-scale effort that involved habitat assessments, bridge surveys, and passive acoustic monitoring surveys for bats (see

Appendix 12C, *2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report* for details on methods and results).

The majority of the parcels assessed during field surveys contained bat foraging and roosting features and were considered highly suitable habitat. At the time of the 2009 field surveys, DWR biologists initially identified 145 bridges in their survey area. Eleven of the 145 bridges were not accessible and thirteen were determined to not be suitable for bats. Evidence of bat presence was observed at six of the bridges and bat sign (guano, urine staining, odor, or vocalizations) was observed at 26 of the bridges. biologists observed Mexican free-tailed bats at four of the bridges and unidentified species at the remaining two bridges. One of these bridges, over the Yolo Causeway, was used by approximately 10,000 Mexican free-tailed bats, indicating a maternity roost. A second roost site of about 50 individuals was observed under a bridge in eastern Solano County.

The remaining 89 bridges contained structural features that were considered conducive to maternity, solitary, day and/or night roosting. Night roosts may have crevices and cracks but more often have box beams or other less protected roosting spots where bats rest temporarily while feeding. Day roosts are commonly found in bridges with expansion joints, crevices, or cracks where bats are protected from predators and weather. Seventeen bridges in the survey area had no potential for roosting because they lacked surface features from which bats could hang and offered no protection from weather or predators.

Construction and restoration associated with Alternative 9 conservation measures would result in both temporary and permanent losses of foraging and roosting habitat for special-status bats as indicated in Table 12-4-61. Protection and restoration for special-status bat species focuses on habitats and does not include manmade structures such as bridges. The conservation measures that would be implemented to achieve the biological goals and objectives that would also benefit special-status bats are summarized below.

- Protect or restore 142,200 acres of high-value natural communities (Objective L1.1, associated with CM3). This objective includes protecting and restoring a variety of habitat types described below (BDCP Chapter 3, Table 3.3-4).
    - Protect 150 acres of alkali seasonal wetland in CZ 1, CZ 8, and/or CZ 11 among a mosaic of protected grasslands and vernal pool complex (Objective ASWNC1.1, associated with CM3).
    - Protect 600 acres of existing vernal pool complex (Objective VPNC1.1, associated with CM3).
    - Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
    - Protect 8,100 acres of managed wetland (Objective MWNC1,1, associated with CM3 and CM11).
    - Protect 48,625 acres of cultivated lands (Objective CLNC1.1, associated with CM3 and CM11).
    - Protect, restore, or create 2,740 acres of rice land or equivalent habitat type for the giant garter snake (Objective GGS3.1, associated with CM3, CM4, and CM10).
    - Restore 2,000 acres of grasslands to connect fragmented patches of protected (Objective GNC1.2, associated with CM3 and 8).
    - Restore 67 acres of vernal pool complex (Objective VPNC1.2, associated with CM3 and 9).

- Restore and protect 65,000 acres of tidal natural communities (Objective L1.2, associated with CM2, 3, and 4).
- Restore or create 5,000 acres of valley/foothill riparian natural community (Objective VFRNC1.1, associated with CM3 and CM7).
- Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).

As explained below, with the restoration and protection of these amounts of habitat, in addition to mitigation measures to reduce potential effects, impacts on special-status bats would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Table 12-9-61. Changes in Special-Status Bat Roosting and Foraging Habitat Associated with Alternative 9[a]

Conservation Measure[b]	Habitat Type[c]	Permanent NT	Permanent LLT[d]	Temporary NT	Temporary LLT[d]	Periodic[e] CM2	Periodic[e] CM5
CM1	Roosting	74	74	284	284	NA	NA

[a] See Appendix 12E for a detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
[b] See discussion below for a description of applicable CMs.
[c] Affected roosting habitat acreages include valley/foothill riparian habitat and orchards. An unknown number of buildings, bridges, tunnels, and individual trees could also be affected but were not included in this analysis. Foraging habitat includes all natural communities, cultivated lands, and developed lands in the study area. Foraging habitat effects for CM2-CM18 were not considered adverse as they reflect a conversion from one foraging habitat type (mostly cultivated lands) to another foraging habitat (wetlands).
[d] LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
[e] Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as the maximum possible based on different flow regimes at the proposed notch in Fremont Weir.
NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-166: Loss or Conversion of Habitat for and Direct Mortality of Special-Status Bats

Alternative 9 conservation measure CM1 would result in the permanent and temporary loss combined of up to 358 acres of roosting habitat and 4,872 acres of foraging habitat for special-status bats in the study area. DWR identified 12 bridges that could be affected by Alternative 9 construction in CM1. Conservation measures Fremont Weir/Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5) and would result in the permanent and temporary loss of 1,782 acres of roosting habitat and the conversion of approximately 65,525 acres of foraging habitat from mostly cultivated lands and managed wetlands to tidal and nontidal wetlands. Foraging habitat effects for CM2-CM18 were not considered adverse as they reflect a conversion from one foraging habitat type (mostly cultivated lands) to another foraging habitat (wetlands). Habitat enhancement and management activities (CM11) could result in local adverse effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could affect special-status bat habitat. A summary of combined impacts and NEPA effects and a CEQA conclusion follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operation*: Construction of Alternative 9 conveyance facilities would result in the permanent loss of approximately 74 acres of roosting habitat and 1,289 acres of foraging habitat in the study area. Development of the water conveyance facilities would also result in the temporary removal of up to 284 acres of roosting habitat and up to 3,583 acres of foraging habitat for special-status bats in the study area (Table 12-9-61). DWR identified twelve bridges within the area of channel dredging, fish screen, and operable barrier that provide potential roosting habitat that could be affected by construction for CM1. Two of these bridges had positive sign for bats.

- *CM2 Yolo Bypass Fisheries Enhancement*: Improvements in the Yolo Bypass would result in the conversion of approximately 2,025 acres of foraging habitat into wetlands that could still be used by bats for foraging. CM2 would also result in the permanent removal of 89 acres and temporary removal of 167acres of roosting habitat for special-status bats. The maternity colony of Mexican free-tailed bats located at both ends of the Yolo Causeway bridge could also be affected during construction for CM2. Implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, would ensure that improvements in the Yolo Bypass avoid effects on roosting special-status bats.

- C*M4 Tidal Natural Communities Restoration*: Tidal habitat restoration site preparation and inundation would result in the conversion of approximately 56,810 acres of foraging habitat into wetlands that could still be used by bats for foraging. Approximately 1,425 acres of roosting habitat for special-status bats would permanently affected. This habitat is of low value, consisting of a small, isolated patch surrounded by cultivated lands, and the species has a relatively low likelihood of being present in these areas. The roosting habitat that would be removed consists of relatively small and isolated patches along canals and irrigation ditches surrounded by cultivated lands in the Union Island and Roberts Island areas, and several small patches along the San Joaquin River. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, described below, requires that tidal natural communities restoration avoid effects on roosting special-status bats.

- *CM5 Seasonally Inundated Floodplain Restoration*: Levee construction associated with floodplain restoration would result in the conversion of an estimated 3,690 acres of foraging habitat into wetlands that could still be used by bats for foraging. CM5 would also result in the permanent removal of 57 acres and temporary removal of 45 acres of roosting habitat for special-status bats in the study area.

- *CM11 Natural Communities Enhancement and Management*: Implementation of Alternative 9 would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats. The majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands. Restored foraging habitats primarily would replace agricultural lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Noise and visual disturbances during implementation of riparian habitat management actions could result in temporary disturbances that, if bat roost sites are present, could cause temporary abandonment of roosts. This effect would be minimized with implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*.

- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on special-status bats. Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect special-status bat use of the surrounding habitat in the Yolo Bypass, the Cache Slough area, and the north and south Delta (CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8). Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of the mitigation measures described below.
- Injury and direct mortality: In addition, to habitat loss and conversion, construction activities, such as grading, the movement of construction vehicles or heavy equipment, and the installation of water conveyance facilities components and new transmission lines, may result in the direct mortality, injury, or harassment of roosting special-status bats. Construction activities related to conservation components could have similar affects. Preconstruction surveys would be conducted and if roosting or maternity sites are detected, seasonal restrictions would be placed while bats are present, as described below in the mitigation measures.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and CEQA conclusions are also included.

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA. Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, and CM4 in the near-term.

Alternative 9 would permanently or temporarily affect 1,049 acres of roosting habitat for special-status bats in the near-term as a result of implementing CM1 (358 acres roosting habitat), CM2 (256acres roosting habitat), and CM4 (435 acres roosting habitat). Effects from CM5 would all occur in the late long-term. Most of the roosting habitat losses would occur in an valley/foothill riparian.

Typical NEPA project-level mitigation ratios for those natural communities that would be affected for roosting habitat would be 1:1 for restoration and protection of the valley/foothill riparian natural community. Using these ratios would indicate that 1,049 acres of riparian habitat should be restored and 1,049 acres of riparian habitat should be protected.

Implementation of BDCP actions in the near-term would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats (Objective L1.1). BDCP actions in the near-term would restore 800 acres of riparian roosting and foraging habitat (Objective VFRNC1.1) and 21,288 acres of foraging habitat in natural communities and developed lands (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, and Objective L2.11). In addition, the BDCP would protect 750 acres of riparian roosting and foraging habitat (Objective VFRNC1.2) and 41,445 acres of foraging habitat (Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,). Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Conservation components in the near-term would sufficiently offset the adverse effects resulting from near-term effects from Alternative 9.In addition, activities associated with natural communities enhancement and protection and with ongoing facilities operations and maintenance could affect special-status bat use of surrounding habitat and could result in harassment, injury or mortality of bats. Mitigation Measure BIO-166, described below, requires preconstruction surveys to reduce these effects.

The BDCP also contains commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM10 Restoration of Temporarily Affected Natural Communities.* These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Late Long-Term Timeframe

Alternative 9 as a whole would affect 2,140 acres of roosting habitat (Table 12-9-61). Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, CM4, and CM5 in the late long-term.

Implementation of BDCP actions in the late long-term would result in an overall benefit to special-status bats within the study area through protection and restoration of approximately 142,200 acres of their foraging and roosting habitats (Objective L1.1). Achieving this objective is intended to protect the highest quality natural communities and covered species habitat in the Plan Area to optimize the ecological value of the reserve system for conserving covered species and native biodiversity. The target for total protected and restored acreage is based on the sum of all natural community acreage targets. Achieving this objective is intended to protect and restore natural communities, species-specific habitat elements, and species diversity on a landscape-scale., Achieving this objective is also intended to conserve representative natural and seminatural landscapes in order to maintain the ecological integrity of large habitat blocks, including desired ecosystem function, and biological diversity.

BDCP actions in the late long-term would restore and protect 5,750 acres of riparian roosting and foraging habitat (Objective VFRNC1.1 and Objective VFRNC1.2), and 136,450 acres of foraging habitat (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, Objective L2.11, Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,) in natural communities and developed lands. Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats.

Should any of the special-status bat species be detected roosting in the study area, construction of water conveyance facilities and restoration activities would have an adverse effect on roosting special-status bats. Noise and visual disturbances and the potential for injury or mortality of individuals associated within implementation of the restoration activities on active roosts would be minimized with implementation of Mitigation BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*. Conservation components would sufficiently offset the adverse effects resulting from late long-term effects from CM1, CM2, CM4, and CM5.

NEPA Effects: In the near-term the losses of roosting habitat for special-status bats associated with implementing Alternative 9 are not expected to result in substantial adverse effects on special-status bats, either directly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of special-status bats because the BDCP has committed to protecting the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of roosting habitat for special-status bats associated with Alternative 9, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, and AMM10, and with implementation of Mitigation Measure BIO-166, the effects of Alternative 9 as a whole on special-status bats would not be adverse

***CEQA Conclusion*:**

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would be less than significant for CEQA purposes. Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, and CM4 in the near-term.

Alternative 9 would permanently or temporarily affect 1,049 acres of roosting habitat for special-status bats in the near-term as a result of implementing CM1 (358 acres roosting habitat), CM2 (256 acres roosting habitat), and CM4 (435 acres roosting habitat). Effects from CM5 would all occur in the late long-term. Most of the roosting habitat losses would occur in an valley/foothill riparian.

Typical CEQA project-level mitigation ratios for those natural communities that would be affected for roosting habitat would be 1:1 for restoration and protection of the valley/foothill riparian natural community. Using these ratios would indicate that 1,049 acres of riparian habitat should be restored and 1,049 acres of riparian habitat should be protected.

Implementation of BDCP actions in the near-term would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats (Objective L1.1). BDCP actions in the near-term would restore 800 acres of riparian roosting and foraging habitat (Objective VFRNC1.1) and 21,288 acres of foraging habitat in natural communities and developed lands (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, and Objective L2.11). In addition, the BDCP would protect 750 acres of riparian roosting and foraging habitat (Objective VFRNC1.2) and 41,445 acres of foraging habitat (Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,). Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Conservation components in the near-term would sufficiently offset the adverse effects resulting from near-term effects from Alternative 9.In addition, activities associated with natural communities enhancement and protection and with ongoing facilities operations and maintenance could affect special-status bat use of surrounding habitat and could result in harassment, injury or mortality of bats. Mitigation Measure BIO-166, described below, requires preconstruction surveys to reduce these impacts to a less-than-significant level.

The permanent loss of roosting habitat from Alternative 9 would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure there is no significant impact under CEQA on roosting special-status bats, either directly or through habitat modifications and no substantial reduction in numbers or a restriction in the range of special-status bats. The BDCP also contains commitments to implement AMM1–AMM6 and AMM10. These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Late Long-Term Timeframe

Alternative 9 as a whole would affect 2,140 acres of roosting habitat (Table 12-9-61). Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, CM4, and CM5 in the late long-term.

Implementation of BDCP actions in the late long-term would result in an overall benefit to special-status bats within the study area through protection and restoration of approximately 142,200 acres of their foraging and roosting habitats (Objective L1.1). Achieving this objective is intended to protect the highest quality natural communities and covered species habitat in the Plan Area to optimize the ecological value of the reserve system for conserving covered species and native biodiversity. The target for total protected and restored acreage is based on the sum of all natural community acreage targets. Achieving this objective is intended to protect and restore natural communities, species-specific habitat elements, and species diversity on a landscape-scale., Achieving this objective is also intended to conserve representative natural and seminatural landscapes in order to maintain the ecological integrity of large habitat blocks, including desired ecosystem function, and biological diversity.

BDCP actions in the late long-term would restore and protect 5,750 acres of riparian roosting and foraging habitat (Objective VFRNC1.1 and Objective VFRNC1.2), and 136,450 acres of foraging habitat (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, Objective L2.11, Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,) in natural communities and developed lands. Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Should any of the special-status bat species roost in the study area, construction of water conveyance facilities and restoration activities could have an adverse effect on roosting special-status bats. Noise and visual disturbances and the potential for injury or mortality of individuals associated within implementation of construction activities would be minimized with implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*. Conservation components would sufficiently offset the adverse effects resulting from late long-term effects from CM1, CM2, CM4, and CM5.

The permanent loss of roosting habitat from Alternative 9 would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure that there would be no significant impact on roosting special-status bats, either directly or through habitat modifications, and that there would be no substantial reduction in numbers or a restriction in the range of special-status bats. Therefore, Alternative 9 would not result in a significant impact on special-status bats under CEQA.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

The following measure was designed to avoid and minimize adverse effects on special-status bats. However, baseline data are not available or are limited on how bats use the study area, and on individual numbers of bats and how they vary seasonally. Therefore, it is difficult to determine if there would be a substantial reduction in species numbers. Bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as buildings and bridges. Daily and seasonal variations in habitat use are common. To obtain the highest likelihood of detection, preconstruction bat surveys will be conducted by DWR and will include these components.

- Identification of potential roosting habitat within project area.
- Daytime search for bats and bat sign in and around identified habitat.
- Evening emergence surveys at potential day-roost sites, using night-vision goggles and/or active full-spectrum acoustic monitoring where species identification is sought.

- Passive full-spectrum acoustic monitoring and analysis to detect bat use of the area from dusk to dawn over multiple nights.
- Additional on-site night surveys as needed following passive acoustic detection of special status bats to determine nature of bat use of the structure in question (e.g., use of structure as night roost between foraging bouts).
- Qualified biologists will have knowledge of the natural history of the species that could occur in the study area and experience using full-spectrum acoustic equipment. During surveys, biologists will avoid unnecessary disturbance of occupied roosts.

Preconstruction Bridges and Other Structure Surveys

Before work begins on the bridge/structure, qualified biologists will conduct a daytime search for bat sign and evening emergence surveys to determine if the bridge/structure is being used as a roost. Biologists conducting daytime surveys would listen for audible bat calls and would use naked eye, binoculars, and a high-powered spotlight to inspect expansion joints, weep holes, and other bridge features that could house bats. Bridge surfaces and the ground around the bridge/structure would be surveyed for bat sign, such as guano, staining, and prey remains.

Evening emergence surveys will consist of at least one biologist stationed on each side of the bridge/structure watching for emerging bats from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Night-vision goggles and/or full-spectrum acoustic detectors shall be used during emergence surveys to assist in species identification. All emergence surveys would be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted).

Additionally, passive monitoring with full-spectrum bat detectors will be used to assist in determining species present. A minimum of four nights of acoustic monitoring surveys will be conducted within the season that the construction would be taking place. If site security allows, detectors should be set to record bat calls for the duration of each night. To the extent possible, all monitoring will be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted). The biologists will analyze the bat call data using appropriate software and prepare a report with the results of the surveys. If acoustic data suggest that bats may be using the bridge/structure as a night roost, biologists will conduct a night survey from 1–2 hours past sunset up to 6 hours past sunset to determine if the bridge is serving as a colonial night roost.

If suitable roost structures would be removed, additional surveys may be required to determine how the structure is used by bats, whether it is as a night roost, maternity roosts, migration stopover, or for hibernation.

Preconstruction Tree Surveys

If tree removal or trimming is necessary, qualified biologists will examine trees to be removed or trimmed for suitable bat roosting habitat. High-value habitat features (large tree cavities, basal hollows, loose or peeling bark, larger snags, palm trees with intact thatch, etc.) will be identified and the area around these features searched for bats and bat sign (guano, culled insect parts, staining, etc.). Riparian woodland, orchards, and stands of mature broadleaf trees should be considered potential habitat for solitary foliage roosting bat species.

If bat sign is detected, biologists will conduct evening visual emergence survey of the source habitat feature, from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Methodology should follow that described above for the bridge emergence survey.

Additionally, if suitable tree roosting habitat is present, acoustic monitoring with a bat detector will be used to assist in determining species present. These surveys would be conducted in coordination with the acoustic monitoring conducted for the bridge/structure.

Protective Measures for Bats using Bridges/Structures and Trees

Avoidance and minimization measures may be necessary if it is determined that bats are using the bridge/structure or trees as roost sites and/or sensitive bats species are detected during acoustic monitoring. Appropriate measures will be determined in coordination with CDFW and may include measures listed below.

- Disturbance of the bridge will be avoided between April 15 and September 15 (the maternity period) to avoid impacts on reproductively active females and dependent young.
- Installation of exclusion devices from March 1 through April 14 or September 15 through October 30 to preclude bats from occupying the bridge during construction. Exclusionary devices will only be installed by or under the supervision of an experienced bat biologist.
- Tree removal will be avoided between April 15 and September 15 (the maternity period) to avoid impacts on pregnant females and active maternity roosts (whether colonial or solitary).
- All tree removal will be conducted between September 15 and October 30, which corresponds to a time period when bats have not yet entered torpor or would be caring for non-volant young.
- Trees will be removed in pieces, rather than felling the entire tree.
- If a maternity roost is located, whether solitary or colonial, that roost will remain undisturbed until September 15 or until a qualified biologist has determined the roost is no longer active.
- All tree removal will be conducted between September 15 and October 30, which corresponds to a time period when bats would not likely have entered winter hibernation and would not be caring for flightless young. If weather conditions remain conducive to regular bat activity beyond October 30th, later tree removal may be considered in consultation with CDFW.
- Trees will be removed in pieces, rather than felling the entire tree.
- If a maternity roost is located, whether solitary or colonial, that roost will remain undisturbed with a buffer as determined in consultation with CDFW until September 15 or until a qualified biologist has determined the roost is no longer active.
- If a non-maternity roost is found, that roost will be avoided and an appropriate buffer established in consultation with CDFW. Every effort should be made to avoid the roost, as methods to evict bats from trees are largely untested. However, if the roost cannot be avoided, eviction will be attempted and procedures designed in consultation with CDFW to reduce the likelihood of mortality of evicted bats. In all cases:

- ○ Eviction will not occur before September 15th and will match the timeframe for tree removal approved by CDFW.
- ○ Qualified biologists will carry out or oversee the eviction tasks and monitor the tree trimming/removal.
- ○ Eviction will take place late in the day or in the evening to reduce the likelihood of evicted bats falling prey to diurnal predators.
- ○ Eviction will take place during weather and temperature conditions conducive to bat activity.
- ○ Special-status bat roosts will not be disturbed.

Eviction procedures may include but are not limited to:

- ○ Pre-eviction surveys to obtain data to inform the eviction approach and subsequent mitigation requirements. Relevant data may include the species, sex, reproductive status and/or number of bats using the roost, and roost conditions themselves such as temperature and dimensions. Surveys may include visual emergence, night vision, acoustic, and/or capture.
- ○ Structural changes may be made to the roost, performed without harming bats, such that the conditions in the roost are undesirable to roosting bats and the bats leave on their own (e.g., open additional portals so that temperature, wind, light and precipitation regime in the roost change).
- ○ Non-injurious harassment at the roost site to encourage bats to leave on their own, such as ultrasound deterrents or other sensory irritants.

- Prior to removal/trimming, after other eviction efforts have been attempted, any confirmed roost tree would be shaken, repeatedly struck with a heavy implement such as an axe and several minutes should pass before felling trees or trimming limbs to allow bats time to arouse and leave the tree. The biologists should search downed vegetation for dead and injured bats. The presence of dead or injured bats will be reported to CDFW.

Compensatory mitigation for the loss of roosting habitat will also be determined through consultation with CDFW and may include the construction and installation of suitable replacement habitat onsite. Depending on the species and type of roost lost, various roost replacement habitats have met with some success (e.g., bat houses, “bat bark,” planting cottonwood trees, leaving palm thatch in place rather than trimming). The creation of natural habitat onsite is generally preferable to artificial.

Artificial roosts are often unsuccessful, and care must be taken to determine as closely as possible the conditions in the natural roost to be replaced. Even with such care, artificial habitat may fail. Several artificial roosts have been highly successful in replacing bridge roost habitat when incorporated into new bridge designs. “Bat bark” has been successfully used by Arizona Department of Game and Fish to create artificial crevice-roosting bat habitat mounted on pine trees (Mering and Chambers 2012: 765). Bat houses have at best an inconsistent track record but information is mounting on how to create successful houses. There is no single protocol or recipe for bat-house success. Careful study of the roost requirements of the species in question; the particular conditions at the lost roost site including temperature, orientation of the openings, airflow, internal dimensions and structures (cavity vs. crevice, etc.) should increase the chances of designing a successful replacement.

Restoring riparian woodland with plantings shows signs of success in Colorado. Western red bat activity has been positively correlated with increased vegetation and tree growth, canopy complexity and restoration acreage at cottonwood-willow restoration sites along the Lower Colorado River (Broderick 2012: 39). These complex woodland areas would ultimately provide a wider range of bat species with preferred roost types, including both foliage-roosting and crevice-/cavity-roosting bats.

Impact BIO-167: Indirect Effects of Plan Implementation on Special-Status Bats

Construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on special-status bats and their roosting habitat over the term of the BDCP.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove special-status bat habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in disturbances to roosting bats, if present. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, is available to address these adverse effects.

Increased exposure to methylmercury associated with tidal natural communities restoration would potentially indirectly affect special-status bat species. *CM12 Methylmercury Management* describes the process by which tidal natural communities restoration may increase methyl mercury levels in wetlands in the study area. Mercury has been found in high concentrations in some bat species, such as the Indiana bat. Many bat species forage heavily on aquatic insects, which might result in rapid bioaccumulation (Evers et al. 2012). Measures described in *CM12 Methylmercury Management* are expected to reduce the effects of methylmercury on special-status bat species resulting from BDCP tidal natural communities restoration.

NEPA Effects: Implementation of the Mitigation Measure BIO-166 for special-status bats would avoid the potential for substantial adverse effects on roosting special-status bats, either indirectly or through habitat modifications. This mitigation measure would also avoid and minimize effects that could substantially reduce the number of special-status bats, or restrict species' range. Therefore, the indirect effects of Alternative 9 would not have an adverse effect on special-status bats.

CEQA Conclusion: Indirect effects from conservation components operations and maintenance as well as construction-related noise and visual disturbances could have a significant impact on special-status bat species, either indirectly or through habitat modifications. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, would reduce this impact to a less-than-significant level and ensure Alternative 9 would not result in a substantial reduction in numbers or a restriction in the range of species.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

See Mitigation Measure BIO-166 under Impact BIO-166.

Impact BIO-168: Periodic Effects of Inundation of Special-Status Bat Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from *CM2 Yolo Bypass Fisheries Enhancement* would periodically affect 324 acres of roosting habitat and 21,265 acres of foraging habitat for special-status bats in the study area (Table 12-9-61).

CM5 Seasonally Inundated Floodplain Restoration would periodically inundate up to 411 acres of roosting habitat and 10,137 acres of foraging habitat for special-status bats (Table 12-9-61). Potential roosting trees are likely to be retained within seasonally flooded areas, although high velocity flooding could uproot some trees. Seasonal flooding would not adversely affect foraging habitat for the species. The overall effect of seasonal inundation in existing riparian natural communities may instead be beneficial. Historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants. In the late long-term, seasonal inundation in areas currently occupied by riparian vegetation may contribute to the establishment of high-value habitat for special-status bats that use riparian habitats.

NEPA Effects: Periodic effects on roosting and foraging habitat for special-status bats associated with implementing Alternative 9 are not expected to result in substantial adverse effects on special-status bats, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of special-status bats. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, is available to address any effects of periodic inundation on special-status bats and roosting habitat. Therefore, Alternative 9 would not adversely affect the species.

CEQA Conclusion: Periodic inundation under CM2 and floodplain restoration under CM5 would periodically affect foraging and roosting habitat for special-status bats in the study area. Any impact of periodic inundation on special-status bats would be mitigated through implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, which would ensure there is no significant impact on roosting special-status bats, either directly or through habitat modifications and no substantial reduction in numbers or a restriction in the range of special-status bats.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

See Mitigation Measure BIO-166 under Impact BIO-166.

Plant Species

The effects of constructing the water conveyance facilities under Alternative 9 would be substantially different than under any of the other alternatives. However, effects of implementing habitat restoration would be the same as under Alternative 1A.

Vernal Pool Plants

Five covered plant species and 12 noncovered special-status plant species occur in vernal pools in the study area (Tables 12-2, 12-3, summarized in Table 12-9-62). The vernal pool habitat model used for the impact analysis was based on vegetation types and associations from various data sets which were used to create maps showing the distribution of vernal pool habitat in the study area according to three habitat types in which the species are known to occur, including vernal pool complex and degraded vernal pool complex, and alkali seasonal wetland habitat. Vernal pool complex habitat consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Degraded vernal pool complex habitat consists of habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. Because wetlands in the degraded vernal pool complex are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or small populations of species that are found in vernal pools and swales. However, they do not possess the full complement of ecosystem and community characteristics of natural vernal pools, swales and their associated uplands and they are generally ephemeral features that are eliminated during the course of normal agricultural practices. A small amount of alkali seasonal wetland habitat was included in the model because alkaline vernal pools are also present in some areas mapped as alkali seasonal wetland.

Because each of the vernal pool species addressed in this EIR/EIS have specific microhabitat affinities, and because vernal pool habitat within the study area is highly heterogeneous with respect to habitat parameters such as soil type and pool depth, the vernal pool habitat model greatly overestimates the extent of habitat in the study area occupied by each species. However, the vernal pool habitat model is likely to encompass all or most of the potential area within which special-status vernal pool plant species would occur. Therefore, it is not likely to underestimate the extent of occupied habitat or to underestimate the effects of Alternative 9.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered vernal pool plants (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect two currently unprotected occurrences of alkali milk-vetch in the Altamont Hills or Jepson Prairie core recovery areas (Objective VPP1.1, associated with CM3).
- Maintain no net loss of Heckard's peppergrass in Conservation Zones 1, 8, or 11 within restoration sites or within the area of affected tidal range of restoration projects (Objective VPP1.2, associated with CM3 and CM9).

The restoration activities covered under Alternative 9 could have impacts on special-status vernal pool plants. No modeled habitat and no known occurrences of the 17 vernal pool plants are within the proposed footprint for the Alternative 9 water conveyance facilities. Modeled vernal pool habitat would be affected by tidal habitat restoration, although no known occurrences of 17 vernal pool plants are within the hypothetical footprint for restoration activities. Table 12-9-62 summarizes the acreage of modeled vernal pool habitat in the study area, the number of occurrences of each special-status vernal pool plant in the study area, and the potential effects.

Table 12-9-62. Summary of Impacts on Vernal Pool Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Modeled Habitat					
Vernal pool complex	9,557	1			Habitat loss from tidal habitat restoration
Degraded vernal pool complex	2,576	370			Habitat loss from tidal habitat restoration
Alkali Seasonal Wetland	188	0			None
Total	12,321	372			
Covered Species					
Alkali milk-vetch			16	0	None
Dwarf downingia			12	0	None
Boggs Lake hedge-hyssop			1	0	None
Legenere			8	0	None
Heckard’s peppergrass			4[a]	0	None
Noncovered Species					
Ferris’ milk-vetch			6	0	None
Vernal pool smallscale			2	0	None
Hogwallow starfish			0	0	None
Ferris’ goldfields			4	0	None
Contra Costa goldfields			7	0	None
Cotula-leaf navarretia			5	0	None
Baker’s navarretia			3	0	None
Colusa grass			1	0	None
Bearded popcorn-flower			5	0	None
Delta woolly marbles			3	0	None
Saline clover			9	0	None
Solano grass			1	0	None

[a] One additional occurrence is in alkali seasonal wetlands.

Impact BIO-169: Effects on Habitat and Populations of Vernal Pool Plants

Alternative 9 could affect habitat for special-status vernal pool plants. The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operations*: No modeled habitat and no known occurrences of the 17 vernal pool plants are within the proposed footprint for the Alternative 9 water conveyance facilities. Therefore, under Alternative 9, construction and operation of the water conveyance facilities would not affect the five covered vernal pool plant or the 12 noncovered special-status plants.

- *CM2 Yolo Bypass Fisheries Enhancement*: No modeled vernal pool habitat and no known occurrences of the 17 vernal pool plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements. Therefore, construction and operation of the Yolo Bypass fisheries enhancements would not affect the covered or noncovered vernal pool plants.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes to benefit covered vernal pool plants by protecting 600 acres of vernal pool complex in CZs 1, 8, and 11 (Objective VPNC1.1). The protected vernal pool habitat would be managed and enhanced to sustain populations of native vernal pool species. These benefits also would accrue to any noncovered vernal pool plants occurring in the protected vernal pool complex.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration would result in the inundation of 372 acres of vernal pool complex and would, therefore, potentially affect special-status vernal pool plants. However, no known occurrences of covered and noncovered vernal pool plants would be affected. Most of this modeled habitat (370 acres) consists of degraded vernal pool habitat that is unlikely to contain special-status plants. In addition, 257.8 acres of critical habitat for Contra Costa goldfields could be affected.
- *CM5 Seasonally Inundated Floodplain Restoration*: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for floodplain restoration. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on covered and noncovered vernal pool plants.
- *CM6 Channel Margin Enhancement*: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered vernal pool plants.
- *CM7 Riparian Natural Community Restoration*: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered vernal pool plants.
- *CM8 Grassland Natural Community Restoration*: Although the vernal pool complex habitat includes grassland matrix within which the vernal pools occur, grassland restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands that are not included within vernal pool complex habitat. Therefore, grassland communities restoration would have no impacts on covered and noncovered vernal pool plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: If, through unforeseen circumstances, BDCP activities result in the net loss of vernal pool habitat, CM9 would be implemented to compensate for that loss. Because vernal pool complex restoration would focus on habitat that had been cleared and leveled but maintained an intact duripan or claypan, the likelihood of affecting any special-status vernal pool plants would be low. However, vernal pool restoration could adversely affect remnant populations of special-status vernal pool plants or affect vernal pool habitat adjacent to the restoration areas.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid vernal pool habitat and would have no impacts on covered and noncovered vernal pool plants.

- *CM22 Avoidance and Minimization Measures*: Effects on covered vernal pool plants potentially resulting from implementation of CM4 would be avoided or minimized though *AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring, AMM12 Vernal Pool Crustaceans*, and *AMM37 Recreation*. AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools. In addition, AMM11 specifies that individual projects be designed to avoid critical habitat for listed plant and wildlife vernal pool species. AMM12 limits the direct removal of vernal pool crustacean habitat to no more than 10 wetted acres and the indirect effect to no more than 20 wetted acres through the life of the Plan. AMM12 also requires that that tidal natural communities restoration or other ground-disturbing covered activities in Conservation Zones 1 and 11 will not result in the adverse modification of primary constituent elements of critical habitat for vernal pool fairy shrimp, conservancy fairy shrimp, and vernal pool tadpole shrimp. These protections would also apply to critical habitat for Contra Costa goldfields, where it overlaps with critical habitat for these vernal pool crustaceans. AMM37 requires that new recreation trails avoid populations of covered vernal pool plants.

In addition, the BDCP includes species-specific goals to benefit covered vernal pool plants. This includes protecting two occurrences of alkali milkvetch (Objective VPP1.1) and requiring no net loss of Heckard's peppergrass (Objective VPP1.2).

In summary, no adverse effects on covered special-status vernal pool plants would be expected from implementing Alternative 9. No known occurrences of 17 special-status vernal pool plants would be affected. Beneficial effects on special-status vernal pool plants could occur by protecting 600 acres of vernal pool complex in CZs 1, 8, and 11 and by protecting occurrences of alkali milk-vetch.

The GIS analysis estimated that up to 371 acres of vernal pool complex could be adversely affected by covered activities under Alternative 9. However, the actual effect on habitat for special-status vernal pool plants is expected to be much less than the estimated impact because the BDCP limits the total loss of wetted vernal pool habitat resulting from specific projects to 10 acres (approximately 67 acres of vernal pool complex) over the permit term (AMM12). At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat for special-status vernal pool plants (Objective VPNC1.2, associated with CM9). This would be consistent with typical NEPA and CEQA project-level mitigation ratios for vernal pool impacts. The limitation on the loss of wetted vernal pool habitat will constrain the implementation of tidal restoration projects that are adjacent to vernal pool complex, which could affect the feasibility of restoring 65,000 acres of tidal habitat (Objective TPANC1.1, associated with CM4).

NEPA Effects: Implementation of the BDCP under Alternative 9 would not have an adverse effect on threatened and endangered vernal pool plant species.

CEQA Conclusion: Because loss of modeled habitat for vernal pool plant species would be offset through restoration, and because impacts on occurrences of special-status vernal pool plants would be avoided, implementation of Alternative 9 would not result in a reduction in the range or numbers of 17 covered and noncovered special-status vernal pool plants in the study area. Therefore, impacts on special-status vernal pool plants be less than significant. No mitigation is required.

Alkali Seasonal Wetland Plants

Five covered species and three noncovered plants occur in alkali seasonal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-9-63). Alkali seasonal wetland habitat was modeled separately for four covered plant species occurring in seasonal alkali wetlands.

The San Joaquin spearscale habitat model approximated the distribution of suitable San Joaquin spearscale habitat in the study area according to the species' preferred habitat types, intersected with soil series and slope position. Historical and current records of San Joaquin spearscale in the study area indicate that its current distribution is limited to alkaline soil areas with shallow basin or swale microtopography along the western border. The vegetation cover of the alkaline soils is typically a combination of alkaline soil-adapted species and annual grasses, including annual ryegrass and Mediterranean barley. Habitat types used for the model included alkali seasonal wetlands, vernal pool complex, and grasslands. Soil series used in the model consisted of either clays or clay loams with alkaline horizons. San Joaquin spearscale typically occurs in swales or in level terrain but occasionally occurs on the lower slopes adjacent to streams or swales or where seeps are present. Because some of the soil series with which San Joaquin spearscale is associated can occur on hillsides, slope was used to limit the extent of the model to the toe of the slope where these soils occur by excluding areas with slope greater than 1%. Land uses that are incompatible with the species' habitat requirements, such as modeled habitat polygons falling on leveled or developed lands, were removed from the model.

Modeled habitat for brittlescale was mapped as hydrologic features such as stream corridors and playa pools located on alluvium associated with the Montezuma Block along the western boundary of the study area or on alluvium associated with tertiary formations located along the southwest boundary of the study area. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15.2 meters) on either side of their centerlines to capture the estimated maximum extent of alluvium deposits in proximity to the streams. Mapped habitat that was occupied by urban or intensive agricultural uses was removed from the model.

The habitat model for heartscale was based on the species distribution in the study area (Solano and Yolo Counties) and on the soil types and plant communities within which it occurs. Potential habitat was determined by intersecting the GIS coverage for three parameters: 1) Yolo and Solano County boundaries; 2) Solano, Pescadero, and Willows soils; and 3) grassland, alkali seasonal wetland, and vernal pool complex natural communities. The model excluded areas that have been developed or cultivated, i.e., where the topography, soils, and hydrology have been substantially altered.

Delta button-celery habitat was modeled as alkali seasonal wetland complex, vernal pool complex, other natural seasonal wetland, and grassland occurring on Brentwood, Grangerville, Marcuse, Solano, and Vernalis soil map units within the San Joaquin Basin (i.e., south of the mainstem San Joaquin River). For this species, land cover north of the Discovery Bay area where intensive agriculture was classified as annual grassland were manually deleted from the area of predicted habitat. Additionally, other areas of potential habitat that have been developed were also manually deleted.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered alkali seasonal wetland plants (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Of the 150 acres of alkali seasonal wetland complex protected under Objective ASWNC1.1, 600 acres of vernal pool complex protected under Objective VPNC1.1, and 8,000 acres of grassland natural community protected under Objective GNC1.1, protect at least 75 acres of suitable brittlescale habitat and 75 acres of suitable heartscale habitat in Conservation Zones 1, 8, or 11 (Objective BRIT/HART/SJSC1.1, associated with CM3).
- Protect two currently unprotected occurrences of San Joaquin spearscale in Conservation Zones 1, 8, or 11 (Objective BRIT/HART/SJSC1.2, associated with CM3).

No adverse effects on Delta button celery, crownscale, palmate-bracted bird's-beak or recurved larkspur would be expected. Table 12-9-63 summarizes the acreage of modeled alkali seasonal wetland habitat in the study area and the number of occurrences of each special-status alkali seasonal wetland plant in the study area.

Table 12-9-63. Summary of Impacts on Seasonal Alkali Wetland Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
San Joaquin spearscale modeled habitat	14,933	680			Habitat loss from tidal habitat restoration, Yolo Bypass fisheries enhancements, and levee construction
Brittlescale modeled habitat	451	4			Habitat loss from tidal habitat restoration
Heartscale modeled habitat	6,528	306			Habitat loss from tidal habitat restoration and Yolo Bypass fisheries enhancements
Delta button celery modeled habitat	3,330[a]	0			None
Alkali seasonal wetlands	3,273	72			Habitat loss from tidal habitat restoration and Yolo Bypass fisheries enhancements
Covered Species					
San Joaquin spearscale			19	1	Population loss from tidal habitat restoration
Brittlescale			8	0	None
Heartscale			3	0	None
Delta button celery			1[b]	0	None
Heckard's peppergrass			1c	1	Population loss from tidal habitat restoration
Noncovered Species					
Crownscale			17	0	None
Palmate-bracted bird's-beak			1	0	None
Recurved larkspur			4	0	None

[a] A portion of this acreage consists of riparian habitat.
[b] A second occurrence in study area is in riparian habitat.

[c] Four additional occurrences of Heckard's peppergrass are associated with vernal pools.

Impact BIO-170: Effects on Habitat and Populations of Alkali Seasonal Wetland Plants

Alternative 9 would have adverse effects on modeled seasonal alkali wetland habitat for San Joaquin spearscale, brittlescale, and heartscale. It could also have adverse effects on occurrences of San Joaquin spearscale and Heckard's peppergrass.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operations*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for construction of the water facilities or channel dredging. Therefore, construction and operation of the water conveyance facilities would have no impacts on covered and noncovered alkali seasonal wetland plant species.
- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo Bypass fisheries improvements would permanently remove 56 acres of modeled habitat for San Joaquin spearscale. No known occurrences of San Joaquin spearscale would be affected. No modeled habitat and no known occurrences of the seven other alkali seasonal wetland plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes to benefit alkali seasonal wetland plants by protecting 150 acres of alkali seasonal wetland in Conservation Zones 1, 8, and/or 11. The protected alkali seasonal wetland habitat would be managed and enhanced to sustain populations of native plant species.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration is expected to convert alkali seasonal wetlands on the margins of tidal wetlands to freshwater or brackish tidal marsh. Tidal habitat restoration would convert 680 acres of modeled habitat for San Joaquin spearscale to tidal marsh. Tidal habitat restoration would permanently remove 4 acres of modeled habitat for brittlescale in CZ 1 near Lindsey Slough and in CZ 11 near Nurse Slough; however, the BDCP would allow up to 50 acres of modeled habitat to be converted to tidal wetlands. Tidal habitat restoration would remove 306 acres of modeled habitat for heartscale in CZ 1 in the vicinity of Jepson Prairie and in CZ 11 adjacent to Suisun Marsh. The extent to which the modeled habitat is actually occupied by these species is not known; modeled habitat is assumed to encompass all potential habitat for a species and may therefore overestimate the area actually occupied. Tidal habitat restoration could adversely affect an occurrence of Heckard's peppergrass at Hass Slough and an occurrence of San Joaquin spearscale at Main Prairie, both in CZ 1. These occurrences are based on historic records, and the whether or not the populations still exist is not known. In each case, the loss of modeled habitat and occurrences for covered species would be adverse effects. Delta button celery, crownscale, palmate-bracted bird's-beak, and recurved larkspur would not be affected by tidal habitat restoration.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would result in the removal of 2 acres of modeled habitat for San Joaquin spearscale. No known occurrences of San Joaquin spearscale would be affected. No other alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas

proposed for floodplain restoration. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on covered and noncovered alkali seasonal wetland plants.

- *CM6 Channel Margin Enhancement*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered alkali seasonal wetland plants.
- *CM7 Riparian Natural Community Restoration*: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered alkali seasonal wetland plants.
- *CM8 Grassland Natural Community Restoration*: Although the alkali seasonal wetland habitat includes the grassland matrix within which the wetlands occur, grassland restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands that are not included within alkali seasonal wetland habitat. Therefore, grassland communities restoration would have no impacts on covered and noncovered alkali seasonal wetland plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Although some vernal pools are alkaline, alkali seasonal wetlands in the study area consist of alkali grassland, alkali meadow, or iodine bush scrub. Therefore, vernal pool restoration would avoid alkali seasonal wetland habitat and would have no impacts on covered and noncovered alkali seasonal wetland plants. In addition, the BDCP would compensate for the loss of alkali seasonal wetlands from other CMs by restoring or creating 72 acres of alkali seasonal wetlands in Conservation Zones 1, 8, or 11 to achieve no net loss of this habitat.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid alkali seasonal wetland habitat and would have no impacts on covered and noncovered alkali seasonal wetland plants.
- *CM22 Avoidance and Minimization Measures*: Effects on special-status alkali seasonal wetland plants potentially resulting from implementation of CM4 would be avoided or minimized though *AMM11 Covered Plant Species*, *AMM2 Construction Best Management Practices and Monitoring*, and *AMM37 Recreation*. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2. In addition, AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools, which would protect those species with modeled habitat that includes vernal pool complex. Occurrences of covered species in vernal pools near tidal wetlands would not be affected by tidal habitat restoration where critical habitat for vernal pool species is present and would be avoided under AMM11. AMM37 requires that new recreation trails avoid populations of covered alkali seasonal wetland plants.

In summary, one historic occurrence of Heckard's peppergrass and one historic occurrence of San Joaquin spearscale could be affected by tidal restoration activities, if those occurrences still exist. AMM11 would be implemented to avoid an adverse effect on the Heckard's peppergrass and San Joaquin spearscale occurrences.

The primary effect of Alternative 9 on special-status alkali seasonal wetland plants would be the loss of potential (i.e., modeled) habitat for San Joaquin spearscale, brittlescale, heartscale, and Delta button-celery. Approximately 72 acres of this habitat loss would be alkali seasonal wetlands. The actual effect on modeled habitat for alkali seasonal wetland plants is expected to be somewhat less than the estimated impact because some of this habitat is composed of vernal pool complex, and the BDCP limits the total loss of wetted vernal pool habitat to 10 acres (approximately 67 acres of vernal pool complex) over the permit term (AMM12). Loss of modeled habitat would be compensated for by restoring or creating vernal pool complex, alkali seasonal wetlands, and grasslands, in proportion to the amount of each habitat removed. At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat composed of vernal pool complex (Objective VPNC1.2, associated with CM9). Approximately 72 acres of alkali seasonal wetlands would be restored (Objective ASWC1.2, associated with CM9). Loss of modeled habitat composed of grasslands would be compensated for by restoring grassland habitat on a 1:1 basis (Objective GNC1.1, associated with CM8). These compensation levels would be consistent with typical NEPA and CEQA project-level mitigation ratios for impacts on vernal pools, alkali seasonal wetlands, and grasslands.

Alternative 9 would have a small beneficial effect on special-status alkali seasonal wetland plants by protecting 150 acres of alkali seasonal wetland habitat. The BDCP also includes the species-specific goals that 75 acres of the protected alkali seasonal wetland habitat would be modeled habitat for brittlescale and heartscale (Objective BRIT/HART/SJSC1.1) and that 2 occurrences of San Joaquin spearscale would be protected (Objective BRIT/HART/SJSC1.2). The benefits of habitat protection and management also would accrue to any noncovered alkali seasonal wetland plants occurring in the protected habitat.

***NEPA Effects*:** Under Alternative 9, loss of modeled habitat for alkali seasonal wetland plant species would be offset through restoration of grassland, vernal pool, and alkali seasonal wetland habitat (CM8, CM9), and impacts on one occurrence of San Joaquin spearscale and one occurrence of Heckard's peppergrass would be avoided through AMM11. With avoidance and habitat restoration, these effects would not be adverse.

***CEQA Conclusion*:** Because loss of modeled habitat for alkali seasonal wetland plant species would be offset through restoration, and because impacts on occurrences of covered alkali seasonal wetland plants would be avoided, impacts on alkali seasonal wetlands as a result of implementing Alternative 9, would not result in substantially reducing the number or restricting the range of five covered and three noncovered plant species, and this impact would be less than significant. No mitigation is required.

Grassland Plants

One covered plant and 11 noncovered special-status plants occur in grasslands in the study area (Tables 12-2, 12-3, summarized in Table 12-9-64). The only covered plant species occurring in grassland is Carquinez goldenbush. Carquinez goldenbush modeled habitat included hydrological features such as stream corridors on alluvium derived from the Montezuma Formation. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15 meters) on either side in an effort to capture the estimated maximum extend of alluvium deposits in close proximity to the actual rivers/streams.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered grassland plants (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect three unprotected occurrences of the Carquinez goldenbush in Conservation Zones 1 and/or 11 (Objective CGB1.1, associated with CM3).
- Maintain and enhance occupied Carquinez goldenbush habitat to slow erosion and reverse degradation from livestock grazing (Objective CGB1.2, associated with CM11).

Of 78,047 acres of grasslands in the study area, Alternative 9 would adversely affect 2,706 acres under Alternative 9, including 4 acres that are modeled habitat for Carquinez goldenbush. For 10 of the plants, no known occurrences would be affected. One of five Parry's rough tarplant occurrences in the study area could be affected by Alternative 9. Table 12-9-64 summarizes the acreage of grassland habitat in the study area and the number of occurrences of each special-status grassland plant in the study area.

Table 12-9-64. Summary of Impacts on Grassland Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Carquinez goldenbush modeled habitat	1,346	4			Habitat loss from tidal habitat restoration
Grassland	78,047	2,706			Habitat loss from construction of water conveyance facilities, tidal restoration, Yolo Bypass fisheries enhancements, floodplain restoration, and construction of conservation hatcheries facilities
Covered Species					
Carquinez goldenbush			10	1	Occurrence affected by tidal restoration
Noncovered Species					
Big tarplant			5	0	None
Round-leaved filaree			2	0	None
Pappose tarplant			7	0	None
Parry's rough tarplant			5	1	Periodic inundation of one occurrence as a result of Yolo Bypass operations
Small-flowered morning-glory			0	0	None
Diamond-petaled poppy			1	0	None
Stinkbells			1	0	None
Fragrant fritillary			4	0	None
Gairdner's yampah			0	0	None
Streamside daisy [a]			1	0	None
Caper-fruited tropidocarpum			8	0	None

[a] This species actually occurs in upland woodland, a habitat that has not been mapped or quantified in the BDCP.

Impact BIO-171: Effects on Habitat and Populations of Grassland Plant Species

Alternative 9 could have adverse effects on modeled habitat for Carquinez goldenbush. It could also affect one occurrence of Carquinez goldenbush and one occurrence of Parry's rough tarplant. Although Alternative 9 would have no expected effects on known occurrences of the other special-status plant species that occur in grasslands, the loss of 3,389 acres of grassland would have the potential to adversely affected undocumented populations of special-status grassland species.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operations*: No modeled habitat for Carquinez goldenbush and no known occurrences of the 12 special-status grassland plants are within the proposed footprint for the Alternative 9 water conveyance facilities. About 427 acres of grassland habitat would be affected by construction of the water conveyance facilities. However, this grassland habitat consists of small patches of herbaceous ruderal vegetation along levees that do not provide habitat for special-status grassland species. Therefore, under Alternative 9, construction and operation of the water conveyance facilities would not affect the 12 special-status grassland plants.
- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo Bypass fisheries enhancements would remove 627 acres of grassland habitat. Yolo Bypass operations would result in more frequent and longer inundation of 1,597 acres of grasslands in the Yolo Causeway (CZ 2) that include habitat for one occurrence of Parry's rough tarplant. Parry's rough tarplant is a summer-blooming plant that occurs in areas subject to occasional inundation during the wet season, such as swales and seasonal wetlands. Increasing the frequency or duration of inundation may decrease the distribution in some areas by making some conditions too wet but would also expand the distribution into areas that may currently be too dry. Overall, changing the frequency and duration of inundation in the area of this occurrence should not result in a substantial change in the range of numbers of Parry's rough tarplant. Construction and operation of the Yolo Bypass fisheries enhancements would not affect modeled habitat for Carquinez goldenbush or known occurrences of other special-status grassland plants.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes to preserve 8,000 acres of grassland habitat, some of which may contain modeled habitat for Carquinez goldenbush. Protection of grassland habitat may also protect undiscovered occurrences of special-status plant species.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration would permanently remove 1,122 acres of grassland habitat Four acres of modeled habitat for Carquinez goldenbush along the eastern side of Suisun Marsh could be loss as a result of habitat conversion, including part of one known occurrence. Tidal restoration would have not affect other known occurrences of special-status grassland plants.
- *CM5 Seasonally Inundated Floodplain Restoration*: Construction of new floodplain levees would result in the loss of 85 acres of grassland habitat, and periodic inundation of the floodplain would affect 513 acres of grassland habitat,. However, no modeled habitat for Carquinez goldenbush or known occurrences of special-status grassland plants are present within areas proposed for floodplain restoration, and the affected grassland habitat consists of herbaceous ruderal vegetation that does not support special-status grassland plants. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on covered and noncovered grassland plants.
- *CM6 Channel Margin Enhancement*: No known occurrences of special-status grassland plants are present within areas proposed for channel margin habitat enhancement. Areas mapped as grassland along levees that would be affected by channel margin habitat enhancement are small patches of ruderal vegetation along levees that do not provide habitat for special-status

grassland species and are not modeled habitat for Carquinez goldenbush. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered grassland plants.

- *CM7 Riparian Natural Community Restoration*: No modeled habitat for Carquinez goldenbush or known occurrences of special-status grassland plants are present within areas proposed for riparian habitat enhancement. About 401 acres of grassland habitat would be converted to riparian habitat. The affected grassland habitat consists of herbaceous ruderal vegetation that does not support special-status grassland plants. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered grassland plants.
- *CM8 Grassland Natural Community Restoration*: Grassland restoration would restore 2,000 acres of grassland habitat. Restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands. These areas do not currently provide habitat for special-status grassland plants. Therefore, grassland community restoration would have no impacts on covered and noncovered grassland plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: Vernal pool complex includes vernal pools as well as the surrounding grassland matrix. Because the habitat to be restored would consist of areas of former vernal pool complex that have been leveled for cultivation, special-status grassland plants would not be present. Therefore, vernal pool complex restoration would not affect special-status grassland plants.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid grassland habitat and would have no impacts on covered and noncovered grassland plants.
- *CM18 Conservation Hatcheries*: Construction of the conservation hatcheries would remove 35 acres of grassland habitat. The removed habitat would consist of ruderal herbaceous vegetation that would not be likely to provide habitat for special-status grassland plants. Therefore, construction of the conservation hatcheries would not be expected to affect special-status grassland plants.
- *CM22 Avoidance and Minimization Measures*: Effects on Carquinez goldenbush potentially resulting from implementation of CM4 and potential effects on undiscovered populations of special-status grassland plants would be avoided or minimized though *AMM11 Covered Plant Species*, *AMM2 Construction Best Management Practices and Monitoring*, and *AMM37 Recreation*. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2. AMM37 requires that new recreation trails avoid populations of Carquinez goldenbush.

The primary effect of Alternative 9 on special-status grassland plants is the loss of potential (i.e., modeled) habitat for Carquinez goldenbush, including part of one known occurrence. Adverse effects on the occurrence will be minimized through AMM11. Protecting three unprotected occurrences of Carquinez goldenbush (Objective CGB1.1, associated with CM3) and maintaining and enhancing occupied Carquinez goldenbush (Objective CGB1.2, associated with CM11) would compensate for any residual effects. One occurrence of Parry's rough tarplant would be affected by CM2, but the effect is not expected to be adverse. No known occurrences of the other special-status grassland plants would be affected.

Alternative 9 would have a potential beneficial effect on special-status grassland plants by protecting 8,000 acres of grassland habitat. To ensure that this habitat preservation would specifically benefit Carquinez goldenbush, the plan proposes to protect three Carquinez goldenbush occurrences in CZs 1 and 11 that are currently not protected and to maintain and enhance occupied Carquinez goldenbush habitat. The preservation of modeled or potential habitat, together with avoidance and minimization of impacts on species occurrences, would reduce any effects Alternative 9 on covered grassland plants to a level that is no longer adverse.

NEPA Effects**:** The loss of modeled and occupied habitat for Carquinez goldenbush would be offset through CM3, CM8, and CM11. Therefore, implementation of Alternative 1B would result in no adverse effects on special-status grassland plants.

CEQA Conclusion**:** Because adverse effects on special-status grassland plant species would be avoided or compensated for, Alternative 9 would not result in substantially reducing the numbers or restricting the range of one covered or 11 noncovered special-status grassland plants, and this impact would be less than significant. No mitigation is required.

Valley/Foothill Riparian Plants

Two covered plants and two noncovered special-status plants occur in valley/foothill riparian habitat in the study area (Tables 12-2, 12-3, summarized in Table 12-9-65). The valley/foothill riparian habitat model for Delta button-celery and slough thistle was mapped as all of the study area along the flood plain of the San Joaquin River between the levees from the Mossdale Bridge to Vernalis. Whether or not this modeled habitat is actually occupied by Delta button-celery and slough thistle is unknown; all known occurrences of these species within the area of modeled habitat are believed to be extirpated.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered valley/foothill riparian plants (BDCP Chapter 3 Section 3.3, *Biological Goals and Objectives*).

- Protect and enhance two occurrences of delta button celery. If occurrences are not found in the Plan Area, establish self-sustaining occurrences of delta button celery for a total of two occurrences within the restored floodplain habitat on the mainstem of the San Joaquin River in Conservation Zone 7 between Mossdale and Vernalis. (Objective DBC1.1, associated with CM3 and CM11)
- Protect and enhance two occurrences of slough thistle. If occurrences are not found in the Plan Area, establish self-sustaining occurrences of slough thistle for a total of two occurrences within the 10,000 acres of restored floodplain on the mainstem of the San Joaquin River in Conservation Zone 7 between Mossdale and Vernalis (Objective ST1.1: associated with CM3 and CM11).

Of 17,966 acres of valley/foothill riparian habitat in the study area, Alternative 9 would adversely affect 1,116 acres, including 15 acres that are modeled habitat for Delta button-celery and 11 acres that are modeled habitat for slough thistle. Table 12-9-65 summarizes the acreage of modeled habitat for Delta button-celery and slough thistle and the number of occurrences of each special-status grassland plant in the study area.

Table 12-9-65. Summary of Impacts on Valley/Foothill Riparian Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Delta button celery modeled habitat	3,361 [a]	15			Habitat loss from floodplain restoration
Slough thistle modeled habitat	1,834	11			Habitat loss from floodplain restoration
Valley/foothill riparian habitat	17,966	1,116			Habitat loss from construction of water conveyance facilities, tidal restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Covered Species					
Delta button celery			1 [b]	1	Occurrence potentially affected by floodplain restoration
Slough thistle			2	2	Occurrences potentially affected by floodplain restoration
Noncovered Species					
Northern California black walnut			1	0	None
Wright's trichocoronis			1	0	None

[a] A portion of this acreage consists of alkali seasonal wetland
[b] A second occurrence is in alkali seasonal wetland

Impact BIO-172: Effects on Habitat and Populations of Valley/Foothill Riparian Plants

No extant occurrences of Delta button-celery, slough thistle, Northern California black walnut, or Wright's trichocoronis are present in the study area. Therefore, no impacts on special-status valley/foothill riparian plants are expected. Modeled habitat for Delta button-celery and slough thistle, which may support undocumented occurrences of these species, would be affected by restoration of seasonally inundated floodplain.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operations*: Construction of the water conveyance facilities would remove 310 acres of valley-foothill riparian habitat under Alternative 9. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the proposed footprint for the Alternative 9 water conveyance facilities. Therefore, under

Alternative 9, construction and operation of the water conveyance facilities would not affect covered or noncovered special-status valley/foothill riparian plants.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction and operation of the Yolo Bypass fisheries enhancements would adversely affect 176 acres of valley/foothill riparian habitat. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements. Therefore, construction and operation of the Yolo Bypass fisheries enhancements would not affect the covered or noncovered valley/foothill riparian plants.
- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes to protect 552 acres of existing valley/foothill riparian forest in CZ 7. This action would have no substantial effects on special-status valley/foothill plants because no extant occurrences of special-status valley/foothill plants are present in the study area.
- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration would inundate 552 acres of valley/foothill riparian habitat. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the hypothetical footprint for tidal restoration. Therefore, tidal restoration would not affect the covered or noncovered valley/foothill riparian plants.
- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would remove about 78 acres of valley/foothill riparian habitat, including 15 acres of modeled habitat for Delta button-celery along the San Joaquin River in CZ 7. In addition, floodplain restoration would result in more frequent and longer inundation of 18 acres of modeled habitat for Delta button-celery in this area. The area affected contains one historic occurrence of Delta button celery. This occurrence is considered to be extirpated, because all habitat for Delta button-celery at his location has been converted to agriculture (California Department of Fish and Wildlife 2013). Therefore, Alternative 9 would not have an adverse effect on Delta button celery in CZ 7.

  The BDCP proposes to benefit Delta button-celery at this location by restoring 5,000 acres of valley/foothill riparian habitat and re-introducing two occurrences of Delta button-celery. Although Delta button celery occurs in riparian habitat, it is not associated with woodland or scrub habitats; rather, it occurs in alkali seasonal wetlands in floodplains, which may or may not also contain adjacent woody riparian habitat. Restoring habitat for Delta button-celery may not be compatible with restoring woody riparian habitat. In addition, establishing new populations of Delta button-celery is an untried, unproven procedure and may not be feasible. Therefore, any beneficial effects on Delta button-celery would be speculative.

  Floodplain restoration levee construction would remove 11 acres of modeled habitat for slough thistle and would result in more frequent and longer inundation of 6 acres of modeled habitat for slough thistle along the San Joaquin River in CZ 7. However, the BDCP would allow up to 50 acres of modeled habitat to be converted to riparian habitat. Whether the affected modeled habitat is actually occupied by slough thistle is not known; however, of two historic occurrences of slough thistle present in the study area, only one is considered to be extirpated (California Department of Fish and Wildlife 2013). The BDCP would protect and enhance two occurrences of slough thistle. If occurrences are not found in the study area, then two, self-sustaining occurrences of slough thistle would be established using locally-sourced genetic material for a total of two occurrences within the restored floodplain habitat on the main stem of the San

Joaquin River in CZ 7 between Mossdale and Vernalis. Establishing new populations of slough thistle is an untried, unproven procedure and may not be feasible. Therefore, any beneficial effects on slough thistle would be speculative.

One historic occurrence of Wright's trichocoronis in the study area near Lathrop (CZ 7) could also be affected by floodplain restoration. The occurrence is presumed to be extant because the presence or absence of suitable habitat has not been verified by field surveys (California Department of Fish and Wildlife 2013). However, the species has not been observed at this location for nearly a century, and habitat for Wright's trichocoronis, which would have been similar to that for Delta button celery and slough thistle, no longer appears to be present in aerial photographs of the area. Therefore, Alternative 9 would not be expected to have an adverse effect on Wright's trichocoronis.

- *CM6 Channel Margin Habitat Enhancement*: No modeled habitat or occurrences of special-status valley/foothill riparian plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM7 Riparian Natural Community Restoration*: No extant occurrences of special-status valley/foothill riparian plants are present within areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM8 Grassland Natural Community Restoration*: No occurrences of special-status valley/foothill riparian plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No occurrences of special-status valley/foothill riparian plants are present within areas proposed for vernal pool and alkali seasonal wetland complex restoration. Therefore, vernal pool complex restoration would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid valley/foothill riparian habitat and would have no impacts on covered and noncovered valley/foothill riparian plants.
- *CM22 Avoidance and Minimization Measures*: Effects on Delta button-celery and slough thistle potentially resulting from implementation of CM5 would be avoided or minimized though *AMM11 Covered Plant Species* and *AMM2 Construction Best Management Practices and Monitoring*. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2.

Because no extant occurrences of special-status valley/foothill riparian plants are known to occur in the study area, Alternative 9 is not expected to adversely affect any special-status valley/foothill riparian plants. Modeled habitat for both Delta button-celery and slough thistle would be affected. Under AMM11, surveys for covered plants would be performed during the planning phase for floodplain restoration. If Delta button-celery or slough thistle were found to be present in the floodplain restoration area, then the project would be designed to avoid impacts on the populations. Therefore, Alternative 9 would not have an adverse effect on these species.

The BDCP proposes to benefit Delta button-celery and slough thistle by restoring 5,000 acres of valley/foothill riparian habitat and re-introducing two occurrences of both species. Establishing new populations of Delta-button-celery or slough thistle would be a beneficial effect. However, establishing new populations is an untried, unproven procedure and may not be feasible.

NEPA Effects: Implementation of the BDCP under Alternative 9 would not have an adverse effect on special-status valley/foothill riparian plant species.

CEQA Conclusion: Alternative 9 would not result in a reduction in the range and numbers of covered and noncovered valley/foothill riparian plants. This impact would be less than significant. No mitigation is required.

Tidal Wetland Plants

Seven covered plants and one noncovered special-status plant occur in tidal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-9-66). Five tidal wetland habitat models were developed for the seven covered plant species occurring in tidal wetland habitat.

Modeled habitat for Mason's lilaeopsis and Delta mudwort was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover type, which was obtained from the BDCP GIS vegetation data layer.

The side-flowering skullcap model mapped the distribution of suitable habitat in the study area according to the species' habitat association with woody riparian habitat. The model selected Delta riparian vegetation types providing the habitat characteristics that side-flowering skullcap seems to require, namely, woody substrate in freshwater tidal areas. The model included vegetation subunits of the BDCP Valley Riparian natural community characterized by California dogwood, white alder, and arroyo willow.

The modeled habitat for soft bird's-beak consisted of pickleweed- and saltgrass-dominated vegetation units located west of the Antioch Bridge. Modeled habitat for these two plant species was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover types. The model used all Tidal Brackish Emergent Wetland polygons that were limited by specific vegetation units that are known to be closely associated with soft bird's-beak habitat.

Habitat for Delta tule pea and Suisun Marsh aster was modeled separately based on the salinity of the water. For the tidal freshwater emergent wetland BDCP land cover type, modeled habitat was mapped as the area within 10 feet (3 meters) of the landward side of the landward boundary, exclusively where this land cover type is adjacent to grassland, vernal pool complex, valley/foothill riparian, or cultivated land habitat cover types. For brackish water areas in and near Suisun Marsh, the model used all tidal brackish emergent wetland polygons within an elevation range of 7 to 10 feet (2 to 3 meters) to capture elevations 1 foot (30 centimeters) below intertidal to 2 feet (60 centimeters) above intertidal.

The modeled habitat for Suisun thistle in and near Suisun Marsh consists of all tidal brackish emergent wetland polygons with the appropriate vegetation. This included vegetation units dominated by saltscale, saltgrass, pickleweed, and broad-leaved peppergrass.

Full implementation of Alternative 9 would include the following conservation actions over the term of the BDCP to benefit covered tidal wetland plants (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- No net loss of Mason's lilaeopsis and delta mudwort occurrences within restoration sites, or within the area of affected tidal range of restoration projects (Objective DMW/ML1.1, associated with CM4 and CM11).
- No net loss of Delta tule pea and Suisun Marsh aster occurrences within restoration sites (Objective DTP/SMA1.1, associated with CM4 and CM11).
- Restore tidal inundation to wetlands in the Hill Slough Ecological Reserve and to the ponded area at Rush Ranch (Objective SBB/SuT1.1, associated with CM4).
- Complete seed banking of all existing Suisun Marsh populations and the representative genetic diversity using accepted seed banking protocols (Objective SBB/SuT1.2, associated with CM11).
- Establish a cultivated population of Suisun thistle from wild seed using accepted seed collection protocols (Objective SBB/SuT1.3, associated with CM11).
- Establish two occurrences of Suisun thistle in Conservation Zone 11 (Objective SBB/SuT1.4, associated with CM11).

Of 17,357 acres of tidal wetlands in the study area, Alternative 9 would affect 193 acres, including areas that are modeled habitat for Mason's lilaeopsis, Delta mudwort, side-flowering skullcap, Delta tule pea, Suisun Marsh aster, soft bird's-beak, and Suisun thistle. Known occurrences of all of these species would be affected. In addition, three occurrences of Bolander's water-hemlock, a noncovered special-status plant, could be affected by tidal habitat restoration. Table 12-9-66 summarizes the acreage of modeled habitat for covered tidal wetland species and the number of occurrences of each special-status tidal wetland plants in the study area.

Table 12-9-66. Summary of Impacts on Tidal Wetland Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Delta mudwort/ Mason's lilaeopsis modeled habitat	6,081	163			Habitat loss from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Side-flowering skullcap modeled habitat	2,497	173			Habitat loss from construction of water conveyance facilities, conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Soft bird's-beak modeled habitat	1,228	73			Habitat loss from tidal habitat restoration
Delta tule pea/ Suisun Marsh aster modeled habitat	5,853	26			Habitat loss from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Suisun thistle modeled habitat	1,281	73			Habitat loss from tidal habitat restoration
Tidal brackish emergent wetland	8,501	0			None
Tidal freshwater emergent wetland	8,856	193			Habitat loss from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Covered Species					
Delta mudwort			58	10	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration
Delta tule pea			106	30	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration
Mason's lilaeopsis			181	27	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration
Side-flowering skullcap			12	1	Occurrences affected by construction of water conveyance facilities
Soft bird's-beak			13	7	Occurrences affected by tidal habitat restoration
Suisun Marsh aster			164	27	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration
Suisun thistle			4	0	None
Noncovered Species					
Bolander's water hemlock			8	3	Occurrences affected by construction of water conveyance facilities and tidal habitat restoration

Impact BIO-173: Effects on Habitat and Populations of Tidal Wetland Plants

Alternative 9 would have adverse effects on tidal marsh special-status plants through implementation of CM1, CM2, CM4, and CM5. No adverse effects are expected from implementation of CM3, CM6, CM7, CM8, and CM9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operations*: Construction of the Alternative 9 water conveyance facilities would remove 163 acres of modeled habitat for delta mudwort and Mason's lilaeopsis, 173 acres of modeled habitat for side-flowering skullcap, and 26 acres of modeled habitat for Delta tule pea and Suisun Marsh aster. The extent to which modeled habitat is actually occupied by these species is not known; however, 12 occurrences of Mason's lilaeopsis, eight occurrences of Delta mudwort, one occurrence of Suisun Marsh aster, two occurrences of side-flowering skullcap, and one occurrence of Bolander's water-hemlock in the study area could be affected by construction impacts. No known occurrences of soft bird's-beak or Suisun thistle would be affected by construction of the water conveyance facilities.

- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo Bypass fisheries enhancements would remove 5 acres of modeled habitat for Mason's lilaeopsis and delta mudwort. The extent to which modeled habitat is actually occupied by these species is not known; however, no known occurrences in the study area would be affected. Yolo Bypass operations would result in more frequent and longer inundation of 8 acres of modeled habitat Delta tule peas and Suisun Marsh aster. Two occurrences of Suisun Marsh aster would be affected by Yolo Bypass operations. Habitat for these species is normally periodically inundated or saturated; therefore, a small increase in the frequency and duration of periodic inundation of the habitat would not be expected to have a substantial effect.

- *CM3 Natural Communities Protection and Restoration*: The BDCP proposes restoring or creating 20 linear miles of transitional tidal areas within other natural communities that would be created or restored, including 6,000 acres of tidal brackish emergent wetland and 24,000 acres of tidal freshwater emergent wetland. In addition, the habitat and ecosystem functions of these areas would be maintained and enhanced. The BDCP does not specifically propose to protect any occurrences of tidal wetland plants nor does it propose active restoration of affected habitat or occurrences. Instead, the BDCP assumes that the 20 linear miles of restored transitional tidal areas will be passively colonized by the covered tidal wetland plants.

- *CM4 Tidal Natural Communities Restoration*: Tidal habitat restoration would permanently remove 6 acres of modeled habitat for Mason's lilaeopsis and Delta mudwort. Habitat loss would occur through conversion of the species habitat (at and immediately above the tidal zone in marshes and along rivers and streams) to inundated tidal habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, 14 of 176 known occurrences of Mason's lilaeopsis and three of 57 known occurrences of delta mudwort in the study area could be affected by tidal habitat restoration.

  Tidal habitat restoration would remove 4 acres of modeled habitat for side-flowering skullcap. Whether the affected modeled habitat is actually occupied by side-flowering skullcap is not known; however, none of the 12 known occurrences in the study area would be affected.

  Tidal habitat restoration would remove 2 acres of modeled habitat for Delta tule pea and Suisun Marsh aster. However, the BDCP would allow up to 50 acres of modeled habitat to be removed. Habitat loss would result from conversion of the species habitat (at and immediately above the tidal zone in marshes and along rivers and streams) to inundated tidal habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, 26 of 112 known occurrences of Delta tule pea and 24 of 145 occurrences of Suisun Marsh aster in the study area would be affected.

Tidal habitat restoration could affect 73 acres of modeled habitat for soft bird's-beak and Suisun thistle, including 1.3 acres of critical habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, seven of 12 known occurrences of soft bird's-beak in the study area could be affected. None of the four known occurrences of Suisun thistle in the study area would be affected.

Tidal habitat restoration could affect three of eight known occurrences of Bolander's water-hemlock, a noncovered special-status species in the study area. Because Bolander's water-hemlock occurs in tidal marsh, it may benefit from tidal marsh restoration. However, site preparation, earthwork, and other site activities could adversely affect Bolander's water-hemlock through direct habitat removal.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would remove 3 acres of modeled habitat for Mason's lilaeopsis and delta mudwort and 2 acres of modeled habitat for side-flowering skullcap. No known occurrences of these species in the study area would be affected by floodplain restoration.

  Floodplain restoration would result in more frequent and longer inundation of 2 acres of modeled habitat for Mason's lilaeopsis and delta mudwort, 18 acres of modeled habitat for side-flowering skullcap, and 1 acre of modeled habitat for Delta tule peas and Suisun Marsh aster. No known occurrences of these species in the study area would be affected by periodic inundation of restored floodplain habitat. Habitat for these species is normally periodically inundated or saturated; therefore, a small increase in the frequency and duration of periodic inundation of the habitat would not be expected to have a substantial effect.

- *CM6 Channel Margin Enhancement*: Effects of channel margin enhancement were not analyzed separately from the effects of tidal habitat restoration. Channel margin enhancement would have adverse effects on tidal wetland plants through direct removal and habitat modification. However, it would have beneficial effects on these species by improving the habitat functions for these species as a result of riprap removal and creation of floodplain benches. Side-flowering skullcap would benefit from installation of large woody material, which it appears to colonize.

- *CM7 Riparian Natural Community Restoration*: Riparian habitat restoration is not expected to adversely affect special-status tidal wetland plants. Preparatory work that involves habitat disturbance would occur during implementation of CM4 and CM5. Riparian plantings carried out for CM7 would be placed in floodplain areas, not in tidal wetlands.

- *CM8 Grassland Natural Community Restoration*: No tidal wetlands or occurrences of special-status tidal wetland plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on covered and noncovered tidal wetland plants.

- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No tidal wetlands or occurrences of special-status tidal wetland plants are present within areas proposed for vernal pool complex restoration. Therefore, vernal pool complex restoration would have no impacts on covered and noncovered tidal wetland plants.

- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid tidal wetland habitat and would have no impacts on covered and noncovered tidal wetland plants.

- *CM22 Avoidance and Minimization Measures*: Effects on covered tidal wetland plants potentially resulting from implementation of CM1, CM2, CM4, and CM5 would be avoided or minimized though *AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring, AMM12 Vernal Pool Crustaceans, AMM30 Transmission Line Design and Alignment Guidelines,* and *AMM37 Recreation*. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2. In addition, AMM11 contains specific guidance to avoid adverse modification of any of the primary constituent elements for Suisun thistle or soft bird's-beak critical habitat. AMM30, which specifies that the alignment of proposed transmission lines will be designed to avoid sensitive terrestrial and aquatic habitats when siting poles and towers, to the maximum extent feasible, would avoid some impacts on Mason's lilaeopsis. AMM37 requires that new recreation trails avoid populations of covered tidal wetland plants.

In summary, the GIS analysis indicates that Alternative 9 would result in the loss of modeled habitat for all of the covered species and result in adverse effects on known occurrences of most of the special-status plants occurring in tidal wetlands. However, the BDCP predicts that habitat restoration activities would greatly expand the amount of habitat available to each of these species, offsetting any potential loss of habitat or occurrences resulting from covered activities.

Delta mudwort could lose 163 acres of modeled habitat (2.7%), including all or part of ten occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Delta mudwort, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Delta mudwort; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DMW/ML1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11-21, associated with CM11).

Mason's lilaeopsis could lose 163 acres of modeled habitat (2.7%), including all or part of 27 occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Mason's lilaeopsis, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Mason's lilaeopsis; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DMW/ML1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11-21, associated with CM11).

Delta tule pea could lose 26 acre of modeled habitat (0.4%), including all or part of 30 occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Delta tule pea, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Delta tule pea; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DTP/SMA1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11-22, associated with CM11).

Suisun Marsh aster could lose 26 acre of modeled habitat (0.4%), including all or part of 27 occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Suisun Marsh aster, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Suisun marsh aster; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would occur and result in no net loss of occurrences (Objective DTP/SMA1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11-22, associated with CM11).

All four of these species (Delta mudwort, Mason's lilaeopsis, Delta tule pea, and Suisun Marsh aster) are widespread in the study area with many occurrences. Habitat modification and loss are the primary stressors that are responsible for their decline and that currently limit their distribution and abundance. Therefore, restoring large areas of habitat and improving habitat functions for these species would provide a reasonable expectation that the distribution and abundance of these species would also improve. Because a relatively small amount of modeled habitat would be adversely affected (less than 1% of the total), it is likely that the initial adverse effects of covered activities on these species would be offset and that the overall effect of Alternative 9 on these species would not be adverse.

Side-flowering skullcap could lose 173 acres of modeled habitat (7%), including all or part of one occurrence. Under AMM11, this occurrence would be surveyed for, and because this is a tidal freshwater wetland species, avoidance of the habitat during project construction would be highly likely. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by side-flowering skullcap, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for side-flowering skullcap; creation of suitable habitat under these measures could also help offset this habitat loss. No active restoration of this species is proposed, and no post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done. Because impacts on occurrences of side-flowering skullcap would be avoided, and because loss of modeled habitat for the species would be offset through restoration, the overall effect of Alternative on this species would not be adverse.

Soft bird's-beak could lose 73 acres of modeled habitat (6%), including all or part of seven occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by soft bird's-beak, which could offset this habitat loss. Tidal restoration in the Hill Slough Ecological Reserve would be done to increase potential habitat there for soft bird's-beak

(Objective SBB/SuT1.1, associated with CM4). In addition, activities to control invasive plants and manage livestock in tidal marsh habitat under CM11 could enhance habitat for soft bird's-beak. Although no active restoration of this species is proposed, post-implementation monitoring of soft bird's-beak occurrences in proximity to tidal restoration sites would be done to confirm that occurrences are stable or increasing (Monitoring Action CM11-22, associated with CM11). Soft bird's-beak has a restricted distribution in the study area with highly localized occurrences, and habitat modification is the primary factor responsible for the species' decline and limiting the species' distribution and abundance. Improving habitat functions for this species would provide a reasonable expectation that the distribution and abundance of soft bird's-beak would also improve. Although a substantial amount of modeled habitat could be affected, the primary habitat for soft bird's-beak is high tidal brackish marsh, and the affected habitat is low tidal brackish marsh. Therefore, it is likely that the overall effect of Alternative 9 on this species would not be adverse.

Suisun thistle could lose 73 acres of modeled habitat (6%), although no occurrences would be affected. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Suisun thistle, which could offset this habitat loss. Tidal restoration in the Hill Slough Ecological Reserve and at Rush Ranch would be done to increase potential habitat there for Suisun thistle (Objective SBB/SuT1.1, associated with CM4). In addition, activities to control invasive plants and manage livestock in tidal marsh habitat under CM11 could enhance habitat for Suisun thistle. In addition, two new occurrences of Suisun thistle would be established in CZ 11 (Objective SBB/SuT1.4, associated with CM11). Post-implementation monitoring of Suisun thistle occurrences in proximity to tidal restoration sites would be done to confirm that occurrences are stable or increasing (Monitoring Action CM11-22, associated with CM11). Habitat restoration, enhancement of habitat functions, and establishment of new occurrences would offset any potential loss of modeled habitat for Suisun Marsh thistle.

Three occurrences of Bolander's water-hemlock could be affected. Although the extent of potential habitat affected was not determined, it would be comparable to that for Delta tule pea and Suisun Marsh aster (5 acres). Tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) could increase the extent of habitat available for colonization by Bolander's water-hemlock, which could offset this habitat loss. Because only a few scattered occurrences of Bolander's water-hemlock are present in the study area, there is no reasonable expectation that habitat restoration without active species-specific restoration activities would result in the establishment of new occurrences to offset the losses. Also, because Bolander's water-hemlock is a noncovered species, the species protections and occurrence monitoring afforded to covered species under the BDCP would not apply to this species. Therefore, the effects of Alternative 9 on Bolander's water hemlock could be adverse.

NEPA Effects: The loss of modeled and occupied habitat for special-status tidal wetland plants would be offset through tidal habitat restoration (CM4). Therefore, implementation of Alternative 9 would result in no adverse effects on seven of eight special-status grassland plants in the study area. Alternative 9 would result in a reduction in the range and numbers of Bolander's water-hemlock, which would be an adverse effect. Adverse effects on Bolander's water-hemlock could be avoided or offset through implementation of Mitigation Measure BIO-170.

CEQA Conclusion: Because loss of occurrences and modeled habitat for covered tidal habitat plant species would be offset through habitat restoration, impacts on covered tidal wetland plants as a result of implementing Under Alternative 9 would not be significant. However, the loss of Bolander's water-hemlock populations in CZ 11 would result in a reduction in the range and numbers of this species and would be a significant impact. Implementation of Mitigation Measure BIO-170 would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species

DWR will evaluate all projects for their impacts on special-status plants, avoid or minimize impacts on species that occur on project sites, and compensate for impacts on species. All impacts on federally listed noncovered species, diamond-petaled California poppy, or caper-fruited tropidocarpum shall be avoided. Impacts on other special-status plant species shall be avoided to the extent feasible, and any unavoidable impacts shall be compensated for.

- DWR shall conduct surveys for the special-status plant species within and adjacent to all project sites. Special-status plant surveys required for project-specific permit compliance will be conducted during the planning phase to allow design of the individual restoration projects to avoid adverse modification of habitat for specified covered plants. The purpose of these surveys will be to verify that the locations of special-status plants identified in previous record searches or surveys are extant, identify any new special-status plant occurrences, and cover any portions of the project area not previously surveyed. The extent of mitigation of direct loss of or indirect effects on special-status plants will be based on these survey results.
- All surveys shall be conducted by qualified biologists using the using *Guidelines for Conducting and Reporting Botanical Inventories for Federally Listed, Proposed and Candidate Plants* (U.S. Fish and Wildlife Service 1996) and *Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities* (California Department of Fish and Game 2009) during the season that special-status plant species would be evident and identifiable, i.e., during their blooming season. Locations of special-status plants in proposed construction areas will be recorded using a GPS unit and flagged.
- The construction monitoring plan for the protection of covered fish, wildlife, and plant species, prepared by DWR before implementing an approved project, will provide for construction activity monitoring in areas identified during the planning stages and species/habitat surveys as having noncovered special-status plant species.
- Where surveys determine that a special-status plant species is present in or adjacent to a project site, direct and indirect impacts of the project on the species shall be avoided through the establishment of activity exclusion zones, within which no ground-disturbing activities shall take place, including construction of new facilities, construction staging, or other temporary work areas. Activity exclusion zones for special-status plant species shall be established around each occupied habitat site, the boundaries of which shall be clearly marked with standard orange plastic construction exclusion fencing or its equivalent. The establishment of activity exclusion zones shall not be required if no construction-related disturbances will occur within 250 feet of the occupied habitat site. The size of activity exclusion zones may be reduced through consultation with a qualified biologist and with concurrence from USFWS or CDFW based on project site-specific conditions.
- Where avoidance of impacts on a special-status plant species is infeasible, DWR will compensate for loss of individuals or occupied habitat of a special-status plant species

through the acquisition, protection, and subsequent management in perpetuity of other existing occurrences at a 2:1 ratio (occurrences affected:occurrences preserved). DWR will provide detailed information to USFWS and CDFW on the location of the preserved occurrences, quality of the preserved habitat, feasibility of protecting and managing the areas in-perpetuity, responsible parties, and other pertinent information. If suitable occurrences of a special-status plant species are not available for preservation, then the project shall be redesigned to remove features that would result in impacts on that species.

Inland Dune Plants

Impact BIO-174: Effects on Habitat and Populations of Inland Dune Plants

Alternative 9 would have no adverse effects on inland dune plants (Table 12-9-67). No construction activities or habitat restoration would take place where the species occur. No specific actions to benefit inland dune species are proposed.

Table 12-9-67. Summary of Impacts on Inland Dune Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Modeled Habitat					
Inland Dunes	19	0			None
Noncovered Species					
Hoover's cryptantha			1	0	None
Antioch Dunes buckwheat			1	0	None
Mt. Diablo buckwheat			1	0	None
Contra Costa wallflower			3	0	None
Antioch Dunes evening-primrose			9	0	None

NEPA Effects: Implementation of the BDCP under Alternative 9 would not affect special-status inland dune plant species.

CEQA Conclusion: Implementation of Alternative 9 would have no impacts on inland dune species. No mitigation is required.

Nontidal Wetland Plants

No covered plant species occur in nontidal wetlands in the study area; however, six noncovered special-status plant species occur in nontidal wetlands in the study area. Table 12-9-68 summarizes the acreage of nontidal wetland habitat in the study area and the number of occurrences of each special-status nontidal wetland plant in the study area.

Table 12-9-68. Summary of Impacts on Nontidal Wetland Plants under Alternative 9

	Acres in Study Area	Acres Affected	Occurrences in Study Area	Occurrences Affected	Impacts
Habitat					
Nontidal freshwater aquatic	5,567	269			Loss of habitat from construction of Yolo Bypass fisheries enhancements, tidal habitat restoration, and floodplain restoration
Nontidal freshwater perennial emergent wetland	1,509	151			Loss of habitat from construction of water conveyance facilities, tidal habitat restoration, Yolo Bypass fisheries enhancements, and floodplain restoration
Noncovered Species					
Watershield			3	0	None
Bristly sedge			18	1	Loss of habitat from construction of water conveyance facilities
Woolly rose-mallow[a]			121	14	Loss of habitat from construction of water conveyance facilities, tidal habitat restoration
Eel-grass pondweed			1	1	Loss of habitat from construction of water conveyance facilities
Sanford's arrowhead			23	2	Loss of habitat from construction of water conveyance facilities, tidal habitat restoration
Marsh skullcap[a]			5	1	Loss of habitat from construction of water conveyance facilities

[a] Also occurs in valley/foothill riparian habitat.

Impact BIO-175: Effects on Habitat and Populations of Nontidal Wetland Plants

Under Alternative 9, known occurrences eel-grass pondweed, bristly sedge, woolly rose-mallow, Sanford's arrowhead, and marsh skullcap would be within the proposed footprint for the water conveyance facilities or within the hypothetical footprint for restoration activities and would be adversely affected. Alternative 9 would have no adverse effects on watershield.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- *CM1 Water Facilities and Operations*: Under Alternative 9, the primary effect on noncovered plants would be the loss of occupied habitat as a result of in-stream island dredging and construction of operable barriers. One occurrence of bristly sedge in CZ 5 would be adversely affected by construction of a temporary access road. One occurrence of Sanford's arrowhead in CZ 5 would be adversely affected by installation of an operable barrier and associated transmission lines. Thirteen occurrences of woolly rose-mallow would be affected by channel dredging, construction of operable barriers, and other construction activities: five in CZ 6, one in

CZ 5, one in CZ 4, and six in CZ 8. One occurrence of eel-grass pondweed at the Webb Tract and one occurrence of marsh skullcap on the Middle River are present within areas in CZ 6 that would be affected by construction of water conveyance facilities. The locations of these two occurrences are not known with certainty (i.e., nonspecific occurrences), so the likelihood or extent of the impact cannot be determined.

- *CM2 Yolo Bypass Fisheries Enhancement*: No known occurrences of special-status nontidal wetland plants are present in the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements. Therefore, construction and operation of the Yolo Bypass Fisheries enhancements would not affect special-status nontidal marsh plants.
- *CM3 Natural Communities Protection and Restoration*: No specific natural communities protection is proposed for nontidal wetlands under the BDCP. Therefore, no occurrences of special-status nontidal plants are proposed for protection.
- *CM4 Tidal Natural Communities Restoration*: One known occurrence of Sanford's arrowhead is present within areas that could be affected by tidal habitat restoration in CZ 2. One known occurrence of woolly rose-mallow is present within areas that could be affected by tidal habitat restoration in CZ 7. No other known occurrences of special-status nontidal wetland plants are present within areas proposed for tidal habitat restoration. Therefore, tidal habitat restoration could have adverse effects on three special-status nontidal wetland plants.
- *CM5 Seasonally Inundated Floodplain Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for floodplain restoration.
- *CM6 Channel Margin Enhancement*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status nontidal wetland plants.
- *CM7 Riparian Natural Community Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on special-status nontidal wetland plants.
- *CM8 Grassland Natural Community Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on special-status nontidal wetland plants.
- *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*: No known occurrences of special-status nontidal wetland plants are present within areas proposed for vernal pool complex restoration. Therefore, vernal pool complex restoration would have no impacts on special-status nontidal wetland plants.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid existing nontidal marsh and would have no adverse effects on special-status nontidal wetland plants. The BDCP may benefit nontidal wetland species by creating 400 acres of nontidal freshwater marsh, including components of nontidal perennial aquatic and nontidal freshwater perennial emergent wetland communities, and by maintaining and enhancing the habitat functions of protected and created nontidal wetland habitats for covered and other native species. However, no specific actions to benefit noncovered species are proposed.

Under Alternative 9, 1,500 acres of nontidal marsh would be restored (Objective NFEW/NPANC1.1, addressed under CM10). However, these wetlands would be restored primarily as habitat for giant garter snake. These habitat restoration activities would be unlikely to expand the amount of habitat available to bristly sedge, woolly rose-mallow, eel-grass pondweed, marsh skullcap, and Sanford's arrowhead, potential loss of habitat or occurrences resulting from covered activities would not be compensated for. Moreover, because special-status nontidal wetland plant species are not covered under the BDCP, the species protections afforded to covered species under CM22 do not apply to these species, and the effects of Alternative 9 on these species would be adverse.

NEPA Effects: Implementation of the BDCP under Alternative 9 could result in a reduction in the range and numbers of bristly sedge, woolly rose-mallow, eel-grass pondweed, marsh skullcap, and Sanford's arrowhead, five noncovered nontidal wetland species, which would be an adverse effect. Adverse effects on these species could be avoided or offset through implementation of Mitigation Measure BIO-170.

CEQA Conclusion: Under Alternative 9, construction of the water conveyance facilities and tidal habitat restoration would result in a reduction in the range and numbers of bristly sedge, woolly rose-mallow, eel-grass pondweed, marsh skullcap, and Sanford's arrowhead. These impacts would be significant. Implementation of Mitigation Measure BIO-170, *Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species*, would reduce these impacts to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species

Please see Mitigation Measure BIO-170 under Impact BIO-173.

General Terrestrial Biology Effects

Wetlands and Other Waters of the United States

Alternative 9 actions would both permanently and temporarily remove or convert wetlands and open water that is potentially jurisdictional as regulated by USACE under Section 404 of the CWA. The following two impacts address the project-level effects of CM1 on these potential wetlands and waters, and the programmatic-level effects of other relevant conservation actions (CM2–CM10). Conservation Measures 11–22 would not directly result in loss or conversion of wetlands or other waters of the United States. The methods used to conduct these analyses are described in Section 12.3.2.4 of this chapter.

Impact BIO-176: Effects of Constructing Water Conveyance Facilities (CM1) on Wetlands and Other Waters of the United States

Construction of the Alternative 9 water conveyance facilities would both temporarily and permanently remove potential wetlands and other waters of the United States as regulated by Section 404 of the CWA (Table 12-9-69). Based on the methodology used to conduct this analysis, these effects would occur at channel dredging sites, canal construction sites, operable barrier construction sites and channel widening sites throughout the study area, and at multiple temporary work areas associated with the construction activity. The permanent and temporary wetland effects (1,565 acres) would occur primarily in open tidally-influenced channels of the central and south Delta, including Middle River, Victoria Canal and Old River from channel dredging and canal construction. Construction of various operable barriers in major rivers, canals and sloughs throughout the central and south Delta would also contribute to the large acreage affected by water conveyance construction. Most of the construction and dredging activities would not permanently remove the waterways, but would permanently modify the channel bottoms and eliminate any associated aquatic vegetation. An additional effect on waters of the United States is the dredging of 517 acres of tidal flow in Middle River and Victoria and North Canals.

Table 12-9-69. Potential Wetlands and Other Waters of the United States Filled by Construction of Alternative 9 Water Conveyance Facilities

Wetland/Other Water Type[a]	Permanent	Temporary	Total
Open Water			
Nontidal Flow	41	10	51
Muted Tidal Flow	0	0	0
Tidal Flow[b]	670	362	1,032
Pond or Lake (nontidal)	5	<1	5
Clifton Court Forebay	13	0	13
Wetland			
Nontidal Wetland	17	21	38
Tidal Wetland	74	332	406
Seasonal Wetland	12	8	20
Total Impact Acres	**832**	**733**	**1,565**

[a] Wetland types are described in Section 12.3.2.4, *Methods Used to Assess Wetlands and Other Waters of the United States*.
[b] Alternative 9 also includes channel dredging impacts on 517 acres of tidal flow in Middle River and Victoria and North Canals
Source: California Department of Water Resources 2013b

NEPA Effects: The permanent and temporary loss of these potential jurisdictional wetlands as a result of constructing Alternative 9 water conveyance facilities would be a substantial effect if not compensated by wetland protection and/or restoration. This loss would represent a removal of federally protected wetlands as defined by Section 404 of the CWA. However, Alternative 9 includes conservation measures (CM4 and CM10) that would restore and protect large acreages of both tidal and nontidal wetlands and open water in the study area. Through the course of the BDCP restoration program, this alternative would restore 65,000 acres of tidal and 1,200 acres of nontidal wetland or open water. Impacts to wetlands from CM1 construction would occur in the first 10 years after BDCP approval. Approximately 19,550 acres of this wetland restoration would occur during this time period, thereby offsetting the impacts of CM1 construction. These acreages greatly exceed the no net loss (1:1 replacement ratio) requirement for Alternative 9 (1,569 acres). Therefore, there would be an overall beneficial effect on potential jurisdictional wetlands and other waters of the United States from Alternative 9 implementation.

CEQA Conclusion: The permanent and temporary loss of potential jurisdictional wetlands as a result of constructing Alternative 9 water conveyance facilities would be a substantial effect if not compensated for by wetland protection and/or restoration. This loss would represent either temporary or permanent removal of federally protected wetlands or other waters of the United

States as defined by Section 404 of the CWA. However, Alternative 9 includes conservation measures (CM4 and CM10) that would restore and protect large acreages of both tidal and nontidal wetlands and open water. Through the course of the BDCP restoration program, this alternative would result in restoration of 65,000 acres of tidal and 1,200 acres of nontidal wetlands and open water. Impacts to wetlands from CM1 construction would occur in the first 10 years after BDCP approval. Approximately 19,550 acres of this wetland restoration would occur during this time period, thereby offsetting the impacts of CM1 construction. These acreages greatly exceed the no net loss (1:1 replacement ratio) requirement for Alternative 9 (1,565 acres). Therefore, there would be a beneficial impact on potential jurisdictional wetlands and other waters of the United States resulting from Alternative 9 implementation.

Impact BIO-177: Effects of Implementing Other Conservation Measures (CM2–CM10) on Wetlands and Other Waters of the United States

The habitat protection and restoration activities associated with Alternative 9's other conservation measures (CM2–CM10) would alter the acreages and functions and values of wetlands and Waters of the United States in the study area during the course of BDCP conservation action implementation. Because these conservation measures have not been defined to the level of site-specific footprints, it is not possible to delineate and quantify these effects in detail. Several of the conservation measures (CM2, CM4, and CM5) have been described with theoretical footprints for purposes of the effects analysis contained in BDCP Chapter 5, *Effects Analysis*. These theoretical footprints have been used to predict the acres of natural communities that would be affected through loss or conversion, which gives some indication of jurisdictional wetland effects. Any CM2–CM10 effects ascribed to tidal perennial aquatic, tidal brackish emergent, tidal freshwater emergent, other natural seasonal, nontidal freshwater perennial emergent, and nontidal perennial aquatic wetlands natural communities are likely to also be effects on wetlands and other Waters of the US. Effects ascribed to other natural communities and land cover types with small jurisdictional wetland components (valley/foothill riparian, alkali seasonal wetland complex, vernal pool complex, managed wetland, grassland and cultivated land) are not easily converted to effects on wetlands and other Waters of the US by the use of theoretical footprints. Because of this lack of detail, a programmatic assessment is provided for these other conservation measures.

NEPA Effects: The conversion of existing wetland natural communities to other types of wetland natural communities through implementation of CM2–CM10 for Alternative 9 would be in the range of 5,500 to 6,000 acres, assuming that 100% of the predominantly wetland natural communities listed in Table 12-9-69 and that 10% of all of the non-wetland natural communities listed in that table would qualify as wetlands or other Waters of the US under the CWA. Most of these wetlands would be converted to tidal and nontidal wetlands and open water through implementation of CM4, and CM10. The wetlands and open water created by these two restoration actions would be approximately 66,200 acres, far exceeding what is required under the no net loss policy used by the USACE in considering Section 404 permits, even if one were to assume that all conversions represented a functional wetland loss. Therefore, there would be a beneficial effect on potential jurisdictional wetlands and other Waters of the US from implementing CM2–CM10.

CEQA Conclusion: The permanent and temporary loss of potential jurisdictional wetlands as a result of implementing the other conservation measures (CM2–CM10) of Alternative 9 would be a substantial effect if not compensated for by wetland protection and/or restoration. This loss would represent a removal of federally protected wetlands or other Waters of the US as defined by Section

404 of the CWA. However, Alternative 9 includes conservation measures (CM4 and CM10) that would restore large acreages of both tidal and nontidal wetlands and open water in the study area. Over the life of the BDCP restoration program, this alternative would result in restoration of 66,200 acres of tidal and nontidal wetlands and open water, of which 19,550 acres would be restored in the first 10 years. These acreages greatly exceed the no net loss (1:1 replacement ratio) requirement for Alternative 9 (5,500–6,000 acres). Therefore, there would be a beneficial impact on potential jurisdictional wetlands and other Waters of the US from implementing CM2–CM10 under Alternative 9.

Shorebirds and Waterfowl

Managed wetlands, tidal natural communities, and cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands) provide freshwater nesting, feeding, and resting habitat for a large number of Pacific flyway waterfowl and shorebirds. The primary effects of concern for shorebirds and waterfowl are related to the conversion of managed wetland and cultivated lands to tidal marsh associated with habitat restoration. Ducks Unlimited (2013) conducted an analysis to determine the effects of BDCP conservation measures on waterfowl, as well as to determine whether BDCP actions would impede attainment of the goals established by the Central Valley Joint Venture (CVJV) Implementation Plan for the Delta, Yolo, and Suisun Marsh drainage basins. The CVJV efforts are guided by its 2006 Implementation Plan, which is founded on the principles of strategic habitat conservation (Central Valley Joint Venture 2006). Those principles emphasize the establishment of population abundance objectives and the use of species-habitat models to link population objectives to habitat needs. The CVJV has used species-habitat models to translate bird abundance objectives into habitat objectives, while explicitly identifying the biological assumptions that underpin these models and the data used to populate them. As a result, the CVJV's biological planning provides a framework for evaluating the effects of the BDCP on waterfowl.

The Ducks Unlimited waterfowl analysis focused primarily on dabbling ducks. Less than 5% of all geese in the Central Valley occur in the Yolo, Delta, and Suisun Marsh drainage basins. Moreover, geese in the Central Valley rely mostly on agricultural habitats to meet their food energy needs. The BDCP's effect on agricultural habitats is limited to the Delta Basin where about 2500 acres of corn now available to geese would be converted to other habitats (Ducks Unlimited 2013: Table 5). Food supplies for geese would still be well in excess of demand even with the loss of these agricultural habitats (Central Valley Joint Venture 2006, Ducks Unlimited 2013). The duck population objectives used in the analysis were taken directly from the CVJV Plan. Dabbling duck species make up 92% of this objective, while diving duck species make up the remaining 8%. Thus, the results were mostly driven by dabbling duck needs and largely interpreted in the context of dabbling duck foraging ecology. The 55,000 acres of Tidal Natural Communities Restoration (CM4) would be expected to benefit diving ducks by providing deep water foraging habitat. Refer to the Ducks Unlimited Report (Ducks Unlimited 2013) for details of the analysis and methods with respect to the TRUMET model used to quantify effects on food biomass and food quality.

An analysis was conducted to determine the effects of the BDCP covered activities on wintering and breeding shorebird habitat (ICF International 2013). This analysis evaluated the relative increase and decrease in natural communities known to provide important foraging, roosting, and breeding habitat. Similar to the waterfowl analysis, the results were broken up into the three Central Valley Joint Venture Basins that overlap with the BDCP study area: Yolo, Delta, and Suisun. Natural community losses and gains were then translated into species-specific outcomes, comparing the relative habitat value of each BDCP natural community for each Central Valley shorebird species (Table 1, ICF International 2013). The shorebird species ranking system displayed in Table 1 (ICF International 2013) was modified from a table in Stralberg et. al (2011). The table was created using survey data and experts' species-specific habitat rankings. The survey data included fall, winter, and spring density data. This resulted in an overall, cross-season representation of habitat requirements.

Impact BIO-178: Loss or Conversion of Habitat for Waterfowl and Shorebirds as a Result of Water Conveyance Facilities Construction

Development of the water conveyance facilities (CM1) would result in the permanent removal of approximately 3 acres of managed wetland, 6 acres of tidal wetlands, 13 acres of nontidal wetlands, and 2,541 acres of suitable cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands). In addition, 83 acres of managed wetland, 6 acres of tidal wetlands, 10 acres of nontidal wetlands, and 899 acres of cultivated lands would be temporarily impacted.

These losses of habitat would occur within the first 10 years of Alternative 9 implementation in the Delta Basin. The BDCP has committed to the near-term protection of 15,400 acres of non-rice cultivated lands, 200 acres of rice, and 700 acres of rice or "rice equivalent" natural communities including nontidal wetlands in the near-term. In addition, 4,100 acres of managed wetlands would be created, protected, and enhanced, 8850 acres of freshwater tidal wetlands would be restored, and 2,000 acres of tidal brackish emergent wetland would be restored (Table 3-4, Chapter 3, *Description of Alternatives*).

Construction activities could have an adverse effect on nesting shorebirds or waterfowl if they were present in or adjacent to work areas and could result in destruction of nests or disturbance of nesting and foraging behaviors. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

NEPA Effects: Habitat loss from construction of the Alternative 9 water conveyance facilities would not result in an adverse effect on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected in the near-term timeframe. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be an adverse affect on nesting shorebirds and waterfowl. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

CEQA Conclusion: Habitat loss from construction of the Alternative 9 water conveyance facilities would have a less-than-significant impact on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected in the near-term timeframe. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be a significant impact. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact on nesting birds to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-179: Loss or Conversion of Habitat for Wintering Waterfowl as a Result of Implementation of Conservation Components

Suisun Marsh: Managed seasonal wetlands in Suisun Marsh would be reduced by an estimated 8,818 acres as a result of Alternative 9 implementation. This would represent a 25% decrease in managed seasonal wetlands compared with long-term conditions without Alternative 9 (Ducks Unlimited 2013, Table 5). There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in Suisun Marsh's managed wetlands, which makes it difficult to identify the amount of mitigation needed. To address this uncertainty, three levels of food biomass and three levels of nutritional quality were modeled for these existing habitats (Ducks Unlimited 2013, Table 7). Three mitigation scenarios based on these energetic assumptions of biomass and food quality were then run to determine a minimum acreage of managed seasonal wetlands to be protected and enhanced to compensate for the loss of productivity resulting from habitat conversion to tidal wetlands.

- Scenario 1) Assume that existing managed seasonal wetlands provide low food biomass and low food quality. Under this assumption, the managed seasonal wetlands in Suisun Marsh produce 50% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, and these seeds have 60% of the metabolizable energy of seeds produced outside of Suisun Marsh. Given the assumption that managed seasonal wetlands in Suisun could be enhanced to provide high food biomass and high food quality (equal to wetlands in the Central Valley), 5,000 acres of managed wetlands protected and managed for high biomass and high food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.
- Scenario 2) Assume that the managed seasonal wetlands lost provide medium food biomass and medium food quality. Under this assumption, the managed seasonal wetlands in Suisun Marsh produce 75% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, and these seeds have 80% of the metabolizable energy of seeds produced outside of Suisun Marsh. Given the assumption that managed seasonal wetlands in Suisun Marsh could be enhanced to provide high food biomass and high food quality (equal to wetlands in the Central Valley), 13,300 acres of managed wetlands protected and managed for high biomass and high food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.
- Scenario 3) Assume that existing managed seasonal wetlands provide low food biomass and low food quality. Given the assumption that managed seasonal wetlands in Suisun Marsh could only be enhanced to provide medium food biomass and medium food quality (produce 75% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, with these seeds having 80% of the metabolizable energy of seeds produced outside of Suisun Marsh), 8,800 acres of managed wetlands protected and managed for medium biomass and medium food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.

The BDCP has committed to protecting and enhancing a minimum of 5,000 acres of managed seasonal wetlands in Suisun Marsh to compensate for the loss of productivity from habitat conversion to tidal marsh. This minimum commitment of 5,000 acres would mitigate the reduced productivity resulting from conversion of managed seasonal wetlands under the assumptions that 1) existing managed seasonal wetlands on average in Suisun Marsh provide low biomass and low-quality food to wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high food quality. However, the food biomass and productivity in Suisun Marsh would need to be quantified in order to determine if the 5,000 acres was sufficient to avoid an adverse effect on wintering waterfowl in the Suisun Marsh, or if additional mitigation would be needed. Mitigation Measure BIO-179a, *Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh*, would be available to address this adverse effect.

Yolo and Delta Basins: The replacement of 1,400 acres of managed seasonal wetland with 19,000 acres of palustrine tidal wetlands in the Delta watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo watershed would not be expected to have an adverse effect on food productivity, under the assumption that these wetlands would provide adequate food sources. However, a monitoring component and a food study in these tidal habitats would be necessary in order to demonstrate that there would be a less than significant loss of food value in these habitats for wintering waterfowl. If it is determined from monitoring that there in fact would be a significant loss in food productivity resulting from habitat conversion to tidal wetlands, the protection and enhancement of managed wetlands in these watersheds would require mitigation for the change in food biomass and quality. Mitigation Measure *BIO-179b, Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins*, would be available to address this uncertainty.

NEPA Effects: There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in Suisun Marsh's managed wetlands, which makes it difficult to identify the level of effect that Alternative 9 habitat loss or conversion would have. The BDCP has committed to protecting and enhancing a minimum of 6,600 acres of managed seasonal wetlands in Suisun Marsh to compensate for the loss of productivity resulting from habitat conversion to tidal marsh. Of this 6,600 acres, at least 5,000 acres would be managed to benefit wintering waterfowl. This minimum commitment of 5,000 acres for wintering waterfowl would mitigate the reduced productivity from conversion of managed seasonal wetlands under the assumptions that 1) existing managed seasonal wetlands on average in Suisun Marsh provide low biomass and low-quality food to wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high-quality food. However, the food biomass and productivity in Suisun Marsh would need to be quantified to determine if the 5,000 acres would be sufficient for Alternative 9 to avoid an adverse effect on wintering waterfowl in the Suisun Marsh. Mitigation Measure BIO-179a, *Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh*, would be available to address this adverse effect.

The replacement of 1,400 acres of managed seasonal wetlands with 19,000 acres of palustrine tidal wetlands in the Delta watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo watershed would not be expected to alter food productivity for wintering waterfowl. However, the conclusion that these new wetlands would provide adequate food sources is entirely dependent on assumptions about food production in palustrine tidal habitats. Mitigation Measure BIO-179b, *Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins*, would be available to address this uncertainty and avoid an adverse effect on wintering waterfowl.

CEQA Conclusion: There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in Suisun Marsh's managed wetlands, which makes it difficult to identify the level of impact that Alternative 9 habitat loss or conversion would have. The BDCP has committed to protecting and enhancing a minimum of 6,600 acres of managed seasonal wetlands in Suisun Marsh to compensate for the loss of productivity resulting from habitat conversion to tidal marsh. Of this 6,600 acres, at least 5,000 acres would be managed to benefit wintering waterfowl. This minimum commitment of 5,000 acres for wintering waterfowl would mitigate the reduced productivity resulting from conversion of managed seasonal wetlands under the assumptions that 1) existing managed seasonal wetlands on average in Suisun Marsh provide low biomass and low-quality food for wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high-quality food. However, the food biomass and productivity in Suisun Marsh would need to be quantified to determine if the 5,000 acres would be sufficient for Alternative 9 to avoid having a significant impact on wintering waterfowl in the Suisun Marsh, or if additional mitigation would be needed. Implementation of Mitigation Measure BIO-179a, *Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh*, would address this potential significant impact.

The replacement of 1,400 acres of managed seasonal wetlands with 19,000 acres of palustrine tidal wetlands in the Delta watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo watershed would not be expected to alter food productivity. However, the conclusion that these tidal wetlands would provide adequate food sources for wintering waterfowl is entirely dependent on assumptions about food production in palustrine tidal habitats. Studies of food biomass and food quality in palustrine tidal habitats are needed to confirm that no mitigation for wintering waterfowl would be required in the Yolo and Delta Basins. Implementation of Mitigation Measure BIO-179b, *Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins*, would address this uncertainty and would reduce this impact on wintering waterfowl to a less-than-significant level.

Mitigation Measure BIO-179a: Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh

Poorly managed wetlands (considered low biomass and food quality) will be identified and managed by BDCP proponents to improve food quality and biomass. Studies will be required to quantify 1) food production of existing managed wetlands in Suisun Marsh and 2) energetic productivity of brackish and tidal marsh habitats. Protected wetlands will be monitored to measure changes in the energetic productivity of these sites. Based on the food studies and monitoring results, BDCP proponents will determine if the minimum commitment of 5,000 acres is sufficient to meet the goal of 1:1 compensation for loss of wintering waterfowl habitat with the protection and management of managed wetlands in perpetuity. If monitoring demonstrates that additional acreage is needed to meet this goal, additional acreage of protection or creation of managed wetlands and management will be required.

Mitigation Measure BIO-179b: Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins

In order to address the uncertainty of the impact of loss of managed wetlands in the Yolo and Delta Basins on wintering waterfowl, BDCP proponents will conduct food studies and monitoring to demonstrate the food quality of palustrine tidal habitats in these basins. If studies show that the assumption of no effect was inaccurate, and the food quality goal of 1:1

compensation for wintering waterfowl food value is not met, additional acreage of protection or creation of managed wetland and management will be required.

Impact BIO-180: Loss or Conversion of Habitat for Breeding Waterfowl from Implementation of Conservation Components

Alternative 9 would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 9 would reduce semipermanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203 acres, respectively. While a reduction in these semipermanent habitats would represent a habitat loss for breeding waterfowl, with the restoration of 24,000 acres of palustrine tidal wetlands (Table 3-4, Chapter 3, *Description of Alternatives*) in the Yolo and Delta basins there would be a less than adverse effect on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (i.e., March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to the BDCP.

Suisun Marsh: Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres from the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but this could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared to seasonally managed habitats (Central Valley Joint Venture 2006).

The BDCP includes a commitment to protect and enhance 1,600 acres of permanently flooded managed wetlands in Suisun Marsh to provide habitat for breeding waterfowl. In addition, 5,000 acres of semipermanent wetlands that would be protected and enhanced for wintering and migratory waterfowl (Table 3-4, Chapter 3; BDCP Chapter 3, *Conservation Strategy*, Objective MWNC1.1,).

Food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. These studies would be needed in order to quantify impacts on breeding waterfowl in Suisun Marsh and to determine not only the number of acres that would compensate for loss of breeding habitat at a ratio of 1:1 for habitat value, but how those acres should be managed. Mitigation Measure BIO-180, *Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh*, would be available to address the uncertainty of this effect.

In addition to providing semipermanent wetlands to breeding waterfowl, the Suisun Marsh contains several key upland areas that have significant nesting value. The largest block of upland habitat in the region is the core area on the Grizzly Island Wildlife Area. This area does not overlap with the hypothetical footprint for *CM4 Tidal Natural Communities Restoration*. However, this core area includes over 2,000 acres of upland grasslands that have some of the highest duck nesting densities in California (Central Valley Joint Venture 2006). A few small wetland areas are scattered within this core grassland mosaic that provide necessary freshwater brooding habitat. If restoration footprints were changed during the implementation process of BDCP to overlap with this area, the effects on breeding waterfowl would likely be greatly increased.

NEPA Effects: Alternative 9 would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres, respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 9 would reduce semi-permanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203 acres, respectively. The reduction in these semi-permanent habitats would represent a habitat loss for breeding waterfowl. However, with the restoration of 24,000 acres of palustrine tidal wetlands in the Yolo and Delta basins, Alternative 9 would not have an adverse effect on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to Alternative 9 implementation. Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres with the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but such management could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared with seasonally managed habitats. The protection and enhancement of 1,600 acres of permanently flooded managed wetlands would provide habitat for breeding waterfowl. However, food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. Therefore, the loss of breeding waterfowl habitat resulting from implementation of Alternative 9 could have an adverse effect. Mitigation Measure BIO-180, *Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh*, would be available to address the uncertainty of model assumptions and the potential adverse effect of habitat conversion on breeding waterfowl in Suisun Marsh.

CEQA Conclusion: Alternative 9 would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres, respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 9 would reduce semi-permanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203, acres respectively. The reduction in these semi-permanent habitats would represent a habitat loss for breeding waterfowl. However, with the restoration of 24,000 acres of palustrine tidal wetlands in the Yolo and Delta basins, Alternative 9 would have a less-than-significant impact on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to Alternative 9.

Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres with the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but this management could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared with seasonally managed habitats. The protection and enhancement of 1,600 acres of permanently flooded managed wetlands would provide habitat for breeding waterfowl. However, food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. Therefore, the loss or conversion of habitat from implementation of Alternative 9 could have a significant impact on breeding waterfowl in Suisun Marsh. Implementation of Mitigation Measure BIO-180, *Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh*, would address the uncertainty of model assumptions and reduce the impact to a less-than-significant level.

Mitigation Measure BIO-180: Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh

To address the uncertainty of the impact of loss of managed wetlands in Suisun Marsh on breeding waterfowl, BDCP proponents will conduct food studies and monitoring to determine how increases in tidal marsh and salinity levels will affect the overall reproductive capacity of the marsh.

The required studies will examine how increases in tidal marsh and salinity levels will affect the overall reproductive capacity of the Marsh. Reproductive studies will address but will not be limited to the following questions:

- How does the distribution of breeding waterfowl in Suisun Marsh differ in tidal versus managed habitats and across salinity gradients?
- How does waterfowl nest success and nest density vary with respect to tidal versus managed habitats and across salinity gradients?
- What are the patterns of habitat selection and movements by waterfowl broods in relation to tidal vs. managed habitats, and are there impacts on duckling survival?
- What is the current relationship between waterfowl reproductive success and interactions with alternate prey and predators, and how is tidal restoration likely to alter these relationships?

Impact BIO-181: Loss or Conversion of Habitat for Shorebirds from Implementation of Conservation Components

Shorebird use of the study area varies by species and fluctuates both geographically and by habitat type throughout the year. Shallow flooded agricultural fields and wetlands support large numbers of wintering and migrating shorebirds (Shuford et al. 1998), particularly least and western sandpipers, dunlin, greater yellowlegs and long-billed dowitcher. Rice lands of the Sacramento Valley provide important breeding habitat for shorebirds such as American avocet and black-necked stilt (Shuford et al. 2004) and have been designated as a Western Hemisphere Shorebird Reserve Network Site of International Importance (Hickey et al. 2003). Managed wetlands provide suitable foraging and roosting habitat for shorebirds; black-necked stilts, avocets, and yellowlegs use this habitat type almost exclusively. Water depth in all of these habitat types is an important habitat variable as the majority of shorebird species require water depths of approximately 10-20cm for foraging (Isola et al. 2000, Hickey et al. 2003).

Managed Wetlands

Yolo Basin: Primarily as a result of *CM4 Tidal Natural Communities Restoration* within the Yolo Basin, 1,185 acres of managed wetland habitat would be permanently converted; 1,066 acres of which are protected. In addition, 42 acres of managed wetland habitat would be temporarily lost by construction-related activities associated with tidal restoration (CM4) and Fisheries Enhancement activities (CM2) (Table 2, ICF International 2013). Increased inundation frequency, depth and duration associated with the ongoing operation of a modified Fremont Weir (CM2) could periodically affect managed wetlands ranging from an estimated 643 acres during a notch flow of 1,000 cfs to an estimated 2,055 acres during a notch flow of 4,000 cfs Table 5.4-2, in BDCP Chapter 5, *Effects Analysis*) in the Yolo Basin.

Delta Basin: Within the Delta Basin, 90 acres of managed wetland habitat would be permanently converted, as a result of tidal restoration (CM4). Thirteen of the 90 acres are protected (Table 3, ICF International 2013). Periodic flooding would not affect this natural community type in Delta Basin.

Suisun Basin: Within the Suisun Basin, 11,532 acres of managed wetland habitat would be permanently converted as a result of tidal restoration (CM4); 10,354 of which are protected. (Table 4, ICF International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for managed wetland habitat suitability (Table 1, ICF International 2013): black-necked stilt (*Himantopus mexicanus*), greater yellowlegs (*Tringa melanoleuca*), and long-billed dowitcher (*Limnodromus scolopaceus*). Dunlin (*Calidris alpine*), least sandpiper (*Calidris minutilla*), semipalmated plover (Charadrius semipalmatus), and western sandpiper (*Calidris mauri*), had a rank 2 for managed wetland habitat suitability. Black-bellied plover (*Pluvialis squatarola*) and whimbrel (*Numenius phaeopus*) both had rank 3 for managed wetland habitat suitability.

Managed wetlands would decrease in overall extent by 20% (Table 5, ICF International 2013). Most of this loss would occur in Suisun with some additional acreage loss in the Yolo Basin. The loss of managed wetland habitat for covered species and waterfowl would be compensated for with 8,200 acres remaining managed wetland protection in Suisun Marsh. Of these 8,200 acres, the 5,000 acres of seasonal wetland protected, enhanced, and managed to provide overwintering waterfowl foraging habitat would be the habitat type most likely to benefit overwintering shorebirds. However, the 1,600 acres of semi-permanent and permanent managed wetlands for breeding waterfowl and 1,500 acres of managed wetlands for salt marsh harvest mouse would also be expected to have some benefit to wintering and breeding shorebirds.

Cultivated Lands

Yolo Basin: Primarily as a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2) within the Yolo Basin, 8,309 acres of cultivated lands would be permanently converted; 1,272 acres of which are protected. Also within the Yolo Basin, increased inundation frequency, depth and duration associated with the ongoing operation of a modified Fremont Weir (CM2) could affect an estimated 3,219 acres of cultivated lands during a notch flow of 1,000 cfs to an estimated 5,512 acres during a notch flow of 6,000 cfs (Table 5.4-2, in BDCP Chapter 5, *Effects Analysis*)

Delta Basin: Within the Delta Basin, as a result of tidal restoration (CM4) and floodplain restoration (CM5), 25,633 acres of cultivated lands would be permanently converted. There would also be an additional 112 acres lost temporarily due to CM5 activities. Of the total permanently converted lands, 3,925 acres are protected (Table 3, ICF International 2013). Seasonal flooding (CM5) on the restored floodplain would periodically affect 738 acres of cultivated lands in Delta.

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for cultivated lands habitat suitability (Table 1, ICF International 2013): killdeer (*Charadrius vociferous*), long-billed curlew, and whimbrel within pasture habitat and sandhill crane was ranked 1 for grain and hay crops. Long-billed dowitcher and killdeer both had a rank 2 for idle crop habitat suitability and black-bellied plover was ranked 2 for pasture habitat. Red-necked phalarope (*Phalaropus lobatus*) and Wilson's phalarope (*Phalaropus tricolor*) were both ranked 2 for grain and hay crops. Long-billed dowitcher, dunlin, least sandpiper, and long-billed curlew were all ranked 3 for rice habitat suitability and killdeer was ranked 3 for field crop habitat suitability.

Cultivated land loss would occur in all three basins, but the majority of acreage loss would occur in the Delta basin. Pasture crop types would decrease in overall extent by 15% over baseline (Table 5, ICF International 2013), but would increase in protection by 135%. More than half of all cultivated lands within the 48,000-acre BDCP cultivated lands reserve would be in pasture production (primarily alfalfa) and enhanced and managed to benefit Swainson's hawk. Idle crop types are not identified as a specific conservation target in the BDCP, are expected to occur within the reserve and are recognized in the BDCP as having "moderate" foraging habitat value for Swainson's hawk, white-tailed kite, and greater sandhill crane.

Grain and hay crop would be expected to decrease by 13% (Table 5, ICF International 2013) while protection, enhancement and management would be expected to increase by 28% (Table 6, ICF International 2013). These crop types would be managed for a tricolored blackbirds, Swainson's hawk, white-tailed kite, greater sandhill crane, and burrowing owls.

Rice would decrease in overall extent by 2% (Table 5, ICF International 2013) but increase in total protection by 57%. Rice lands would be protected, enhanced, and managed for the benefit for giant garter snake.

Tidal Wetlands

Yolo Basin: As a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2) within the Yolo Basin, 194 acres of tidal wetland habitat would be permanently converted; 180 acres of which are protected. In addition, 12 acres of tidal wetland habitat would be temporarily lost by construction-related activities associated with Fisheries Enhancement activities (CM2) (Table 2, ICF International 2013). Periodic flooding in Yolo Bypass would affect 3,957 acres of tidal wetlands in Yolo Basin.

Delta Basin: Within the Delta Basin, 54 acres of tidal wetlands would be permanently converted as a result of tidal restoration (CM4) (Table 3, ICF International 2013). Of the total permanently converted lands, 26 acres are protected. Periodic flooding in Yolo Bypass would affect 26 acres of tidal wetlands in Delta Basin.

Suisun Basin: Within the Suisun Basin, 219 acres of tidal wetland habitat would be permanently converted as a result of tidal restoration (CM4); 215 of which are protected. (Table 4, ICF International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for tidal mudflat habitat suitability (Table 6, ICF International 2013): black-bellied plover, dunlin, least sandpiper, marbled godwit (*Limosa fedoa*), semipalmated plover, short-billed dowitcher (*Limnodromus griseus*), western sandpiper, and willet (*Tringa semipalmata*). Long-billed curlew (*Numenius americanus*) and whimbrel both had a rank 2 for tidal mudflat habitat suitability. American avocet (*Recurvirostra americana*) was ranked 3 for tidal mudflat habitat suitability. For tidal brackish emergent wetland/tidal freshwater emergent wetland, willet was ranked 2 and long-billed curlew and whimbrel were both ranked 3 for habitat suitability.

Tidal mudflat habitat would be estimated to increase in extent by 1,780 acres. This extremely large increase in tidal mudflat habitat would occur almost exclusively in Suisun Marsh as the result of tidal restoration and the conversion of existing mid- and high-marsh types to low marsh and tidal mudflats in response to sea level rise. BDCP Appendix 3.B, *BDCP Tidal Habitat Evolution Assessment*, details the methods and assumptions modeled to come about this result. Tidal mudflat habitats would be expected to require management, however, sediment augmentation has been discussed as an experimental method that could be employed in places like Suisun to combat the loss of intertidal marshes in the face of sea level rise and reduced sediment supplies.

Tidal emergent wetland habitat would increase in extent by 152% (Table 5, ICF International 2013). Of the 30,000 acres of emergent wetland restoration, 6,000 acres would be in the Suisun Basin and the rest would be distributed between the Yolo and Delta Basins. Enhancement and management on these lands would be likely to be focused on nonnative, invasive species management. Any additional actions in Suisun would be focused on salt marsh harvest mouse, Suisun shrew, California clapper rail, black rail, Suisun thistle, and soft bird's-beak. In freshwater marshes, enhancement and management would be likely to focus on black rail, western pond turtle, and, in some cases, giant garter snake.

Nontidal Wetlands

Yolo Basin: As a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2) within the Yolo Basin, 313 acres of nontidal wetland habitat would be permanently converted; 119 acres of which are protected. In addition, 11 acres of nontidal wetland habitat would be temporarily lost by construction-related activities associated with Fisheries Enhancement activities (CM2) (Table 2, ICF International 2013). Periodic flooding in Yolo Bypass associated with ongoing Fremont Weir operation (CM2) would affect 305 acres of nontidal wetlands in Yolo Basin, specifically nontidal perennial aquatic habitat.

Delta Basin: Within the Delta Basin, 99 acres of nontidal wetlands would be permanently converted as a result of tidal restoration (CM4) and floodplain restoration (CM5) (Table 3, ICF International 2013). There would also be 8 acres of nontidal perennial aquatic habitat temporarily lost from CM5 activities. Of the total permanently converted lands, 29 acres are protected. Periodic flooding from CM5 would affect 4 acres of nontidal perennial aquatic habitat in Delta Basin.

Suisun Basin: Within the Suisun Basin, 1 acre of nontidal wetland habitat, specifically vernal pool complex, would be permanently converted as a result of tidal restoration (CM4); and is not protected. (Table 4, ICF International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2011, the following species of shorebirds had a rank 1 designation for nontidal wetland habitat suitability (Table 6, ICF International 2013): red-necked phalarope and Wilson's phalarope for nontidal freshwater perennial emergent wetland and American avocet for alkali seasonal wetland complex. Greater yellowlegs had a rank 2 for vernal pool complex habitat suitability. Red-necked phalarope and western sandpiper were both ranked 3 for alkali seasonal wetland habitat suitability and greater yellowlegs was ranked 3 for nontidal freshwater perennial emergent wetland habitat suitability.

Nontidal freshwater emergent wetland would increase in extent by 88% as a result of BDCP implementation (Table 5, ICF International 2013). These lands would be managed to benefit giant garter snake and located within the Delta Basin (likely in the vicinity of White Slough) and the Yolo Basin (in the Cache Slough area).

Impacts on wetted acres of vernal pool complex and alkali seasonal wetland complex would be avoided and thus loss of this community is not expected. However, up to 10 acres of wetted acre loss could be permitted under the Plan. Protection of vernal pool complex natural community would increase by 13% and by 6% for alkali seasonal wetlands (Table 6, ICF International 2013). Protection of these two community types would enhance and manage habitat for vernal pool crustaceans and alkali-related plant species.

The protection and restoration of natural communities would also include management and enhancement actions under *CM11 Natural Communities Enhancement and Management.* The following management activities to benefit shorebirds would be considered for implementation under CM11 in areas where they would not conflict with covered species management.

- Managed Wetlands
  - Managed wetlands can be potentially manipulated to provide the optimum water depths for foraging shorebirds and islands for nesting (Hickey et al. 2003).
  - During fall and spring, stagger the timing and location of draining and flooding to optimize the extent of shallow-water habitat; varying depths within the wetland unit helps to create temporal variation in foraging opportunities. During warm, dry springs when wetland units dry quickly, wetland units can be re-supplied with water to extend habitat availability for shorebirds.
  - Provide open, shallow water habitat adjacent to minimally vegetated, shallowly sloped edges for nesting shorebirds between April and July.
  - Provide islands with little to no vegetation to increase the likelihood of shorebird roosting and nesting.
  - Create low slopes on islands and levees; gradual angles (10-12:1) are better than steep angles.
  - Limit levee maintenance during the nesting season (April through July). However, mowing the center of levees is fine.
  - Potentially add material to levees or to islands to encourage nesting for some species.
- Cultivated Lands
  - Maintaining a mosaic of dry and flooded crop types, and varying water depths will promote a diverse community of waterbirds, including shorebirds, during fall migration and winter (Shuford et al. 2013).
  - To provide wintering habitat for multiple waterbird guilds, including shorebirds, use a combination of flooding practices that include one-time water application and maintenance flooding while also providing unflooded habitat (Strum et al. *in review*).
  - The post-harvest flooding of winter wheat and potato fields in early fall (July- September) can provide substantial benefits to shorebirds at a time of very limited shallow-water habitat on the landscape (Shuford et al. 2013).
  - Stagger the drawdown of flooded rice and other winter-flooded agricultural fields to prolong the availability of flooded habitat (Iglecia et al. 2012). Be aware of soil type because this practice may not be as effective on soils that drain quickly.
  - Remove as much stubble as possible in rice and other agricultural fields after harvest to increase the potential shorebird habitat on intentionally flooded or unflooded fields that may passively gather rain water (Iglecia et al. 2012).

- Shallowly flood available agricultural fields during July, August, and September to provide early fall migration habitat for shorebirds. Fields should be free of vegetation prior to flooding, have minimal micro-topography (e.g. no large clods), and should remain flooded for up to three week periods (after three weeks, vegetation encroachment reduces habitat value for shorebirds) (ICF International 2013).
- Manage levee habitats to have minimal vegetation but do not spray herbicide directly or drive on levees during the nesting season (April- July, Iglecia et al. 2012).
- Maintain a minimum top-width of 30 inches for levees, based on increased avocet use of wider levees (Iglecia et al. 2012).
- When possible, flood fields with nesting habitat (modified levees and islands) in late April to provide nesting habitat for American avocets (Iglecia et al. 2012).
- Finer grained substrate (clods smaller than a fist) in rice and other agricultural fields may be more appealing for nesting shorebirds (Iglecia et al. 2012).
- Maintain gently sloping levees and island sides (10-12:1; Iglecia et al. 2012).
- Islands should be disked along with the rest of the field after harvest to help inhibit vegetation growth (Iglecia et al. 2012).

***NEPA Effects*:** Alternative 9 implementation would result in the conversion of managed wetland and cultivated lands to tidal natural communities, including tidal mudflat. The result would be substantial loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While substantial losses of cultivated lands would be incurred, protection, enhancement, and management of the remaining acres would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these crop types are being driven by covered species, these management actions would also benefit shorebirds. The protection, enhancement, and management of remaining managed wetlands in Suisun Marsh, in compensation for the loss of substantial acreage, would have some incremental benefits for shorebirds, but would be unlikely to compensate for the overall loss. However, with the protection and restoration of acres in the Delta and Yolo watersheds, in addition to the implementation of the management actions outlined in *CM11 Natural Communities Enhancement and Management*, habitat conversion would not be expected to result in an adverse effect on shorebird populations in the study area.

***CEQA Conclusion*:** Alternative 9 implementation would result in the conversion of managed wetland and cultivated lands to tidal natural communities, including tidal mudflat. The result would be significant loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While significant losses of cultivated lands would be incurred, protection, enhancement, and management of the remaining acres would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these types are being driven by covered species, these management actions would also benefit shorebirds. The protection, enhancement, and management of remaining managed wetlands in Suisun Marsh, in compensation for substantial acreage loss, would have some incremental benefits for shorebirds, but would be unlikely to compensate for the overall loss. However, with the protection and restoration of acres in the Delta and Yolo watersheds, in addition to the implementation of the management actions outlined in *CM11 Natural Communities Enhancement and Management*, habitat conversion would be expected to have a less-than-significant impact on shorebird populations in the study area.

Impact BIO-182: Effects on Shorebirds and Waterfowl Associated with Electrical Transmission Facilities

New transmission lines installed in the study area would increase the risk for bird-power line strikes, which could result in injury or mortality of shorebirds and waterfowl. The existing network of power lines in the study currently poses a risk for shorebirds and waterfowl in the Delta. New transmission lines would increase this risk and have an adverse effect on shorebird and waterfowl species in the absence of other conservation actions. However, transmission lines constructed under Alternative 9 would be temporary and would be removed after the completion of CM1 construction activities (within the first 10 years of Plan implementation). In addition, implementation of *AMM20 Greater Sandhill Crane* would reduce potential effects through the installation of flight-diverters on new transmission lines, and selected existing transmission lines in the study area.

***NEPA Effects*:** New transmission lines would increase the risk for shorebird and waterfowl power line strikes. With the implementation of *AMM20 Greater Sandhill Crane*, the potential effect of the construction of new transmission lines on shorebird and waterfowl would not be adverse.

***CEQA Conclusion*:** New transmission lines would increase the risk for shorebird and waterfowl power line strikes. The implementation of *AMM20 Greater Sandhill Crane* would reduce the potential impact of the construction of new transmission lines on shorebirds and waterfowl to a less-than-significant level.

Impact BIO-183: Indirect Effects of Plan Implementation on Shorebirds and Waterfowl

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect shorebird and waterfowl use of modeled habitat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect shorebirds and waterfowl or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to shorebirds and waterfowl in the study area could also have a negative effect on these species. AMM1–AMM7 would ensure that measures were in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including shorebird and waterfowl species. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect shorebirds and waterfowl, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on shorebirds and waterfowl.

Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including shorebird and waterfowl species. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on shorebirds and waterfowl species.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on shorebirds and waterfowl from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

***NEPA Effects*:** Noise and visual disturbances from the construction of Alternative 9 water conveyance facilities could reduce shorebird and waterfowl use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect shorebird and waterfowl use of the surrounding habitat. AMM1–AMM7 would minimize these effects, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals. Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects associated with noise and visual disturbances, and increased exposure to selenium from Alternative 9 implementation would not have an adverse effect on shorebirds and waterfowl. Tidal habitat restoration is unlikely to have an adverse effect on shorebirds and waterfowl through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes with elevated methylmercury levels. However, it is unknown what concentrations of methylmercury are harmful to species of waterfowl and shorebirds, and the potential for increased exposure would vary substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in *CM12 Methylmercury Management*, would address the uncertainty of methylmercury levels in restored tidal marsh. Once site-specific sampling and other information is developed, the site-specific planning phase of marsh restoration would be the appropriate place to assess the potential risk of shorebird and waterfowl exposure to methylmercury.

***CEQA Conclusion*:** Noise, potential hazardous spills, and increased dust and sedimentation as a result of Alternative 9 water conveyance facilities construction and operation and maintenance would have a significant impact on shorebirds and waterfowl. AMM1–AMM7 would minimize these impacts, and implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce the impacts to a less-than-significant level. Tidal habitat restoration is unlikely to have a significant impact on shorebirds and waterfowl species through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes with elevated methylmercury levels. However, it is unknown what concentrations of methylmercury are harmful to species of waterfowl and shorebirds. Site-specific restoration plans that address the creation and mobilization of mercury, as well as the monitoring and adaptive management described in CM12, would be the appropriate place to assess the potential risk of shorebird and waterfowl exposure to methylmercury in the study area. Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 9 implementation would have a less-than-significant impact on shorebirds and waterfowl.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Common Wildlife and Plants

Common wildlife and plants are widespread, often abundant, species that are not covered under laws or regulations that address conservation or protection of individual species. Examples of common wildlife and plants occurring in the study area are provided within the discussion for each natural community type in Section 12.1.2.2, *Special-Status and Other Natural Communities*. Impacts on common wildlife and plants would occur through the same mechanisms discussed for natural communities and special-status wildlife and plants for each alternative.

Impact BIO-184: Effects on Habitat and Populations of Common Wildlife and Plants

Effects on habitat of common wildlife and plants, including habitat removal and conversion, are discussed in the analysis of Alternative 9 effectson natural communities. In general, effects on habitat of common wildlife and plants would not be adverse. Through the course of implementing the Plan over a 50-year time period, several natural communities and land cover types would be reduced in size, primarily from restoration of other natural communities. Grassland, managed wetland and cultivated lands would be reduced in acreage, so the common species that occupy these habitats would be affected. However, the losses in acreage and value of these habitats would be offset by protection, restoration, enhancement and management actions contained in the BDCP, including *CM3 Natural Communities Protection and Restoration*, *CM4 Tidal Natural Communities Restoration*, *CM5 Seasonally Inundated Floodplain Restoration*, *CM6 Channel Margin Enhancement*, *CM7 Riparian Natural Community Restoration*, *CM8 Grassland Natural Community Restoration*, *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration*, *CM10 Nontidal Marsh Restoration*, and *CM11 Natural Communities Enhancement and Management*. In addition, the AMMs contained in Appendix 3.C of the BDCP would be in place to reduce or eliminate the potential to adversely affect both special-status and common wildlife and plants.

Direct effects on common wildlife and plants from constructing water conveyance facilities and implementing Alternative 9 conservation measures would include construction or inundation-related disturbances that result in injury or mortality of wildlife or plants and the immediate displacement of wildlife. Indirect effects include project-related disturbances to nearby wildlife and plants during construction (e.g., disruption of breeding and foraging behaviors from noise and human activity, habitat degradation from fugitive dust and runoff) and effects occurring later in time (e.g., collisions of birds with transmission lines, habitat fragmentation, vegetation management). Indirect effects could result both from construction and from operations and maintenance (e.g., ground disturbances could result in the spread and establishment of invasive plants).

***NEPA Effects*:** The direct and indirect effects associated with implementing the conservation measures of Alternative 9 would not be adverse because the conservation measures and AMMs also expand and protect natural communities, avoid or minimize effects on special-status species, prevent the introduction and spread of invasive species, and enhance natural communities. These actions would result in avoiding and minimizing effects on common wildlife and plants as well.

***CEQA Conclusion*:** Construction and operation of the water conveyance facilities and habitat restoration activities would have impacts on common wildlife and plants in the study area through habitat loss and through direct or indirect loss or injury of individuals. The loss of habitat would not be substantial, because habitat restoration would increase the amount and extent of habitat available for use by most common wildlife and plant species. Conservation measures to avoid or minimize effects on special-status species, to prevent the introduction and spread of invasive species, and to enhance natural communities also would result in avoiding and minimizing effects on common wildlife and plants. Consequently, implementation of the BDCP is not expected to cause any populations of common wildlife or plants to drop below self-sustaining levels, and this impact would be less than significant. No mitigation would be required.

Wildlife Corridors

ECAs are lands likely to be important to wildlife movement between large, mostly natural areas at the state wide level. The ECAs form a functional network of wildlands that are considered important to the continued support of California's diverse natural communities. Four general areas were identified within the Plan Area that contain ECAs (Figure 12-2). The BDCP also identified important landscape linkages in the Plan Area to guide reserve design, which can also be seen on Figure 12-2.

Impact BIO-185: Effect of BDCP Conservation Measures on Wildlife Corridors

Alternative 9 would have conveyance facility construction occurring within the Mandeville Island-Staten Island ECA. The conveyance facility construction would also occur along two linkages identified in the BDCP, the *Middle River* linkage (#6 in Figure 12-2) and the *White Slough to Stone Lakes* linkage (#11 in Figure 12-2).

The construction of an operable barrier and associated transmission lines would occur on the northwestern tip of Mandeville Island. These facilities would not create a substantial barrier to wildlife movement within and outside of this ECA. The construction of transmission lines may result in localized impacts on sandhill cranes and other avian species during periods of low visibility, but these transmission lines are relatively short and would not substantially affect flight patterns.

The Alternative 9 dredge spoils areas and an operable barrier identified along Middle River (linkage #6) would greatly conflict with the BDCP's plan for riparian conservation and establishing riparian connectivity along this stretch of Middle River. The dredge disposal areas could make a substantial section of Middle River unsuitable for BDCP riparian conservation actions.

The construction of a transmission line across BDCP the *White Slough to Stone Lakes* linkage would not substantially conflict with the BDCP's plans for giant garter snake conservation along this corridor.

Restoration activities would be implemented in the ECAs within Yolo Bypass (*CM2 Yolo Bypass Fisheries Enhancement*) and within the Grizzly Island-Lake Marie ECA (*CM4 Tidal Natural Communities Restoration*). These activities would generally improve the movement of wildlife within and outside of the study area. In addition, the preservation of restored lands (CM3) and the enhancement and management of these areas (CM11) would improve and maintain wildlife corridors within the study area.

***NEPA Effects*:** Alternative 9 would conflict with the BDCP's planned riparian conservation along Middle River; however, compared to No Action this alternative would not result in adverse effects on wildlife corridors.

***CEQA Conclusion*:**

The construction of an operable barrier and associated transmission lines would occur on the northwestern tip of Mandeville Island. These facilities would not create a substantial barrier to wildlife movement within and outside of the Mandevill Island-Staten Island ECA. The construction of transmission lines may result in localized impacts on sandhill cranes and other avian species during periods of low visibility, but these transmission lines are relatively short and would not substantially affect flight patterns.

The Alternative 9 dredge spoils areas and an operable barrier identified along Middle River (linkage #6) would greatly conflict with the BDCP's plan for riparian conservation and establishing riparian connectivity along this stretch of Middle River. The dredge disposal areas could make a substantial section of Middle River unsuitable for BDCP riparian conservation actions.

The construction of a transmission line across BDCP the *White Slough to Stone Lakes* linkage would not substantially conflict with the BDCP's plans for giant garter snake conservation along this corridor.

Restoration activities would be implemented in the ECAs within Yolo Bypass (*CM2 Yolo Bypass Fisheries Enhancement*) and within the Grizzly Island-Lake Marie ECA (*CM4 Tidal Natural Communities Restoration*). These activities would generally improve the movement of wildlife within and outside of the study area. In addition, the preservation of restored lands (CM3) and the enhancement and management of these areas (CM11) would improve and maintain wildlife corridors within the study area.

Alternative 9 would conflict with the BDCP's planned riparian conservation along Middle River; however, under the Existing Conditions, this alternative would overall result in less-than-significant impacts on wildlife corridors.

Invasive Plant Species

The invasive plant species that primarily affect each natural community in the study area, which include water hyacinth, perennial pepperweed, giant reed, and Brazilian waterweed, are discussed in Section 12.1.4. Invasive species compete with native species for resources and can alter natural communities by altering fire regimes, hydrology (e.g., sedimentation and erosion), light availability, nutrient cycling, and soil chemistry but also have the potential to harm human health and the economy by adversely affecting natural ecosystems, water delivery, flood protection systems, recreation, agricultural lands, and developed areas (Randall and Hoshovsky 2000). The construction and restoration activities covered under the BDCP could result in the introduction or spread of invasive plant species by creating temporary ground disturbance that provides opportunities for colonization by invasive plants in the study area.

The primary mechanisms for the introduction of invasive plants as the result of implementation of Alternative 9 are listed here.

- Grading, excavation, grubbing, and placement of fill material.
- Breaching, modification, or removal of existing levees and construction of new levees.
- Modification, demolition, and removal of existing infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure).
- Maintenance of infrastructure.
- Removal of existing vegetation and planting/seeding of vegetation.
- Maintaining vegetation and vegetation structure (e.g., grazing, mowing, burning, trimming).
- Dredging waterways.

Clearing operations and the movement of vehicles, equipment, and construction materials in the study area would facilitate the introduction and spread of invasive plants by bringing in or moving seeds and other propagules. These effects would result from four activities.

- Spreading chipped vegetative material from clearing operations over topsoil after earthwork operations are complete.
- Importing, distributing, storing, or disposing of fill, reusable tunnel material, borrow, spoil, or dredge material.
- Traffic from construction vehicles (e.g., water and cement trucks) and personal vehicles of construction staff.
- Transport of construction materials and equipment within the study area and to/from the study area.

Table 12-9-70 lists the acreages of temporary disturbance in each natural community in the study area that would result from implementation of Alternative 9 of the BDCP.

Table 12-9-70. Summary of Temporary Disturbance in Natural Communities under Alternative 9

Natural Community	Temporary Impacts (acres)
Tidal perennial aquatic	360
Tidal brackish emergent wetland	0
Tidal freshwater emergent wetland	123
Valley foothill riparian	367
Grassland	590
Inland dune scrub	0
Alkali seasonal wetland complex	0
Vernal pool complex	0
Other natural seasonal wetland	0
Nontidal freshwater perennial emergent wetland	25
Nontidal perennial aquatic	27
Managed wetlands	65
Agricultural lands	1,959
Total	3,516

Impact BIO-186: Adverse Effects on Natural Communities Resulting from the Introduction and Spread of Invasive Plant Species

Under Alternative 9, the BDCP would have adverse effects on natural communities from the introduction and spread of invasive plant species through implementation of CM1–CM10 and CM22 (AMM6). No adverse effects are expected from implementation of CM11–CM21.

- *CM1 Water Facilities and Operations*: Construction of the Alternative 9 water conveyance facilities would result in the temporary disturbance of 3,507 acres that would provide opportunities for colonization by invasive plant species.
- *CM2 Yolo Bypass Fisheries Enhancement*: Construction of the Yolo Bypass fisheries enhancements would result in the temporary disturbance of 758 acres that would provide opportunities for colonization by invasive plant species. Vegetation maintenance activities for the Fremont Weir and Yolo Bypass improvements may include the removal of giant reed; however, the clearing of linear areas to facilitate water flow may also result increased opportunities for invasion. Sediment removal, transportation, and application as a source material for restoration or levee projects as part of Fremont Weir and Yolo Bypass maintenance activities could also result in the spread of invasives if the sediment contains viable invasive plant propagules.
- *CM3 Natural Communities Protection and Restoration*: The restoration activities in the natural communities located in the eleven CZs would result in the temporary disturbance of restoration areas that would provide opportunities for colonization by invasive plant species.
- *CM4 Tidal Natural Communities Restoration*: The activities associated with the restoration of tidal perennial aquatic, tidal mudflat, tidal freshwater emergent wetland, and tidal brackish emergent wetland in ROAs would result in the temporary disturbance of tidal areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by designing restoration projects to minimize the establishment of nonnative

submerged aquatic vegetation, and early restoration projects would be monitored to assess the response of nonnative species to restoration designs and local environmental conditions. If indicated by monitoring results, the BDCP Implementation Office would implement invasive plant control measures in restored natural communities to help ensure the establishment of native marsh plain plant species. Additionally, the BDCP Implementation Office would actively remove submerged and floating aquatic vegetation in subtidal portions of tidal natural community restoration sites.

- *CM5 Seasonally Inundated Floodplain Restoration*: Floodplain restoration levee construction would result in the temporary disturbance of 1,285 acres along channels in the north, east, and south Delta (San Joaquin, Old, and Middle Rivers) that would provide opportunities for colonization by invasive plant species.
- *CM6 Channel Margin Enhancement*: The temporary effects of channel margin enhancement were not estimated because specific locations for this activity and their areal extent have not been developed. Channel margin enhancement (Sacramento River between Freeport and Walnut Grove, San Joaquin River between Vernalis and Mossdale, Steamboat and Sutter Sloughs, and salmonid migration channels in the interior Delta) would result in the temporary disturbance of channel areas that would provide opportunities for colonization by invasive plant species.
- *CM7 Riparian Natural Community Restoration*: The restoration of valley/foothill riparian habitat would result in the temporary disturbance of riparian areas that would provide opportunities for colonization by invasive plant species.
- *CM8 Grassland Natural Community Restoration*: The restoration of grassland habitat in CZs 1, 8 and/or 11 would result in the temporary disturbance of degraded grassland or cultivated land that would provide opportunities for colonization by invasive plant species.
- *CM9 Vernal Pool and Alkali Season Wetland Complex Restoration*: The restoration of vernal pool and alkali seasonal wetland complexes in CZs 1,8, or 11 would result in the temporary disturbance of grassland areas that would provide opportunities for colonization by invasive plant species.
- *CM10 Nontidal Marsh Restoration*: Nontidal marsh restoration, which would take place through conversion of agricultural lands in CZs 2 and 4, would result in the temporary disturbance of fallow agricultural areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by monitoring the development of marsh vegetation to determine if nonnative vegetation needs to be controlled to facilitate the establishment of native marsh vegetation or if restoration success could be improved with supplemental plantings of native species. If indicated by monitoring, nonnative vegetation control measures and supplemental plantings would be implemented.
- *CM22 Avoidance and Minimization Measures*: *AMM6 Spoils, Reusable Tunnel Material, and Dredged Material Disposal Plan* would have adverse effects if spoils, RTM, dredged material, or chipped vegetative materials containing viable invasive plant propagules are used as topsoil in uninfested areas.

The adverse effects that would result from the introduction and spread of invasive plants through colonization of temporarily disturbed areas would be minimized by implementation of CM11, AMM4 AMM10 and AMM11.

CM11 Natural Communities Enhancement and Management would reduce these adverse effects by implementing invasive plant control within the BDCP reserve system to reduce competition on native species, thereby improving conditions for covered species, ecosystem function, and native biodiversity. The invasive plant control efforts would target new infestations that are relatively easy to control or the most ecologically damaging nonnative plants for which effective suppression techniques are available. In aquatic and emergent wetland communities, Brazilian waterweed, perennial pepperweed, barbgrass, and rabbitsfoot grass would be controlled (and tidal mudflats would be maintained). In riparian areas, invasive plant control would focus on reducing or eliminating species such as Himalayan blackberry, giant reed, and perennial pepperweed. In grassland areas, techniques such as grazing and prescribed burning may be used to decrease the cover of invasive plant species.

Implementation of AMM4, AMM10, and AMM11 would also reduce the adverse effects that could result from construction activities. The AMMs provide methods to minimize ground disturbance, guidance for developing restoration and monitoring plans for temporary construction effects, and measures to minimize the introduction and spread of invasive plants. AMM4 would include the preparation and implementation of an erosion and sediment control plan that would control erosion and sedimentation and restore soils and vegetation in affected areas. The restoration and monitoring plans for implementation of AMM10 would involve methods for stockpiling, storing, and restoring topsoil, revegetating disturbed areas, monitoring and maintenance schedules, adaptive management strategies, reporting requirements, and success criteria. AMM10 would also include planting native species appropriate for the natural community being restored, with the exception of some borrow sites in cultivated lands that would be restored as grasslands.

AMM11 specifies that the BDCP Implementation Office would retain a qualified botanist or weed scientist prior to clearing operations to determine if affected areas contain invasive plants. If areas to be cleared do contain invasive plants, then chipped vegetation material from those areas would not be used for erosion control but would be disposed of to minimize the spread of invasive plant propagules (e.g., burning, composting). During construction of the water conveyance facilities and construction activities associated with the other conservation measures, construction vehicles and construction machinery would be cleaned prior to entering construction sites that are in or adjacent natural communities other than cultivated lands and prior to entering any BDCP restoration sites or conservation lands other than cultivated lands. Vehicles working in or travelling off paved roads through areas with infestations of invasive plant species would be cleaned before travelling to other parts of the study area. Cleaning stations would be established at the perimeter of BDCP covered activities along construction routes as well as at the entrance to reserve system lands. Biological monitoring would include locating and mapping locations of invasive plant species within the construction areas during the construction phase and the restoration phase. Infestations of invasive plant species would be targeted for control or eradication as part of the restoration and revegetation of temporarily disturbed construction areas.

NEPA Effects: The implementation of AMM4, AMM10, AMM11, and CM11 would reduce the potential for the introduction and spread of invasive plants and avoid or minimize the potential effects on natural communities and special-status species; therefore, these effects would not be adverse.

CEQA Conclusion: Under Alternative 9, impacts on natural communities from the introduction or spread of invasive plants as a result of implementing the BDCP would not result in the long-term degradation of a sensitive natural community due to substantial alteration of site conditions and would, therefore, be less than significant. No mitigation would be required.

Compatibility with Plans and Policies

Impact BIO-187: Compatibility of the Proposed Water Conveyance Facilities and Other Conservation Measures with Federal, State, or Local Laws, Plans, Policies, or Executive Orders Addressing Terrestrial Biological Resources in the Study Area

Constructing the water conveyance facilities (CM1) and implementing CM2–CM22 for Alternative 9 have the potential for being incompatible with plans and policies related to managing and protecting terrestrial biological resources of the study area. A number of laws, plans, policies, programs, and executive orders that are relevant to actions in the study area provide guidance for terrestrial biological resource issues as overviewed in Section 12.2, *Regulatory Setting*. This overview of plan and policy compatibility evaluates whether Alternative 9 would be compatible or incompatible with such enactments, rather than whether impacts would be adverse or not adverse, or significant or less than significant. If the incompatibility relates to an applicable plan, policy, or executive order adopted to avoid or mitigate terrestrial biological resource effects, then an incompatibility might be indicative of a related significant or adverse effect under CEQA and NEPA, respectively. Such physical effects of Alternative 9 on terrestrial biological resources are addressed in the impacts on natural communities and species. The following is a summary of compatibility evaluations related to terrestrial biological resources for laws, plans, policies, and executive orders relevant to the BDCP.
Federal and State Legislation

- The federal *Clean Water Act*, *Endangered Species Act*, *Fish and Wildlife Coordination Act*, *Migratory Bird Treaty Act*, *Rivers and Harbors Act* and *Marine Mammal Protection Act* all contain legal guidance that either directly or indirectly promotes or stipulates the protection and conservation of terrestrial biological resources in the process of undertaking activities that involve federal decision making. The biological goals and objectives contained in the BDCP that provide the major guidance for implementing the various conservation elements of Alternative 9 are all designed to promote the long-term viability of the natural communities, special-status species, and common species that inhabit the study area. While some of the conservation measures of the alternative involve permanent and temporary loss of natural communities and associated habitats during facilities construction and expansion of certain natural communities, the long-term guidance in the Plan would provide for the long-term viability and expansion of the habitats and special-status species populations in the study area. Alternative 9 conservation actions would be compatible with the policies and directives for terrestrial biological resources contained in these federal laws.

- The *California Endangered Species Act*, *California Native Plant Protection Act*, *Porter-Cologne Water Quality Control Act*, and *Natural Communities Conservation Planning Act* are state laws that have relevance to the management and protection of terrestrial biological resources in the study area. Each of these laws promotes consideration of wildlife and native vegetation either through comprehensive planning or through regulation of activities that may have an adverse effect on the terrestrial and aquatic natural resources of the state. The BDCP, which is the basis for Alternative 9, contains biological goals and objectives that have been developed to promote the species protection and natural resource conservation that are directed by these state laws. Alternative 9 conservation actions would be compatible with the policies and directives contained in these laws.

- The *Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992* (*Delta Protection Act*) and the *Sacramento-San Joaquin Delta Reform Act*, which updated the Delta Protection Act, promote the maintenance and protection of natural resources and the protection of agricultural land uses in the Delta's primary zone through the goals and policies contained in the 2009 updated Land Use and Resources Management Plan (LURMP). While nothing in the LURMP is binding on state agencies that are BDCP proponents, the LURMP does promote restoration and enhancement of habitats for the terrestrial and aquatic species of the Delta on public land. The BDCP biological goals and objectives would be compatible with these LURMP goals (Delta Protection Commission 2010).
- The *Suisun Marsh Preservation Act* of 1974 was designed to protect the Suisun Marsh for long-term use as wildlife habitat, with a goal of preserving and enhancing the quality and diversity of the Marsh's aquatic and wildlife habitats. The BDCP and its plans for protection and restoration of tidal marsh habitats in Suisun Marsh would be compatible with the intent of the Suisun Marsh Preservation Act.

Plans, Programs, and Policies

- *The Delta Plan*, which was developed by the Delta Stewardship Council in compliance with the 2009 Sacramento-San Joaquin Delta Reform Act, is mandated to achieve two co-equal goals: provide for a more reliable water supply for California and protect, restore, and enhance the Delta ecosystem. The co-equal goals are to be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place. The BDCP is intended to become a component of the Delta Plan. The Delta Stewardship Council would determine whether the BDCP is compatible with the goals and objectives of the Delta Plan prior to its incorporation into the Plan. The compatibility of the BDCP with the Delta Plan is considered in detail in Section 13.2.2.2 of Chapter 13, *Land Use*.
- *California Wetlands Conservation Policy*, which was adopted by Executive Order in 1993, promotes a long-term gain in the quantity, quality and permanence of wetlands acreages and values in California. Alternative 9 conservation measures that provide for a significant expansion of wetland acreage and quality in the Delta and Suisun Marsh are compatible with the intent of the California Wetlands Conservation Policy.
- *The North American Waterfowl Management Plan* (*NAWMP*) and *Central Valley Joint Venture* (*CVJV*) strive to maintain and expand wetlands and uplands for waterfowl and shorebirds in the major basins of California's Central Valley. The NAWMP is a management plan jointly approved by the United States and Canada in 1986. It contains general guidance from the principal wildlife management agencies of the two countries for sustaining abundant waterfowl populations by conserving landscapes through self-directed partnerships (joint ventures) that are guided by sound science. The CVJV is the joint venture established for overseeing NAWMP implementation in the Central Valley. The CVJV is made up of 21 conservation organizations, state and federal government agencies, and one corporation that have formed a partnership to improve the habitat conditions for breeding and nonbreeding waterfowl, breeding and nonbreeding shorebirds, waterbirds, and riparian-dependent songbirds in the Central Valley. The CVJV's 2006 Implementation Plan (Central Valley Joint Venture 2006) establishes conservation objectives and priorities for these bird groups within the basins of the Central Valley. The BDCP Plan Area includes all or portions of three Implementation Plan basins—the Delta, Yolo and Suisun basins. The 2006 Implementation Plan contains basin-specific objectives for wetland

restoration, protection of existing wetland habitats, wetland enhancement, adequate power and water supplies for wetland management, agricultural land enhancement, farmland easements that maintain waterfowl food resources on agricultural land, and farmland easements that buffer existing wetlands from urban and residential growth.

Implementation of the Alternative 9 conservation measures would result in significant reductions in cultivated land and managed wetland acreage in the Delta, Yolo and Suisun basins; however, significant increases in tidal and nontidal wetlands in these basins would be another result. Because of the large conversion of managed wetland in the Suisun basin, the BDCP has included a large managed wetland conservation and enhancement goal for this area. For the Suisun basin conversions to be compatible with the 2006 Implementation Plan goals, this EIR/EIS has added mitigation that would require food production studies and adaptive management to ensure that the Suisun basin would continue to provide the waterfowl and shorebird habitat envisioned in the Implementation Plan.

- *Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan*, *Cosumnes River Preserve Management Plan*, *Brannan Island and Franks Tract State Recreation Areas General Plan*, *Yolo Bypass Wildlife Area Land Management Plan*, *Grizzly Island Wildlife Area Management Plan*, and the *Lower Sherman Island Wildlife Area Land Management Plan* are primarily designed to preserve and enhance the natural resource and recreation qualities of these areas. Implementing Alternative 9, especially construction of CM1 and CM2 facilities, and land modification associated with CM4 restoration activities, could create temporary disruptions to the terrestrial biological resource management activities in these management areas. The ultimate goals of aquatic and terrestrial habitat enhancement and restoration contained in the BDCP would be compatible with the long-term management goals of these areas. Proposed restoration areas in the Yolo Bypass, on Sherman Island, and in Suisun Marsh would be designed to be compatible with and to complement the current management direction for these areas and would be required to adapt restoration proposals to meet current policy established for managing these areas.

- *Suisun Marsh Preservation Agreement* and *Suisun Marsh Plan* are the most recent efforts by the state and federal agencies responsible for Suisun Marsh (the Marsh) to maintain its long-term viability as managed wetlands and wildlife habitat, consistent with the Suisun Marsh Preservation Act. The Suisun Marsh Preservation Agreement (SMPA) was signed in 1987 and modified in 2005 by DWR, CDFW, Reclamation and the Suisun Resource Conservation District to establish the mitigation approach in the Marsh for effects of operating the SWP and CVP. The primary concerns were the effects of CVP and SWP Delta diversions on salinity in the Marsh. The SMPA focused on ways to ensure adequate water quality and quantity for the managed wetlands and wildlife habitats in the Marsh to assure equal waterfowl values in the Marsh. The Suisun Marsh Plan (SMP), for which a Final EIS/EIR was released in 2010 by these agencies, provides for restoration of tidal marsh habitat and enhancement of managed wetland in the Marsh, maintenance of waterfowl hunting and recreational opportunities in the Marsh, maintenance and improvement of the Marsh levee system, and protection and enhancement of water quality for beneficial uses of the Marsh. An integral component of the SMP is balancing continued managed wetland operation with new tidal wetland restoration to provide improved and greater habitat for fish and wildlife species. The SMP is a programmatic, long-term plan and does not include specific projects, project proponents, or funding mechanisms. However, the SMP relies on tidal restoration to allow for managed wetland operations to continue. The BDCP would provide a funding mechanism and increased management potential relative to existing and restored habitats, assisting the SMP in meeting its broader ecological goals, consistent with long-term operation of the SWP and CVP water conveyance facilities. The conservation actions contained in the BDCP, which are designed to ensure the long-term protection and recovery of special-status fish and wildlife species dependent on the Marsh, would be compatible with the water quality and habitat restoration goals of the SMPA and SMP.

- *California Aquatic Invasive Species Management Plan* does not address terrestrial invasive species. Implementation of the Plan's long-term control and management objectives affect terrestrial species that utilize study area aquatic habitats. These effects are positive in that Plan objectives are to control and remove invasive aquatic species that are detrimental to native aquatic and terrestrial species. Implementation of BDCP's conservation actions would be undertaken with the goal of avoiding any further spread of aquatic invasive species. Alternative 9 would, therefore, be compatible with the objectives of the California Aquatic Invasive Species Management Plan.
- *Habitat Conservation Plans* and *Natural Community Conservation Plans* are the subject of a detailed analysis at the end of this chapter. The analysis considers the compatibility of the BDCP with all HCPs and NCCPs that share planning area with the BDCP Plan Area.

Executive Orders

- *Executive Order 11990: Protection of Wetlands* requires all federal agencies to consider wetland protection in their policies and actions. The BDCP proposes to protect, enhance and expand the wetlands of the Plan Area, and, therefore, would be compatible with Executive Order 11990.
- *Executive Order 13112: Invasive Species* directs federal agencies to prevent and control the introduction and spread of invasive species in a cost-effective and environmentally sound manner. Alternative 9 construction and restoration actions have the potential to both introduce and spread invasive species in the study area. Implementation of mitigation measures described in this chapter would be capable of making Alternative 9 implementation compatible with Executive Order 13112.
- *Executive Order 113443: Facilitation of Hunting Heritage and Wildlife Conservation* directs federal agencies whose activities affect public land management, outdoor recreation, and wildlife management to facilitate the expansion and enhancement of hunting opportunities, and the management of game species and their habitat. Alternative 9 conservation measures that involve conversion of cultivated land and managed wetland to tidal and nontidal wetlands and other natural communities would conflict with the hunting expansion and enhancement aspects of this executive order. Refer to Chapter 15, *Recreation*, for a detailed analysis of the effects of alternatives on hunting opportunities. The habitat protection and expansion conservation measures of Alternative 9 would be compatible with the executive order's goal of facilitating the management of habitats for some game species.

CEQA Conclusion: The potential plan and policy incompatibilities of implementing Alternative 9 identified in the analysis above indicate the potential for a physical consequence to the environment. The primary physical consequence of concern is the conversion of large acreages of cultivated land and managed wetland to natural wetland and riparian habitat in the Plan Area. The physical effects are discussed in the Shorebirds and Waterfowl analysis above and no additional CEQA conclusion is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Section 13.2.3 of Chapter 13, *Land Use*, for a further discussion of the responsibilities of state and federal agencies to comply with local regulations and the relationship between plan and policy consistency and physical consequences to the environment.

12.3.3.17 Cumulative Effects on Terrestrial Biological Resources

Assessment Methodology

The cumulative effects analysis for terrestrial biological resources addresses the potential for the BDCP alternatives to act in combination with other past, present, and reasonably foreseeable future projects, programs or conditions to create a cumulatively significant adverse impact. The analysis also considers whether any incremental effect of the alternative is cumulatively considerable. Chapter 4 Section 4.2, *Resource Chapter Organization*, provides the regulatory and statutory basis for the cumulative analyses found in this document.

The geographic scope of the analysis for natural communities is the terrestrial biology study area (the BDCP Plan Area and the two transmission corridors that extend beyond the Plan Area) and lands immediately adjacent to this study area where past, present or reasonably foreseeable activities might indirectly affect the natural communities in the study area. While the natural communities extend beyond these boundaries, the focus of the actions that might affect these resources is the Delta and other lands involved in BDCP conservation efforts. The geographic scope of the cumulative analysis for each of the covered and noncovered species varies, depending on the potential for other projects or programs to influence individuals that rely on the study area for some stage of their life history. For some wildlife species, such as migratory birds, this area includes their entire range within California. For other species whose individuals do not range beyond the study area and its immediate surroundings, the geographic range of the cumulative analysis has been limited to this smaller area. The geographic scope for cumulative effects from spread of invasive species is the study area.

The projects and programs that have been considered as part of the cumulative analysis have been drawn primarily from a list developed for this EIR/EIS and contained in Appendix 3D, *Defining Existing Conditions, No Action Alternative, No Project Alternative, and Cumulative Impact Conditions*. This list was compiled in part by reviewing the projects addressed in the cumulative impacts analysis for the Delta Land Use and Resource Management Plan (Delta Protection Commission 2010). The list was augmented by reviewing the BDCP Alternatives Development Report (Appendix 3A) and other recent environmental documents for Delta-area projects, and by coordinating with local, state, and federal agencies that are sponsoring activities in the Delta area or on other lands within the relevant range of individual species. The list of past, present and reasonably foreseeable future projects and programs has been evaluated to determine which of these activities may have effects on terrestrial habitats and terrestrial species that are known to occur within the study area. The list of projects and programs relevant to terrestrial biological resources is contained in Table 12-8. Most of these projects and programs are also a part of the NAA that is addressed in Section 12.3.3.1.

In addition, the effects of global climate change have been considered in addressing the cumulative effects of alternatives on terrestrial biological resources. Changes that might occur within the study area related to climate change are considered reasonably foreseeable and part of the cumulative condition that might combine with the effects of BDCP implementation. Climate change is also considered an element of the No Action Alternative (see Section 12.3.3.1). Chapter 29, *Climate Change*, provides background and assumptions associated with climate change in the Plan Area, and also addresses general effects on terrestrial habitat and species.

To assess whether implementation of the alternatives would contribute to an adverse cumulative effect on the terrestrial biological resources of the study area, a judgment must first be made regarding potential adverse effects of the alternatives. Where adverse effects are anticipated, a determination must be made as to whether these effects would contribute to a cumulative adverse effect on a terrestrial biological resource. If there is a contribution to a cumulative adverse effect, a final judgment must be made as to whether the effect of the alternative represents a considerable contribution to the cumulative effect.

Cumulative Effects of No Action

Effects of Past, Present and Reasonably Foreseeable Projects and Programs

The current conditions of study area biological resources are the byproduct of past and ongoing human activity and natural processes. The present geographic range and condition of natural communities, special-status and common plants and wildlife, and invasive species are described in Section 12.1, *Environmental Setting/Affected Environment*. A brief synopsis of general environmental conditions and their evolution in the study area is presented in Section 12.1.1, *Historical Trends in Biodiversity of the Plan Area*. This discussion provides a context of gradually declining acreages of natural habitat due to agricultural, urban development, flood control and water management activities.

The various projects and programs listed in Table 12-8 will have cumulative effects on the existing biological resources of the study area over the next 50 years. The most relevant elements of these projects and programs are their ability to modify land use patterns, modify land management practices, and change the patterns of hydrology and vegetation in the study area. Most of the local, state and federal land use and land management programs that are affecting or will affect the Delta are designed to preserve open space and agricultural lands, and to manage the resources of the area for multiple uses, including agriculture, recreation, fish and wildlife habitat, flood protection and water management. The restoration programs will increase primarily wetland and riparian natural communities by converting agricultural land or managed wetland. The special-status and common plants and wildlife that rely on wetland and riparian habitats for some stage of their life will benefit from these changes over time. Other species that rely on agricultural land and managed wetland, but do not benefit from wetland and riparian expansion, may decline in the study area. On the upland fringes of the Delta, plans exist for small expansions of urban development that would remove primarily agricultural land uses. The management of state- and federally owned wildlife areas, including Grizzly Island, Sherman Island and Yolo Bypass State Wildlife Areas and Stone Lakes NWR, will continue to focus on multiple uses, including wildlife habitat improvement, public access for wildlife viewing, wildlife-friendly agricultural production, and hunting opportunities. Natural habitat will be improved and expanded. The principal changes that are likely to result from the various habitat conservation plans that overlap with the study area would be expected to include the restoration and protection of the habitats that support the same special-status species being addressed in the BDCP (see *Effects of Other BDCP Conservation Measures on Overlapping Conservation Plans*, below). These changes would be expected to result in increases of wetland, grassland and riparian habitats, and a decrease in agricultural lands, and possibly managed wetlands in the study area.

Implementation of the water management strategies associated with the programs listed in Table 12-8 would not significantly modify the principal natural communities in the study area. These management strategies are designed, in part, to improve aquatic habitat conditions in the Delta for the benefit of special-status fish species. Periodic levee and channel maintenance activities associated with the flood management programs in Table 12-8 would result in localized disturbances to valley/foothill riparian, grassland, and tidal perennial aquatic natural communities, and to a lesser extent to tidal brackish and tidal freshwater emergent wetlands. To the extent that ongoing levee repair and replacement involves use of reinforcing rock and discouragement of replanting streamside vegetation, there could be a gradual decline in the extent and value of valley/foothill riparian habitat and grassland along minor and major waterways. Several of the water management and transportation projects listed in Table 12-8 require localized removal of natural communities and agricultural land for expanding infrastructure. Most of these activities are on the periphery or just outside of the study area, including the Contra Costa Water District fish screen and diversion structure modifications, the Delta Mendota Canal/California Aqueduct intertie project, the South Bay Aqueduct improvement project, and California High Speed Rail.

Effects of Global Climate Change

As discussed in Chapter 29, global climate change is expected to result in many physical changes to the BDCP Plan Area. From a terrestrial biology perspective, the most significant changes would include a gradual rise in sea level, increasing water and air temperatures, more frequent drought and extreme rainfall events, and changes in the hydrologic patterns of the rivers and the Delta channels that influence the terrestrial and aquatic habitats used by terrestrial plants and wildlife. The BDCP climate change analysis included in Chapter 29 considers sea level increases at various levels, including 18–55 inches during the Plan period (see Chapter 29, Section 29.5.1.2). Air temperatures are projected to rise by 2–5 degrees F by 2050 and water temperatures are projected to increase as some proportion (2–3 degrees F) of the air temperature rise (see Appendix 29C, Section 29C.2.1). The changed frequency of drought and extreme rainfall events has not been predicted, but these events are expected to be part of future California conditions with global climate change. Hydrologic conditions in the rivers and Delta channels are expected to be altered by changes in precipitation patterns, with a portion of precipitation shifting from snow to rainfall in the winter months. This would increase river flows in winter and early spring, and decrease flows in the remainder of the year as snowmelt runoff decreases. The changes in river flows would generate subsequent changes in west Delta and Suisun Marsh salinity levels.

The physical changes in conditions in the study area related to the climate change described above, especially the sea level rise, could change the distribution and value of study area habitats. The sea level rise is expected to gradually inundate existing habitats on the periphery of the Delta, in the lower Yolo Bypass, and the northern and southern edges of Suisun Marsh. This pattern of inundation, which assumes a 55-inch sea level rise, is shown in Figure 29-1. Tidal brackish and freshwater marsh could be gradually inundated and converted to more subtidal habitat. In areas where there is no upland barrier (e.g., levees, roads, residential development, agricultural fields), some portion of the tidal marsh may re-establish upslope with the higher water levels if there is sufficient sediment available to provide an appropriate substrate. However, decreases in sediment availability that have occurred in the Delta and Suisun Marsh over time and that may continue may not keep pace if the higher estimated rates of sea level rise occur (Barnard et al. 2013). The result could be a gradual loss of these tidal marshes. Where barriers exist upslope of existing marsh, the tidal marsh habitat could be gradually inundated and subtidal areas would remain. Subtidal habitat is less valuable to the special-status and common terrestrial plants and wildlife of the study area. Low-lying upland grassland and riparian areas that border the study area waterways could also be gradually converted to tidal marsh, but would be expected to re-establish upslope where open ground exists and there are no physical barriers. Where these deeper water incursions bisect existing wildlife corridors, the ability of certain species to move and interact with adjacent populations would decrease. Population numbers of riparian, grassland, and tidal marsh species would be likely to decrease and population distribution would be altered. The habitats adjacent to study area waterways would also be exposed to more frequent inundation and desiccation as precipitation levels show greater fluctuation.

Land subsidence, sea level rise, gradual or catastrophic levee failure, or a combination of these conditions, should they occur, would result in flooding and inundation that could significantly damage existing facilities and infrastructure, uproot and kill vegetation to an unknown extent, permanently flood Delta islands, and drastically alter the salinity of Delta waterways and wetlands. Depending on the extent and duration of flooding, significant short- and long-term changes could occur in the availability of shallow tidal wetlands, riparian and grassland habitats and managed lands useful to certain special-status and common species (e.g., cultivated lands, managed wetland). Depending on the amount of human intervention to drain islands and rebuild levees, there may be a gradual succession of habitats less valuable to the plant and animal species currently relying on the Delta for growth and seed production, cover, breeding, nesting, resting, movement corridors and foraging. Refer to Appendix 3E, *Potential Seismic and Climate Change Risks to SWP/CVP Water Supplies*, for a further discussion of seismic and climate change effects that might occur in the study area under the no action condition. While similar risks would occur under implementation of the action alternatives, these risks may be reduced by BDCP-related levee improvements, along with implementation of those projects identified for the purposes of flood protection in Table 12-7.

The negative elements of global climate change described above would be a contributing factor to any cumulative effects of implementing the projects and programs that are part of the No Action scenario (Table 12-8). Any negative effects on terrestrial biological resources associated with the action alternatives (see below), when considered with all of the above effects of the No Action Alternative, could create adverse cumulative effects to these terrestrial biological resources.

Cumulative Effects of the Action Alternatives

Based on the analyses presented in earlier parts of this chapter, the alternatives would have little or no negative effect or would have a long-term beneficial effect on nearly all of the terrestrial biological resources of concern in the study area. This is consistent with the goal of HCP/NCCP programs, which is to improve the long-term viability of special-status species and their habitats. The positive effects of implementing the BDCP are similar in all of the project alternatives other than the No Action Alternative. There are relatively small variations in the acres affected by construction of the alternative water conveyance facilities (CM1), but the restoration, protection, enhancement and stressor reduction elements of the alternatives are the same for Alternatives 1A, 1B, 1C, 2A, 2B, 2C, 3, 4, 6A, 6B, 6C, 8 and 9. These elements of the BDCP have the greatest potential to modify natural communities and affect special-status plants and wildlife. There are reductions in tidal marsh restoration (CM4) associated with Alternative 5, and expansion of channel margin habitat enhancement (CM6) and floodplain restoration (CM5) associated with Alternative 7 that create significant variances from the rest of the alternatives. Where relevant, these differences are addressed in the impact analysis that follows.

While construction and restoration activities in the near-term period of the alternatives would temporarily or permanently remove natural communities and modeled habitat for special-status plant and wildlife species, the near-, mid- and long-term conservation actions would replace, enhance and in most cases expand habitat acres and value for these species. The positive effects the alternatives would have on special-status species would also provide benefits to common terrestrial wildlife and plants.

The potential adverse effects of implementing all of the action alternatives include potential disturbance of nesting colonies of bank swallows, should they be present adjacent to construction activity at the north end of the Yolo Bypass, and the potential that BDCP-related changes in river stage upstream of the study area on the Sacramento and Feather Rivers could adversely affect bank swallow colonies. Though the alternatives using the east (Alternatives 1B, 2B, and 6B) and west (Alternatives 1C, 2C, and 6C) alignments would provide the same conservation benefits as the other alternatives, the construction of the canal portions of the conveyance facilities would create substantial barriers to wildlife movement within and through the study area. Also, the canal associated with the east alignment alternatives (1B, 2B, and 6B) would adversely affect movement and connectivity between subpopulations of giant garter snake in the vicinity of White Slough in the eastern Delta.

Because these are the only potential adverse effects that could combine with the projects and programs in Table 12-8 and with global climate change to create a cumulatively considerable effect, the discussion that follows is limited to these issues.

Table 12-8. Programs, Projects, and Policies Included In the Cumulative Impact Analysis for Terrestrial Biological Resources

Agency	Program/Project/Policy	Comments
Alameda County	East Alameda County Conservation Strategy	Approved in 2011. There is less than a 2% overlap with BDCP (4,643 acres) and this overlap only occurs in one conservation zone. The conservation strategy addresses the conservation needs of 19 species, including eight species that overlap with the BDCP. Currently no planned conservation activity in the overlap area, so the conservation strategy would not affect BDCP species in the Plan Area. The East Alameda strategy would have beneficial effects on eight of the BDCP covered species.
California Department of Fish and Wildlife	Calhoun Cut/ Lindsey Slough Restoration	Increase intertidal marsh habitat and adjacent riparian habitat on 927 acres in Cache Slough ROA.
California Department of Fish and Wildlife	Ecosystem Restoration Program Conservation Strategy	Created in 2000. Ongoing program to preserve, restore, and enhance terrestrial natural communities and ecosystems in the San Francisco Bay and Sacramento-San Joaquin Delta. Protected and restored more than 150,000 acres of habitat, including 3,900 acres and 59 miles of riparian and riverine aquatic habitat (as of 2010) after 7 of the planned 30 years of the project. This conservation strategy creates beneficial impacts on the natural communities and special-status species included in this EIR/EIS.

Agency	Program/Project/Policy	Comments
California Department of Fish and Wildlife	Fremont Landing Conservation Bank	Established in 2006. Enhances 40 acres of riparian habitat and restores 60 acres of riparian woodlands and sloughs. This bank provides benefits to salmonid species in the Sacramento Valley and many riparian bird, reptile and mammal species that also occupy the Delta.
California Department of Fish and Wildlife	Grizzly Island Wildlife Area Land Management Plan	Estuarine marsh that contains about 15,300 acres of wildlife habitat. Will continue to be managed for wildlife, with an emphasis on waterfowl, threatened and endangered species, and the resident tule elk herd. CDFW actions at this wildlife area will maintain and enhance managed wetland as some of the private wetland is converted to tidal marsh.
California Department of Fish and Wildlife	Lower Sherman Island Wildlife Area Land Management Plan	Ongoing program. Directs habitat and species management on 3,100 acres of marsh and open water. The Plan's goals are to restore and improve marsh and upland habitats for threatened and endangered species, control invasive species and allow for hunting and fishing recreation activities. The Plan has a positive effect on species of concern in BDCP.
California Department of Fish and Wildlife	Private Lands Incentive Program	Includes 29,000 acres of habitat in Tulare Basin, Grasslands, Suisun Marsh, and Sacramento Valley. Encourages development and enhancement of habitat for shorebirds and waterfowl on private lands. This program has beneficial effects on waterfowl and shorebird species in the Plan Area, and encourages wildlife-friendly farming practices.
California Department of Fish and Wildlife	Restoring Ecosystem Integrity in the Northwest Delta	Originally funded in 2004. Ongoing program. Focused on habitat restoration. Currently concentrating acquisition efforts on 3 specific properties consisting of about 150 acres and baseline monitoring. The project centers on Calhoun Cut and Lindsay Slough in the Cache Slough ROA. The plan is designed to create a restored, protected corridor extending from Jepson Prairie to Prospect Island, doubling the overall acreage of marsh and riparian habitats, doubling the protected acres of vernal pool/perennial grasslands and increasing the abundance and local distribution of at risk and other native plant and animal species. It is consistent with BDCP goals for habitat restoration in the Cache Slough ROA.

Agency	Program/Project/Policy	Comments
California Department of Fish and Wildlife	Staten Island Wildlife-Friendly Farming Demonstration	Ongoing program. Objective is ecosystem restoration; 2,500–5,000 acres of corn will be flooded to increase habitat availability and to improve wildlife-friendly agriculture to foster recovery of at-risk species and to investigate effects of agriculture on water quality. This program is focused on improving agricultural land as seasonal habitat for greater and lesser sandhill cranes, a target species of the BDCP.
California Department of Fish and Wildlife	Yolo Bypass Wildlife Area Land Management Plan	Ongoing program. Provides for multiple use management of 16,000 acres of mixed agricultural, grassland and managed wetland habitats. This wildlife area is managed to support wintering waterfowl populations, shorebird migration, waterfowl hunting, and active wildlife observation, especially bird watching. This is accomplished by actively managing wetland habitats and providing for wildlife-friendly farming.
California Department of Water Resources	Central Valley Flood Protection Plan	Proposes significant expansion of flood protection features in the study area, including expansion of the Yolo Bypass. This flood protection improvement project would potentially conflict with BDCP's effort to improve giant garter snake habitat just outside of the current floodway, and to improve fish passage through Yolo Bypass waterways.
California Department of Water Resources	Delta Levees Flood Protection Program	Ongoing program. Includes modification to Delta levees within the Sacramento-San Joaquin Delta and portions of the Suisun Marsh, with a focus on western Delta island levees. The project works with 60 reclamation districts and strives to complete levee rehabilitation projects with no net loss of habitat in the Delta. The program has some potential to remove grassland, emergent marsh and riparian habitats in the short-term to strengthen levees. Habitat losses would have to be offset with protection or restoration actions.
California Department of Water Resources	FloodSAFE California	Promotes public safety through integrated flood management while protecting environmental resources; emphasizes action in the Delta. This program is very broad, but is designed to improve flood safety throughout the state while encouraging sound conservation actions that benefit California's native fish and wildlife and promote wildlife-friendly agricultural practices. The program should not reduce habitat values in the Delta.

Agency	Program/Project/Policy	Comments
California Department of Water Resources	Levee Repair-Levee Evaluation Program	Ongoing program. Upgrading levees along the Sacramento and San Joaquin Rivers and Delta; 1,600 miles of levees included in Central Valley. Most of the program efforts are geotechnical, bathymetric and geomorphic evaluations that have little to no effect on terrestrial wildlife in the study area.
California Department of Water Resources and MOA Partners	Lower Yolo Restoration Project	In Cache Slough ROA, reintroduce tidal action to half of 3,408-acre Yolo Ranch. This project would eliminate existing agricultural land used primarily for grazing, and create tidal marsh for the benefit of special-status Delta anadromous and resident fish species. It is expected to be part of BDCP's early implementation program. It will adversely affect some grassland species in favor of tidal marsh and riparian species.
California Department of Water Resources	Dutch Slough Tidal Marsh Restoration Project	Converts 240–840 acres from agricultural uses and grazing to wetland, riparian, and upland habitats. The project also includes development of a recreation center at one end of the property. The restoration will benefit tidal marsh and riparian habitats and species in the western Delta on lands with considerable topographic diversity and little to no land subsidence.
California High Speed Rail Authority	Sacramento to Merced Section of High Speed Rail System	One possible alignment for the section from Sacramento to Merced would includes major infrastructure construction along the I-5 corridor between French Camp and Lathrop, which would pass through the portion of the study area around the I-5 and Hwy. 120 junction. The potential alignment from the Bay Area to Stockton would cross the study area from the west near Tracy and head east to Lathrop. These alignments are within or parallel existing rail corridors. The project has the potential to remove grassland and cultivated lands along existing rights of way in the study area.
California Partners in Flight	Riparian Habitat Joint Venture	Ongoing program. Promotes and supports riparian conservation and enhancement, contributes to flood control and maximizes habitat available to wildlife. Protects and restores riparian areas with intact adjacent upland habitats. The program has a positive influence on the value of riparian habitat.
Central Valley Joint Venture Program	Central Valley Joint Venture	Ongoing program. Strives to protect, restore, and enhance wetlands. Contributes to habitat conservation on a total of 714,000 acres in California. This program has the potential to convert agricultural land to managed wetland or natural wetlands.

Agency	Program/Project/Policy	Comments
Contra Costa County and East Contra Costa County Habitat Conservancy	East Contra Costa County HCP/NCCP	Approved in 2007. Encompasses about 175,000 acres and contains 30,000 acres of preserved land. Purpose is to purchase, restore, and permanently protect large, interconnected and biologically rich blocks of habitat. A 63,073 acre overlap with the BDCP boundary. This HCP/NCCP will result in restoration of native grassland, vernal pools and oak woodland on the southwestern edge of the BDCP Plan Area.
Contra Costa Water District	Contra Costa Canal Fish Screen Project	Completed in 2011. Designed to restore Delta ecosystems. Minor terrestrial impact at fish screen sites.
Contra Costa Water District, U.S. Bureau of Reclamation, and California Department of Water Resources	Contra Costa Water District Middle River Intake and Pump Station (Alternative Intake Project)	Completed in 2010. Resulted in permanent conversion of 6–8 acres of rural agricultural land. Features about 12,000 feet of pipe across Victoria Island and under Old River.
Delta Protection Commission	Land Use and Resource Management Plan	Outlines long-term land use requirements for the Sacramento-San Joaquin Delta. This plan directs the long-term protection of agricultural, recreational, and open space uses of the Delta and restricts urban and other types of development that would reduce the value of these uses. The Plan supports protection and restoration of riparian and aquatic habitats in the Delta, and improvement in water quality in Delta channels.
National Marine Fisheries Service, U.S. Bureau of Reclamation, and Department of Water Resources	Biological Opinion (BiOp) on the Long-Term Operations of the Central Valley Project and State Water Project	Ongoing program. Action area consists of the Oroville Reservoir, Feather River downstream of Oroville, Sacramento River downstream of Feather River, Sacramento-San Joaquin Delta, and adjacent habitats that are dependent on or influenced by waterways. Designed to conserve freshwater, estuarine, nearshore, and offshore aquatic habitats, for the benefit of federally protected fish species. Includes 8,000-acre tidal wetland restoration requirement, which will result in conversion of agricultural land and managed wetland in the Delta and Suisun Marsh.
Reclamation District 2093	Liberty Island Conservation Bank	Under implementation. Permits and approvals acquired in 2009. Project site is on northern tip of Liberty Island. Over 160 acres in the project site with about 50 acres proposed to be converted to open water channels, emergent marsh wetland, and riparian habitat. Focuses on Delta fish habitat but will restore 2.7 acres of riparian habitat.

Agency	Program/Project/Policy	Comments
Sacramento Area Flood Control Agency, Central Valley Flood Protection Board, and U.S. Army Corps of Engineers	Central Valley Flood Management Program	Ongoing program. Supports flood management planning in Sacramento and San Joaquin Valleys. To be updated every 5 years with first update to be completed in 2017. Combined total of about 2.2 million acres of land within the Central Valley. The program supports improvements in flood management structures, including levees and bypasses. Facilities improvements could result in local removal of vegetation in the study area as flood control facilities are improved and expanded.
San Joaquin Council of Governments	San Joaquin County Multi-Species Habitat Conservation and Open Space Plan	Ongoing program. Approved in 2011. Includes most of San Joaquin County. Assumes 100,000 acres of open land conversion and provides about 100,000 acres of preserves. About 35% of this plan overlaps with BDCP so competition for restoration sites and land acquisition would exist. There are 39 covered species in common and very similar land acquisition targets, such as riparian forests and grasslands. The Plan is likely to result in conversion of agricultural land to native vegetation, including riparian and grassland areas in the south and east Delta areas.
Semi Tropic Water District	Delta Wetlands	Flood storage and habitat conservation project on four Delta islands. This project could convert four large Delta islands into 11,000 acres of freshwater storage and 9,000 acres of managed agricultural lands, wetlands, riparian areas and other types of wildlife habitat. A significant amount of agricultural land would be removed from production.
Solano County	Solano County Multispecies Habitat Conservation Plan	Establishes habitat conservation goals for Solano County, including approximately 205,000 acres of the study area. This conservation plan focuses on protection and restoration of 13,000-15,000 acres of valley floor grassland and vernal pool habitat for a range of special-status species. Many of the target species are common with the BDCP, including fairy shrimp, Swainson's hawk, western burrowing owl, giant garter snake, California red-legged frog, and Mason's lilaeopsis.

Agency	Program/Project/Policy	Comments
U.S. Army Corps of Engineers	CALFED Levee Stability Program	Includes maintaining and improving levee stability in the Delta. Long-term strategy will include ecosystem restoration. Partially funds McCormack-Williamson Tract Restoration in Cosumnes-Mokelumne ROA; 1,500 acres of tidal and floodplain habitat restoration would expand habitats also targeted by BDCP.
U.S. Bureau of Reclamation	Delta Mendota Canal/California Aqueduct Intertie	Construction completed in April 2012. Includes construction of a pump and 500-foot pipeline between the two canals near the Jones Pumping Plant. No special-status plant community was affected. The majority of the habitat disturbed was nonnative annual grassland.
U.S. Bureau of Reclamation, U.S. Fish and Wildlife Service, National Marine Fisheries Service, Department of Water Resources and Department of Fish and Wildlife	San Joaquin River Restoration Program	Initiated in 2006. Ongoing program; 150 miles of the river is planned for restoration, with an emphasis on improving fish passage and riparian habitats within and adjacent to the river's floodplain. This program does not include lands within the BDCP Plan Area, but would provide habitat connections along the San Joaquin River upstream of the Plan Area.
U.S. Fish and Wildlife Service, U.S. Bureau of Reclamation and California Department of Fish and Wildlife	San Joaquin Basin Action Plan	Includes a habitat acquisition and wetland enhancement project on 23,500 acres in northern San Joaquin River basin, outside of the BDCP Plan Area. This program is focused on supplying adequate water to state and federal refuges and managed wetlands in the San Joaquin Valley for the benefit of migratory waterfowl and other species that are supported by these managed wetlands. These habitats are elements of the larger Central Valley flyway that includes wetlands in the BDCP Plan Area
U.S. Fish and Wildlife Service and Sacramento County	South Sacramento Habitat Conservation Plan	Establishes conservation goals for south Sacramento County, including approximately 43,000 acres of the study area. This plan targets habitat restoration and preservation for 16 species that are common to the BDCP. Habitat improvements are sought for grassland, wetland, agricultural land and riparian areas. There is overlap in the demand for land acquisition sites between the BDCP and the South Sacramento Plan. The Plan also provides for an urban expansion area within the BDCP Plan Area. Collaborative planning for the two HCPs could improve the opportunities to create a continuous band of preserved land from giant garter snake populations in the White Slough area to Stone Lakes NWR and Cosumnes River Preserve.

Agency	Program/Project/Policy	Comments
U.S. Fish and Wildlife Service	Recovery Plan for Sacramento-San Joaquin Delta Native Fishes	Released in 1995, the recovery plan includes developing additional shallow water habitat, riparian vegetation zones and tidal marsh to restore wetland habitats for the benefit of 8 native species throughout the Bay-Delta ecosystem. The objective of the plan is to establish self-sustaining populations of the species included in the plan. The goals for chinook salmon, green sturgeon, and splittail include providing for a limited harvest that can be sustained. The estuary is to be managed so that it is better habitat for aquatic life in general and for the fish species of concern in particular. This plan complements the goals of the BDCP, for both terrestrial and aquatic species in the Delta.
U.S. Fish and Wildlife Service	Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan	Drafted in 2006. Ongoing program. Directs habitat and species management on approximately 17,600 acres of grassland, agricultural land, managed wetland and riparian habitat. The managed lands of the refuge are a major conservation feature on the eastern boundary of the BDCP Plan Area. Lands within the refuge are owned in fee title or cooperatively managed with landowners through easements. The goals of the refuge are to conserve, restore and manage wetland, grassland, and riparian habitat for the benefit of fish, wildlife and plants, and special-status species; conserve enhance, and restore high quality migrating, wintering and breeding habitat for migrating birds; provide visitors with wildlife-dependent recreation, education and interpretation opportunities; and identify and protect cultural resources. The refuge represents an excellent opportunity for cooperative habitat conservation between the USFWS and BDCP implementing entities.

Agency	Program/Project/Policy	Comments
U.S. Fish and Wildlife Service, U.S. Bureau of Reclamation and California Department of Water Resources	BiOp on the Long-Term Operations of the Central Valley Project and State Water Project (Delta smelt)	Ongoing program. The opinion directs reasonable and prudent actions associated with the ongoing operation of the CVP and SWR, as they relate to the long-term survival of delta smelt. It directs actions associated with reducing entrainment of adult, juvenile and larval smelt in the south Delta pumps; improving habitat for smelt within the Delta by regulating river outflow, restoring or creating at least 8,000 acres of intertidal and related subtidal habitat for delta smelt in the Delta and Suisun Marsh; and initiating a monitoring and reporting program. This program is a principal element in controlling west Delta and Suisun Marsh salinity levels that might affect terrestrial species and habitats.
Yolo County	Yolo Natural Heritage Program Plan	First administrative draft plan released in June 2013. Establishes habitat conservation goals for Yolo County (653,818 acres), including 111,383 acres of the BDCP study area. The principal areas of overlap are in the Yolo plan's Planning Units 17 and 18, northern and southern Yolo Bypass. This corresponds primarily with BDCP CZ 2. Thirty-two species are being considered for ESA and NCCPA coverage, including Swainson's hawk and giant garter snake. The Yolo plan proposes to restore or protect over 76,000 acres of valley oak woodland, valley foothill riparian, fresh emergent wetland, shrubland, agricultural land and grassland. This plan provides the potential to work toward common habitat protection, restoration and enhancement with the BDCP in the Yolo Bypass area (Yolo County Habitat/Natural Community Conservation Plan Joint Powers Authority 2013).
Zone 7 Water Agency and Department of Water Resources	South Bay Aqueduct Improvement and Enlargement Project	Estimated completion in 2012. More than 40 miles of pipelines, a 500 acre-foot reservoir and new pumping facilities will be built. The project is located outside of the BDCP Plan Area, but will remove grassland, riparian and related habitats in the hills west of the Plan Area.

Impact BIO-188: Cumulative Indirect Effects of the Construction of Conservation Components on Bank Swallow

Noise and visual disturbances during restoration activities for Alternatives 1A–9 could result in temporary disturbances that cause bank swallow to abandon active nest burrows adjacent to construction areas, and construction-related disturbances could result in an adverse effect on individuals. The noise and visual disturbance could result from implementing *CM2 Yolo Bypass Fisheries Enhancement*, and *CM4 Tidal Natural Communities Restoration* including operation of earthmoving equipment and human activities at work sites. Bank swallow colonies with occupied burrows have been recorded in CZ 2 and CZ 5. Various activities related to *CM11 Natural Communities Enhancement and Management* could also have indirect impacts on bank swallow.

A number of other projects and programs listed in Table 12-8 also have the potential to directly or indirectly affect bank swallow in the study area and in areas upstream of the study area along the Sacramento and Feather Rivers. They include:

- DWR Central Valley Flood Protection Plan (Yolo Bypass widening)
- DWR Delta Levees Flood Protection Program
- DWR FloodSAFE California
- Sacramento Area Flood Control Agency, Central Valley Flood Protection Board, U.S. Army Corps of Engineers Central Valley Flood Management Program
- U.S. Army Corps of Engineers CALFED Levee Stability Program

All of the flood control and levee protection programs and plans listed above could involve modification and armoring of levees within the range of known bank swallow colonies adjacent to and north of the study area. Additional bank protection could further reduce the availability of bank swallow nesting sites and could involve indirect disturbance of active nesting colonies. Alternatives 1–9, in combination with the other projects and programs listed above, could result in adverse effects on bank swallow nesting colonies that are individually limited but cumulatively considerable.

NEPA Effects: The indirect disturbance to bank swallow nesting colonies caused by implementing Alternatives 1A–9, in combination with the potential direct and indirect effects on these colonies caused by other past, present, or reasonably foreseeable projects and programs would create an adverse cumulative effect on this species adjacent to and north of the study area. The disturbances could result in take of a state-listed threatened species. Although the potential effect of the alternatives is restricted to few colonies, the state recognizes this species as both imperiled and vulnerable because of its restricted range and low populations. Therefore, the effect of the alternatives represents a cumulatively considerable contribution to an adverse cumulative effect. Implementation of Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would be available to address this effect.

CEQA Conclusion: The indirect disturbance to bank swallow nesting colonies caused by implementing Alternatives 1–9, in combination with the potential direct and indirect effects on these colonies caused by other past, present or reasonably foreseeable projects and programs would create a significant cumulative impact on this species adjacent to and north of the study area. The disturbances could result in take of a state-listed threatened species. Although the potential effect of the alternatives is restricted to a single colony, the state recognizes this species as both imperiled and vulnerable because of its restricted range and low populations. Therefore, the impact of the alternatives represents a cumulatively considerable contribution to a significant cumulative impact. Implementation of Mitigation Measure BIO-146, *Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized*, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized

To the extent practicable, BDCP proponents will not construct conservation components during the bank swallow nesting season (April 1 through August 31). If construction activities cannot be avoided during nesting season, a qualified biologist will conduct preconstruction surveys to determine if active bank swallow nesting colonies are present within 500 feet of work areas. If no active nesting colonies are present, no further mitigation is required.

If active colonies are detected, BDCP proponents will establish a nondisturbance buffer (determined in coordination with CDFW and the Bank Swallow Technical Advisory Committee) around the colony during the breeding season. In addition, a qualified biologist will monitor any active colony within 500 feet of construction to ensure that construction activities do not affect nest success.

Impact BIO-189: Cumulative Upstream Effects of Reservoir and Water Conveyance Facilities Operations on Bank Swallow

Bank swallows are a riparian species that have evolved to deal with a dynamic system that changes with annual variation in variables such as rainfall, or late snowpack runoff. The primary threat to the species is loss of nesting habitat from the placement of rock revetment for levee stabilization. Because of this limited available habitat, and the reduction of natural river process, the species is highly sensitive to 1) reductions in winter flows which are necessary to erode banks for habitat creation, and 2) high flows during the breading season. The potential impacts of changes in upstream flows during the breeding season on bank swallows are the flooding of active burrows and destruction of burrows from increased bank sloughing. Bank swallows arrive in California and begin to excavate their burrows in March, and the peak egg-laying occurs between April and May (Bank Swallow Technical Advisory Committee 2013). Therefore, increases in flows after the March when the swallows have nested and layed eggs in the burrows could result in the loss of nests. On the Sacramento River, breeding season flows between 14,000 and 30,000 cfs have been associated with localized bank collapses which resulted in partial or complete colony failure (Stillwater Sciences 2007).

The CALSIM II modeling results of mean monthly flow were analyzed for three flow gauge stations on the Sacramento (Sacramento River at Keswick, Sacramento River upstream of Red Bluff, Sacramento River at Verona) and two flow gauge stations on the Feather River (Feather River high-flow channel Thermalito Dam, and Feather River at the Confluence with the Sacramento River). Flows were estimated for wet years (W), above normal years (AN), below normal years (BN), dry years (D), critical years (C) and an average (A; see Section 5.3.1 Methods for Analysis, Chapter 5 *Water Supply*, for a description of the model).

On the Sacramento River, at the Keswick and Red Bluff gauges, mean monthly flows under Alternatives 1A–9 would increase between April and August in some water years which could lead to inundation of active colonies. However, the flows under Existing Conditions and the predicted flows in the late long-term without the project also show increases in flows during the breeding season (April–August) in these water year types. Similar trends occur for the Feather River. In addition, under Alternatives 1A–9 flows are predicted to be greater than 14,000 cfs during the breeding season (April–August,) during certain water years which could lead to bank collapse. However, flows of this height are recorded under Existing Conditions at this flow gauge and are also predicted for the late long-term time without the project (the No Action Alternative).

NEPA Effects: High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternatives 1A–9 would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. Soil type, high winter flows, and low spring flows all contribute to successful nesting of bank swallow, and even moderate changes in seasonal flows could have an adverse effect on breeding success for the species. Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would be available to address the uncertainty of potential adverse effects of upstream operations on bank swallow. Because the state recognizes this species as both imperiled and vulnerable due to its restricted range and low populations, any negative effect of the alternatives would represent a cumulatively considerable contribution to an adverse cumulative effect.

CEQA Conclusion: High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternatives 1A–9 would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of upstream impacts on bank swallow from changes in operations. There are many variables that dictate suitable habitat for the species that cannot be clearly quantified, and seasonal changes in flow could increase or decrease suitable habitat for bank swallow depending on soil type and location of current colonies. Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area* would address this significant impact and further determine if additional mitigation is required for bank swallow. Because the state recognizes this species as both imperiled and vulnerable due to its restricted range and low populations, any adverse impact of the alternatives would represent a cumulatively considerable contribution to a significant cumulative impact.

Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area

To address the uncertainty of the impact of upstream spring flows on existing bank swallow habitat, DWR will monitor existing colonies upstream of the study area and collect habitat suitability data including soil type, number of active burrows per colony, and height of average burrows. In addition, to determine the degree to which reduced winter flows are contributing to habitat loss, DWR will quantify the winter flows required for river meander to create suitable habitat through lateral channel migration and bank resurfacing. If impacts of upstream flows on bank swallow are identified, further mitigation may be required after consultation with CDFW and the Bank Swallow Technical Advisory Committee. Recommended mitigation for changes in flow regimes associated with water conveyance includes conservation easements on currently occupied habitat or revetment removal projects to create habitat for bank swallow (Bank Swallow Technical Advisory Committee 2013).

Impact BIO-190: Cumulative Effect of Constructing Conveyance Facilities on Giant Garter Snake Movements and Connectivity between Subpopulations

The construction of the conveyance facilities (CM1) under the alternatives using the eastern (Alternatives 1B, 2B, and 6B) alignments would adversely affect movement and connectivity for the Coldani Marsh/White Slough subpopulation of giant garter in the study area. The facilities would eliminate Coldani Marsh/White Slough subpopulation connectivity with areas containing current or previous occurrences of giant garter snake, specifically in the vicinity of Stone Lakes NWR to the north and in the Delta to the southwest (Figure 12-15B). An unknown number of small agricultural ditches and drains between Disappointment Slough and Stone Lakes would be lost, rerouted, or directed into culverts and affect species' movements and connectivity. Siphons would be constructed underneath sloughs (Disappointment Slough, White Slough, Sycamore Slough, Hog Slough, and Beaver Slough) and Stone Lakes Drain, and a tunnel would be constructed under the Lost Slough/Mokelumne River area that connects with Snodgrass Slough. These sloughs and drains would still provide some aquatic habitat and opportunities for movement and connectivity between giant garter snakes in the vicinity of Stone Lakes NWR and the Coldani Marsh/White Slough subpopulation.

A number of other factors, projects, or programs also have the potential to directly or indirectly affect giant garter snake movements and connectivity in the study area. They include:

- Urbanization which continues to be one of the greatest threats to the giant garter snake throughout much of its extant range. Environmental impacts associated with urbanization are loss of habitat, introduction of non-native species with a resulting loss of biodiversity, fragmentation of habitat due to road construction, and degradation of habitat due to pollutants. Within the current range of the giant garter snake, cities that are rapidly expanding and, in some instances, intruding upon or otherwise impacting giant garter snake habitat include, but are not limited to: Chico, Woodland, Yuba City/Marysville, Sacramento, Galt, Stockton, Gustine, Los Banos, Merced, and Fresno. Urbanization increasingly threatens the viability of giant garter snake populations as urban landscapes encroach on ever-diminishing habitat for this listed species, including eliminating rice agriculture that serves as an alternative habitat for the giant garter snake.
- A number of HCP's have been issued by USFWS for projects anticipated to impact the giant garter snake, which include the San Joaquin County multi-species HCP, the East Contra Costa County HCP, and the PG&E San Joaquin Valley HCP. In addition, eight other HCPs which include areas within the range of the giant garter snake are currently being developed and include: Butte County, South Sacramento, Solano County, Yolo County, Yuba/Sutter County, Placer County, PG&E Statewide Operations and Maintenance, and PG&E Bay Area.
- Giant garter snakes found in rice fields or agricultural canals are threatened by conversion of rice crops to non-agricultural land uses and other crops such as grape-producing vineyards, fruit or nut producing orchards, or annual row crops (e.g., cotton). Unlike flood irrigated rice fields, other agricultural cropping systems do not hold sufficient water for long enough time periods to create artificial, temporary wetlands.
- The White Slough Wildlife Management Area (WSWA) is owned by the California Department of Water Resources and managed by the California Department of Fish and Wildlife. WSWA consists of 880 acres of man-made ditches, canals, and freshwater marshes with associated grassland/upland habitats used for hunting and fishing. Between 1974 and 1978, 13 rectangular

borrow pits were excavated from one to five miles west of Interstate 5 to provide fill for freeway construction. The pits are fed by groundwater and periodic runoff from precipitation, irrigation, and high canal flows, creating a series of ponds characterized by vegetated sloping or vertical banks and open water with adjacent uplands and high ground. As a management area, WSWA comprises a discontinuous series of properties encompassing ponds 5-13, which occur along a roughly 11-mile stretch between Thornton and Stockton. WSWA supports the preponderance of the Coldani Marsh/ White Slough giant garter snake population, one of 13 giant garter snake populations described in the USFWS 1999 Draft Recovery Plan for the Giant Garter Snake. In the 1970's, CDFW stocked large-mouth bass, channel catfish, and red-eared sunfish in at least two of the ponds: each of these species probably prey on giant garter snakes and compete with them for smaller prey (58 FR 54053).

- DWR Central Valley Flood Protection Plan (Yolo Bypass widening) which proposes expansion of flood protection features in the study, including expansion of the Yolo Bypass. This flood protection improvement project would potentially conflict with BDCP's effort to improve giant garter snake habitat just outside of the current floodway.
- National Marine Fisheries Service, U.S. Bureau of Reclamation, and Department of Water Resources: Biological Opinion (BiOp) on the Long-Term Operations of the Central Valley Project and State Water Project which includes the Sacramento River downstream of Feather River, Sacramento-San Joaquin Delta, and adjacent habitats that are dependent on or influenced by waterways. The BiOp includes landscape designs to conserve freshwater, estuarine, nearshore, and offshore aquatic habitats, for the benefit of federally protected fish species. Including 8,000-acre tidal wetland restoration requirement, which would result in conversion of agricultural land and managed wetland in the Delta and Suisun Marsh, which could negatively affect giant garter snake connectivity and movement in the study area.
- Sacramento Area Flood Control Agency, Central Valley Flood Protection Board, U.S. Army Corps of Engineers Central Valley Flood Management Program is an ongoing program that supports flood management planning in Sacramento and San Joaquin Valleys. The program supports improvements in flood management structures, including levees and bypasses. Facilities improvements could result in local removal of vegetation in the study area as flood control facilities are improved and expanded which could include effects on giant garter snakes in the study area.

Past development within the study area, including urbanization and the construction of irrigation canals, levees, local roads, highways, agricultural development, and the development of wildlife management areas, has already affected the ability for giant garter snake to move within and through the study area.

NEPA Effects: The construction of the water conveyance facilities under Alternatives 1B, 2B, and 6B, in combination with past, present or reasonably foreseeable projects would create an adverse cumulative effect on giant garter snake movement and connectivity within and in the vicinity of the study area. The alternatives' effects represent a cumulatively considerable contribution to an adverse cumulative effect. There is no feasible mitigation to address this effect.

CEQA Conclusion: The construction of the water conveyance facilities under Alternatives 1B, 2B and 6B, in combination with past, present or reasonably foreseeable projects would create a significant cumulative impact on giant garter snake movement and connectivity within and in the vicinity of the study area. The alternatives' impact would represent a cumulatively considerable contribution to a significant cumulative impact. This impact would be significant and unavoidable. There is no feasible mitigation to reduce this impact to a less-than-significant level.

Impact BIO-191: Cumulative Effect of Constructing Conveyance Facilities on Wildlife Corridors

The construction of the conveyance facilities (CM1) under the alternatives using the eastern alignment (Alternatives 1B, 2B, and 6B) and western alignment (Alternatives 1C, 2C, and 6C) would adversely effect wildlife corridors within and through the study area. The intakes, forebays, and canal portions of these alternatives would create barriers to the movement of nonavian wildlife within and through the study area. Nonavian wildlife in large portions of the study area would be restricted to moving across the canals via roads and bridges that would likely act as deterrents to wildlife movement and would be a source of wildlife mortality. The canal for the eastern alignment would act as a major barrier to the movement of nonavian wildlife within the eastern portion of the Delta. The canals for the western alignment would create a substantial barrier to the east-west movement of nonavian wildlife from Clifton Court Forebay north to around the community of Knightsen, and to the north-south movement of wildlife from the town of Hood west to the Sacramento Deep Water Ship Channel. Avian species would also be subject to increased mortality where new transmission lines are installed; however, these lines would not serve as major barriers to avian species' ability to disperse within and through the study area.

One project listed in the Table 12-8, the California High Speed Rail, would also have the potential to adversely affect wildlife corridors in the study area and region. One of the proposed alignments for the Sacramento-to-Merced section of the California High Speed Rail would pass through the study area between French Camp and Lathrop, generally following the I-5 corridor and eventually heading east along State Route 120. A proposed option for the Bay Area-to-Central Valley alignment passes through the study area from just west of Tracy east to around Lathrop, a route that generally follows the existing Union Pacific Rail Road corridor. Both of these area already have barriers to species dispersal, but increased rail traffic and the speed of the trains could serve as deterrents and sources of mortality to wildlife trying to cross these areas.

Past development within the study area, including the construction of irrigation canals, levees, local roads, highways, and agricultural development, has already affected the ability for wildlife to move within and through the study area.

NEPA Effects: The construction of the water conveyance facilities under Alternatives 1B, 1C, 2B, 2C, 6B, and 6C, in combination with past, present or reasonably foreseeable projects, would create an adverse cumulative effect on wildlife corridors within and in the vicinity of the study area. The alternatives' effects represent a cumulatively considerable contribution to an adverse cumulative effect. There is no feasible mitigation to address this effect.

CEQA Conclusion: The construction of the water conveyance facilities under Alternatives 1B, 1C, 2B, 2C, 6B, and 6C, in combination with past, present or reasonably foreseeable projects, would create a significant cumulative impact on wildlife corridors within and in the vicinity of the study area. The alternatives' impact would represent a cumulatively considerable contribution to a significant cumulative impact. This impact would be significant and unavoidable. There is no feasible mitigation to reduce this impact to a less-than-significant level.

12.3.3.18 Effects on Other Conservation Plans

Impact BIO-192: Potential for Conflicts between Implementation of the BDCP and Other Conservation Plans

To comply with CEQA, potential conflicts with the provisions of an adopted HCP, NCCP, or other approved local, regional, or state habitat conservation plan must be analyzed. Within or near the study area, numerous HCPs, NCCPs, and other regional conservation plans have been permitted or are in process, including those listed below.

- Placer County Conservation Plan (TRA Environmental Services 2011)
- Yuba-Sutter HCP/NCCP (Yuba County et al. 2011)
- Natomas Basin HCP (City of Sacramento et al. 2003)
- Yolo Natural Heritage Program (YNHP) (Yolo County Habitat/Natural Community Conservation Plan Joint Powers Authority 2013)
- South Sacramento HCP (Sacramento County 2010)
- Solano County Multispecies HCP (Solano County MSHCP) (Solano County Water Agency 2009)
- East Contra Costa County HCP/NCCP (ECCCHCP/NCCP) (East Contra Costa Habitat Conservation Plan Association 2006)
- San Joaquin County Multi-Species HCP and Open Space Plan (SJCMSHCP) (Jones & Stokes 2000)
- East Alameda County Conservation Strategy (EACCS) (East Alameda County Conservation Strategy Steering Committee 2010)

Of these, the first three plans have little (less than 1%) or no physical overlap with the study area boundary and, thus, no potential for conflict with BDCP actions (Figure 12-3). The Placer County Conservation Plan is found in western Placer County and does not overlap with BDCP. The Yuba-Sutter HCP/NCCP covers Yuba and Sutter Counties and overlaps with less than 200 acres of the study area at the northern end of the Yolo Bypass (Table 12-9). The Natomas Basin HCP is found in northwestern Sacramento and southern Sutter Counties. This plan is adjacent to the study area but does not overlap with it. Because of the lack of overlap and the location of these plans upstream of BDCP, they are not discussed further in this section.

The remaining six plans overlap with the study area to varying extents (Table 12-9). Each of these six plans includes a conservation strategy that implements land restoration, enhancement and/or acquisition within or near their respective boundaries. The following discussion addresses whether the implementation of BDCP covered activities and conservation actions have the potential to conflict with these plans and their conservation strategies.

Table 12-9. Summary Table of Conservation Plans that Overlap with BDCP

Conservation Plan	Plan Status	Plan Area (ac)	Boundary Overlap with BDCP (ac)	Overlap Relative to Other Plans	Overlap relative to BDCP
East Contra Costa County HCP/NCCP	Approved in 2007	174,116	63,073	36.2%	7.3%
San Joaquin County MSHCP and Open Space Plan	Approved in 2001	912,386	317,355	34.8%	37.0%
East Alameda County Conservation Strategy	Approved in 2011	271,486	4,643	1.7%	0.5%
Solano County MSHCP	In Process	581,874	198,149	34.1 %	22.9%
South Sacramento HCP	In Process	374,733	41,130	11.0%	4.8%
Yolo Natural Heritage Program	In Process	653,818	111,383	17.1%	12.9%
Yuba-Sutter HCP/NCCP	In Process	469,137	198	0.04%	0.02%

Sources: ICF International 2011; Cal-Atlas Geospatial Clearinghouse; TRA Environmental Services 2011; Solano County Water Agency 2009; Radmacher pers. comm.

Table 12-10 lists the amount of conservation remaining in each of the three approved plans based on summary reports released in 2011. Because EACCS was just approved in 2011, no land has been acquired to date for its reserve system. The acreage provided in Table 12-10 is the estimated amount needed for the entire plan area under each plan, and is not limited to the overlap area.

Table 12-10. Conservation Status of Approved Plans (acres)

Plan	Target Reserve System Size	Current Reserve System Size	Amount Remaining to Acquire
East Contra Costa County HCP/NCCP*	30,300	4,589	25,711
San Joaquin County MSHCP **	100,841	8,942	91,899
East Alameda County Conservation Strategy***	N/A	0	N/A

Sources: ICF International 2011; San Joaquin Council of Governments 2010.

* Reserve System Size based on Maximum Development Scenario

** Based on estimated acreage of take according to mitigation ratios. Actual amount remaining likely to be much less.

*** Conservation Strategy is implemented project-by-project according to established mitigation ratios. Because the strategy is not dependent on a certain amount of development occurring, there is no target reserve system size.

Effects of Water Conveyance Facilities Construction on Other Conservation Plans

The BDCP conservation measures that have the potential to affect overlapping conservation plans include the construction and operation of new water conveyance facilities associated with the SWP and CVP, and the implementation of restoration and acquisition actions and other conservation activities. The effects of restoration, acquisition, and other conservation activities are discussed in the next section. To quantify the potential effects of the construction of the water conveyance facilities on overlapping plans, the permanent surface impacts of the construction of Alternatives 1A, 1B, 1C, 2A, 2B, 2C, 3, 4, 5, 6A, 6B, 6C, 7, 8, and 9 were identified.

Construction of the water conveyance facilities would result in permanent surface disturbance within the BDCP Plan Area. Depending upon the alternative, a portion of these impacts would occur outside of the plan area boundaries for the six overlapping plans (Figure 12-4). The remaining impacts would be small relative to the size of the overlapping plan areas, varying from less than 1% of total plan areas, to a maximum of 2.7% of the East Contra Costa County HCP/NCCP area under Alternatives 1C, 2C, and 6C (4,755 acres of impacts within a 174,115-acre plan area). The impacts of Alternative 1A construction would be less than 1% of each plan's respective total acreage (Table 12-11). However, construction of the water conveyance facilities would reduce the amount of available cultivated land for acquisition by overlapping conservation plans by as little as 11 acres in the East Alameda County Conservation Strategy (Alternative 9) and as much as 14,016 acres in the San Joaquin County HCP (Alternatives 1B, 2B, 6B).

The construction of the water conveyance facilities would avoid all existing reserve lands of the East Contra Costa County HCP/NCCP because these lands are outside of the study area (Figure 12-4). Similarly, construction of the water conveyance facilities using the west alignment, Modified Pipeline/Tunnel Alignment, or Pipeline/Tunnel Alignment would avoid all existing reserve lands of the San Joaquin County HCP (Figure 12-4). Construction of the east canal has the potential to temporarily affect existing preserve lands of the San Joaquin County HCP near Sycamore Slough and Walnut Grove. See the section below on this plan for details of these potential impacts and mitigation measures.

Table 12-11. Impacts from BDCP Alternatives Relative to Total Area of Overlapping Conservation Plans

Plan	Plan Area (ac.)	Alternative	Permanent Surface Impacts (ac.)	Surface Impacts Relative to Plan (% of Plan Area)

Effects of BDCP Acquisition and Restoration on Other Conservation Plans

Like the BDCP, each of the six overlapping conservation plans contains a conservation strategy composed of a variety of actions or measures. Approved conservation plans (ECCCHCP/NCCP, SJCMSHCP, EACCS) are required to implement those actions in order to meet their permit conditions. Proposed plans (YNHP, South Sacramento HCP, and Solano County MSHCP) are not yet permitted but are far enough along in their development process to predict the nature and general location of likely conservation actions. In all overlapping conservation plans (approved or in process), the primary conservation actions are a combination of land preservation through acquisition in fee title or conservation easement and restoration of natural communities. All of the overlapping plans focus primarily on terrestrial species (see Table 1-4 in Chapter 1 of the BDCP for the overlap of covered species) and, consequently, on the preservation and restoration of terrestrial natural communities and adjacent wetland and stream systems.

This regional focus on land protection and conservation to benefit endangered species creates opportunities for coordination, partnerships, and achieving common conservation goals. However, the need to fulfill acquisition and restoration targets in geographically overlapping areas also creates the potential for conflicts. For example, in certain areas, sites available for acquisition and restoration with rare natural communities or physical conditions may be limited. This limitation may cause plans to compete for conservation lands, particularly to meet HCP obligations that are driven by mitigation-to-impact ratios.

Conservation components under Alternatives 1B, 1C, 2A, 2B, 2C, 3, 4, 6A, 6B, 6C, 8 and 9 would be the same as those under Alternative 1A. Conservation components under Alternative 5 would be the same as those under Alternative 1A, except that 25,000 acres, rather than 65,000 acres, of tidal habitat would be restored. Conservation components under Alternative 7 would be similar to those under Alternative

1A, but 40 linear miles, rather than 20 linear miles, of channel margin habitat would be enhanced, and 20,000 acres, rather than 10,000 acres, of seasonally inundated floodplain would be restored to further improve fish and wildlife habitat, particularly along the San Joaquin River.

This analysis addresses the potential for conflict by analyzing the conservation needs of the BDCP and each of the six plans with substantial (more than 1%) overlap with the BDCP (Table 12-11).

Methodology

To understand the conservation issues of all plans relative to the overlap areas, several analyses were conducted. First, a crosswalk table was developed for all natural community types with restoration or acquisition targets in the BDCP. Because each plan uses a different land-cover dataset, a crosswalk was created that broadly assimilates these land-cover types into six categories relevant for conservation: wetlands, tidal, riparian, grassland, agriculture, and streams (Table 12-12). The BDCP dataset contains both tidal and nontidal wetlands. Tidal wetlands were assigned to the "tidal" community, while nontidal wetlands were assigned to the "wetland" community. Note that land cover types without restoration or acquisition targets in the BDCP (e.g., chaparral, urban, conifer) were not crosswalked because the analysis is limited to understanding how the implementation of BDCP restoration and acquisition targets might affect other plans.

Table 12-12. Crosswalk of BDCP Natural Communities with those of Overlapping Conservation Plans

BDCP Natural Communities		ECCC HCP/NCCP	SJCMSHCP	EACCS	Solano MSHCP	South Sacramento HCP	YNHP
Wetlands	Vernal pool complex	Perennial Wetland	Vernal Pool Grassland	Alkali Wetland	Vernal Pools	Vernal Impoundment	(riparian and wetlands)
	Alkali seasonal wetland complex	Seasonal Wetland	Wetlands	Seasonal Wetland		Vernal Pool	
	Managed wetland	Alkali Wetland		Valley Sink Scrub		Vernal Swale	
	Nontidal freshwater perennial emergent wetland					Seasonal Wetlands	
	Other natural seasonal wetland					Freshwater Marsh	
Tidal	Tidal brackish emergent wetland/ Tidal freshwater emergent wetland		Delta Water's Edge*		Coastal Marsh		
	Tidal mudflat						
	Tidal perennial aquatic						
Riparian	Valley/foothill riparian[1]	Riparian Woodland Scrub	Riparian		Riparian Vegetation	Valley Oak Riparian Woodland	(riparian and wetlands)
						Mine Tailing Riparian Woodland	
						Mixed Riparian Woodland	
						Mixed Riparian Scrub	
Agriculture	Cultivated lands	Cropland	Flooded Field		Agriculture	Cropland	
			Agricultural			Vineyard	
						Orchards	
						Irrigated Pasture-Grassland	
Grassland	Grassland	Alkali Grassland	Grassland	Alkali Meadow and Scalds	Valley Floor Grasslands	Valley Grassland	Grasslands
		Annual Grasslands		California Annual Grassland			
Dune Scrub	Inland dune scrub						
Streams	Nontidal perennial aquatic (lakes, ponds, streams)	Perennial Streams	Submerged Aquatic Vegetation	Streams			

Note: All natural communities are crosswalked to column B NOT to each other.
Crosswalk based on aggregated Preserve Types from 2000 SJC MSCP and Open Space Plan Table 5.4.2. Each preserve includes multiple vegetation types resulting in overlaps between the preserves and the major natural community types created by the crosswalking exercise.

The six natural community categories were analyzed for each of the six plans with respect to both acquisition and restoration. Tables 12-13 through 12-17 summarize the acquisition targets for each plan, if available. In order to roughly approximate potential acquisition needs of each plan in the overlap areas, the acquisition targets from each plan for each natural community type were multiplied by the proportion of each community type in the overlap area relative to each plan as a whole. This method assumes that acquisition will be evenly distributed throughout each plan area and roughly approximates potential acquisition in the overlapping zones. In cases where acquisition was focused geographically (i.e., did not fit this assumption), a "correction factor" was applied to account for underestimates or overestimates based on plan requirements and ICF's familiarity with each overlapping plan. We used the U.S. Forest Service's California Vegetation (CALVEG) and BDCP vegetation datasets to calculate the proportion of each natural community type in the overlap areas. Because the draft conservation strategy for the YCHP has not been released, acquisition targets were not provided, only the overlap acres (Table 12-17).

Table 12-13. Estimated Overlap in Acquisition Activities by Major Natural Community Type for ECCCHCP/NCCP

	East Contra Costa County HCP/NCCP				
	Overlap with BDCP	Plan-Wide Target (acres)	Correction Factor	Estimated Acquisition Needs in BDCP Plan Area (acres)	Notes
Agriculture	96%	400	1.04	400	All agriculture acquisition will occur in BDCP overlap area.
Grassland	11%	17,750	0.5	957	Most grassland will be protected outside of the BDCP overlap area; includes alkali grassland.
Riparian	60%	70	1	42	
Wetlands	94%	336	0.4	127	Most wetlands will be preserved in foothills, not agricultural areas.

Table 12-14. Estimated Overlap in Acquisition Activities by Major Natural Community Type for San Joaquin County MSHCP and Open Space Plan

	San Joaquin County MSHCP and Open Space Plan[a]				
	Overlap with BDCP	Plan-Wide Target (acres)	Correction Factor	Estimated Acquisition Needs in BDCP Plan Area (acres)	Notes:
Agriculture	40%	36,382	1	14,487	
Grassland	9%	12,744	1	1,099	Approximately half of the proposed tidal restoration would occur in the overlap area.
Riparian	81%	1,231	1	992	
Streams	71%	2,269	1	1,609	
Tidal	100%	6,048	0.6	3,629	
Wetlands	89%	701	1	624

Table 12-17. Overlap by Major Natural Community Type for Yolo Natural Heritage Program

	Yolo Natural Heritage Program		
	Amount in Plan Area (acres)	Overlap with BDCP (acres)	Overlap
Agriculture	365,392	72,666	20%
Grassland	100,662	10,639	11%
Riparian	6,657	3,074	46%
Streams	6,105	1,157	19%
Tidal	4,949	4,926	100%
Wetlands	11,501	10,932	95%

Effects of BDCP Acquisition of Cultivated Land on Other Conservation Plans

By far the BDCP's largest land acquisition need is for cultivated land, which the BDCP calls "cultivated lands." BDCP would acquire cultivated lands for three primary purposes. First, cultivated land would be acquired to build the water conveyance facilities, as describe above and quantified in Tables 12-18 through 12-21. Second, cultivated land would be acquired by BDCP for preservation as foraging habitat for three covered species (Swainson's hawk, sandhill crane, and tricolored blackbird). Finally, cultivated land would be acquired for restoration to tidal wetland, floodplains, riparian woodland, or nontidal marsh.

This acquisition and preservation has the greatest potential for conflict with overlapping conservation plans that have substantial needs for acquisition of cultivated lands to satisfy their own conservation requirements. Acquisition by BDCP of cultivated land reduces the amount of such land available for overlapping plans. The assessment of this potential conflict compares the amount of cultivated land not already protected (i.e., that available for acquisition) with the need for cultivated land by BDCP and each plan in the overlap area. The analysis also takes into account that BDCP and each plan would remove cultivated lands through their own covered activities, further reducing the available cultivated land for preservation. This assessment assumes all covered activities in each plan are implemented and, therefore, all mitigation or conservation needs for cultivated lands are realized in each plan. In reality, some plans may not have the development assumed by the plan and, therefore, would not have the full need assumed by the plan for mitigation or conservation (which is proportional to the development that occurs).

The cultivated preservation needs of BDCP and the other conservation plan are deemed to be without conflict if the available cultivated land with full buildout is at least double the sum of the needs of the two plans in the overlap area. This assumption is based on the need to have more cultivated land for preservation than required to ensure that enough willing sellers are available for each plan.

One limitation of this analysis is that it is a snapshot at the end of the permit terms of each plan. In reality, each plan will be gradually preserving cultivated land in the overlap area at the same time. BDCP and overlapping plans would also be coordinating and cooperating in their land acquisition activities. For example, BDCP Chapter 3, Section 3.4.1.3.1, *Land Protection*, describes a process for coordination among BDCP, South Sacramento HCP, and San Joaquin Multiple Species Conservation Plan to ensure that sufficient lands are available in the overlap area for each plan to meet its conservation obligations. Additionally, for NCCPs in development that have planning agreements, discretionary projects within the plan area that are subject to CEQA are subject to review by the CDFW to ensure that they do not conflict with the preliminary conservation objectives of an NCCP under development (Fish and Game Code Section 2810(b)(8)). Both the gradual preservation in the overlap area over time and ongoing coordination would help to minimize any conflicts that might arise with individual acquisitions or with a gradual shortage that might arise near the end of the last permit.

Table 12-18. Amount of Cultivated Land Preservation by BDCP in Each Overlap Area (Pipeline/Tunnel Alignment; Alternatives 1A, 2A, 6A)

Plan with Overlap	Amount of Unprotected Cultivated Land in Overlap Area[a] (acres)	Estimated Amount Lost to Covered Activities (acres)	Percent of Overlap of Each HCP with BDCP	Est. Amount Lost to Covered Activities in Overlap Area (acres)	Est. Amount Lost to BDCP Covered Activities in Overlap Area (acres)	Est. Preservation Need for each Plan in Overlap Area (acres)		Est. Preservation Need for BDCP in Overlap Area (acres)		Est. Cultivated Lands Available for Preservation at End of Permit Terms[e] (acres)	Total Preservation Needs in Overlap Areas (acres)		Est. Cultivated Lands Remaining After Preservation for Covered Activities and Restoration (acres)	
						Low	High	Low	High		Low	High	Low	High

Tables 12-22 through 12-25 summarize the restoration targets for each plan and estimate the overlap with BDCP. The restoration targets are multiplied by the percentage of overlap between each plan area and the BDCP to approximate the potential for competition over land cover for restoration. Like the analysis for Table 12-22, a correction factor was applied to targets and plans where additional information regarding the location of restoration was available. Because the draft conservation strategy for the YNHP has not been released, a restoration table was not developed. The acres of each natural community type relative the YNHP plan area and the overlap area are provided in Table 12-17.

Table 12-22. Estimated Overlap in Restoration Activities by Major Natural Community Type for ECCCHCP/NCCP

East Contra Costa County Habitat Conservation Plan				
	Plan-Wide Target (acres)	Overlap	Correction Factor[a]	Estimated Overlap (acres)
Wetlands	315	36%	0.4	45
Riparian	55	36%	1	20

[a] Wetlands are less likely to be restored within the BDCP Plan Area because of the location of existing preserves outside of the BDCP Plan Area (wetland restoration must occur on the preserves).

Table 12-23. Estimated Overlap in Restoration Activities by Major Natural Community Type for San Joaquin County MSHCP and Open Space Plan

San Joaquin County MSHCP and Open Space Plan[a]				
	Plan-Wide Target (acres)	Overlap	Correction Factor	Estimated Overlap (acres)
Wetlands	350	35%	1	123
Riparian	751	45%	1	338

[a] Table based on remaining acres for restoration from 2011 San Joaquin County MSHCP and Open Space Plan Annual Report. Vegetation management and enhancement in other natural community types (e.g., riparian) occurring in SJC MSHCP preserves acquired under the plan. However, specific targets for this restoration is not associated with the acreages provided for plan mitigation. Riparian includes: Great Valley Riparian Forest (R), Great Valley Oak Riparian Forest (R2), Arroyo Willow Thicket (R4), Great Valley Mixed Riparian Forest (R5), Riparian Scrub (RS2), and Great Valley Riparian Scrub(S)

Table 12-24. Estimated Overlap in Restoration Activities by Major Natural Community Type for Solano County MSHCP

Solano County MSHCP				
	Plan-Wide Target (acres)	Overlap	Correction Factor	Estimated Overlap (acres)
Wetlands	270–400	34%	1	62–92
Tidal	75–100	34%	2.94[a]	75–100
Riparian	50	34%	1	17

[a] All tidal wetland restoration is expected to occur in the overlap area.

Table 12-25. Estimated Overlap in Restoration Activities by Major Natural Community Type for South Sacramento HCP

	South Sacramento HCP			
	Plan-Wide Target (acres)	Overlap	Correction Factor	Estimated Overlap (acres)
Wetlands	722	11%	1	79
Riparian	315	11%	1	35

Note that for Tables 12-13 through 12-25, if a plan did not set an acquisition or restoration target for a given natural community type, that community type was not included in the table.

Plan-Specific Analysis

East Contra Costa County

The ECCCHCP/NCCP was adopted in 2006 by Contra Costa County and the cities of Brentwood, Clayton, Pittsburg, and Oakley. Permits were issued in 2007 by USFWS and CDFW for a 30-year term. A joint powers authority of the agencies receiving the permits and the East Bay Regional Park District formed the East Contra Costa County Habitat Conservancy to implement the plan.

The HCP/NCCP provides regional conservation while improving and streamlining the permit process for endangered species. In 2012, the Corps issued a Regional General Permit to the East Contra Costa County Habitat Conservancy to provide additional streamlining for wetland regulations. Within the 174,115-acre plan area, the HCP/NCCP covers 8,670–11,853 acres of development and 1,126 acres of rural infrastructure projects. The HCP/NCCP requires creation of a preserve system of 23,800–30,300 acres that will be managed for the benefit of 28 covered species and their associated natural communities. The range of impacts and conservation requirements varies depending on whether the current urban limit lines of the participating cities are expanded.

The BDCP overlaps with the ECCCHCP/NCCP in the central western portion of the study area (Figure 12-3). The two plans have 15 covered species in common, including San Joaquin kit fox, western burrowing owl, and Swainson's hawk (BDCP Chapter 1, Table 1-4). While approximately 36% of the ECCC plan area overlaps with that of the BDCP (Table 12-9), the overlap area is largely cultivated land outside of the urban limit lines of the county and participating cities.

The proposed preserve system for the ECCCHCP/NCCP occurs almost entirely outside of the BDCP boundary. Construction of the water conveyance facilities would have impacts in the ECCCHCP/NCCP plan area (e.g., new forebay adjacent to Clifton Court), but not on any existing preserves. Some riparian acquisition and restoration may occur in the overlap area, particularly in the lower reaches of Marsh Creek or Kellogg Creek. Preservation and acquisition of riparian woodland and streams in the overlap area would not be likely to result in conflicts because each plan has many options for riparian restoration both inside and outside of the overlap area. These needs present an opportunity for coordination of East Contra Costa County Habitat Conservancy efforts with proposed tidal marsh restoration for the BDCP (see discussion below).

While acquisition and restoration needs of the ECCCHCP/NCCP for wetlands, grasslands, and riparian land cover are relatively low within the overlap area, all acquisition of cultivated lands will occur there (Table 12-13). Because the ECCCHCP/NCCP acquisition target for agriculture is only 400 acres, and there are more than 30,000 acres of cultivated lands within the overlap area, implementation of the BDCP is not anticipated to conflict with the ability of ECCCHCP/NCCP to meet its conservation obligations. Each plan is expected to be able to meet its conservation requirements for cultivated lands easily; together, both plans would need less than 11% of the cultivated land available at the end of the permit term of both plans once covered activities "consumption" of cultivated land is taken into account.

Below is a description of specific BDCP actions and a brief discussion of how they might affect implementation of the ECCCHCP/NCCP Conservation Strategy.

- **Permanent Surface Disturbance.** The water conveyance facilities (CM1) would be located within the ECCCHCP/NCCP area (Subzone 6d), resulting in permanent surface impacts that may remove lands available for conservation. Under all alternatives, this represents less than 3% of the total acreage within the ECCCHCP/NCCP area (Table 12-11), and land in this area is designated as having a "lower" level of acquisition effort by the ECCCHCP/NCCP, with the exception of "higher" priority acquisition lands near Byron Airport–an area where BDCP actions are not projected to occur.
- **Grasslands and Vernal Pools Restoration**. The northwest portion of CZ 8 of the BDCP overlaps with the southeast corner of the ECCCHCP/NCCP Acquisition Analysis Zone 6 (Figure 12-3). Implementation of CM3 would secure and protect at least 1,000 acres of grassland and 1,000 acres of wetlands (i.e., vernal pools and alkali seasonal wetland) within CZ 8. Within Acquisition Analysis Zone 6, ECCCHCP/NCCP intends to acquire 250–400 acres of agriculture, 100–300 acres of grassland (i.e., alkali grasslands) and 20–40 acres of wetlands (i.e., alkali wetlands). Because more than half of BDCP CZ 8 lies outside of the ECCCHCP/NCCP, implementation of the BDCP conservation strategy is not likely to preclude any grassland or wetland acquisition and restoration for the ECCCHCP/NCP. Grassland restoration is also targeted in BDCP CM8. Some of this restoration could take place in the southeast portion of the ECCCHCP/NCCP around Byron Airport. The ECCCHCP/NCCP does not target a specific acreage of grassland restoration, but does target lands surrounding Byron Airport for preservation. However, the BDCP area overlaps with a relatively small proportion of the total amount of grassland in ECCCHCP/NCCP area (Table 12-13).
- **Restoration of Dutch Slough**. BDCP CM4 identifies Dutch Slough, located with the ECCCHCP/NCCP area, as an area suitable for restoration, as does the ECCCHCP/NCCP. However, the BDCP targets tidal areas for restoration or acquisition while the ECCCHCP/NCCP targets riparian and stream communities, creating an opportunity for restoration synergies in streams, riparian, and tidal areas, including in Dutch Slough.
- **Riparian Habitat Restoration**. BDCP CM7 proposes 5,000 acres of riparian forest and scrub protection, a portion of which may occur in CZs 6 and 8, which overlap with the ECCCHCP/NCCP area (Figure 12-4). Table 12-13 indicates a moderate amount of overlap in riparian land cover targeted for preservation, but little relative to the amount existing in the ECCCHCP/NCCP area (less than 10%). Based on the proportion of overlap between the two plans, Table 12-22 indicates a relatively small area of potential overlap for riparian restoration priorities.

San Joaquin County Multi-Species Habitat Conservation and Open Space Plan

The SJCMSHCP was permitted in 2000 and is administered by the San Joaquin Council of Governments. This 50-year plan addresses 97 special-status plant, fish and wildlife species (47 of which are on the federal permit) throughout most of San Joaquin County (more than 900,000 acres), including a substantial portion of the eastern Delta. The plan participants include the County of San

Joaquin and the cities of Stockton, Lodi, Manteca, Tracy, Ripon, Escalon and Lathrop. Activities covered under the plan include urban development, mining, expansion of existing urban boundaries, nonagricultural activities occurring outside of urban boundaries, levee maintenance undertaken by the San Joaquin Area Flood Control Agency, transportation projects, school expansions, nonfederal flood control projects, new parks and trails, maintenance of existing facilities for non-federal irrigation district projects, utility installation, maintenance activities, managing preserves, and similar public agency projects.

The study area overlaps a substantial portion (almost 35%) of the SJCMSHCP (Figure 12-3), which itself overlaps approximately half of the legal Delta. The plans have 39 covered species in common, including San Joaquin kit fox, western burrowing owl, giant garter snake, and Swainson's hawk (BDCP Table 1-4). Within the overlapping area, the SJCMSHCP targets for acquisition include flooded fields, grasslands, riparian woodland, row and field crops, and wetlands. The potential exists for competition for restoration sites and land acquisition in these land cover types. BDCP proposes to acquire and restore freshwater tidal, seasonal floodplains, riparian forest, grassland, and nontidal marsh in portions of the overlapping area. However, because the acquisition and restoration requirements of the SJCMSHCP are based upon mitigation ratios applicable to the natural community types where impacts occur, and the plan operates on a "pay-as-you-go" basis, the acquisition targets depend on the amount and location of impacts occurring within the county. In the 11 years of plan implementation, the vast majority of impacts and, consequently, preservation and creation efforts have occurred on cultivated land. The mitigation needs for other community types, including wetlands and riparian areas, have been minimal (Tables 12-26 and 12-27). There have been almost no impacts to wetlands in the SJCMSHCP since its inception. Most of the impacts with San Joaquin County occur on cultivated land; therefore, this land cover type has the greatest potential for competition with BDCP. A more detailed assessment is provided below for each natural community type.

Table 12-26. SJCMSHCP Preserve Acreages by SJCMSHCP Zone with Overlap of BDCP

Habitat Type	Central	Delta	Vernal Pool	Total
Wetlands	--	--	6.00	6.00
Agricultural	2,036.70	1,837.20	--	3,873.90
Agricultural and Grassland	360.00	--	--	360.00
Natural[a]	27.00	--	--	27.00
Total	2,423.70	1,837.20	6.00	4,260.90

[a] This table includes preserves in the entirety of all SJCMSHCP Zones, regardless of the proportion of each Zone that overlaps with BDCP. The SJCMSHCP 2010 Annual Report does not identify specific habitat types within preserves. Natural Habitat Lands are lands which "retain natural vegetation and are not irrigated or cultivated agricultural lands."

Table 12-27. SJCMSHCP Mitigation (acres) Owed from Existing Impacts by Habitat Type as of 2010

Habitat Type	Central	Central/Southwest	Delta	Vernal Pool	Total
Wetlands	--	15.27	--	--	15.27
Tidal	0.07	--	--	--	0.07
Riparian	--	--	--	--	0.00
Agriculture	1,948.28	1,087.33[a]	9.44	--	1,957.72
Grassland	17.21	--	--	0.85	18.06
Streams	66.13	50.46	--	--	116.59
Total	2,031.69	65.73	9.44	0.85	2,107.71

[a] The SJCMSHCP was partially through the easement acquisition process for a large grassland preserve of approximately 1,095 acres to close in 2011 which would negate the row and field crop mitigation acreage required in the Central/Southwest Zone.

Below is a description of specific BDCP actions and a discussion of their effects on implementation of the SJCMSHCP.

- **Permanent Surface Disturbance and Connectivity.** Under CM1, construction of water conveyance facilities located in the SJCMSHCP area would result in permanent surface impact that would remove between 2,660 acres and 14,000 acres of land available for conservation (Table 12-11). However, under all alternatives, this land represents less than 1.6 % of the total SJCMSHCP area (Table 12-11). Above-ground conveyance would permanently impact habitat connectivity for less mobile species. Although the eastern alignment (Alternative 1B) would not affect known occurrences of giant garter snake in San Joaquin County, it would adversely affect the giant garter snake population in the vicinity of White Slough in San Joaquin County by impairing habitat connectivity in this area: this could affect the ability for SJCMSHCP to achieve its conservation goals for giant garter snake.

- **Cultivated Lands Preservation.** The southern portion of the BDCP, including almost all of CZ 7, the eastern portions of CZs 5, 6, and 8, and the southern portion of CZ 4, overlaps the SJCMSHCP area (Figure 12-4). There is an estimated 218,370 acres of cultivated land in the overlap area that is not protected (Tables 12-18 through 12-21). Of this total, approximately 16,770 acres would be lost to covered activities planned by the SJCMSHCP and 32,580 acres expected under BDCP. BDCP effects on cultivated lands would result primarily from construction of the water facilities and restoration of tidal wetlands and floodplains in the South Delta and Cosumnes-Mokelumne ROAs. The SJCMSHCP needs approximately 14,487–36,382 acres of cultivated land acquisition to mitigate for the remaining impacts under that plan, or 9%–22 % of the total remaining. BDCP would need between 7,400–12,987 acres of acquisition in the overlap area (4%–8% of the total), depending on the habitat values of the cultivated land lost to covered activities. At the end of the permit terms, there would be an estimated 169,000 acres of cultivated land available for preservation. The combined preservation needs of the SJCMSHCP and the BDCP in the overlap area is between 21,887 and 49,369 acres, or 13%–30% of the total cultivated lands available for preservation. The Delta Wetlands Project (Delta Wetlands Project 2010), a water supply and habitat restoration project that is independent of SJMSHCP and BDCP, will require an additional estimated 20,000 acres of cultivated lands (11,000 acres for water storage and 9,000 acres of conservation easements to offset the loss of cultivated lands) within the overlap area: this would reduce the amount of lands available for preservation to 149,000. With implementation of the Delta Wetlands project, the preservation needs in the overlap area for the SJCMSHCP and the BDCP would still constitute only 15%-33% of the total cultivated lands available for preservation. This analysis demonstrates that enough cultivated lands would remain to meet the conservation and mitigation needs of both plans, even after full implementation of covered activities. In reality, preservation would occur gradually over time, prior to full implementation of all covered activities. Nonetheless, this analysis provides a conservative assessment of the potential for conflict between BDCP and the SJCMSHCP with respect to conservation and mitigation of cultivated lands. The East Alignment (BDCP Alternatives 1B, 2B, and 6B) of the proposed water conveyance system poses potential impacts to the 783-acre East and West Nuss cultivated land preserves in the SJCMSHCP. However, these impacts would be temporal in nature because the impacted area would be restored to pre-existing baseline conditions following the construction of the water conveyance facilities. Loss of cultivated lands habitat from the construction of the water conveyance facilities would have a less-than-significant impact on agriculturally-dependent species, such as Swainson's hawk, because the enhancement and management of 8,000 acres of cultivated lands as foraging habitat for Swainson's hawk distributed throughout Conservation Zones 1, 2, 3, 4, and 7 of the BDCP would provide ample foraging habitat for these species in the long term. Additionally, if the East Alignment alternative is chosen as the preferred alternative, the BDCP Implementation Office would pursue a temporary conservation easement over the affected preserve that would extend for the duration of the construction and restoration activities.

Each plan is expected to be able to meet its conservation requirements for cultivated lands easily; together, both plans would need less than 30% of the cultivated land available at the end of the permit term of both plans once covered activities "consumption" of cultivated land is taken into account.

- **Tidal Wetland Restoration.** There is a large amount of overlap between the SJCMSHCP and BDCP in tidal areas (Table 12-14). The SJCMSHCP does not include any requirements for tidal wetland preservation or restoration, so there would be no direct conflicts with BDCP on these targets. However, BDCP proposes to convert an estimated 2,200 acres of cultivated land to tidal wetlands. Under Alternative 5, tidal habitat restoration would be reduced from 65,000 acres to 25,000 acres, which would not meet the BDCP restoration target for this natural community type. As a result, the extent to which the BDCP would support the recovery and long-term survival of the covered species that depend on these habitats would be substantially reduced compared with other alternatives.

The tidal restoration proposed in the South Delta ROA (CZ 7) has the potential to conflict with the with the existing 300-acre Ishizuka Preserve in the SJCMSHCP. In addition, tidal restoration proposed in the Cosumnes/Mokelumne ROA (CZ 4) has potential to conflict with the existing 350-acre Wing Levee Road preserve in the SJCMSHCP. These preserves provides protection for cultivated lands which the BDCP may convert to tidal natural communities. If tidal restoration occurs on one of these sites (or any other owned by the SJCMSHCP), the BDCP Implementation Office would provide compensation to property owners for the conversion of existing land use and the associated economic losses. Additionally, the BDCP Implementation Office would coordinate with SJMSHCP to identify and acquire lands of equal or greater biological value to replace the conservation needs for SJCMSHCP, as described in BDCP Chapter 3, Section 3.4.3 *Conservation Measure 3*. Mitigation Measure AG-1 requires the BDCP Implementation Office to develop an Agricultural Lands Stewardship Plan (ALSP) to preserve agricultural productivity of Important Farmland and land subject to Williamson Act contracts and to compensate off-site. In addition to Mitigation Measure AG-1, as discussed above in the cultivated land preservation section, the enhancement and management of 8,000 acres of cultivated lands as foraging habitat for Swainson's hawk distributed throughout Conservation Zones 1, 2, 3, 4, and 7 of the BDCP would provide ample foraging habitat for these species in the long term. Additional tidal restoration is targeted in the South Delta ROA (at least 5,000 acres) and the Cosumnes-Mokelumne ROA (up to 1,500 acres). All of the South Delta ROA and approximately half of the Cosumnes-Mokelumne ROA are within the SJCMSHCP plan area.

- **Riparian Preservation and Restoration.** BDCP proposes to acquire 750 acres of riparian natural community in CZ 7 under CM7. In addition, BDCP would restore at least 5,000 acres of riparian woodland and forest in the Plan Area. Approximately 40–50% of the acquisition and restoration of riparian woodland and forest is expected to occur in the overlap area of San Joaquin County (i.e., up to 375 acres of preservation and 2,500 acres of restoration). The majority of the restoration would occur on cultivated lands.

  The SJCMSHCP has an estimated need of 992 acres of riparian woodland preservation in the overlap area (Table 12-14) and 25 acres of riparian restoration if all impacts to this community occur. The SJCMSHCP permits allow removal of up to 750 acres of riparian woodland in San Joaquin County, most of which would occur in the study area (Table 12-23). There are an estimated 17,930 acres of riparian woodland and forest in the study area and approximately 8,070 acres in the overlap area. This amount is enough to meet the riparian preservation and impact needs of both plans.

- **Floodplain Restoration.** The SJCMSHCP does not require restoration of floodplains so would not conflict with BDCP in this restoration action. In BDCP, CM5 calls for restoration of 10,000 acres of seasonally inundated floodplains. Under Alternative 7, seasonally inundated floodplain restoration would be increased from 10,000 acres to 20,000 acres, which would increase costs and reduce the practicability of the conservation strategy, but would increase benefits to some covered species. Floodplains would be created by breaching and/or setting back existing levees and seasonally flooding cultivated lands, similar to what is done now in the Yolo Bypass. In this situation, cultivated lands continue to produce food but the periodic flooding limits the suitable crop types and the duration of the growing season. CM5 identifies the most promising opportunities for large-scale floodplain restoration as being in the south Delta along the San Joaquin, Old, and Middle Rivers all of which are located within the SJCMSHCP area. Therefore, this action would cause the loss or degradation of cultivated lands within the restored floodplains. The amount of cultivated land affected is estimated at 7,750–9,100 acres. This represents less than 2% of the total cultivated lands available for preservation within the SJCMSHCP area.

- **Channel Margin Enhancement.** Channel margin enhancement (CM6) would be performed along the Sacramento River between Freeport and Walnut Grove, and along the San Joaquin River between Vernalis and Mossdale, which lies within the SJCMSHCP area. Under Alternative 7, channel margin enhancement would be increased from 20 linear miles to 40 linear miles. This alternative would increase costs and reduce the practicability of the conservation strategy, but would increase benefits to some covered species. However, channel margin enhancements are not likely to conflict with SJCMSHCP conservation requirements. These actions are not likely to convert a substantial amount of agricultural land, and the SJCMSHCP is unlikely to need large amounts of riparian or channel margin habitat to meet its mitigation requirements because of the limited impacts to this land cover type in the county.

- **Grassland Preservation and Restoration.** The BDCP target of 8,000 acres of grassland preservation would occur in CZ 1 and 8, outside of the SJCMSHCP area. The SJCMSHCP plan also has substantial grassland preservation needs but these would be met largely in the inner Coast Range in southwestern San Joaquin County, outside of the study area (San Joaquin Council of Governments 2010).

  The BDCP may restore a portion of its target of 2,000 acres of grassland (CM8) in the western portion of the SJCMSHCP area, primarily from existing degraded grasslands. The SJCMSHCP does not specifically target grassland for restoration. However, based on the limited proportion of grassland overlap between the plans (Table 12-14), potential conflicts in acquisition or restoration targets are minimal.

- **Nontidal Marsh Restoration.** CM10 of the BDCP targets 400 acres of nontidal marsh for restoration, a portion of which could occur adjacent to habitat occupied by the Coldani Marsh/White Slough giant garter snake population in CZ 4 within the SJCMSHCP area. However, the proposed restoration would be designed to meet the conservation goals of each plan for giant garter snake and Swainson's hawk. This conservation measure is likely to provide a mutual benefit to both plans, as the SJCMSHCP specifies avoidance for known giant garter snake habitat.

East Alameda County Conservation Strategy

EACCS provides a mechanism for endangered species permitting under CESA and ESA within 271,485 acres of eastern Alameda County. The Conservation Strategy does not directly result in permits for any participating local agency but provides a framework for endangered species permitting of projects in the study area. The strategy was completed in early 2011 and is currently being utilized by local jurisdictions. The plan was prepared by Alameda County; the cities of Dublin, Livermore, and Pleasanton; Alameda County Waste Management Authority; the Alameda County Congestion Management Agency; East Bay Regional Parks District; the Alameda County Resource Conservation Service; the Natural Resource Conservation Service and in consultation with the USFWS, CDFW, and the San Francisco Regional Water Quality Control Board. The conservation strategy addresses the conservation needs of 19 species, including eight species that overlap with the BDCP (BDCP Table 1-4). In June 2012, USFWS issued a programmatic Section 7 Biological Opinion with the USACE that can be used for Clean Water Act Section 404 compliance using the framework of the conservation strategy for federally-listed species.

Only a small portion of the northeastern corner of the EACCS study area overlaps with the study area (less than 2%) and the overlap occurs in one conservation zone only (zone 7 of the EACCS). There is little anticipated urban development in that area that would be permitted using the strategy guidelines, due in part to Alameda County Measure D, which does not allow for growth outside of the existing urban limit line for the county. However, several large commercial solar energy facilities have been proposed in the overlap area. Despite this, it is unlikely that BDCP implementation would negatively affect any of the provisions associated with EACCS or vice-versa.

Below is a description of specific BDCP activities and a brief discussion of the overlap with EACCS:

- **Permanent Surface Impacts.** A small portion of the water conveyance facilities may be located in the EACCS area, resulting in permanent surface impacts of up to 1,245 acres that would remove lands available for conservation (Table 12-11). However, under all alternatives, this land only represents 0.1 % or less of the total EACCS area.

- **Restoration and Acquisition Overall.** CZ 8 of the BDCP intersects with Conservation Zone 7 of the EACCS. Within BDCP CZ 8 (Figure 12-3), BDCP would acquire or protect riparian forest and scrub, grassland, and vernal pool communities (CM7, CM8, and CM9, respectively). However, based on the relatively small amount of overlap between the two plans (Table 12-9), the potential for conflict is minimal.

Solano County Multi-Species Habitat Conservation Plan

The Solano County Water Agency is developing the Solano County MSHCP to support the issuance of an incidental take permit under the ESA for a period of 30 years. The plan covers activities within the Solano County Water Agency's contract service area, including the cities of Fairfield, Vacaville, Vallejo, Suisun City, the Solano Irrigation District, and the Maine Prairie Water District. The plan area also covers all of unincorporated Solano County and a small portion of Yolo County.

Primary conservation actions include preservation (primarily through avoidance), restoration, invasive species control, and improvement of water quality. The plan area covers 580,000 acres, which includes 12,000 acres of proposed development and the creation of reserve system to protect natural communities and habitat for covered species[2].

- 10, 500 to 11,500 acres of valley floor grassland and vernal pools.
- 5,700 acres of cultivated lands, 1,000 of nesting and associated foraging habitat, and 1,000 of grassland/oak savanna for Swainson's hawk and burrowing owls.
- 3,300 acres of upland habitat for the California red-legged frog and callippe silverspot butterfly.
- 50 acres of riparian woodland.
- 36 acres of freshwater marsh, pond, and seasonal wetlands.

The two plans share 29 covered species (BDCP Table 1-4), including Swainson's hawk, California clapper rail, and salt marsh harvest mouse.

The Solano County MSHCP overlaps substantially with the study area in Suisun Marsh and Cache Slough (Figure 12-2) including the entirety of BDCP CZs 1 and 11, the southern portions of CZs 2 and 3, and a small, western portion of CZ 5. Most of the overlap area occurs within the Suisun Marsh and Cache Slough, which the BDCP identifies as restoration opportunity areas. The Solano County MSHCP identifies providing additional funding for management and restoration of Suisun Marsh and the Delta as one of its main objectives. The areas of overlap, therefore, are likely to represent opportunities for collaboration, based upon like objectives between BDCP and Solano County MSHCP. Below is a description of specific BDCP action and a discussion of how they might affect the Solano County MSHCP.

- **Floodplain Restoration.** The BDCP proposes to increase the frequency, duration, and magnitude of floodplain inundation in the Yolo Bypass (CM2). This would restore habitat in the Suisun Marsh and Cache Slough and bays downstream of the bypass that overlap with the Solano County MSHCP area. Restoration targets for wetlands and tidal communities would be designed to benefit covered species in common with both plans such as the giant garter snake.

[2] Conservation targets for the Solano HCP are based on a June 2011 working draft plan and are therefore preliminary.

- **Wetlands and Vernal Pools Restoration.** Within CZs 1 and 11, the BDCP intends to protect a portion of the 600 acres of existing vernal pool complex in the Jepson-Prairie core vernal pool recovery area (U.S. Fish and Wildlife Service 2005), a portion of the 400 acres of existing alkali seasonal wetland complex, and at least 1,000 acres of existing grassland, which may include vernal pool complex and several occurrences of covered plant species (see Table 12-15 for summary of wetland acquisition). The BDCP proposes no net loss of vernal pool acreage, and a portion of proposed restoration and acquisition which would occur in CZ 1 and/or CZ 11, both of which overlap with the Solano County MSHCP plan area. The Solano County MSHCP does identify acreage targets for wetlands restoration (Table 12-15), including vernal pools. However, all of the vernal pool acquisition and restoration needs of the Solano County MSHCP will be acquired from existing commercial mitigation banks that have adequate capacity to meet the requirements of the Plan. Therefore, BDCP wetland preservation and restoration is not expected to conflict with the Solano County MSHCP.
- **Cultivated Lands Preservation.** The cultivated land acquisition target for the Solano County MSHCP is 5,700 acres of agricultural foraging habitat for Swainson's hawk and burrowing owl. Most of the cultivated land preservation will take place in the northern or northeastern portion of the county (near Dixon Ridge), which is outside of the study area. These areas have been selected for preservation because they are cultivated with crops such as alfalfa, which is preferred by Swainson's hawk as foraging habitat for. The BDCP may also maintain a portion of non-rice agriculture as foraging habitat for Swainson's Hawk in CZs 1, 2, and 3, all three of which overlap with the Solano County MSHCP (Figure 12-3). However, based on emphasis of the Solano County MSHCP to preserve cultivated lands in the northern portion of the county, outside of the areas where the Plans overlap, there is limited potential for conflicting acquisition and restoration priorities.
- **Tidal Habitat Restoration.** The BDCP identifies the Cache Slough ROA as a substantial area of land with elevations suitable for freshwater tidal natural community restoration (CM4). Almost all of the Cache Slough ROA occurs in Solano County. This would result in the conversion of approximately 5,000 to 7,000 cultivated lands to tidal natural communities. As described above, neither the loss of cultivated land or the creation of tidal natural communities is expected to conflict with the Solano County MSHCP conservation strategy, because the Cache Slough area is only targeted for conservation by BDCP. The Solano County MSHCP targets 75–100 acres of tidal habitat (coastal marsh habitat) for restoration (Table 12-15), with more than 50,000 acres available in the overlap area. Consequently, there is minimal potential for conflicting acquisition and restoration priorities.

South Sacramento Habitat Conservation Plan

The proposed South Sacramento HCP would address issues related to species conservation, agricultural protection, and urban development in 341,000 acres of south Sacramento County. The plan is being prepared by Sacramento County; the cities of Sacramento, Elk Grove, Galt, and Rancho Cordova; Sacramento Regional County Sanitation District; and the Capital Southeast Connector Joint Powers Authority. The HCP would cover 30 species of plants and wildlife, including 10 that are state- or federally listed as threatened or endangered. The western extent of the South Sacramento HCP plan area, approximately 11%, overlaps the study area Conservation Zone 4 (Figure 12-3). Included in the overlap is a portion of the South Sacramento HCP's Urban Development Area. Sixteen species are covered by both plans, including greater sandhill crane, Swainson's hawk, and giant garter snake (BDCP Table 1-4).

The South Sacramento HCP, over its permit term, intends to conserve at least 41,923 acres, most of which would be agricultural and grassland land cover types with limited overlap with the BDCP (Table 12-9). The South Sacramento HCP also intends to restore 1,786 acres, most of which would be wetland and riparian land cover types. Most of the preservation and restoration would be directed towards Primary Conservation Zones identified by the plan. Small portions of the Primary Conservations Zones for valley elderberry longhorn beetle, California tiger salamander, giant garter snake, and western burrowing owl, and most of the Primary Conservation Zone for Swainson's hawk overlap with BDCP. In these areas, the potential for conflict in acquisition efforts between the plans would be greatest, but so would the potential for restoration collaboration, especially in regards to freshwater marsh and giant garter snake habitat.

The South Sacramento HCP aims to preserve mostly grassland, by a ratio of more than 2:1 relative to other land cover types, and the BDCP does not target grassland preservation in CZ 4, thereby limiting the amount of potential conflict between the two plans overall. Approximately 41% (20,041 of 48,832 acres) of CZ 4 consists of existing protected lands, so there are ample opportunities in this zone to link the reserve system with existing open space. Stone Lakes National Refuge Wildlife Refuge and Cosumnes Preserve occupy a majority of the land in the northern half of CZ 4, which signifies less private land ownership and potential conflicts in meeting the preservation targets of both plans. The BDCP Implementing Office would protect a corridor that would be composed of contiguous patches of agricultural, restored tidal, and nontidal wetlands, grassland, vernal pool complex, and other seasonal wetlands. This corridor would extend from the Caldoni Marsh/White Slough giant garter snake subpopulation area north to Stone Lakes National Wildlife Refuge, and to the extent possible would also connect to the Cosumnes River Preserve. The corridor would be configured to provide a giant garter snake movement habitat along this north-south corridor. Tables 12-16, 12-18 through 12-21 and 12-25 summarize potential overlap in acquisition and restoration targets, respectively.

- **Permanent Surface Disturbance**. The construction of the water conveyance facilities poses the greatest permanent surface impacts to the South Sacramento HCP area; an estimated 2,050 acres would be lost under alternative 4. However, because of the limited geographic overlap between the two plans, and the Sacramento HCP's emphasis on acquisition of grassland, which is ample in the South Sacramento HCP overall area (more than 175,000 acres available), there is limited potential for conflicting acquisition priorities. Under CM1, construction of the water conveyance facilities located in the South Sacramento HCP would result in permanent surface impacts that would remove between 150 acres and 3,998 acres of land available for conservation (Table 12-11). However, under all alternatives this represents less than 1.1 % of the total South Sacramento HCP area (Table 12-11).

- **Cultivated Lands Preservation.** The northeastern portion of the BDCP, including over half of CZ 4 and the northern portion of CZ 5 (Figure 12-3). There is an estimated 17,583 acres of cultivated land in the overlap area that is not protected (Tables 12-18 through 12-21). Of this total, approximately 1,900 acres would be lost to covered activities planned by the South Sacramento HCP and 3,556 acres expected under the BDCP. The water conveyance facilities footprint impacts are the among the largest in the South Sacramento HCP area. BDCP impacts to cultivated lands would occur primarily from construction of the water facilities and restoration of tidal wetlands and floodplains in the Cosumnes-Mokelumne ROA. After subtracting all the remaining impacts assumed from both plans, there would be an estimated 13,181 acres available for preservation. The combined preservation needs of the South Sacramento HCP and the BDCP in the overlap area is between 3,341 and 13,090 acres, or 25–99% of the total cultivated lands available for preservation. If all the preservation needs of both plans were to be acquired in the overlap area, there is potential for conflict in meeting the acquisition targets of both plans. Alternative 1B poses the greatest impacts to the South Sacramento HCP overlap area (4,024 acres), and could present conflicts in achieving cultivated land preservation targets for both plans in the overlap area (Table 12-19). However, as discussed above, there is an estimated 60,000 acres of cultivated land remaining for preservation in the South Sacramento HCP area that does not overlap with the BDCP study area, so both plans would easily be able to achieve their cultivated land preservation targets. As described in the BDCP, Section 3.4.3 *Conservation Measure 3*, if during the permit terms of the overlapping plans, the South Sacramento HCP is unable to meet its mitigation requirements due to a lack of willing sellers and due in part to acquisition by BDCP in the overlap area, a credit swap of easement(s) would be initiated. Determination that this criterion has been met would be made jointly by CDFW, USFWS, the BDCP Implementation Office, and the South Sacramento HCP implementing entity. Land owned by the BDCP Authorized Entities or Supporting Partners in the overlap area in fee title or conservation easements would be identified for their applicability to the South Sacramento HCP conservation strategy. The South Sacramento HCP would acquire conservation easements or fee title on land outside of the overlap area with equivalent or greater conservation value to BDCP as the land identified in the criteria above. This land acquired would be within the BDCP Plan Area but could be outside Sacramento County. As an alternative, the BDCP Authorized Entities or Supporting Partners could acquire the additional lands with funds from the South Sacramento HCP. Once the additional land is acquired outside of the overlap area, the BDCP land within the overlap area would be transferred in fee title or conservation easement holder to the South Sacramento HCP. The land acquired by the South Sacramento HCP outside of the plan area with equivalent or greater conservation value to BDCP would be transferred to a BDCP Authorized Entity or Supporting Partner. Once the transfers are complete, the credit assigned to each plan for the conserved land would also be transferred. BDCP would ultimately acquire no more than 3,000 acres in the overlap area with South Sacramento HCP.

- **Tidal Habitat Restoration.** Approximately half of the proposed 3,072 acre Cosumnes Mokelumne ROA overlaps with the South Sacramento HCP, resulting in an estimated 1,535 acres of cultivated land converted into tidal natural communities. However, as discussed above, both plans would easily achieve their cultivated lands preservation targets through the implementation of MM AG-1 and the preservation of cultivated lands in the South Sacramento HCP area that does not overlap with the BDCP study area.

- **Nontidal Marsh Restoration.** The South Sacramento HCP proposes to restore 600 acres of nontidal wetland habitat in Caldoni Marsh/ White Slough, which overlaps with the CZ 4 of the BDCP. The BDCP proposes 200 acres of nontidal restoration in CZ 4. In total, the two plans propose to convert 800 acres of the approximately 1,700 available acres of cultivated land in the overlap area to nontidal wetland natural communities. This represents less than half of the total cultivated land available in the overlap area and as such both plans would be able to meet their restoration targets in this area. CZ 4 of the BDCP contains the Caldoni Marsh/White Slough subpopulation of giant garter snake, providing opportunities for joint preservation of agricultural land and restoration of nontidal and riparian habitats to protect and expand this subpopulation and create habitat connectivity with the giant garter snakes in the Stone Lakes area.

- **Wetlands and Vernal Pools Restoration.** The BDCP proposes to protect 600 acres of existing vernal pool habitat and 400 acres of existing alkalai seasonal wetland complex, with the majority of the preservation occurring in CZ 1, 8, and 11. The South Sacramento HCP proposes to preserve a total of 1,048 acres of vernal pool, or vernal impoundment and 170 acres of vernal swale in a matrix of valley grassland, and restore a total of 363 acres of vernal pool or vernal impoundment in a matrix of valley grassland. The total preservation and restoration of vernal pools and alkalai seasonal wetlands proposed by the South Sacramento HCP is approximately 1,800 acres, or 24%, of an estimated 7,500 acres available in the South Sacramento HCP area. The BDCP does not have specific requirements for vernal pools or alkalai seasonal wetland preservation in CZ 4, so there is minimal potential for conflict in achieving the preservation targets of the South Sacramento HCP in the overlap area.

Yolo Natural Heritage Program

The Yolo County NCCP/HCP Joint Powers Authority (JPA), consisting of five local public agencies, launched the YNHP in March 2007. Member agencies are Yolo County and the cities of Davis, Woodland, West Sacramento, and Winters. In addition, a representative of University of California, Davis, serves as an ex-officio member of the JPA board. The YNHP covers a 653,818-acre planning area, 17% of which overlaps with the BDCP. The YNHP documents are in development. The proposed list of covered species contains 32 sensitive species in five principal natural communities. The YNHP overlaps with the BDCP in the Yolo Bypass area (CZs 2 and 3) (Figure 12-3) and has 20 species in common with the BDCP (BDCP Table 1-4). Within the overlapping area, the YNHP targets for acquisition include annual grasslands, riparian, and cultivated lands. BDCP proposes to acquire cultivated lands, acquire or restore grasslands, and restore nontidal marsh in portions of the overlapping area, primarily to benefit giant garter snake. Additionally, BDCP proposes tidal restoration in the Cache Slough ROA, which partly overlaps with the YNHP plan area. The potential exists for competition for restoration sites and land acquisition, but the overlap also creates opportunities for coordination, partnerships, and achieving common conservation goals.

Based on a simple analysis of the major natural community types for the intersecting area of the two plans (Table 12-17), there is significant overlap between tidal and wetland land cover types. In other words, most conservation targets for these land cover types in the YNHP would need to be addressed within the overlap area. However, the overlap area has more than 10,000 acres of mapped wetland available for acquisition or restoration and almost 5,000 acres of tidal land cover type. BDCP CM4 would restore or create at least 24,000 acres of tidal freshwater emergent wetland, a portion of which would be located in CZ 2 (within the overlap area). The BDCP targets 600 acres of nontidal marsh restoration (crosswalked to “wetlands” in this analysis), 200 acres of grassland protection or restoration, and 700 acres of cultivated lands protection within or adjacent to habitat occupied by the giant garter snake Yolo/Willow Slough subpopulation in CZ 2, entirely within Yolo County. The YNHP also has conservation targets for giant garter snakes in this subpopulation, but it is focused in the YNHP Willow Slough Basin Planning Unit, only a small portion of which overlaps with the BDCP Plan Area. The two plans could work together to jointly achieve conservation for giant garter snake in the Yolo/Willow Slough subpopulation.

Below is a description of specific BDCP actions and a brief discussion of the overlap with YNHP.

- **Permanent Surface Disturbance.** Under CM1, water conveyance facilities located in the YNHP area would result in permanent surface impacts of up to 5,834 acres under Alternative 1C that may remove lands available for conservation (Table 12-11). There would be no permanent surface impacts of the water conveyance facilities from the other alternatives.

- **Cultivated Lands Preservation.** Within CZs 2 and 3, BDCP may protect a portion of the total conservation goal of 1,000 acres of cultivated lands as foraging habitat for Swainson's hawk (CM3), thus removing it from conservation under the YNHP. There is an approximately 17,500 acres of cultivated land in the area where the BDCP overlaps with the YNHP. An estimated 6,158 acres of cultivated would be lost under CM1 in the overlap area, approximately 35% of the cultivated land available for preservation. BDCP CM4 would restore or create at least 24,000 acres of tidal freshwater emergent wetland, a portion of which would occur in CZ 2, within the overlap area.
- **Riparian Restoration.** CM7 would restore 5,000 acres of riparian forest and scrub in the BDCP Plan Area in association with restoration of tidal wetlands and floodplains. A portion of this restoration would occur in CZ 2, although most is expected to occur in CZ 7, outside the overlap area. The YNHP also has conservation targets for riparian but most of it is targeted for YNHP planning units outside the overlap area.
- **Floodplain Restoration.** Implementation of BDCP CM2 would increase the annual average inundation of the Yolo floodplain within the overlap area of the two plans. This measure would help to restore habitat in Cache Slough (a portion of which is within the YNHP area) for delta smelt, longfin smelt, and other BDCP covered fish species. The YNHP conservation strategy does not include any conservation measures within the Yolo Bypass, so an increase in inundation frequency and duration as a result of BDCP is not expected to affect the YNHP. BDCP will mitigate for any significant impacts on terrestrial species that would result from inundation.
- **Wetlands Restoration.** CM10 would restore 600 acres of nontidal marsh within or adjacent to habitat occupied by the giant garter snake Yolo/Willow Slough subpopulation in CZ 2. Approximately 58% of CZ 2 consists of protected land, and there remain ample opportunities to protect cultivated lands and associated natural communities in large blocks connected to open space. Yolo Bypass Wildlife Area and other open space lands owned by CDFW are present in the central and northern portions of CZ 2, while Liberty Island, owned by the Trust for Public Lands, and other land owners by the U.S. Army Corps of Engineers and the Bureau of Reclamation are present in the southern portion. Based on the amount of overlap between YNHP and BDCP areas (Table 12-9), there may be limited potential for conflict and possibilities for joint collaboration in restoration efforts.

Effects of Other BDCP Conservation Measures on Overlapping Conservation Plans

The BDCP contains management-based conservation measures designed to meet or contribute to the biological goals and objectives identified in BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*. Many of these conservation measures are designed to address "other stressors" of the BDCP covered fish. While many of these conservation measure are expected to occur within the overlapping conservation plans (Table 12-28), most would occur within the aquatic environment of the Delta, resulting in minimal overlap with the other conservation plans (which focus primarily on upland and terrestrial areas). Potential areas for overlap are identified in this section and are considered to be manageable and/or avoidable.

- *CM11 Natural Communities Enhancement and Management* outlines a suite of management techniques to be applied across the BDCP reserve system and for each natural community. CM11 would overlap all other conservation plans and be applied wherever BDCP acquires land for the reserve system. The management techniques described in CM11 are similar or the same as those of the other conservation plans, so management is expected to be highly compatible where conservation lands of overlapping plans occur adjacent or near to each other.

- *CM13 Invasive Aquatic Vegetation Control* would be applied in aquatic systems throughout the BDCP Plan Area, with concentrated activities expected within the five ROAs. Therefore, this conservation measure is likely to overlap with most of the other conservation plans (Table 12-28). Invasive aquatic vegetation is a serious problem identified in several other conservation plans, so this BDCP conservation measure is expected to be consistent with the other overlapping plans.
- *CM14 Stockton Deep Water Ship Channel Dissolved Oxygen Levels* would only be applied in the Stockton Deep Water Ship Channel in San Joaquin County. This measure is compatible with the goals of the SJCMSHCP, which also covers green sturgeon. This species is expected to be benefit from this conservation measure.
- *CM15 Localized Reduction of Predatory Fishes* would be applied in select locations throughout the Plan Area. The conservation measure is likely to be applied in the overlap areas of the SJCMSHCP, Yolo HCP, and South Sacramento HCP, and may be applied in the Solano HCP and ECCC HCP/NCCP. Predator control measures would not conflict with existing or planned conservation plans because they would be applied in aquatic systems only, which does not overlap with most plans. Of these plans, only the SJCMSHCP and Solano HCP cover fish also covered by BDCP.
- *CM18 Conservation Hatcheries* requires the establishment of new hatcheries, and the expansion of existing conservation propagation programs for delta and longfin smelt. CM18 would be implemented near Rio Vista in Solano County. A small amount of land would need to be acquired to build the longfin smelt hatchery. Because the planned site is already disturbed, this acquisition would not conflict with the Solano HCP.
- *CM19 Urban Stormwater Treatment*, *CM20 Recreational Users Invasive Species Program*, and *CM21 Nonproject Diversions*, would be implemented throughout the BDCP Plan Area and are likely to overlap with almost all of the other conservation plans. The exact locations of their implementation are not known because CM19 and CM21 rely on willing participants that have not been identified yet. Despite this uncertainty, these conservation measures are likely to be compatible with or at least not conflict with the other conservation plans because they are restricted to aquatic areas that are largely not addressed by the other conservation plans.

Table 12-28. Potential Occurrence of Other BDCP Conservation Measures in Overlapping Conservation Plans

BDCP Conservation Measure	ECCC HCP/NCCP	San Joaquin	EACCS	Solano MSHCP	South Sacramento HCP	YNHP
CM11 Natural Communities Enhancement and Management	Yes	Yes	Potentially	Yes	Yes	Yes
CM12 Methylmercury Management	W Delta ROA (Dutch Slough)	South Delta ROA	None	Suisun Marsh and Cache Slough ROAs	Cosumnes-Mokulemne ROA	Cache Slough ROA
CM13 Invasive Aquatic Vegetation Control	Yes	Yes	None	Yes	Yes	Yes
CM14 Stockton Deep Water Ship Channel Dissolved Oxygen Levels	None	Yes	None	None	None	None
CM15 Localized Reduction of Predatory Fishes	Potentially	Yes	None	Potentially	Yes	Yes
CM16 Nonphysical Fish Barriers	Unlikely	Yes	None	Potentially	Yes	Yes
CM17 Illegal Harvest Reduction	Potentially	Yes	None	Yes	Yes	Yes

CEQA Conclusion

The BDCP overlaps geographically with six conservation plans. Impacts from construction and implementation of BDCP alternatives are not anticipated to affect implementation of the overlapping plans. Understanding whether BDCP acquisition and restoration goals would preclude the implementation of other conservation plans is more challenging. The analysis above indicates that the degree to which this competition would impact the conservation goals of other plans is limited. In most cases, because of the flexibility for acquisition targets incorporated into the BDCP and other plans, the potential conflict would be manageable, and significant conflicts with the implementation of overlapping plans could be avoided. Because the conservation strategy for the YNHP and South Sacramento HCP are not available, further analysis may be required at a later date. In certain cases, especially pertaining to similar restoration objectives, perceived conflicts may also represent opportunities for collaboration to jointly achieve similar conservation goals. Because implementing the BDCP would not result in a conflict with the provisions of an adopted HCP, NCCP or other approved local, regional or state habitat conservation plan, there would be a less-than-significant impact.
